To our knowledge, no study has investigated the ways in which obese individuals are visually depicted in the news. Thus, this study aimed to conduct a content analysis to examine the types of images that accompany online news stories about obesity and to determine how obese people are portrayed in news photographs.

Methods

Sample

We selected photographs by searching five major news Web sites for articles about obesity: MSNBC.com, CNN.com, ABCnews.com, CBSnews.com, and FOXnews.com. We also considered Web sites of major online newspapers (e.g., NYTimes.com, WashingtonPost.com), but subsequently excluded them because we discovered that these sites often did not include images with their archived news stories. In addition, recent research reveals that the majority of Americans are more likely to get their news from online sources, as opposed to print sources (Pew Research Center Publications, 2009).

Therefore, we chose to analyze photographs that were featured with online news articles in order to obtain a sample of images that may have a high level of exposure to a greater number of viewers. After testing several search terms (e.g., fat, obese, weight, overweight) and examining the types of articles produced by each Web site, we determined that the search term obesity produced the most news articles relevant to this study.

After typing obesity into the search box of each Web site, thousands of results were produced, which were automatically sorted by each Web site according to their relevance to the topic of obesity. We conducted searches on each of the five Web sites during a 2-week period in September of 2009. Because the goal of the present study was to examine visual images accompanying articles about obesity, every article produced by our search results was screened to determine whether the primary topic (or a major topic) of the article was about obesity. For some articles, the word obesity appeared in the headline, but for many articles' obesity was prominently discussed in the text of the article. Thus, each article was read by coders in order to determine whether the main focus of the article was obesity.

Articles were selected for inclusion in the content analysis if they met the following criteria:

1. The main topic or a major topic in the article was obesity (e.g., health care spending on obesity, obesity treatment, health consequences of obesity).
2. The article was accompanied by an image.

Because of the high volume of articles produced by each Web site search (e.g., 78,200 articles about obesity were retrieved on MSNBC.com), only the first 500 results on each Web site were included as potential sources of images for this study. After reviewing the first 500 results on each Web site, exclusions were made if the online report was not accompanied by an image or photograph (which was the primary reason for exclusion), and if after reading the article it became apparent that obesity was not a primary focus of the content. Using this exclusion process, 859 images were ultimately retrieved to be included in the content analysis (170 images from MSNBC.com, 367 images from CBSnews.com, 209 images from ABCnews.com, 65 images from CNN.com, and 48 images from FOXnews.com).

Measurement

The unit of analysis in this study was individual images accompanying news stories about obesity (N¼549). To conduct a content analysis, a comprehensive coding tool was developed with specific variables that were chosen to document demographic characteristics and describe the portrayals of obese persons in the photographs. Variables were also chosen to capture ways in which images may be stigmatizing or stereotypical. Variables included the following:

1. News source of the image 2. Date the article was published 3. Story topic 4. Image credit (Associated Press, a stock image, or credited to the news source itself) 5. Demographic characteristics of the person in the image (gender, age, and race) 6. Body weight (underweight, normal weight, overweight, obese, very obese, or pregnant) 7. How the body was portrayed in the image (most of the body, head=face, abdomen, or lower body) 8. Whether the head was cut out of the image 9. Whether the person in the image was clothed (fully clothed, partially clothed, or mostly unclothed) 10. Clothing style (professional, casual, or exercise) 11. Fit of clothes (appropriate or inappropriate; coded as inappropriate only if an obese individual's clothing was distinctly too tight) Images were also coded according to the main role or activity of the person(s) portrayed in the image.

These included the following:

1. Eating and=or drinking 2. Selling, shopping for, serving, and=or cooking food 3. Exercising 4. Being an expert, researcher, advocate, or journalist 5. Being a patient 6. Being a health professional 7. Being the feature of a weight loss success story 8. Being shown as an isolated body part (e.g., only the abdomen is shown) 9. Walking down the street 10. Engaging in sedentary behavior (e.g., watching television, playing a video game) 11. Being featured in a personal interest story (e.g., a photograph of a couple who were denied adoption because of their obesity) 12. Other activities

If there was food or drink present in the photograph, it was coded as either healthy (e.g., fruit, vegetables, water) or unhealthy (e.g., potato chips, fast food, soda). All images were systematically coded by a team of four trained coders. We assessed interrater reliability by having each of the four coders independently code 25% of articles in the sample (n¼137). Because the coded variables were nominal, we calculated reliability using Cohen's kappa for multiple raters. This calculation corrected for chance agreement among coders. Reliability scores in this study ranged from 0.72 (lowest) to 1.0 (highest), which indicates a high level of agreement among all four coders. The lowest score was for the variable assessing the story topic of the news article. Before coding the remaining 75% of the articles, all four coders arbitrated in order to resolve any outstanding coding inconsistencies.

Results

Sample Characteristics

Of the total sample of 859 images, 188 (22%) were excluded from analysis because they did not contain people (these were mostly images of food or other health-related graphics). This exclusion left 671

images published in online news articles about obesity from 2002 to 2009. Among these articles, 15 different categories of story topics were identified. The most prevalent story topics were about the health consequences of obesity (13%), community or government initiatives to prevent obesity (10%), obesity prevalence (9%), and weight loss surgery or drugs (9%). The majority of the images accompanying these reports were credited to the Associated Press (54%). When more than one person was depicted in an image, each person was coded separately, resulting in 441 individual people in the final sample.

Table 1 shows the demographic characteristics of individuals in our sample. Overall, 56% of the sample was male, and 44% was female. The majority of individuals were White (79%), and 18% were racial=ethnic minorities (e.g., Black, Latino, Asian). In addition, 70% were adults and 29% were youths. Sixty-five percent of the sample was overweight=obese, and 27% were nonoverweight. The original weight categories of "overweight," "obese," and "very obese" were collapsed into one "overweight=obese" category, because of relatively small percentages of individuals who were coded as "overweight" or "very obese." The remaining 8% were either pregnant or their weight category could not be determined; thus, they were subsequently excluded from further analysis. All subsequent analyses compare nonoverweight with overweight= obese persons.

Portrayals of Overweight/Obese Persons

Table 2 compares the percentage of overweight=obese persons versus nonoverweight persons who were portrayed with specific characteristics of interest. We performed chi-square tests to determine significant differences between portrayals of overweight=obese people and nonoverweight people. In addition, we calculated odds ratios to maximize the interpretability of the chi-square results. Although there were no differences in gender or race among overweight=obese persons versus nonoverweight persons, several other significant findings emerged. Youths depicted in images were twice as likely to be overweight=obese than were adults who were portrayed in images, v2(1, N¼400) ¼6.75, p¼.009. There were several significant differences in how individuals' bodies were portrayed in the photographs. More than half of overweight=obese people (52%) were portrayed in images with only their abdomens or lower bodies shown, whereas nonoverweight people were never portrayed in this way, v2(1, N¼404) ¼98.44, p<.001. Overweight=obese individuals were 23.3 times more likely to have their heads cut out of the photos than were nonoverweight individuals, v2(1, N¼404)¼97.16, p<.001.

Overweight=obese individuals were also more likely to be photographed from the side and rear view (rather than from the front) than nonoverweight individuals, odds ratio¼2.61, v2(1, N¼403)¼14.26, p<.001. Overweight=obese people were less likely to be appear fully clothed, odds ratio¼0.32, v2(1, N¼400)¼5.73, p¼.02, and were less likely to appear in professional clothing compared with nonoverweight persons, odds ratio¼0.13, v2(1, N¼370)¼65.80, p<.001. Overweight=obese and nonoverweight persons also differed in the types of activities in which they were portrayed in photographs. Overweight=obese individuals were 3.5 times more likely to be shown consuming food compared with nonoverweight persons, v2(1, N¼404)¼4.66, p¼.03. Conversely, nonoverweight individuals were 3.9 times more likely to be shown exercising compared with overweight=obese individuals v2(1, N¼404)¼16.91, p<.001. Nonoverweight individuals were 50 times more likely to be shown as experts, advocates, or journalists than were overweight=obese individuals, v2(1, N¼404)¼90.99, p<.001, and were also more likely than overweight=obese persons to be shown as healthcare providers, odds ratio¼7.69, v2(1,

N¼404)¼34.95, p<.001. There were no significant

Table 1. Demographic characteristics of individuals portrayed in online news images (N¼441) Online news source

Variable	MSNBC (N¼70)	CBS (N¼202)	ABC (N¼103)	CNN (N¼42)	FOX (N¼24)	Total Sample (N¼441)
Weight						
Nonoverweight	39%	24%	33%	61%	71%	33%
Overweight/ Obese	19%	45%	27%	71%	45%	65%

Age						
Youth	30%	26%	34%	19%	29%	8%

differences for being shown in the role of a patient or engaging in sedentary behaviors between overweight=obese and nonoverweight persons.

Characteristics of Individual News Source

Because the sample included images from five distinct news sources, we conducted analyses to determine whether significant differences emerged between each news source for demographic characteristics.

The Breslow-Day Test determined whether there was homogeneity in the odds ratio between news sources, with the criterion for significance set with an alpha of .10.

First, analyses revealed that there were differences between the news sources regarding gender and weight: Breslow-Day v2(4)¼16.55, p¼.002. Specifically, within CBSnews.com, men were 4.2 times more likely to be overweight=obese than were women, v2(1, N¼182)¼14.74, p<.001. There were no significant differences for gender among the other news sources. Second, there were also differences between sources for weight and age of images portrayed: Breslow-Day v2(4)¼8.03, p¼.09. Specifically, within CBSnews.com, the odds of a youth being overweight=obese were 3.6 times greater than the odds of adults being overweight=obese, v2(1, N¼181)¼7.86, p¼.005. There were no significant differences for age among the other sources.

Stigmatizing Portrayals Images were also analyzed to determine whether the portrayals of overweight=obese individuals were stigmatizing. An image was considered stigmatizing if it met one or more of the following criteria:

1. Disproportionately emphasized an overweight=obese person's abdomen or lower body 2. Portrayed an overweight=obese person's abdomen without clothes 3. Featured an overweight=obese person with their head cut out of the image

Table 2. Comparison of portrayals for overweight=obese persons versus nonoverweight persons in online news reports about obesity

Overweight=obese (N¼287)

Nonoverweight (N¼119)

Negative characteristic "Headless" 59% 6% Shown from side or rear angle 40% 20% Only abdomen or lower body shown 52% 0% Shown without clothes or bare midriff 12% 4% Inappropriate fitting clothing 6% 0% Shown eating and=or drinking 8% 3% Engaged in sedentary activity 5% 3% Positive characteristic Wearing professional clothing 11% 50% Shown exercising 6% 20% Portrayed as expert or advocate 1% 33% Portrayed as health care provider 4% 22%

4. Portrayed an overweight=obese person with inappropriately fitting clothing (e.g., a shirt that is distinctly too tight) 5. Portrayed an overweight=obese person eating=drinking an unhealthy food=drink 6. Portrayed an overweight=obese person engaging in a sedentary activity

Overall, 72% of images that portrayed an overweight or obese person met at least one of the aforementioned criteria. Overweight=obese men were slightly more likely than overweight=obese women to be portrayed in a stigmatizing way, odds ratio¼1.6, v2(1, N¼437) ¼5.95, p¼.02. In addition, overweight=obese White individuals were twice as

likely to be portrayed in stigmatizing ways than overweight= obese minorities, v2(1, N¼426) ¼7.85, p¼.005. There were no significant differences by age. Among all the images in the sample for each news source, CBSnews.com had the highest percentage of stigmatizing images (43%), followed by ABCnews.com (35%), MSNBC.com (26%), CNN.com (19%), and FOXnews.com (18%).

Among photos credited to the Associated Press, 46% were stigmatizing. Among the stock photos, 33% were stigmatizing, and 19% of images that were credited to the individual news sources were stigmatizing. Last, news stories about the genetic causes of obesity contained the highest percentage of stigmatizing images (70%), followed by health care spending (63%), and prevalence of obesity (58%). The lowest percentages of stigmatizing images were paired with stories on food=diet (5%) and exercise (8%). There were no significant differences in stigmatizing portrayals by the year of an article's publication.

Discussion

This study demonstrates that the majority (72%) of overweight and obese individuals depicted in online news photographs were stigmatized. Overweight and obese individuals were more likely to have their heads cut out of photos, to be shown from the side or the rear, to be portrayed with only their abdomens or lower bodies shown, and to be partially clothed (e.g., bare stomachs showing) than nonoverweight individuals. These findings confirm the phenomenon of the "headless stomach," which is the tendency for news reports to show obese people with their heads cut out of images. This phenomenon has been fervently discussed by writers in online communities (Cooper, 2007), but it has never been empirically studied. Some may argue that obese individuals' heads and faces are omitted from news photos to protect their privacy. However, images that place unnecessary emphasis on particular body parts seem to intentionally evoke a sense of disgust, rather than merely portray a obese person with their identity concealed. This is especially apparent when news articles are accompanied by stock images that show unclothed obese people (e.g., with no shirt). By isolating certain body parts and emphasizing unflattering portrayals of excess weight, news photographs degrade and dehumanize obese individuals. Consequently, obese people are reduced to being symbols of the epidemic, rather than valued members of society who deserve compassion and respect. In addition to the abundance of negative images of overweight individuals observed in the present study, there was also a considerable lack of positive portrayals. Overweight and obese individuals were less likely to be shown wearing professional-looking clothing, and were far less likely to be portrayed as experts,

advocates, journalists, or healthcare providers than those who were not overweight. In addition, overweight persons were less likely to be shown exercising and more likely to be portrayed eating or drinking than were nonoverweight persons. Such portrayals perpetuate negative weight-based stereotypes about obese persons. Millions of Americans rely on the Internet for their news (Pew Research Center Publications, 2009). Thus, the number of Americans who are exposed to these stigmatizing portrayals of obese persons is vast, which may affect the pervasive stigma and discrimination directed toward obese individuals. Experimental research shows that people who read a news story about obesity that is paired with a stigmatizing photograph subsequently express higher levels of weight bias than do those who read the same news story about obesity paired with a nonstigmatizing photograph (McClure et al., 2011).

As these negative images of obese people have become commonplace, they help to shape societal beliefs about obese persons. In addition to perpetuating societal stigma, negative news images of obese persons may also contribute to the physical and emotional health consequences suffered by persons who experience weight stigma. An

accumulation of research demonstrates that obesity stigma poses a significant threat to psychological and physical health, including increasing vulnerability for depression, anxiety, low self-esteem, disordered eating, lower levels of physical activity, and weight gain (Ashmore, Friedman, Rechmann, & Musante, 2008; Carels et al., 2009; Puhl & Brownell, 2006; Puhl & Heuer, 2009; Puhl, Moss-Racusin, & Schwartz, 2007; Vartanian, Herman, & Polivy, 2005; Vartanian & Shaprow, 2008). Obese individuals who view these stigmatizing images in the news may be vulnerable to internalizing negative weight-based stereotypes, which can, in turn, lead to emotional and physical health consequences (Puhl et al., 2007). Considering both the pervasiveness of negative visual content in the news, and the prevalence of overweight and obesity in American children and adults, the public health impact of these stigmatizing portrayals may be substantial.

Some critics may argue that the use of "positive" (e.g., nonstigmatizing) images of obese persons could potentially normalize obesity in a way that reduces motivation to maintain a healthy weight. However, scientific evidence suggests that weight stigma is not a beneficial tool for motivating weight loss. Weight stigma is counterproductive for public health and increases the likelihood for unhealthy eating behaviors, avoidance of physical activity, impaired weight loss efforts, and decreased use of preventive health services (Amy, Aalborg, Lyons, & Keranen, 2006; Ashmore et al., 2008; Carels et al., 2009; Puhl & Brownell, 2006; Puhl & Heuer, 2010). In contrast, studies suggest that communicating acceptance and providing support, rather than instilling stigma and shame, are more appropriate and effective strategies to promote healthy lifestyle behaviors in obese persons (Lillis, Hayes, Bunting, & Masuda, 2009). The present findings also have potential implications for public health policy. The news media have tremendous power to shape the public's perception of social issues, and, in doing so, can influence the agenda of policymakers (McCombs & Shaw, 1972). To the extent that news images stigmatize obese individuals, they reinforce blame on obese persons (Crandall & Reser, 2005). The media's attribution of obesity as a problem with obese individuals themselves (rather than a more complex societal and public health issue) is underscored by the inclusion of stigmatizing images. When obese individuals are blamed, the need for government involvement and public policy efforts to address obesity is curtailed.

Thus, negative visualframing of obese persons in the news could adversely influence public policy efforts to address obesity. At the same time, the news media can play an important role in reducing societal stigma toward obese individuals by changing the visual content of their news reports about obesity. It is not uncommon for media outlets to establish ethical guidelines that advise journalists against stereotyping and bias.

For example, the Society of Professional Journalists' Code of Ethics states, "Journalists should avoid stereotyping by race, gender, age, religion, ethnicity, geography, sexual orientation, disability, physical appearance or social status" (Society of Professional Journalists, 2010) The Code of Ethics for the National Press Photographers Association states that visual journalists should "avoid stereotyping individuals and groups" (National Press Photographers Association, 2010).

Therefore, it is reasonable to expect the news media to make a concerted effort to correct bias in their visual content when it is exposed. In the present study, more than half of images were credited to the Associated Press, and 46% of these images were found to be stigmatizing. According to the Associated Press Statement of News Values and Principles, "Always and in all media, we insist on the highest standards of integrity and ethical behavior when we gather and deliver the news....

That means we abhor inaccuracies, carelessness, bias or distortions" (Associated Press, 2010). Thus,

in keeping with their stated values and standards, it would be consistent and appropriate for the Associated Press to improve their photographic depictions of obese individuals, as should other mainstream online news outlets. There are several limitations of the present study. First, the sample consisted of Web-based news reports and therefore it is unknown whether images that accompany print articles (e.g., newspapers, magazines) about obesity differ from images used in online news. Additional research is needed to establish the generalizability of these findings to other media sources. Second, it would be useful to obtain larger and more diverse samples of images from online news sources to more closely examine potential differences in portrayals of obese persons related to issues of race, age, sexual orientation, and other characteristics that were beyond the scope of this study. Last, the sample of images selected for this study focused on online news coverage of obesity-related topics. It would be informative for future research to examine whether portrayals of obese and nonobese persons documented in the present study are similar in news stories on topics unrelated to body weight.

Obesity stigma in the mass media contributes to the social acceptability of weight prejudice and its consequences for those who are affected (Puhl & Heuer, 2009). News images of obese persons may be a particularly powerful and insidious source of obesity stigma, especially given that these images are prevalent and rarely challenged.

Our study revealed that the prevalence of stigmatizing images accompanying news stories about obesity remained consistent throughout a 7-year period from 2011to 2018. As this problem persists, efforts are clearly needed to address the visual portrayals of obese persons in the media to help reduce stigma. Photographers, journalists, and editors must be mindful of the power of their photographic content to communicate biases to their readers. As a result of societal weight stigma, overweight individuals are vulnerable to serious health complications, and they face disadvantages in health care, employment, education, and beyond. Just as the news media have the power to perpetuate these disparities, they may also play a vital role in correcting them. Further research is needed to examine the effect of a shift toward positive portrayals of obese individuals in obesity news on public attitudes and approaches to address obesity.

IMMEDIATE EFFECTS OF COST-EFFECTIVE STRAP ON Q-ANGLE AND KNEE FUNCTIONAL PERFORMANCE FOR NON-ATHLETIC UNIVERSITY STUDENTS WITH ANTERIOR KNEE PAIN

Dr. Manash Kanti Chakraborty

ABSTRACT

Objective: To find out immediate effects of cost-effective strap on Q-angle and knee functional performance for non-athletic university students with anterior knee pain. Methods: A quasi experimental single group pre and post study was designed with convenient sampling of 110 non-athletic university students with anterior knee pain. The study has been conducted in SRM University, Kattankulathur campus, Chennai. The Q- angle and Visual analog scale was measured followed by collection of Kujala Patellofemoral pain syndrome scoring sheet and Werner functional knee score for anterior knee pain. The score was tabulated as pre-test measurement .The cost-effective strap which was influenced by the use of Theratogs, was applied over the mid-thigh region with 50% resistance anteroposterior and medial to lateral direction. Then the measurement of Q-angle, visual analog score with Kujala Patellofemoral pain syndrome score and Werner functional knee score were repeatedly taken from the subjects and compared with pre-test measurement score. Results: The statistical analysis of paired t-test showed significant reduction on the measurement of Q- angle($p=0.000$) and visual analog scale($p=0.000$).The study also showed significant improvement on Kujala Patellofemoral scoring sheet($p=0.000$) and Werner functional knee score for anterior knee pain($p=0.000$) at 95% C.I. Conclusion: The study showed significant reduction on Q-angle and improvement of functional knee performance immediately after applying over the subjects with anterior knee pain. So it could concluded that the strap can be used as a conservative physiotherapy management for subjects with anterior knee pain which is also cost effective while comparing with Theratogs.

Key pints: Anterior knee pain, Cost-effective strap, functional knee performance.

INTRODUCTION

The term anterior knee pain is used to describe all symptoms of pain around the front of the knee, which may be caused by a number of conditions such as patellar tendinopathy and patellofemoral pain syndrome.1 Anterior knee pain, diagnosed as Patellofemoral Pain Syndrome (PFPS), is one of the most common musculoskeletal disorders .28

Anterior knee pain and Patellofemoral pain syndrome (PFPS) accounted for 34% of knee injuries as one of the most common orthopedic conditions, particularly in active, young females,8,9 while anterior knee pain is of high socioeconomic relevance as it occurs most frequently in young and active patients. The rate is around 15-33% in active adult population and 21-45% of adolescents.23 The main activities associated with anterior knee pain are sporting, stair climbing and walking which are common in student.8,9They frequently experience pain with prolonged sitting (watching a movie, riding on an airplane) and feel that they have to occasionally straighten their legs out to decrease discomfort.

The onset of symptoms is frequently associated with the start of a new activity or increase in level of intensity of a pre-existing activity. The pain is usually exacerbated by squatting and kneeling. It is generally an aching pain, but can become sharp in nature and even be associated with a burning sensation. This occurs particularly when going down

Assistant Professor, Deptartment of physiotherapy
Janaran Rai Nagar Rajasthan Vidyapeeth, (Deemed To-Be University) Dabok Udaipur

the stairs. With knee flexion and extension, the patella glides through a groove in the distal femur. When the bones in the lower leg are not lined up ideally, it can cause the gliding between the patella and femur to become abnormal. Shortening of the quadriceps muscles, hamstrings and iliotibial band, and relative weakness of the quadriceps muscles are probably the most common causes.

Alignment of the hip, knee and ankle is thought to play a key role in the load distribution at the knee so biomechanical changes resulting from abnormal alignment may influence joint loads, mechanical efficiency of muscles, and proprioceptive orientation and feedback from the hip and knee, resulting in altered neuromuscular function and control of the lower extremities.2, 3

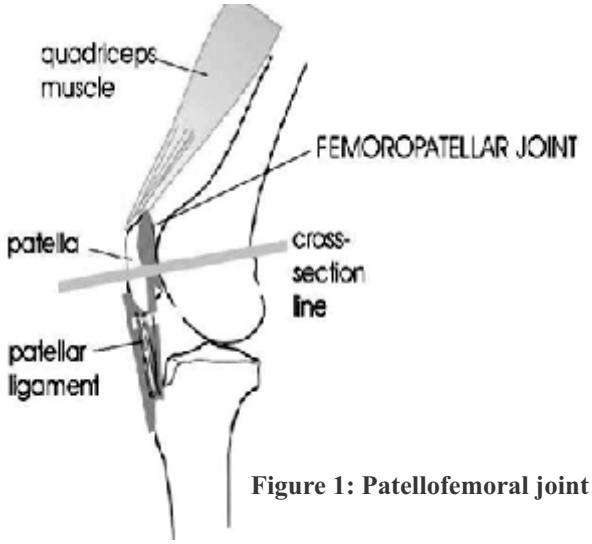

Figure 1: Patellofemoral joint

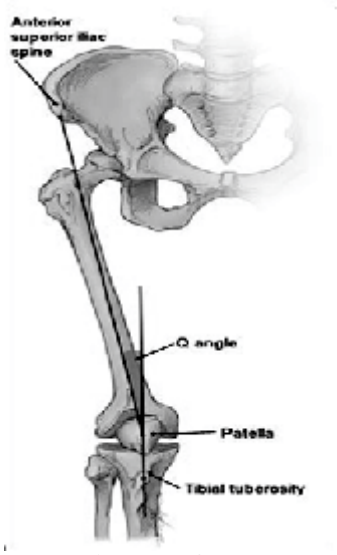

Figure 2: Q- angle

Among these lower extremity alignment variables, the quadriceps angle (Q -Angle) has been frequently studied, which is defined as the angle formed by a line from the anterior superior iliac spine to the patella center and a line from the patella center to the tibial tuberosity.4Q angle is a composite measure of pelvic position, hip rotation, tibial torsion, patella position and foot position.7, 11

As Q angle represents the direction of the quadriceps muscle force vector in the frontal plane, excessive angulation is thought to predispose individuals to injuries caused by abnormal quadriceps forces acting at the patellofemoral joints.5, 6

Altered foot and ankle kinematics may contribute to hip and knee joint mechanics thought to increase patellofemoral joint stress.10,11 The patellofemoral joint reaction force, a measurement of patellar compression against the femur, is influenced by the knee angle as well as the quadriceps force.

This study was aimed to find out the immediate efficacy of a cost effective strap in anterior knee pain which is a custom made elastic material, self-administrative and which can be used under garments easily is mechanically similar with THERATOGS.

THERATOGS is an orthotic undergarment and strapping system that gives clients with sensorimotor impairment a new modality for improving postural alignment and stability, movement skill and precision and joint stability. THERATOGS were designed and developed by Beverly Cusick, PT, MS and provide a Latex free, breathable, comfortable, Velcro sensitive “external skin” for clinicians engaged in sensorimotor training of clients with developmental disabilities, and for clients in rehabilitation after brain injury, stroke, orthopedic surgery, or neurosurgery.

The materials of the strap is not containing any chemicals so that it can be used for longer duration comparing to crepe bandage or other therapeutic

device which are used for conservative pain reducing management without any skin irritation.

Method: The study was designed as a quasi-experimental single group pre and post-test. The study was performed at SRM University, Kattankulathur campus with subjects who were recruited based on the following criteria: 18- 30 years non atheletic male and female participants with diagnosed Anterior Knee Pain or Petellofemoral Pain Syndrome scoring less than 85/100 on Kujala Patellofemoral Pain Syndrome (KPFPS) score-sheet, whose pain intensity was in between 3-7 on Visual analog scale (VAS) and scoring 0-30 on Werner Functional Knee Score (WFKS) for anterior knee pain scoring sheet. The subjects were excluded by presence with any cardiopulmonary disease, any other knee pathology, recent fracture of lower extremities, taking physiotherapy treatment for knee, any inflammatory or degenerative disease for lower extremity or recently undergone for any surgery for lower extremity.

Pre and post measurement of Q- angle with universal goniometer, pre and post score of Visual Analog scale, pre and post score of Kujala Ptellofemoral Pain Syndrome scoring sheet,pre and post score of Werner functional knee score for anterior knee pain were used as the out-come measure for this study.

Procedure: 110 subjects were selected based on the inclusion and exclusion criteria. The purpose of the study was explained to the subjects and signed printed informed consent form was taken. Before performing the main study a small pilot study was performed with 10 samples to identify the complications may occur during the main study. Pre-test measurement of Q -angle in standing position with 50 flexion of knee, Visual analog score, Kujala Patellofemoral pain syndrome score and Werner functional knee score for anterior knee pain was recorded individually for analysis.

The cost effective customized strap was applied over thigh region started the first wrap by rotating the thigh in external rotation with 50% resistant and wrap around the thigh in antero-posterior and medial to lateral direction and finished at below the knee joint. Subjects were asked to perform short-walk, kneeling, stair-climbing up and down, sitting in a chair with 900 knee flexion for 5 minutes to identifying any uneasiness existing or not.

Figure 6: Q-angle performed in standing

Figure 7: Anterior view

Figure 8: Posterior view

Post-test measurement of Q –angle and VAS was measured immediately and subjects were asked to continue some functional activities which were needed as a part of examination of Kujala Patellofemoral pain syndrome score and Werner functional knee score for anterior knee pain by wearing the strap under the garments. The subjects were asked repeatedly for any kind of uncomforting while performing the functional activities such as walking 2 km, climbing steps (up-down), sitting in chair for 30 minutes, etc. All the scoring sheets were kept securely for analysis.

After furnishing of valuable scoring, the subjects were asked to untie the strap and the applied area was examined thoroughly for any skin rash.

	Mean	Std. Deviation	Std. Error Mean	t	df	Sig-(2 -tailed)
Q-angle pre – Q-angle post	5.54545	1.39880	.13337	41.579	109	.000*

Data analysis: The recorded data were tabulated. The data was analyzed using statistical package for social science (SPSS) to present the finding of the immediate effects of cost-effective strap on q-angle and knee functional performance for non-athletic university students with anterior knee pain. Data analysis was done with SPSS Software version 20.0. "p" value was set at less than 0.05 as significance for all analysis, "paired t" test was done.

Table 1: Comparison of pre and post-test measurement of Q-angle in patient with anterior knee pain following strapping

	Mean	Std. Deviation	Std. Error Mean	t	df	Sig-(2 -tailed)
Visual analog pre - Visual analog post	2.56364	.68439	.06525	39.287	109	.000*

*p<0.05

The table shows that there is a significant difference in Q-angle between the pre-test and post-test in patients with anterior knee pain. This indicates that there was a significant reduction in Q-angle following strapping in patient with anterior knee pain. (p<0.05)

Table 2: Comparison of pre and post-test measurement of Visual analog scale in patient with anterior knee pain following strapping *p<0.05

The table shows that there is a significant difference in Visual analog scale between the pre- test and post-test in patients with anterior knee pain. This indicates that there was a significant reduction in Visual analog scale following strapping in patient with anterior knee pain. (p<0.05)

	Mean	Std. Deviation	Std. Error Mean	t	df	Sig-(2 -tailed)
Werner functional knee score pre - Werner functional knee score post	-18.41818	3.42249	.32632	-56.442	109	.000*

Table 3: Comparison of pre and post-test measurement of Kujala Patellofemoral pain syndrome score in patient with anterior knee pain following strapping

*p<0.05

	Mean	Std. Deviation	Std. Error Mean	t	df	Sig-(2 -tailed)
Kujala Patellofemoral pain syndrome score pre – Kujala Patellofemoral pain syndrome score post	-21.01818	3.45610	.32953	-63.783	109	.000*

The table shows that there is a significant difference in Kujala Patellofemoral pain syndrome score between the pre-test and post-test in patients with anterior knee pain. This indicates that there was a significant improvement in Kujala Patellofemoral pain syndrome score following strapping in patient with anterior knee pain. (p<0.05)

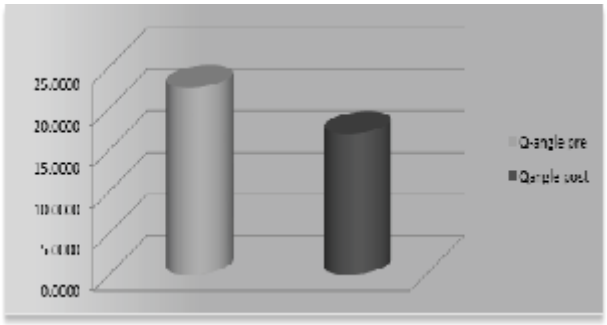
Table 4: Comparison of pre and post-test measurement of Werner functional knee score in patient with anterior knee pain following strapping

*P<0.05

The table shows that there is a significant difference in Werner functional knee score between the pre-test and post-test in patients with anterior knee pain. This indicates that there was a significant improvement in Werner functional knee score pain syndrome score following strapping in patient with anterior knee pain.(p<0.05)

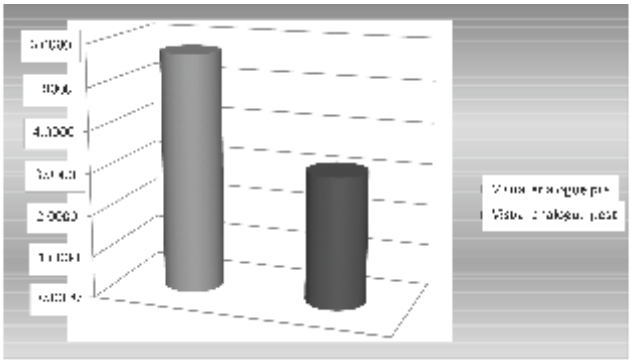
Results: According to TABLE –1 there is a significant difference in Q-angle between the pre-test and post-test in patients with anterior knee pain. This indicates that there was a significant reduction in Q-angle following strapping in patient with anterior knee pain. (p<0.05)

Graph 1: Comparison of pre and post-test measurement of Q-angle in patient with anterior knee pain following strapping



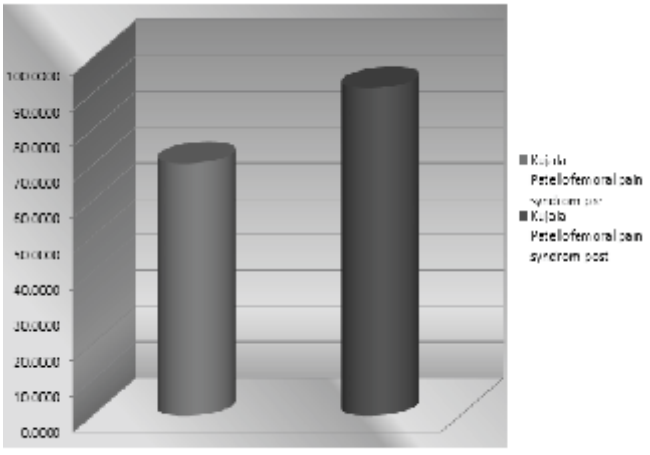
According to TABLE -2 there is a significant difference in Visual analog scale between the pre-test and post-test in patients with anterior knee pain. This indicates that there was a significant reduction in Visual analog scale following strapping in patient with anterior knee pain. (p<0.05)

Graph 2: Comparison of pre and post-test measurement of visual analog scale in patient with anterior knee pain following strapping



According to TABLE -3 there is a significant difference in Kujala Patellofemoral pain syndrome score between the pre-test and post-test in patients with anterior knee pain. This indicates that there was a significant improvement in Kujala Patellofemoral pain syndrome score following strapping in patient with anterior knee pain. (p<0.05)

Graph 3: Comparison of pre and post-test measurement of Kujala Patellofemoral pain syndrome score in patient with anterior knee pain following strapping



According to **TABLE-4** there is a significant difference in Werner functional knee score between the pre-test and post-test in patients with anterior knee pain. This indicates that there was a significant improvement in Werner functional knee score pain syndrome score following strapping in patient with anterior knee pain.($p<0.05$)

Discussion: The aim of the study was to find out the immediate effect of cost effective strap on Q- angle and knee functional performance on non-athletic university students with anterior knee pain. Total 110 subjects (35 females, 75 males) were selected for the study. The statistical result showed that there was a significant effect on Q-angle and knee functional performance immediately after applying of cost effective strap for the non-athletic university students with anterior knee pain.

There are many researches done over the anterior knee pain to identify the cause, prevalence, effective conservative treatments etc. Arlene M. Goodman, Jon G. Divine et al (2009) concluded that the prevalence of anterior knee pain is as high as 1 in 4 females and females are two times more likely to demonstrate anterior knee pain symptoms than male in general population .64In this study Q-angle was measured with a universal goniometer and only in standing position with 50 knee flexion.

The statistical analysis of this study shows that the cost effective strap helped in reduction of the Q-angle which is increased in subjects with anterior knee pain. Mark S. Juhn (1999) reported that, increased Q-angle was one of the four causes for anterior knee pain.50 As the Q-angle reduced, the pain also reduced and the functional performance of knee improved for those subjects.John P. Fulkerson (2002) concluded that non- operative treatment is effective in most subjects. Prone hamstring muscle stretches, static quadriceps strengthening, friction massages, manual therapy techniques, and effective bracing helped most of the subjects with anterior knee pain.43Based on the statistical analysis, there was significant reduction on the Q- angle. The Q-angle measurement is an important integral part for the subject with anterior knee pain. Large Q-angle is thought to create excessive lateral force on the patella that may predispose to pathological changes. An excessively large Q-angle (>200) is usually an indicator of structural malalignment. Increased Q-angle may promote a greater lateral force to deviate the medial femoral torsion. The strap wrapped over the thigh region produced resistance on quadriceps muscles and adductor compartment which reduced the femoral anteversion, this in turn decreased the lateral tilting of patella and similarly in the measurement of Q-angle.

The pain intensity measured with visual analog scale also showed significant reduction in the study. As the strap wrapped over quadriceps muscles indirectly attributes to the strength of hip external rotators and abductors so, during the weight bearing activities the compressive forces on the patellofemoral joint is reduced and it passively reduced the knee pain.

Furthermore, the reduction of the Q-angle and knee pain showed significant improvement of knee functional performance on Kujala Patallofemoral pain syndrome score as well as Werner functional knee score for anterior knee pain.Further research should be done to find out its efficacy in other orthopaedic conditions.

As the THERATOGS is comparatively costly so the customized cost-effective strap was used in the study which is easy to administer,. This study examined only the unilateral problem; future study should be performed with bilateral knee problems and on other knee pathology.

The statistical analysis of this study shows that cost effective strap has a high influence on Q-angle and thereby reducing pain and improving the functional performance of knee in subjects with anterior knee pain. Due to its advantage of user guidelines and cost effectiveness, it can be widely used in the practice of physiotherapy management for improving the functional performance in patients with anterior knee pain.

Conclusion: The study found that the cost effective strap showed immediate effect on reduction of Q-angle and improvement on knee functional performance for the subjects so it concluded that the strap should be used as a conservative treatment for anterior knee pain.

Limitations and recommendations: Limited numbers of samples within the age groups of 18 – 30 years non athletic university students were included for whom immediate effects were only examined in the study so it recommend that The subjects of different age group can be studied, among different institutions, other interventions may compared, long term effect can be compared, bilateral comparison can be studied. Even BMI effect can be observed and Q- angle should measure in every possible position such as supine lying, at 100, 200 and 240 knee flexion.

COMPARISON OF PROPRIOCEPTIVE NEUROMUSCULAR FACILITATION (PNF) STRETCHING VERSUS NEURAL MOBILIZATION BY USING H- REFLEX ON LOW BACK PAIN

Dr. Dharmendra Kumar Sharma

AIM:-

- To compare the effect of PNF stretching versus Neural-mobilization by using H-reflex in low back pain.

Objectives:-

- To study the effect of PNF stretching by using H-reflex in low back pain.
- To study the effects of Neural-mobilization by using H-reflex in low back pain.
- Compare the effects of PNF stretching & neural mobilization by using H-reflex in low back pain.

Design:- Comparative Study.

Setting:- Dr.D.Y.Patil Physiotherapy (OPD) & Department of Neuro-physiotherapy

Participants:- Low back pain patients with radiating unilateral or bilateral, and SLR 2 +ve.

Intervention:- All the patients were randomly assigned to group A (PNF hold relax stretching hamstring) and group B (Neural mobilization tibial nerve) after signing of consent form. Assessment of LBP with radiculopathy by using SLR test & NPRS scale for severity of pain. And check H- reflex. PT sessions included hamstring stretching to group A & Neural mobilization to group B. After the treatment recheck H-reflex and NPRS score.

Results:- Both the group are effective in reducing low back pain, but group B (Neural Mobilization $p < .0001$) more effective than group A (PNF stretching($p < .0001$). Both groups are equally effective to reducing H latency, M Latency & increase H amplitude. But mean of group B is 1.9415 and Group A is 0.5535 shows that there is more reduction in H Latency in group B than group A, and mean difference of group A is 0.3345 & group B is 0.3445 shows that Group B more increase in H amplitude than group A. Conclusion-The study concludes that Neural Mobilization leads to better improvement in reducing pain, H-latency, & M-latency & increasing H-amplitude as compared to PNF Hamstring stretching in low back pain.

INTRODUCTION

Low back pain is a very common condition, with about 80% of people suffering from it. Most frequently in people between the age of 20 to 50 years.According to Len Kvaritz, "Low back pain is the pain in the low back area related to problems with lumbar spine, the disc between the vertebra, the ligaments around the spine, the spinal cord, the nerve roots, muscles of the low back, internal organs of pelvis and abdomen or the skin covering the lumbar area" Low back pain can refer to pain, which remains centered in the low back region, as well as, pain, which radiates from the low back to the buttocks and/or legs.

Depending on the presence or absence of neurologic symptoms and signs LBP can be divided into: Radicular &non-radicular low back pain. Radicular LBP is radiated along the dermatome of a nerve root (radiculopathy) at its connections to the spinal column. A common form of radiculitis is sciatica, or

Assistant Professor, Deptartment of physiotherapy
Janaran Rai Nagar Rajasthan Vidyapeeth, (Deemed To-Be University) Dabok Udaipur

radicular pain radiates along the sciatic nerve. It radiates up to thighs, calf &foot. Non-Radicular LBP is not associated with neurologic symptoms or sign or not associated with spinal nerve root compression. Pain is localized to the spine and paraspinal regions and does not radiate into the leg.

Proprioceptive Neuromuscular Facilitation (PNF) is a more advanced form of flexibility training that involves both the stretching and contraction of the muscle group being targeted. PNF stretching was originally developed as a form of rehabilitation. While there are several variations of PNF stretching, they all have one thing in common; they facilitate muscular inhibition. Various PNF stretching techniques based on Kabat's concept are: Hold Relax, Contract Relax, and Contract Relax Antagonist Contract (CRAC) etc. The Hold Relax (HR) technique involves an isometric contraction of the shortened muscle against maximum resistance followed by relaxation phase

Neural mobilization is used for treatment of low back pain. Neural mobilization techniques are passive or active movements that focus on restoring the ability of the nervous system to tolerate the normal compressive, friction and tensile forces associated with daily and sport activities. It is hypothesized that these therapeutic movements can have a positive impact on symptoms by improving intraneural circulation, axoplasmic flow and neural connective tissue viscoelasticity and by reducing sensitivity of abnormal impulse generating sites.(10)

METHODS

Subjects were selected according to inclusion criteria. 40 patients were randomly allocated in two different groups. Written informed consent was taken & whole study was explained to them prior to treatment. Pre- treatment and Post–treatment H-latency, H-amplitude, M- latency, & pain score on NPRS was recorded.

Group A received PNF Hold relax stretching (hams)

Group B received neural mobilization. (Tibial nerve)

Position of The Patient During Recording –

The H-reflex latency was recorded while the patient will lie down comfortably in prone lying position on bed in a quiet room. The head maintained in mid position to control the possible effects of asymmetrical tonic reflex. The examined leg was placed mid-way between abduction and adduction at hip joint. The knee was slightly flexed by placing a small cushion under the ankle to relax the gastrocnemius to reduce any depressive influence on the H-reflex and ankle was freely positioned in planter flexion outside the plinth.

Stimulation - The H-reflex was elicited by stimulation of the posterior tibial nerve at the popliteal fossa little bit to lateral aspect by stimulating electrode as shown in.

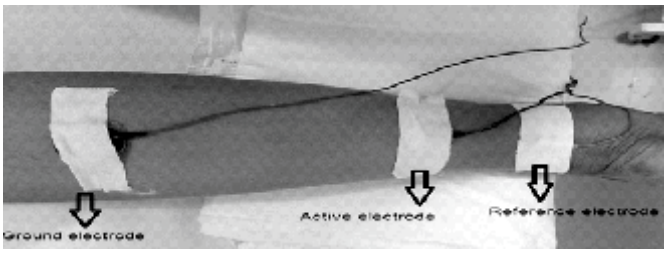

FIG.1ELECTRODE PLACEMENT FOR H-REFLEX

After recording the H-reflex

GROUP A RECEIVED PNF- HOLD RELAX STRETCHING.

PROCEDURE-The subjects were in supine position with their lower extremity strapped down the table. Pre-determined time intervals for stretching, contracting and relaxing was used to standardize the method. For each stretch, the investigator stretched the hamstring muscle by passively flexing the hip with knee fully extended, allowing no hip rotation. The lower leg was rest on the investigators right shoulder. The hamstring muscle was stretched until the subject first reported a mild stretch sensation; this position was held for 7 sec. Next, the subject then isometrically contracted

the hamstring muscle for 3 sec by attempting to push his leg down towards the table against the resistance of the investigator. Following this, the subject was asking to relax for 5 sec. The investigator then passively stretched the muscleuntil a mild stretch sensation is reported. This stretch was maintained for 7sec. This sequence was repeated 5 times.

FIG.2PNF- HOLD RELAX STRETCHING FOR HAMSTRING MUSCLE

GROUP B- RECEIVED NEURAL MOBILIZATION.

PROCEDURE– Patient in supine, the leg was supported so that the hip was in approximately 45° flexion and the leg is in horizontal position. The foot was held so that the therapist's fingers can control the ankle, forefoot and toes. Dorsiflexion/Eversion of the ankle and forefoot and dorsiflexion of the toes are the first movements and these should be taken as far as practicable into the range. Then knee extension was the next and while stabilizing the ankle joint and the rest of the limb, release of dorsiflexion of the forefoot and toes will the final movement to release distal tension from the digital nerves and allowed the tibial part to displace in a proximal direction. Again the hip was flexed to approximately 45° and the leg held horizontal as the starting position. This will release proximal tension and allow distal sliding. The foot and toes will move into dorsiflexion/eversion and the toes into dorsiflexion to move the nerve distally in its tunnel. The same procedure was repeated again and again for approximately 10 repetitions for 3 times for the one session of neural mobilization

DATA ANALYSIS

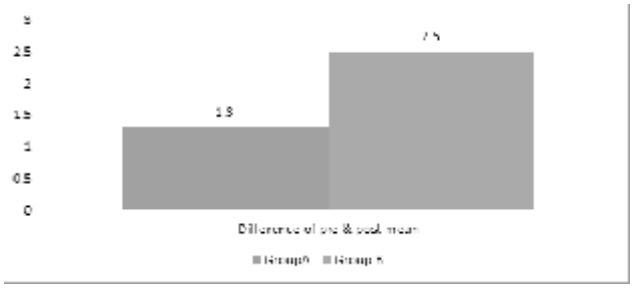
TABLE 1: COMPARISON OF PRE & POST MEANS DIFFERENCE OF NPRS BETWEEN GROUP A & B

Group	Pre & post Mean Difference	Pre & post S.D. Difference	D.B.M	t	D.F	p-value	Level of significance
A	1.3000	0.8013	1.2000	3.40	38	0.002	Significant
B	2.5000	1.3572					

* D.B.M.-Difference between mean..

*** D.F.-Degree of freedom

GRAPH 1



Inference:- Pre & post mean difference of group A was 1.30 (0.8013) & group B was 2.50 (1.3572).

Difference of pre & post mean difference of group A & B was 1.20 & p value is 0.002 which is statistically significant.

Showing that both the groups are effective in reducing low back pain.But group B more effective than group A.

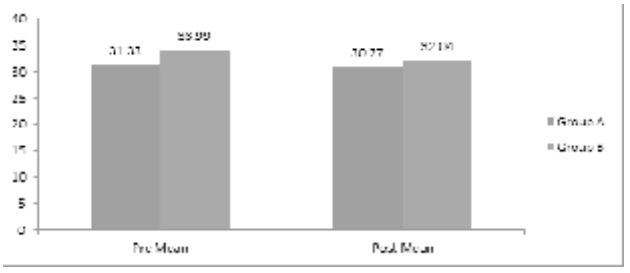
TABLE2: COMPARISON OF PRE& POST MEAN DIFFERENCE OF H-LATENCYBETWEEN GROUP A & B

Group	Pre Mean	S.D.	Post mean	S.D.	D.B.M	t	D.F	p-value	Level of significance
A	31.3325	2.9508	30.7790	2.8680	*0.9101	1.798	37	0.080	Not Significant
B	33.9900	4.1732	32.0485	3.7062					

* D.B.M.-Difference between mean.

**D.S.D.-Difference of Standard deviation.

*** D.F.-Degree of freedom



Inference:- Group A pre H-latency mean score of was 31.33 (2.95) & post H-latency score was 30.77(2.86) Group B pre H-latency mean Score of was 33.99 (4.173) & post H-latency score was 32.04 (3.706)

P value was 0.080 which is statistically not significant.

Showing that both groups are equally effective to reducing H latency in Low back pain.

**ANCOVA using pre value as covariant.

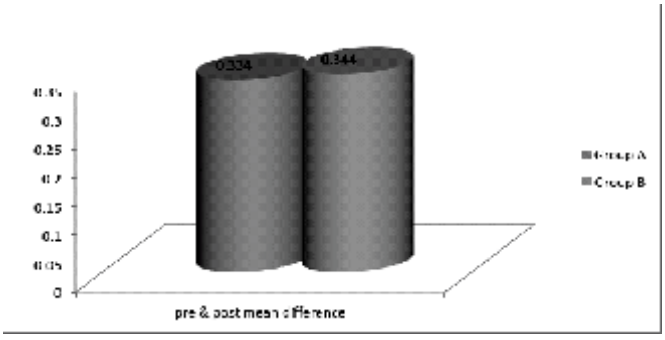
TABLE 3: COMPARISON OF PRE& POST MEAN DIFFERENCE OF H-AMPLITUDE BETWEEN GROUP A& B

Group	Pre & post Mean Difference	Pre & post S.D. Difference	D.B.M	t	D.F	p-value	Level of significance
A	0.3345	0.3163	0.0100	0.10	38	0.925	Not Significant
B	0.3445	0.3481					

* D.B.M.-Difference between mean.

*** D.F.-Degree of freedom

GRAPH 3



Inference:- Pre & post mean difference of group A was 0.3345 (0.3163) & group B was 0.3445(0.3481).

Difference of pre & post mean difference of group A & B was 0.0100 & p value is 0.925 which is statistically not significant.

Showing that both the groups are equally effective to increasing H amplitude in Low back pain.

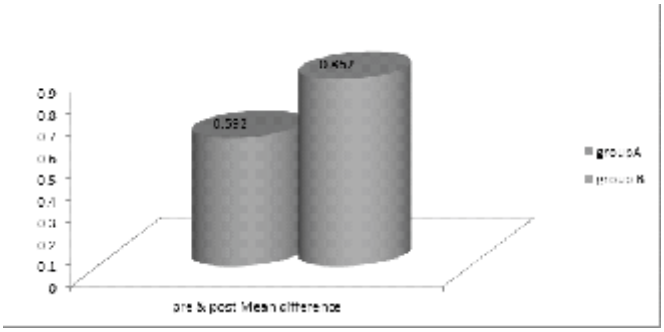
TABLE 4: COMPARISON OF DIFFERENCE OF PRE & POST M-LATENCY BETWEEN GROUP A& B

Group	Pre & post Mean Difference	Pre & post S.D. Difference	D.B.M	t	D.F	p-value	Level of significance
A	0.5920	0.8191	0.2700	0.91	38	0.369	Not Significant
B	0.8620	1.0455					

* D.B.M.-Difference between mean.

**D.F.-Degree of freedom.

GRAPH 4



Inference:- Pre & post mean difference of group A was 0.5920 (0.8191) & group B was 0.8620(1.0455).

Difference of pre & post mean difference of group A & B was 0.2700 & p value is 0.369 which is statistically not significant.

Showing that both the groups are equally effective to reduce M-Latency in Low back pain.

DISCUSSION

The results of this study showed that interventions in form of hamstring stretching, neural mobilization of Tibial Nerve were effective for pain relief and reduce in H latency, M latency & increase in H amplitude in Low Back pain with radiculopathy. But overall improvement with group B that received Neural Mobilization was greater as compared to Group A that received Hamstring stretching.

Pain relief: Pain relief was measured with numerical scale. The reported reliability of NPRS is ICC= 0.85(12) and validity is r = 0.847(13).

The reduction in the pain in the Hamstring stretching group(A) was highly significant ($p<0.01$) when calculated.

In the Neural Mobilization treatment method the reduction of pain was also highly significant ($p<0.01$). The results of study confirm hypothesis

that straight leg raising (SLR) stretching may be beneficial in the management of patients with LBP. SLR stretching was beneficial in improving pain, and promoting centralization of symptoms in this group of patients. Centralization of symptoms in patients with LBP indicates a favorable prognosis and is typically used to guide treatment in patients with low back and lower extremity symptoms.

The result shows that patient with low back pain had increase in H- latency decrease in H-amplitude & increase in M-latency. After the PNF hamstring stretching & neural mobilization reduce H-latency, increase in H- amplitude and decrease in M-latency.

Our results showed H-reflex amplitude asymmetry was more evident than latency changes in patients with radiculopathy. This was represented in the smaller value of the H-reflex where as the latency differences were not always evident. We also noticed that changes in amplitude and latency were associated with chronic low back pain with radiculopathy.(31)

Changes in the amplitude of the reflex can be explained by at least three possibilities: first is alteration in the excitability of the motor neurons, second is variation in the amount of neurotransmitter released by the afferent terminals and third is variation in the intrinsic properties of the motoneurons.

The normal value of H-latency is 30.3 +1.7 (MS) & H-Amplitude is 9.8+-6.1(MV)

But in our result the mean of Group A H latency was 31.3325 & group B 30.7790 which is Normal but the Mean of H amplitude of group A 0.778 & group B 0.620 So it indicate that H-reflex amplitude, compared to latency, may be an earlier indicator of S1 nerve root involvement.

CONCLUSION

The study concludes that Neural Mobilization leads to better improvement in reducing pain, H-latency, & M-latency & increasing H-amplitude as compared to PNF Hamstring stretching in low back pain.

"EFFICACY OF PHYSIOTHERAPY IN BEHAVIOURAL PROBLEMS OF PEDIATRIC NEUROLOGY PATIENTS AND CAREGIVERS."

Dr. Prexa Mistry*, Dr. Ramakrishnan.K.S*, Dr. Advita Neville*, Dr. Swati Patel****

Background and Purpose: Neurological condition leads to mental, physical, psychological and cognitive disabilities or a combination of all. A person may be physically independent but many have various psychological problems. Psychological problems are common complications following cerebral palsy and have an impact on all aspects of recovery. To study the effect of physiotherapy treatment on the behavioural changes of pediatric patients and caregivers of patients with neurological condition.

Subjects: 30 subjects with pediatric patients of neurological condition.

Method: A semi structured questionnaire including the Psychological General Well-being Index (PGWBI) and Gross motor function classification scale (GMFCS) will be used to collect information about Physiotherapy in behavioural problems of neurological condition of pediatric patients and their caregivers.

Result: The final sample was compose of 30 subjects, having mean age of 5.29 years old. (+3.85 SD) physiotherapy interventions were effective in reducing some of the behavioural disturbances ($Z=-4.78$, $p<0.00001$) in patients as well as their caregivers.

Conclusion: Our result indicates physiotherapy treatment may be effective in reducing the behavioural disorders and subjective burden among caregivers.

Keywords: Behavioural problems, Pediatric neurology patient, Caregivers, Physiotherapy

1.INTRODUCTION[1,2]

Cerebral palsy is primarily a disorder of movement and posture. It is defined as an "umbrella term covering a group of non-progressive, but often changing, motor impairment syndromes secondary to lesions or anomalies of the brain arising in the early stages of its development".

Motor sequelae in the cerebral palsy are commonly followed by disorders in the sensation, perception, cognition, communication, and behaviour by epilepsy and secondary muscle skeletal problems.Therefore, brain changes present in the person suffering from cerebral palsy are a biological limitation that may hinder the typical brain development, causing intellectual impairment or specific cognitive disorders.

It may be stated as a static encephalopathy in which, even though the primary lesion, anomaly or injury is static, the clinical pattern of presentation may change with time due to growth and developmental plasticity and maturation of the central nervous system.

1.1 Incidence: The cause of CP to birth trauma and this view has persisted for several decades. Recent advances in neonatal management and obstetric care have not shown a decline in the incidence of CP. On the contrary ,with a decline in infant mortality rate, there has actually been an increase in the incidence and severity of CP. The incidence in premature babies is much higher than in term babies. For the vast majority of term infants who develop CP, birth asphyxia or obstetric complications cannot be ascribed as the cause.

1.2 Classification: CP may be classified by the type of movement disorder, anatomical location of the

MPTScholar of Parul Institute of Physiotherapy, Parul university, Vadodara, Gujarat*

child's impaired motor function, and scope of motor dysfunction. The type of movement Disorders can be described as spastic, hypotonic, dyskinetic, or ataxic.

1.3 Spastic: Spasticity occurs in approximately 75% of all children with CP. It is the most common neurologic abnormality seen in children with CP, including those with diplegia, hemiplegia, and quadriplegia. Spasticity is a complex motor abnormality, often difficult to describe, but a common definition is "hypertonia in which resistance to passive movement increases with increasing velocity of movement."

1.4 Diplegia: Diplegia is the most common form of spastic CP. A white matter infarct in the periventricular areas caused by hypoxia can lead to spastic diplegic CP. It primarily affects bilateral LEs, resulting in issues with gait, balance, and coordination. In standing, children with diplegia often present with an increased lumbar spine lordosis, anterior pelvic tilt, bilateral hip internal rotation, bilateral knee flexion, intoeing, and equinovalgus foot position.

1.5 Hemiplegia: Hemiplegia is a subtype of spastic CP in which the child's upper and lower extremity on the same side of the body are affected. Four main types of brain lesions result in hemiplegic CP. Periventricular white matter abnormalities have been reported as the most common diagnostic finding in children with hemiplegic CP. Cervical–subcortical lesions, brain malformations, and nonprogressive postnatal injuries have also been identified as the main causes of hemiplegia. The UE is typically more affected than the LE, and both tend to have more distal involvement than proximal involvement. Muscle spasticity on the affected side decreases muscle and bone growth, resulting in decreased range of motion (ROM). Therefore, children with hemiplegia often present with contractures and limb-length discrepancies on the involved side. The affected side of the child with hemiplegia often presents with shoulder protraction, elbow flexion, wrist flexion and ulnar deviation, pelvic retraction, hip internal rotation and flexion, knee flexion, and forefoot contact only due to plantar flexed foot. Children with hemiplegia tend to achieve all gross and fine motor milestones but not within the typical time frame.

1.6 Quadriplegic: Quadriplegia is a subtype of CP in which volitional muscle control of all four extremities is severely impaired. This subtype is also often accompanied by neck and trunk involvement. Like diplegic CP, periventricular white matter lesions are the most frequently observed neuroimaging finding in children with quadriplegic CP. Extensive lesions affecting the basal ganglia or occipital area often lead to visual impairments and seizures, both commonly seen in children with this subtype of CP.Cognition can vary from normal to severely impaired and is unique to each child with quadriplegia. It is important to note thatchildren with quadriplegia who are unable to speak are often regarded as being cognitively impaired. However, once provided a means of effective communication, some are able to express their level of understanding and critical thinking.

1.7 Dyskinetic: Dyskinesia and movement disorders result in generally uncontrolled and involuntary movement that includes athetosis, rigidity, tremor, dystonia, ballismus, and Choreoathetosis. Common abnormalities found in imaging include deep gray matter lesions and, to a lesser extent, periventricular white matter lesions.Athetosis always has involuntary movements that are slow and writhing; abnormal in timing, direction, and spatial characteristics; and are usually large motions of the more proximal joints. Athetosis is rare as a primary movement disorder and is most often found in combination with chorea. Rigidity is muchless common and is felt as resistance to both active and passive movement and is not velocity dependent. Tremor, a rhythmic movement of small magnitude, usually of the

smaller joints, rarely occurs as an isolated disorder in CP but rather in combination with athetosis or ataxia. Dystonia is a slow motion with a torsional element that may involve one limb or the entire body and in which the pattern itself may change over time. Ballismusis the most rare movement disorder and involves random motion in large,fast patterns usually of a single limb. Choreoathetosis involves jerky movement, commonly of the digits and varying in the ROM.

1.8 Ataxic: Ataxic CP is primarily a disorder of balance and control in the timing of coordinated movements along with weakness, incoordination, a wide-based gait, and a noted tremor. This type of CP results from deficits in the cerebellum and often occurs in combination with spasticity and athetosis.The cerebellum is a major sensory processing center, and when impaired, ataxia will result.

1.9 Hypotonic: Hypotonia in a child with CP can be permanent but is more often transient in the evolution of athetosis or spasticity and might not represent a specific type of cp.

2.AIMS & OBJECTIVES:

2.1 AIMS:

- To evaluate efficacy of physiotherapy in behavioural problems of pediatric neurology patients and caregivers.

2.2 OBJECTIVES:

- To know efficacy of physiotherapy in behavioural problems of pediatric neurology patients and caregivers.
- To determine the efficacy of physiotherapy in behavioural problems of pediatric neurology patients and caregivers.

3. MATERIAL USED:

1. Informed consent form
2. Questionnaire/ Scales
3. Google forms
4. Mobile
5. Paper/ Pencil/pen

4. METHODOLOGY:

- **SOURCES OF DATA:**

  Parul Sevashram Hospital

  Kashiben Govardhandas Patel children's Hospital

- **STUDY DESIGN:** This is aConvenience sampling.
- **STUDY TYPE:** This is a pre & post survey.
- **SAMPLE SIZE:** In this 30 (n=30) Pediatric patient with neurological condition & Caregivers of patients are taken.
- **STUDY POPULATION:** Pediatric patients (with neurological Condition) & Caregivers of patients.

5. RESULT:

Table-1: Gender distribution of subjects:

Gender	No. of Subjects	Percentage
Female	9	30%
Male	21	70%
Total	3	100%

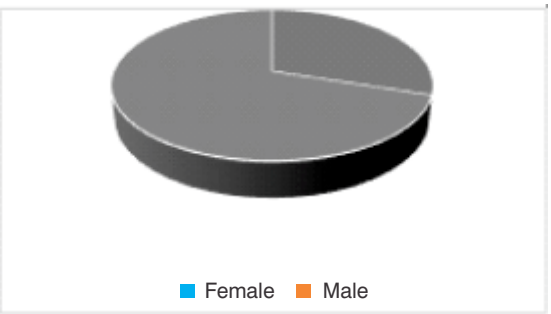

Figure 1. Gender distribution of subjects.

Inference: The above pie graph shows 70% of males and 21% of females are affected with neurological conditions.

5.2 Table-2: Age distribution of subjects studied.

Age in years	No. of subjects
0-2	9
2-4	4
4-6	9
6-8	1
8-10	3
10-12	2
12-14	2
14-16	0

Z value	-4.7821	
p value	<.00001	

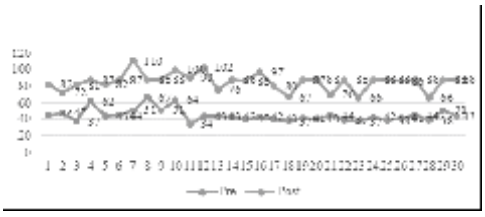

Figure 3. Analysis of psychological well-being index

Inference: The above line graph shows the difference in the mean score and individual score of the applied scale.

5.4 Table-4: Analysis of Gross motor function classification scale (GMFCS).

Parameters	Pre	Post
Mean	2.03333	3.1
SD	0.76489	0.643268
Z value	-4.7821	
p value	<.00001	

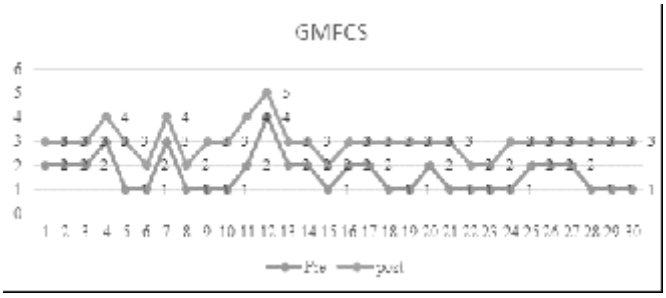

Figure 4. Analysis of gross motor function classification scale

Inference: The graph indicates difference in the change of motor function improvement after physiotherapy treatment.

Interpretation of scales:

Psychological General Well-being Scale: The instrument has qualities that make it suitable also for monitoring well-being during interventions for stress-related exhaustion/clinical burnout.

Gross motor Functional Classification of Scale: The Gross Motor Function Classification System (GMFCS) for cerebral palsy is based on self-initiated movement, with emphasis on sitting, transfers, and mobility.

6. Discussionand Conclusion:

Cerebral palsy leads to mental, physical, psychological and cognitive disabilities or a combination of all. A person may be physically independent but many have various psychological problems.

Psychological problems are common complications following cerebral palsy and have an impact on all aspects of recovery. Children with CP are at increased risk of behavioural and emotional problems, with 1 in 4 developing a behavioural disorder.

Studies investigating behaviour in children with cerebral palsy have found that these children are more likely than there non-disabled peers to struggle with behavioural disorders. The rate of diagnosed disorders in the cerebral palsy population is higher than in the general population of children. As much as 25 to 30 percent of children with cerebral palsy also struggle with a behaviour disorder. It is harder to pinpoint exactly why children with cerebral palsy are more likely to have behavioural challenges. Some risk factors seem to be having learning disabilities, having a seizure disorder, being male, having multiple disabilities, and having communication difficulties. Outside factors may also contribute, including lack of proper care or stress and an inability to cope in the parents. Difficulty with communication seems to be a major factor in challenging behaviours. If a child with cerebral palsy is unable to communicate effectively, he or she may act out to get her needs met. The psychological symptoms were slightly less intense and less frequent in the follow up after a period of six weeks of physiotherapy treatment. Parents and other caregivers of children with cerebral palsy must be aware of the signs of a behavioural disorder so that the child can be evaluated and treated by experts. Living with behavioural challenges is difficult for everyone, for parents and caregivers, for the child with cerebral palsy, and for family members. Recognizing and addressing the problem behaviours early is crucial for helping a child cope and learn new and more appropriate behaviours.

There are several behavioural disorders that have been named and can be diagnosed, including attention deficit hyperactivity disorder, autism, and oppositional defiant disorder, but what is more important for parents and caregivers is to be able to recognize specific behaviours that are frequent, persistent, and problematic. The behavioural problems include Self-injury, Harming other people, Threatening others, Destroying property, Lying, Stealing, Disobedience, Hyperactivity, Impulsivity, These are just some of the potentially problematic behaviours that could indicate a behavioural disorder in a child with cerebral palsy. The general rule is that any behaviour that is inappropriate for a child's developmental age, such as tantrums in a ten year old, is problematic. Problematic behaviours that persist for six months or more may indicate a behavioural disorder.

6.1 The analysis of the data collected showed:

The average score for sample subjects post PT treatment had increased which determined the improvement in the personal wellbeing of the patients as compared to pre PT treatment. (Refer graph 3) During the study it was found that more of males were affected than females. (Refer graph 1). Most of the patients affected by CP were in the age group of 0-2 years, 2-4 years and 4-6years. (Refer graph 2). The difference in the individual scores shows an improvement in the post PT treated patients than the pre PT treated. (Refer graph 4). The rate of improvement in the satisfaction of life as a whole is more in the CP patients post the PT treatment then the pre PT treatment. (Refer graph 4, 5). There is an increase in the standard of living post the PT treatment than the pre PT treatment. (Refer graph 4). Post PT treatment shows increase in the health improvement in CP patients than in the patients before the PT treatment. (Refer graph 4,5) The graph shows an increase improvement in the personal relationships post the PT treatment than in the patient's pre PT treatment. (Refer graph4,5). The feeling of one's safety in CP in more post the PT treatment than in pre PT treated patients. (Refer graph 5). The satisfaction of feeling a part of the community is slightly more in the post PT treated patients than pretreated. (Refer graph 4,5) The study shows that patients post PT treated are more satisfied with their future security than they were pre PT treatment. (Refer graph 4,5)

Parents and other caregivers that believe a child with cerebral palsy is struggling with problem behaviours should consult with professionals who can evaluate the child, make a diagnosis, and help develop a treatment plan. As a parent, you may want to start

with your child's school. A school psychologist or social worker may be able to do an evaluation or direct you to an appropriate professional. For a younger child, a pediatrician is a good place to start. A Pediatric Physiotherapist & behavioural health expert can evaluate your child through a series of observations and tests. Even if your child doesn't meet the criteria for a diagnosis, an expert can still guide you to the appropriate resources or professionals that can help. Any challenging behaviours, even those not labeled as a disorder, are disruptive and should be evaluated and addressed, both for the child and the child's family.

Positive parent-child relationship, encouraging desirable behaviour, teaching new skills and behaviours, managing misbehaviour, and managing high-risk situations. Parents made specific goals for change and were supported in enacting plans for managing challenging parenting situations. This illustrates the urgent need for clinical services to address behavioural and emotional problems in children with CP, as well as the good fit between this clinical need and the efficacy of parenting intervention. Parenting interventions, are ideally translatable. Pediatric Physiotherapy is designed for population-level dissemination, easily implemented within health or educational services, deliverable in high- and low-resource areas, and available in 25 countries.

Anyone may struggle with behavioural conditions or disorders, with challenging behaviours like aggression, impulsiveness, self-harm, and others. Children with cerebral palsy may be more vulnerable to these struggles because of the challenges that the physical disability presents or even because of the underlying brain damage that led to cerebral palsy.

Exactly what causes behaviour disorders is not fully understood, but it is important for parents and other adults to look out for signs of problematic behaviours in children living with cerebral palsy. Experts in behaviour and mental health can help parents and their children cope with and learn to change problem behaviours so that a child living with cerebral palsy can also learn to live with the best quality of life possible.

6.2 Behaviour and Cerebral Palsy:

Studies investigating behaviour in children with cerebral palsy have found that these children are more likely than there non-disabled peers to struggle with behavioural disorders. The rate of diagnosed disorders in the cerebral palsy population is higher than in the general population of children. As much as 25 to 30 percent of children with cerebral palsy also struggle with a behaviour disorder.

It is harder to pinpoint exactly why children with cerebral palsy are more likely to have behavioural challenges. Some risk factors seem to be having learning disabilities, having a seizure disorder, being male, having multiple disabilities, and having communication difficulties. Outside factors may also contribute, including lack of proper care or stress and an inability to cope in the parents. Difficulty with communication seems to be a major factor in challenging behaviours. If a child with cerebral palsy is unable to communicate effectively, he or she may act out to get her needs met.

Parents and other caregivers of children with cerebral palsy must be aware of the signs of a behavioural disorder so that the child can be evaluated and treated by experts. Living with behavioural challenges is difficult for everyone, for parents and caregivers, for the child with cerebral palsy, and for family members. Recognizing and addressing the problem behaviours early is crucial for helping a child cope and learn new and more appropriate behaviours.

There are several behavioural disorders that have been named and can be diagnosed, including attention deficit hyperactivity disorder, autism, and oppositional defiant disorder, but what is more important for parents and caregivers is to be able to recognize specific behaviours that are frequent, persistent, and problematic. These may include:

These are just some of the potentially problematic behaviours that could indicate a behavioural disorder in a child with cerebral palsy. The general rule is that any behaviour that is inappropriate for a child's developmental age, such as tantrums in a ten year old, is problematic. Problematic behaviours that persist for six months or more may indicate a behavioural disorder.

6.3Diagnosis and Treatment :

Parents and other caregivers that believe a child with cerebral palsy is struggling with problem behaviours should consult with professionals who can evaluate the child, make a diagnosis, and help develop a treatment plan. As a parent, you may want to start with your child's school. A school psychologist or social worker may be able to do an evaluation or direct you to an appropriate professional. For a younger child, a pediatrician is a good place to start.

A behavioural health expert can evaluate your child through a series of observations and tests. Even if your child doesn't meet the criteria for a diagnosis, an expert can still guide you to the appropriate resources or professionals that can help. Any challenging behaviours, even those not labeled as a disorder, are disruptive and should be evaluated and addressed, both for the child and the child's family.

Pediatric Physiotherapy & Cognitive behavioural therapy is a typical type of treatment or intervention for behavioural disorders. It is a type of therapy that helps patients become more aware of their behaviours, realize that they are problematic, and learn to change those behaviours by targeting troubling thoughts and emotions. It is an effective type of treatment that helps many people, adults and children, learn to change negative behaviours and replace them with those that are positive and productive.

Recognizing and getting treatment for a child struggling with cerebral palsy-associated behavioural disorders is crucial. These are the first steps toward helping a child learn to cope with negative emotions and other challenges that have led to problematic behaviours. Parents, family, friends, and caregivers of the child must also participate in supporting the treatment and encourage positive changes

Factors that support a child learning to change behaviours include providing all adequate care for cerebral palsy. A child that is not receiving the care he needs will continue to struggle with problematic behaviours. A stress-free home environment is also important. Some studies have shown that a parent's stress level can impact a child's behaviour in a negative way. A calm and caring environment can help support a child as he learns to make positive changes.

Conclusion:

Our result indicates physiotherapy treatment may be effective in reducing the behavioural disorders and subjective burden among caregivers.

Acknowledgements

First and foremost we would like to dedicate this work to all those who contributed to various researches and studies done earlier in the field of physiotherapy and to all those who contributed a lot to add to our knowledge of Physiotherapy.

The path towards this dissertation has been circuitous. Its completion is thanks in large part to the special people who challenged, supported, and stuck with us along the way.

We wish to state our special thanks and credit to our respectable guide and teacher Dr.RAMAKRISHNAN K.S lecturer at Parul Institute of Physiotherapy, Vadodara for his valuable help and guidance, constant encouragement and keen interest shown in this study and without whom this work would not have been possible.

We would also like to thank our God for giving us the strength to finish this study.

We owe this to our lovely parents for their constant support, care and motivation through their blessings.

We express our thanks to all the staff members in Parul Institute of Physiotherapy for their help and valuable suggestions.

To all my friends, especially to Mrugesh Mistry, Laxmi Patel, Roshni Vohra, Hemangi Vaishnav who had helped us to do this study presentable.

Last but not the least we would like to thank all the subjects of our study without whom this task would not have been possible.

Guidelines to Contributors

1. Two copies of the Paper should be submitted and must be printed on only one side of the paper using double spacing throughout (including footnotes and list of references) with sufficient margins on all sides, along with soft copy in CD. Soft copy should be in Microsoft word Times new Roman Font, 12 Font size, double line spacing.
2. The first page of the manuscript should contain only :
   (a) Title of the article, Paper Note or Comment
   (b) Name of the Author.
   (c) Name of the Institution to which author is affiliated.
   (d) Brief academic bio-data and work experience of the author.
   (e) Complete Postal address, e-mail and phone no.
   (f) The subject matter should commence from second page onwards for anonymity so that the referee will not know the identity of the author.
3. The paper should not exceed l0 to 15 pages
4. All manuscripts should include an abstract of about 150 to 300 words.
5. Authors are fully responsible for the accuracy of the data used in the manuscripts. If manuscripts contain statistical, analysis, authors should provide supplementary notes (which will not be published) on the methods used in the analysis for the convenience of the referees. Statistical tables should be clearly titled and the reader should be able to understand clearly the meaning of each row or, column. Units of measurement and sources of data should be clearly stated.
6. The author should certify on a separate page that the manuscript is his/her original contribution. It should also be mentioned that the paper is not submitted or accepted for publication by any other journal.
7. Authors will receive a complementary copy of the journal in which their articles are published.
8. Publication of the article is subject to the review done by the board. once article is sent, it will not be returned to the author if it is not accepted for publication.

All contributions, manuscripts & editorial correspondence should be addressed/E-mail to

COPL/4332

The Effects of Hamstrings Muscles Energy Technique and Postural Correction Exercise in People with Forward Head Posture: A randomized controlled trail

[1]Dr. Niral Gamit, [2]Dr.Ankit Sinha
[1]Assistant Professor, [2] Assistant Professor
Venus Institute of Physiotherapy, Swarrnim Startup & Innovation University, Gandhinagar, Gujarat, India.

ABSTRACT

Objective: To check the effects of hamstring muscle energy technique and postural correction exercises in subjects with forward head posture. **Study design:** Randomized controlled trial.
Method: 40 healthy subjects with forward head posture (FHP) of both gender ages between 20 to 50 years were randomly assigned to experimental and control groups. Both groups were given postural correction exercises but experimental group were given hamstring muscle energy technique (MET). Protocols were performed for 4 sessions per week for 4 weeks. And follow up has been taken in experimental group after 3 months. CVA measurement and popliteal angle measurement has been taken.
Results: within group analysis revealed significant improvements in all variables ($p<0.05$) and between group revealed improvement in CVA ($p<0.05$) in the experimental group in comparison with the control group.
Discussion: Gajdosik et.al. Stated that shortened hamstring muscle would lead to problems at the pelvis and spine, and stretching of the hamstring muscle would restore the normal posture.[20] Muscle chains are essential for the maintenance of the body posture. If any postural problems are in muscle segments, it will lead to shortening or lengthening of the muscles, which can interfere in the physiology of the postural muscles.[9]
Conclusion: Hamstring MET with postural correction exercises was effective in FHP healthy subjects. But this effect was not beneficial for long term. And only postural correction exercises in control group is also effective in FHP healthy subjects.

Key Words: forward head posture, Muscle energy technique, postural correction exercises.

INTRODUCTION

Prevalence of postural abnormalities were including Forward head posture (66%), thoracic kyphosis (38%).[2] The head is move forward is called Forward Head posture, it causes the exaggerated anterior curve of the lower cervical spine and posterior curve of the upper cervical spine maintain the neck balance, it is known as forward head posture.[3]It is mainly caused by the excessive use of mobile phone (text neck), computer workers, abnormal breathing patterns and a backpack on cervical spine.[4,5,6,7] Prolonged adopted posture may results the sub occipital muscle shortening, neck flexors muscle imbalance, which leads the chronic neck pain, neck movement restriction, fatigue and also the joint and muscle loading.[8]

Forward head posture causes the weakness of deep cervical flexors and mid thoracic retractors [rhomboids, serratus anterior, middle and lower fibers of trapezius] so, strengthening of these muscles and stretching exercise for shorten muscles [pectoralis muscles, cervical extensors] may help for the correction of FHP.[7]
Some epidemiological studies suggested that muscle groups are responsible for posture maintenance are arranged and controlled by following a pattern known as “muscle chain”. Muscle chains are essential for the maintenance of the body posture. If any postural problems are in muscle segment, it leads to shortening or lengthening of the muscles, which can interfere in the physiology of the postural muscles. Postural changes are analyzed due to shortening of the different muscle chains. The muscles of orthostatic position against the gravitational action. For this reason, they are known as antigravity muscles.[9]
Posterior chain is composed of the muscle that sole of the foot, triceps surae, hamstrings, spinal erectors, sub occipital muscles.[9] The general statement that can be made about any of these anatomy trains lines is that strain, tension [good and bad], trauma and movement tend to be passes through the structure along with this fascial lines of transmission.[10] The superficial back line is continuting line of fascia and muscles from head to heel with includes both the sub occipital and hamstring. The superficial backline helps to keep us in upright position and connected by the one neural system. The very small sub occipital muscle have a link to the duramater and because of these are often described as a control centre of the SBL, having an effect on the movement of the muscles with the SBL, particularly the hamstring group.[10]
Some postural compensation patterns associated with the superficial back line includes-ankle dorsiflexion limitation, knee hyperextension, hamstring shortness, anterior pelvic tilt, sacral nutation, lordosis, extensor widening in thoracic flexion, sub occipital limitation, It leads to upper cervical hyperextension, anterior shift or rotation of the occiput on the atlas and eye-spine movement disconnection.[10]
There are some simple methods to lengthen the non-contractile or contractile components of the muscle tendinous unit, such as the active stretching, passive stretching applied manually, the active inhibition and self-stretching.11 Other stretching methods can also be used as the ballistic stretching, static stretching and also the stretching techniques by proprioceptive neuromuscular facilitation.12The muscle energy techniques (MET) constitute osteopathic procedures that have the function to lengthen fascias, muscles and also joints. MET is based on the fact that soon after a pre stretching contraction of a determined muscle retracted, this muscle will relax as a result of autogenic inhibition and it will be more easily stretched.[13]
The effect of MET on shortened muscle are neurological effects of loading of the Golgi tendon organ of the skeleton muscle by means of isometric contraction, which produces a post iso metric relaxation effects on shortened muscle. This isometric contraction seems to set the muscle to the new length by inhibiting via influence of the Golgi tendon organ. [13]
There are some studies has been done on the hamstring muscles by treating the sub occipital muscles. Previous studies were not focused on the postural correction. This study is intended to find out the relation of cervical postural correction by increasing hamstring flexibility.

AIM AND OBJECTIVES

The aim of the study to check the effects of hamstring muscle energy technique and postural correction exercises in people with forward head posture.

HYPOTHESIS

NULL HYPOTHESIS-

There will be no significant effects of hamstring MET and postural correction exercise in subjects with forward head posture.

RESEARCH HYPOTHESIS-

There will be significant effects of hamstring MET and postural correction exercise in subjects with forward head posture.

METHODS AND MATERIALS

STUDY DESIGN-Randomized controlled trial

STUDY POPULATION- Healthy subjects with forward head posture

SAMPLING- Purposive sampling

SAMPLE SIZE- 40

RANDOMIZATION-

Block randomization was done to equally distribute the subjects in to two Groups.

STUDY DURATION-April 2018 to May 2019.

STUDY SETTING-

Srinivas Physiotherapy College and research Centre OPD and other government and private clinics in Mangalore [Karnataka] and Surat [Gujarat].

INCLUSION CRITERIA AND EXCLUSION CRITERIA

INCLUSION CRITERIA[3, 13, 20]

- Asymptomatic individuals both male and female with age group 20-50 years.
- Subjects with Cranio- vertebral angle (CVA) less than 50 degree in forward head posture.
- Tight hamstring [Inability to achieve 160˚ of knee extension with hip 90˚ flexion].

EXCLUSION CRITERIA[21]-

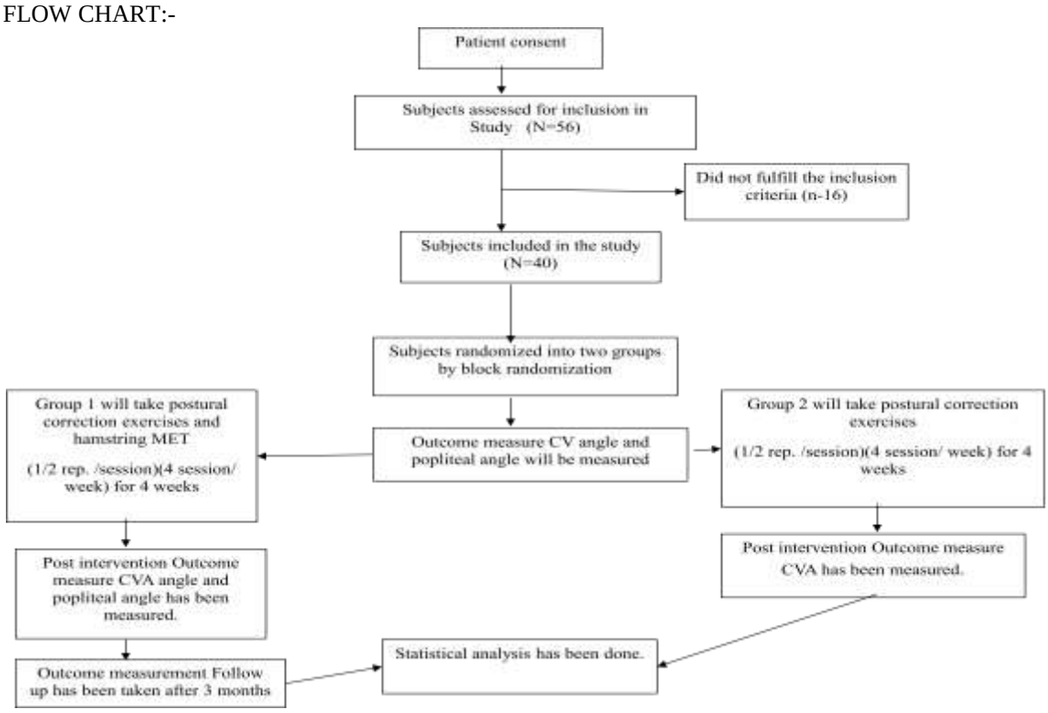
- Recent Cervical fracture or trauma
- Recent Cervical surgery
- Idiopathic scoliosis
- Torticolis
- Acute and chronic hamstring injury

PROCEDURE

The subjects with forward head posture referred for Physiotherapy was screened for inclusion and exclusion criteria. A total of 56 Subjects were screened. In that 40 subjects met the inclusion criteria. The purpose of the study was explained to all the subjects and was asked to sign the written consent form stating the voluntary acceptance to participate in this study. Then, the demographic information (i.e. age, gender, height and weight) was collected from all the subjects. By block randomization, the 40 subjects were assigned randomly into experimental or control group. The pre-treatment measurement for CVA and popliteal angle were taken. Experimental group (n=20) was treated with hamstring MET and postural correction exercises Control group (n=20) was treated with postural correction exercises.

The treatment was given for 4 sessions in a week for a period of four weeks. Post treatment score were evaluated after the last treatment session and follow up was taken after 3 months for experimental group. The data was analyzed and interpreted.

FLOW CHART:-



RESULTS

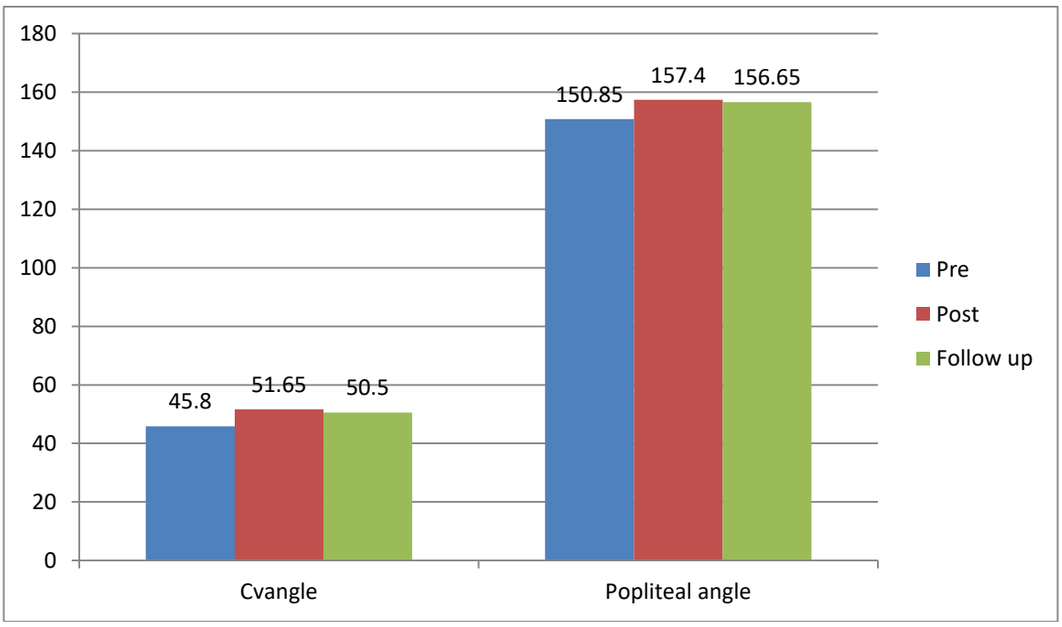
A Total 40 subjects were taken in the study and divided into experimental group and control group. Experimental group consisted of 20 subjects 9 males and 11 females with mean age of 30.35, whereas control group had 20 subjects 7 males and 13 females and mean age 29.35.

Statistical analysis was done using SPSS v.16 Descriptive statistics were subjected to tests of normality and inferential statistics was done using paired t test to compare differences within the groups and repeated measure ANOVA to compare the variables which was based on repeated observations and independent t test was used for analysis between the groups. Confidence interval (CI) for the tests was kept at 95%.

Results showed statistical significance within the groups post intervention in both groups- experimental and control ($p<0.05$) for outcome measures. Between groups post intervention analysis revealed significant differences in CVangle ($p<0.05$).

PARAMETERS		MEAN DIFFERNCE	P VALUE
CVANGLE	PRE	45.80±2.30	0.00
	POST	51.65±2.46	0.00
	FOLLOW UP	50.50±2.66	0.00
POPLITEAL ANGLE	PRE	150.85±4.56	0.00
	POST	157.40±4.63	0.00
	FOLLOW UP	156.65±4.51	0.00

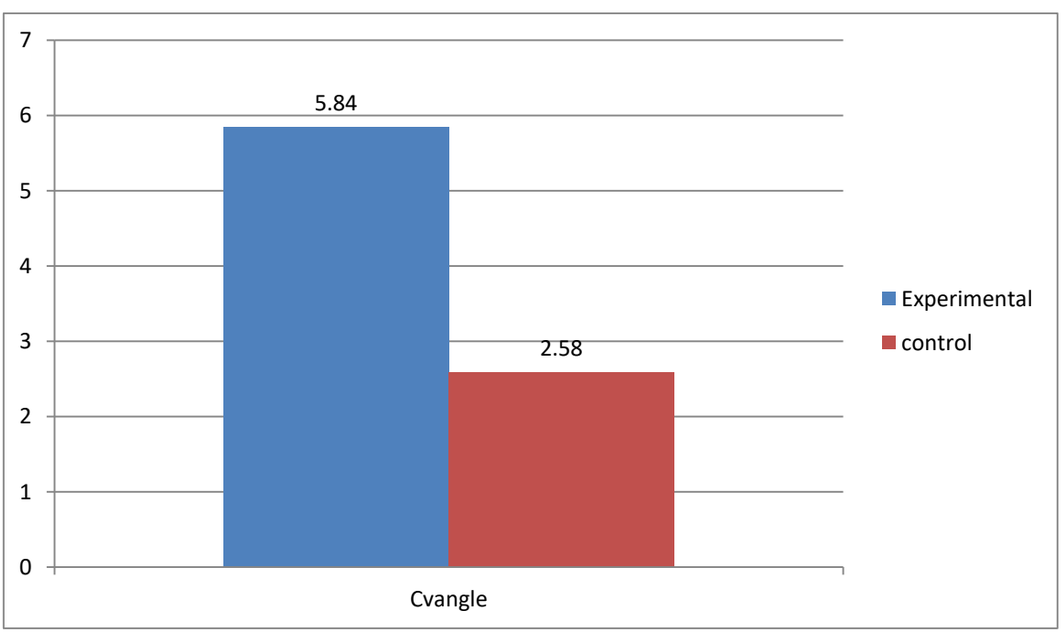
TABLE:1 Shows the mean value of pre, post and follows up of CVangle and popliteal angle in experimental group.



GRAPH:1 shows the mean value of pre, post and follows up of the CVangle and popliteal angle for experimental group.

TABLE:2 shows the mean and standard deviation of post intervention CVangle in experimental and control groups. The mean difference and the significance level (p- value) shows CVangle have p-values<0.05 showing Stastical differences.

PARAMETERS	EXPERIMENTAL	CONTROL	MEAN DIFFERNCE	P VALUE
CVANGLE	5.84±1.45	2.58±1.06	3.26	0.00



GRAPH:2- shows the mean value of post intervention CVangle measurement of experimental and control groups.

DISCUSSION

Prolong adopted posture may result in sub occipital muscle shortening, neck flexors muscle imbalance, which leads to chronic neck pain, neck movement restriction, fatigue and also the joint and muscle loading.8 Forward head posture is the highly prevalent abnormality which may lead to weakness in deep cervical flexors. Forward head posture is usually treated by postural correction exercises.

Gajdosik et.al. Stated that shortened hamstring muscle would lead to problems at the pelvis and spine, and stretching of the hamstring muscle would restore the normal posture. One previous study showed that passive stretching of muscles of the hamstring restore the length of the muscles related to the spine and pelvis, length of those muscles also restore the normal postures.[20]

The successful effects of stretching exercises lies in its physiological mechanism which have been attributed firstly to neurophysiological mechanism in which inhibition of the muscles decreases the activity of the contractile component and result in an increased extensibility of the muscle and an increase in range of motion as well. Secondly to the Biomechanical mechanism that is based on viscoelastic property in which muscles like biologic tissues react viscoelastically to stretch. Elastic behavior refers to the property of a structure to elongate when a force is applied, and to return to its original length when the force is withdrawn.[14] Meanwhile, viscous behavior refers to the property of a structure to elongate when a load is applied and elongation of a muscle is determined by the exerted force and force rate. Due to the above fact, this has been suggested that during the passive hamstring stretching technique subjects shown significant improvement may be due to the changes in viscoelastic property of the muscle.[14]

Likewise a study was done by Schleip and Aparicio et. Al. considered that if the tone of subocipital muscles is decreased, the length of the hamstring muscles and the increase in the amplitude of hip flexion will be greater.14 Some epidemiological studies showed that muscle groups are responsible for posture maintenance and are arranged and controlled by following a pattern known as “muscle chain”. Muscle chains are essential for the maintenance of the body posture. If any postural problems are in muscle segments, it will lead to shortening or lengthening of the muscles, which can interfere in the physiology of the postural muscles.9
Previous studies performed on healthy subjects, aiming to increase the cervical range of motion with giving treatment of hamstring stretching. And the result of this study shown the significantly improved the range of motion in cervical.19
Other study performed to check the effect of sub occipital muscle inhibition technique to improve the flexibility in hamstring. This was showed the effective.[16] But no study could be retrieved on correction of FHP by treating hamstring flexibility. So aim of the current study is to check the effects of hamstring muscle energy technique and postural correction exercises in subjects with forward head posture.
The technique MET was developed and popularized by Mitchell and although many texts promotes the use of MET, it is unforeseen how research, with regards to its effectiveness, is so limited. Of the few studies published to date, most have examined the effects of sub occipital muscles on hamstring muscles. Previous studies not focused on postural correction. Some studies proved that hamstring Proved that hamstring MET treatment is very much effective compare to stretching or other techniques.[20]
The follow up value is reduced because treatment was not given for 3 months. This proves that there is no any long term effect of treatment of this study. But if the treatment will give regularly than it is beneficial to reduce the forward head posture.

LIMITATIONS

1. Limited follow up period.
2. In this study there is only experimental group follow up. There is no follow up for control group.
3. Healthy subjects were included in the study.
4. Homogeneity was not maintained in the genders as in our study. Male participants are less in comparison than females.
5. Small sample size.

RECOMMANDATIONS FOR FURTHER RESEARCH

1. A long term follow up of 6 months to 1 year period can be taken to check the long term effects of MET and postural correction exercises on forward head posture.
2. Study can be done with symptomatic subject.

CONCLUSION

- Hamstring MET with postural correction exercises was effective in FHP healthy subjects. But this effect was not beneficial for long term.
- And only postural correction exercises in control group is also effective in FHP healthy subjects.

ABSTRACT

BACKGROUND: Hereditary spastic paraparesis(HSP) is a genetic disorder characterized by progressive weakness and spasticity of lower limbs. There has not been any single case study on intensive rehabilitation on hereditary spastic paraparesis patient. The objective of the study was to assess the response of a HSP patient to consecutive Eight Week Rehabilitation Program.

CASE DESCRIPTION: This case involved a 16 year old girl with spastic paraparesis that was 5-6 years in duration and slowly worsening. Her complaints mainly included difficulty in walking and keeping feet straight on ground since last 6 years. Both subjective and objective examination was conducted and neurological assessment was done. No bowel,bladder or any loss of sensory system was found.

METHOD: Balance was measured using Berg Balance Scale, 10 Meter Walk Test(10MWT) and Timed Up and Go(TUG) Test. Pre measurements were taken before the treatment began and in the end at 8th week. Data were computed using SPSS 17 software package.

INTERVENTIONS: This included stretching, strengthening, MAT Exercises and gait training for the period of 8 weeks. Each treatment lasted for 60-90 minutes per day, 5-6 days a week.

RESULTS: The result of the study is not quite a lot statistically significant, but clinically there is significant change in patient condition.

CONCLUSION: The findings of the study show that an 8 week rehabilitation program improves overall balance and gait patterns in patient.

INTRODUCTION:

HSP is also known as Hereditary Spastic Paraplegia, Familial Spastic Paraplegia, French Settlement disease or Strumpell - Lorrain disease. The symptoms are a result of dysfunction of long axons in the spinal cord. The affected cells are the primary motor neurons, therefore the disease is an upper motor neuron disease.[1] Worldwide, the prevalence of all Hereditary Spastic Paraplegias combined is estimated to be 2 to 6 in 100000 people.[2] Briefly, the clinical picture in pure HSP is of a slowly progressive, predominately symmetrical, spastic paraplegia. This is frequently accompanied by minor sensory abnormalities (such as absent vibration sensation) and neurological bladder involvement, but bowel involvement is rare.[3] In complex HSP, on addition wide range of neurological features including ataxia, extra pyramidal signs, epilepsy, mental retardation, dementia and peripheral nerve involvement occurs.[4] In pure HSP, life span is not affected.[5] People with HSP complain of muscle stiffness, pain, spasm and cramps, tripping over their toes due to weakness of ankle dorsiflexors and hip flexion, loss of balance, effortful walking and progressively more flexed standing posture[3]. Eventually, walking becomes impossible for some patients, due to a combination of (a) spasticity, (b) weakness particularly of ankle dorsiflexors, (c) loss of range of movement at ankle, knees and hip, making it impossible to stand straight, and (d) loss of motor control leading to delayed postural reflexes and loss of balance. Initial diagnosis of HSP relies upon family history, the presence or absence of additional signs and the exclusion of other non - genetic causes of spasticity.[6] A home exercise program supervised by a patient concentrating on stretches to maintain ROM and reduced spasticity, accomplished by balance exercises in patients with more advanced disease, is the cornerstone of management.[7] There is a recent literature supporting the use of intensive physical therapy i.e. stretching, strengthening, functional re-educative exercises about HSP and fatigue management[8] All these elements attracted our attention and curiosity about how patient with HSP perceive physical therapyand so we devised eight week rehabilitation programme.

CASE REPORT AND ASSESSMENT:

The patient is a 16 years old girl who began facing problems in walking at 10 years of age which was slowly worsening, showing cardinal features of hereditary spastic Para paresis.She has developed scissoring type of gait pattern, has weakness of Gluteus Maximus muscle on the left side. Neurophysiological study shows UMN type of weakness in left lower limb.The case was diagnosed by consulting pediatrician 1 month ago and was referred for physical therapy intervention.She showed no familial history of inheritance or even related disorder. Subject was born out of normal vaginal delivery.Subject's mother has a history of frequent fever during the gestational period and even after the delivery.First symptom began to appear when patient was 10 years old. Spasticity was found in adductors group. Deformities like anterior pelvic tilt, internal femoral torsion, internal tibial torsion,genu valgum, pes planus and toeing out was present. Deep Tendon Reflex examination showed positive plantar reflex bilaterally. Electrophysiological testing of left lower limb showed UMN type of weakness.

Figure 1: Foot arches, left foot signifying pes planus.

Figure 2: Gait pattern of the individual showing scissoring type of pattern.

ASSESSMENTS: Balance was assessed using BBS and TUG, while walking ability by 10MWT . Pre and post measurements were taken before initiating the program and at the end of 8th week. Written informed consent was obtained regarding publication of their case reports.

PHYSIOTHERAPY INTERVENTIONS: Consecutive eight week rehabilitation program was designed to improve functional performance. Stretching, strengthening, gait training and MAT exercises were added. Duration of session was 60-90 minutes/day for 5-6 daysa week which lasted for 8 weeks. Intensities were increased gradually based on performance.

Figure 3: Individual performing MAT exercises.

TABLE 1: Consecutive eight week rehabilitation program for patient with HSP.

INTERVENTION	INTENSITY
1) STRETCHING OF TA, ILIOPSOAS, ADDUCTORS, HAMSTRINGS	20 sec hold/ 4 reps
2) CORE MUSCLE TRAINING (supported bridging)	10 sec/ 10 reps
3) SPINAL MOBILIZATION	
4) STRENGTHENING EXERCISE (SLR, Gluteus medius with assistance and squatting)	10 reps
5) MAT EXERCISE (kneeling, half kneeling)	10 sec/ 10 reps
6) GAIT TRAINING (forward and sideway walking)	

STATISTICAL ANALYSIS:
After the collection of data according to BBS, 10 MWT and TUG, it was analyzed by SPSS 17 software package.

Table 1:

Descriptive Statistics					
	N	Minimum	Maximum	Mean	Std. Deviation
Prewtr	3	10.50	10.90	10.6667	.20817
Valid N (listwise)	3				

The mean value for 3 consecutive Pre 10 Meter Walk Test at regular speed was 10.6+-0.20

Table 2:

	N	Minimum	Maximum	Mean	Std. Deviation
Pre 10MWT fast	3	9.60	9.80	9.7000	.10000
Valid N (listwise)	3				

The mean value for the 3 consecutive Pre 10 Meter Walk Test at fast speed was 9.7±0.10.

Table 3:

	N	Minimum	Maximum	Mean	Std. Deviation
Post 10MWT regular	3	9.70	9.80	9.7667	.05774
Valid N (listwise)	3				

The mean value for the 3 consecutive Post 10 Meter Walk Test at regular speed was 9.7±0.5.

Table 4:

	N	Minimum	Maximum	Mean	Std. Deviation
Post 10MWT fast	3	8.20	8.70	8.5000	.26458
Valid N (listwise)	3				

The mean value for the 3 consecutive Post 10 Meter Walk Test at fast speed is 8.5±0.2.

Table 5:

	N	Minimum	Maximum	Mean	Std. Deviation
Pre TUG	3	11.40	11.43	11.4133	.01528
Valid N (listwise)	3				

The mean value for the 3 consecutive Pre Timed Up and Go test is 11.41±0.1.

Table 6:

	N	Minimum	Maximum	Mean	Std. Deviation
Post TUG	3	8.60	8.80	8.7000	.10000
Valid N (listwise)	3				

The mean value for the 3 consecutive Post Timed Up and Go test is 8.7±0.1.

DISCUSSION:
The main aim of this study is to show that a course of 8 week rehabilitation program improves the functional ability of the patient affected with HSP.

The evaluation of walking speed is widely used in physiotherapy assessment for patient with neurologic diseases (according to Molteni F and et. al). A gait speed of less than 1m/s identifies a person at high risk for negative health outcomes. As well as a study done by Mark Braschinnskyet.al.in 2009 showed that person with HSP represent a high risk group for the 10 min walk test and walking speed in the HSP was more influenced by ROM of hip muscle. In our study we used 3 main outcome measures namely: 10 meter walk test, Berg Balance Scale and Timed Up and Go Test. The values over 8 week didn't show that much statistical improvement but clinically the walking speed and balance was improved. The possible reason for this could be that the patient was regular for 1st four weeks but after that due to some personal reason she wasn't able to follow up, despite this the condition didn't deteriorate. The possible reason being that she was following the home program being given to her. There were significant improvement in Range Of Motion and Manual Muscle Strength Testing following CEREP. A previous study done by Mark et. al. showed that limited Active ROM and increase spasticity on Modified Ashworth Scale results in reduction in walking speed. So this support our results, walking was improved as spasticity was reduced, AROM increased along the course of time. (voluntary muscle grading (VGC) was more than 4).

These results would have been statistically significant if the treatment would have been regular for whole 8 weeks. Patient was also taking intervention prior to the initiation of this study which could also be a reason for marked improvement in gait, balance, ROM and MAS. The results of this study should be interpreted carefully, and it should be verified over larger patient population.

CONCLUSION
The findings of the study show that an 8 week rehabilitation program improves overall balance and gait patterns in patient. Clinically improvements were seen but not relevant statistically. The improvement confirms the therapeutic benefits and benefits of home program both.

LIMITATIONS AND RECOMMENDATIONS: Although the data analysis revealed significant findings to support our result, there are still limitations in this study.

LIMITATIONS:

1) Short duration of study as patient was not able to follow up till the end
2) Limited sample
3) Aspects of cardiac endurance were not tested which are often associated with impaired gait.

RECOMMENDATIONS:

1) Long term effect should be seen
2) Study over larger population can be done
3) Fatigue management technique can be incorporated
4) Comparative study can be done with other neurological disease.

ABSTRACT

Objective: The aim of this study is to see the overall prevalence of diabetes and stratified prevalence in urban area, To Identify the anthropometric, personal and behavioral correlates for diabetes along with OR (odd ratio), and to identify personal habits especially sedentary and physical activity correlates for diabetes along with OR (odd ratio).

Methodology: The cross-sectional study was carried out including total 300 people (121 males, 179 females) from urban area of Ahmadabad. A questionnaire was administered to obtain information about demographic characteristics and risk factors of the Diabetes mellitus and anthropometric and Blood pressure measurements were obtained from participants.

Result: Higher waist circumference, >100 cm for males and >90 cm for females, is the maximum influence on diabetes prevalence with OR of 3.08 ($p<0.001$). Longer sitting time affects diabetes prevalence (OR 1.26) and self-reported hypertension negatively affects diabetic prevalence (OR 0.40). Hypertension based on SBP increase the diabetic prevalence (OR 1.41, $p=0.005$).

Discussion: Over-all prevalence of diabetes in present study is 21.9%. Present study results showed that diabetes increase as age advances. Obesity assessed by BMI is positively associated with diabetes. Waist circumference also positively increases diabetes prevalence. It is also discussed that watching TV more than 2 hrs/day is associated with incidence of diabetes in both men (OR 1.16) and women (OR 1.49) as compared to 1 hr/day TV watching. Physical inactivity is also a major risk factor for diabetes that is supported by several longitudinal studies.

Conclusion: Over-all prevalence of diabetes is 21.9% in this urban community living in Ahmadabad.

Introduction

Diabetes mellitus is one of the most prevalent metabolic, non-communicable disorders in the world. It is estimated, in 2014 there are 422 million adults that having diabetes (nearly doubled since 1980). Prevalence of diabetes has risen faster in low and middle income countries. There are about 1.5 million deaths accounted in 2012 due to diabetes. Increased blood glucose caused an additional 2.2 million deaths due to cardiovascular and other diseases (WHO 2016). The prevalence of diabetes mellitus is predicted to double globally from 171 million in 2000 and 366 million in 2030 with a maximum increase in India (Wild et al. 2014). The etiologies of diabetes mellitus in India include environmental factor, living standard, urbanization, obesity and sedentary life style. The study also shows that the culture, ethinicity, socio-economic conditions also are the major risk factors for diabetes in India. According to ICMR (Indian Council Of Medical Research), the prevalence of diabetes mellitus in Northern India states is greater as compared to South Indian states (Wild et al. 2014, Anjana RM et al. 2011). Indians are more prone to develop complications of diabetes aged between 20 to 48 years as they are genetically predisposed for coronary artery diseases due to dyslipidemia and low level of high density lipoproteins (Mohan et al. 2013). According to a National survey on diabetes and Impaired Glucose Tolerance the age adjusted prevalence was 12.1% for diabetes and 14% for IGT (Ramachandran et al. 2000).

The so called "Asian Indian Phenotype" refers to certain unique clinical and biochemical abnormalities in Indians which include increased insulin resistance, greater abdominal adiposity i.e., higher waist circumference despite lower body mass index, lower adiponectin and higher high sensitive C-reactive protein levels. This phenotype makes Asian Indians more prone to diabetes and premature coronary artery disease. At least a part of this is due to genetic factors. However, the primary driver of the epidemic of diabetes is the rapid epidemiological transition associated with changes in dietary patterns and decreased physical activity as evident from the higher prevalence of diabetes in the urban population.Even though the prevalence of microvascular complications of diabetes like retinopathy and nephropathy are comparatively lower in Indians, the prevalence of premature coronary artery disease is much higher in Indians compared to other ethnic groups. The most disturbing trend is the shift in age of onset of diabetes to a younger age in the recent years (Mohan et al., 2007). Prevalence estimates of diabetes and impaired glucose tolerance (IGT) are high for all Asian countries and are expected to increase further in the next two decades (Unwin et al., 2009).

Diabetes is the name given to a group of different conditions in which there is too much glucose (sugar) in the blood. The pancreas either cannot make insulin or the insulin it does make is not enough and cannot work properly. The effects of diabetes mellitus include long– term damage, dysfunction and failure of various organs. Diabetes mellitus may present with characteristic symptoms such as polydypsia, polyphasia, polyuria, blurring of vision, and weight loss. In its most severe forms, ketoacidosis or a non–ketotic hyperosmolar state may develop and lead to stupor, coma and, in absence of effective treatment, death. Often symptoms are not severe, or may be absent, and consequently hyperglycaemia sufficient to cause pathological and functional changes may be present for a long time before the diagnosis is made. The long–term effects of diabetes mellitus include progressive development of the specific complications of retinopathy with potential blindness, nephropathy that may lead to renal failure, and/or neuropathy with risk of foot ulcers, amputation, Charcot joints, and features of autonomic dysfunction, including sexual dysfunction. People with diabetes are at increased risk of cardiovascular, peripheral vascular and cerebrovascular disease.

Several pathogenetic processes are involved in the development of diabetes. These include processes which destroy the beta cells of the pancreas with consequent insulin deficiency, and others that result in resistance to insulin action. The abnormalities of carbohydrate, fat and protein metabolism are due to deficient action of insulin on target tissues resulting from insensitivity or lack of insulin.

METHODOLOGY

Study Design: Cross sectional study using questionnaire

Sampling method: Random sampling
Response rate: 85.7% (350 people were asked for consent)
Sample size: 300 (121 males, 179 females)

Sample characteristics: Mean ± SD (minimum-maximum values) for age, height, and weight were 47.21 ± 13.54 yrs (30-94), 166.04 ± 9.53 cm (149.20-194.30), 67.01 ± 12.02 Kg (40112) respectively.

Outcome variable: Fasting blood glucose in mg.dL^{-}
Determinants:
1. Age
2. Sex
3. Community
4. Education
5. Income
6. BMI
7. Waist circumference
8. Smoking
9. Alcohol consumption
10. Fruit and vegetable usage (FV)
11. Veg or Non-veg (VNV)
12. ADL for house-hold activities
13. Sleep time
14. TV watching
15. Mobile talking
16. Self-reported hypertension
17. Hypertension
18. Hand-grip strength

Methodology:
Interviewer/investigator, 2 physiotherapists, visited door-to-door and invited the house holders to participate in this study. If they agree (85.7%), informed written consent was taken from all individual members from that house who aged 30 or more. Pre-designed questionnaire (in English), modified from pilot study done in 2015, and was administered to the individual participants and therapist assisted if there was a problem to understand. Following parameters were self-reported: age (in years), height (in centimeters), weight (in kilogram), community (classified into general, backward or schedule), education (classified into illiterate, upto 5th class, 6th-10th class, 11th and 12th class, undergraduate, postgraduate, MPhill, PhD), income (in Rs per month), smoking (yes/no), alcohol habits (yes/no), FV use (no and <14 serves vs>14 serves per week), VNV use (Vegetarian vs Non-vegetarian including egg use), ghee use (no and <7 spoons vs >7 spoons per week), ADL activity (hours per week), TV watching (hours per week), sitting (hours per week), mobile talk (minutes per week), self-reported HTN, family history of HTN, family history of diabetes. BMI was measured using following formula:Weight (Kg).Height^{-2} (in meters).

Following parameters were measured by therapists:
- Waist circumference (WC):
- Blood Pressure (BP) measurement:
- Fasting Blood Glucose (FBG) measurement:
- Hand-grip strength (HGS) measurement:

Definition of Parameters:
Abdominal obesity: 100 cm or more for men; 90 cm or more for women Diabetes: FBG 120 mg.dL^{-1} or more Hypertension: SBP 130 mmHg or more; DBP 85 mmHg or more Obesity: BMI 23 Kg.m^{-1} or more.

After explaining the study population characteristics, we used cross tabulation for chi square test. For the convenience of statistics/results following parameter (continuous values) were qualified (categorical values): age, income PM, ADL at home, sitting time, TV watching time, BMI, WC, BP, FBG, mobile talking, duration of sleep per day, hand-grip strength. Irrespective of significance we calculated OR for all parameters with 95% CI. If there was a significant difference chi-square test, we entered them in multiple logistic regression [enter or forward conditional, backward conditional] and used the best model that explain the diabetes prevalence in this population. All the calculation was done using IBMSPSS (20.0 versions).

RESULT

Table 1. Characteristics of selected variables with percentage (n=300)

S.no	Variable Name	Sub-groups (n)	Percentage
1	Sex	Female (179)	59.7
		Male (121)	40.3
2	Education	Illiterate (50)	16.7
		Primary to higher secondary (135)	45.0
		Graduation or more (115)	38.3
3	Community	General (131)	43.7
		Socially backward (169)	56.3
4	Smoking	No (269)	89.7
		Yes (31)	10.3
5	Alcohol	No (262)	87.3
	Consumption	Yes (38)	12.7
6	Fruit-Vegetable	No-up to 14 serving (222)	74.0
	use	More than 14 serving (78)	26.0
7	Food habit	Vegetarian (263)	87.7
		Non-vegetarian including eggs only (37)	12.3
8	Ghee use	No to 7 spoons per week (75)	25.0
		Greater than 7 spoons per week (225)	75.0

Table 1 shows characteristics, which cannot be quartiled, of selected Ahmedabad urban population. Females were significantly higher than males; only 16.7% of total population was illiterate; socially backward class is significantly higher than general population. 10.3 % of population was smokers and 12.7% of population has taken alcohol; these two parameters should be interpreted cautiously as only men normally do these activities and only 40% of total population was males. 26% of population was taking at least 14 servings/week of fruit and vegetables in their diets and 12.3% were non-vegetarians. 75% of studied population was taking 7 or more spoons/week ghee in their diet.

Table 2. Best model of binary logistic regression when all 6 risk factors* entered

Sno	Variable	Chi square	Significance	OR with 95% CI
Backward Stepwise (Conditional) with Constant 78% correctness				
1	Age		0.052	1.33 (1.00-1.78)
2	WC	25.84	0.004	2.48 (1.35-4.58)
3	Self-reported HTN		0.035	0.35 (0.27-0.95)
Forward Stepwise (Conditional) with Constant- 80.9% correctness				
1	WC		0.002	2.66 (1.45-4.88)
2	Self-reported HTN	25.82	0.018	0.47 (0.26-0.88)
3	HTN based on SBP		0.050	1.82 (1.00-3.33)

*Age, education, WC, sitting time, self-reported HTN and HTN based on SBP

Table 2 shows the best model in binary logistic regression,

when all 6 significant variables were entered, that explains the prevalence of diabetes. We used all the three models (i.e) enter, forward stepwise (conditional) and backward stepwise (conditional)-all three were with constant and found forward stepwise (conditional) with constant that explains 80.9% of diabetes prevalence followed by backward stepwise (conditional) with constant. Four parameters collectively explain in these two models. They are age (OR 1.33), waist circumference (OR 2.66), hypertension based on SBP (OR 1.82) and self-reported hypertension (OR 0.47).

DISCUSSION

Over-all prevalence of diabetes in present study is 21.9%. Present study results showed that diabetes increase as age advances. This is supported by Anjana et al., 2011; Pouranik et al., 2011; Kumar et al., 2008; Ramachandran et al., 2008; Mohan et al., 2003; Haffner et al., 1991. Females are more prone to diabetes than their male counterparts (Hillier et al., 2001; Haffner et al., 1991). However, Indian studies show males are more prone to diabetes than females (Anjana et al., 2011; Ramachandran et al., 2008; Mohan et al., 2003). Diabetes prevalence decrease as the education level progress is supported by Haffner et al., 1991.

Obesity assessed by BMI is positively associated with diabetes [Hartwig et al., 2015 (OR 1.70); Adegbija et al., 2015 (HR 1.8); Bao et al., 2015 (HR 1.16); Gaikwad et al., 2014; Anjana et al., 2011; Berentzen et al., 2011 (HR 1.18); Mohan et al., 2003; Haffner et al., 1991]. Waist circumference also positively increase diabetes prevalence which is supported by Snidjer et al., 2016; Hartwig et al., 2015; Adegbija et al., 2015 and Berentzen et al., 2011 in their longitudinal studies. In India, several cross-sectional studies supported central obesity as a risk factor in diabetes (Anjana et al., 2011; Vijayakumar et al., 2009; Kumar et al., 2008; Ramachandran et al., 2008 and 2004; Mohan et al., 2003).

Dunstan et al., (2004) reported watching TV more than 2 hrs/day is associated with incidence of diabetes in both men (OR 1.16) and women (OR 1.49) as compared to 1 hr/day TV watching. Hu et al., (2003) also reported similar findings (RR 1.10 and 1.30 for 2-5 hrs/week and 6-20 hrs/week as compared to 0-1 hr/week) in their longitudinal study. Long sleep (greater than 7 hours) is associated with higher incidence of diabetes in longitudinal studies [Chaput et al., (2008) (OR 1.58 for 9-10 hrs sleep); Yaggi et al., (2006) (RR 3.12 for >8 hrs sleep); Gottlieb et al., (2005) (OR 1.85 for >9 hrs sleep); Ayas et al., (2003) (RR 1.47 for 9 hrs sleep)].

Hypertension is risk factor for diabetes which is supported by many Indian studies (Gaikwad et al., 2014; Anjana et al., 2011; Vijayakumar et al., 2009; Kumar et al., 2008; Mohan et al., 2003.

Physical inactivity is a major risk factor for diabetes that is supported by several longitudinal studies (Kabeya et al., 2015; Waller et al., 2010; Ansari, 2009; Dunstan et al., 2004; Ramachandran et al., 2004; Helmrich et al., 1991).

CONCLUSION

Based on the results, present study can be concluded with following points

- Over-all prevalence of diabetes is 21.9% in this urban community living in Ahmedabad.
- Age, female sex, obesity (both general and abdominal), low education, lower income, smoking, alcohol habit, being non-vegetarian, low physical activity, longer sitting time with or without TV watching, longer sleeping, hypertension, low hand-grip strength are associated with higher odds for diabetes.
- Out of these 14 variables, age, education, abdominal obesity, sitting time and hypertension based on SBP, self-reported hypertension are significantly influence the diabetes prevalence.
- Out of these 6 variables, 4 variables (i.e) age, abdominal obesity, hypertension based on SBP and self-reported hypertension- explains more than 70% of prevalence of diabetes.

The effect of education classes in addition to home exercise program in community based middle-aged hypertensive adults

Dr. Hirenkumar G. Damor[1], Dr. Mohammedsohel Quadri[2]

[1]Assistant Professor, Venus Institute of Physiotherapy, Swarrnim Startup and Innovation University, Gandhinagar, Gujarat

[2]Assistant Physiotherapy, Venus Institute of Physiotherapy, Swarrnim Startup and Innovation University, Gandhinagar, Gujarat

ABSTRACT

The aims of this study is: To see the effect of education on blood pressure BMI, HR, QOL in community based middle aged hypertensive adults; To see the effect of education classes in addition to home exercise program on blood pressure BMI, HR, QOL in community based middle aged hypertensive adults; and Finally, to compare the effects of education class & education classes in addition to home exercise program on BP, BMI, HR & QOL in community based middle aged hypertensive adults. The study is conducted to see the effect of education classes and education classes in addition to home exercise program on 1.BMI, 2. Heart rate, 3. Systolic BP, 4. Diastolic BP and 5. Quality of life using SF-36. It is a quasi-experimental study. he main findings of the present study were that difference in means of BMI, Systolic BP, Diastolic BP and PCS score and MCS score scores of SF-36 (QOL) questionnaire were found to be statistically significant within group A and group B using paired t-test. In Group C an increase in BMI, HR Systolic BP and Diastolic BP were found, which were statistically significant. There was no change in PCS and MCS scores of SF-36 in group C. The change in Heart Rate, was not significant in group A, B & C. The present study was done to see the effect of education classes in addition to home exercise program in community based middle-aged hypertensive adults with mean age of 47.27±5.869 years in Group A, 44.87±3.720 years in Group B and 47.33±4.964 in Group. In the present study mean difference of HR was not found to be statistically significant within 3 groups. Mean difference of HR was not found to be statistically significant between three group A, B and C. In the present study mean difference of Systolic BP and Diastolic BP in Group A was found to be statistically significant. Mean difference of Systolic BP and Diastolic BP was found to be statistically significant between groups A, B and C. Difference in PCS and MCS scores of SF-36 (QOL) within the group A was found to be statistically significant in the present study. Mean difference of PCS and MCS between groups A & B was also found to be statistically significant. Difference in means in Group C of BMI, Systolic BP, Diastolic BP were increased and statistically significant. Difference in HR was not found to be statistically significant. In Group C PCS & MCS scores did not change pre & post intervention. As a result, it was concluded that, Education classes in middle aged hypertensive subjects decreases BMI, BP & improves QOL. Education + Home Exercise Program for 6 weeks decreases BMI, BP & improves QOL in middle aged hypertensive subjects. Education + exercise in more effective than education alone in decreasing BMI, BP & improves QOL.

Keywords— *Hypertension, Health education, BMI, QOL*

1. INTRODUCTION

The American Heart Association (AHA) defines hypertension as blood pressure of 140 over 90 or higher. Hypertension is sustained high blood pressure (≥140/90mmHg). Blood pressure follows a circadian rhythm in a normal individual. Blood pressure falls during sleep and rises rapidly just before one wake, which is when the risk of cardiovascular events is the highest.[1] Hypertension is an important public health challenge worldwide because of its prevalence. The estimated total number of adults with hypertension in 2000 was 972 million. Of these, 333 million were estimated to be in economically developed countries and 639 million in economically developing countries.[2,3] By 2025, the number of people with hypertension will increase by about 60% to a total of

1.56 billion as the proportion of elderly people will increase significantly. Other reasons are the continuing population increase and change in lifestyle, which includes a diet rich in sugar and high- fat processed foods and sedentary behavior.[2,3]

2. MANAGEMENT OF HYPERTENSION[5]

The goals of antihypertensive therapy are the reduction of cardiovascular and renal morbidity and mortality,with the focus on controlling the systolic BP, as most patients will achieve diastolic BP control when the systolic BP is achieved.[17,18,19] Prehypertension (systolic 120-139 mm Hg, diastolic 80-89 mm Hg) requires health-promoting lifestyle modifications to prevent the progressive rise in blood pressure and cardiovascular disease.[17,18,20] It should be used for the pharmacologic treatment of most cases. In specific high-risk conditions, there are compelling indications for the use of other antihypertensivedrugs.[17,18,19,20] Health

© 2020, www.IJARND.com All Rights Reserved

education and hypertension: Counseling in hypertension is related to lifestyle changes, i.e. non- pharmacological treatment regarding smoking, alcohol, weight, diet, physical activity and stress and is aimed at reducing complications such as stroke and myocardial infarction. Many patients have several risk factors to deal with.[6,7,8]

According to National guidelines (1998), the major objective for hypertension management is to empower patients to actively become involved in the management of their hypertension through lifestyle modification and to ensure that they understand the importance of compliancy to treatment through continued patient health education. In most facilities patients are offered advice on lifestyle modification during consultation because there is not enough time to conduct group education.[9,10,11] According to the data, health workers seem to adhere to the recommendations made in the guidelines with regard to lifestyle modification and patient education. It appears that almost all health workers in all the facilities advice their patients to restrict salt intake in their food, to follow a prudent diet, to do regular physical exercises and to control their body weight.[12,13,14]

3. AIMS AND OBJECTIVE

The aims of the study are:

(a) To see the effect of education on blood pressure BMI, HR, QOL in community based middle-aged hypertensive adults.
(b) To see the effect of education classes in addition to home exercise program on blood pressure BMI, HR, QOL in community based middle-aged hypertensive adults.
(c) Finally, to compare the effects of education class & education classes in addition to home exercise program on BP, BMI, HR & QOL in community based middle-aged hypertensive adults.

The objective of the study is:
To see the effect of education classes and education classes in addition to home exercise program on 1.BMI, 2.Heart rate, 3.Systolic BP, 4.Diastolic BP and 5.Quality of life using SF-36.

4. HYPOTHESIS

Null Hypothesis (0):
There is no significant difference in effect of education classes, education classes in addition to home exercise program and no intervention in community based middle-aged hypertensive adults.
Alternative Hypothesis (H1):

There is significant difference in effect of education classes, education classes in addition to home exercise program and no intervention in community based middle-aged hypertensive adults.

5. MATERIAL AND MATHODOLOGY

5.1 Study Design

A quasi experimental study to see the effect of education classes with and without home exercise program in community based middle-aged hypertensive adults.

5.2 Study Setting

Intervention was conducted in the community of Ahmedabad.

5.3 Study Duration

Total study duration was 12 months; all subjects underwent intervention for 6 weeks.

5.4 Sample Size

45 subjects were divided in three groups.
GROUP A: 15 subjects (Education+ Home exercise) GROUP B: 15 subjects (Education)
GROUP C: 15 subjects (Control group)

5.5 Sampling Design

Convenient sampling

5.6 Inclusion Criteria

(a) Age: 40 to 60 years
(b) Gender: Both males and females
(c) Subjects with clinical diagnosis of hypertension.

5.7 Exclusion Criteria

(a) Doing regular exercise
(b) Any associated systemic involvement
(c) Any musculoskeletal problem
(d) Any neurological problem
(e) Any respiratory and cardiovascular diseases

5.8 Outcome Measures

(a) BMI- Body Mass Index
(b) HR- Heart Rate

© 2020, www.IJARND.com All Rights Reserved

(c) Systolic Blood Pressure
(d) Diastolic Blood Pressure
(e) SF-36(QOL) questionnaire

5.9 Data collection and Procedure

45 subjects from various hospitals & clinics of Ahmedabad were included. Education was given to group A and B. For the education three classes were held. Classes were composed of a half-hour lecture on patho-physiology of hypertension, nutritional advice and effect of exercise on hypertension.

Following suggestions were given in session 2:

(a) Have your blood pressure checked and then monitor it regularly,
(b) Maintain a healthy body weight, reduce intake of dietary saturated fat and cholesterol,
(c) Exercise regularly,
(d) Eat a healthy diet rich in whole grain, more fruits, vegetables and low-fat dairy products,
(e) Reduce sodium in diet,
(f) Maintain an adequate intake of dietary potassium and calcium,
(g) Cut back on caffeine,
(h) Avoid tobacco products & second hand smoke,
(i) Limit alcohol intake,
(j) If prescribed blood pressure medication, take it as directed,
(k) Manage stress, get support from family and friends, for encouragement and emotional or morale boost.

Group A also performed exercises with the following principles:

(a) Intensity: Moderate intensity at RPE 11-13
(b) Frequency: 5days/week
(c) Type:
  - Walking
  - Stretching exercise as warm up
  - 5 minutes cool down exercise (including very slow walking, stretching and relaxed breathing)
(d) Duration: Each session lasted for 30- 45 minutes Session 1: (5 days per week)
(e) Flexibility Exercises (5-repetitions, 10-second hold)
  Hamstring stretches
  Calf stretches
  Thoraco-lumbar fascia stretch Overhead arm stretch and bend
(f) Wall push-ups
(g) Abdominal muscles (5 repetitions), Curl-ups with arms forward (as much as possible)
(h) Walking for 20 minutes.
(i) Cool down exercise: slow walking, stretching and relaxed breathing exercise.

Session 2: (5 days per week)

(a) Flexibility exercises (as above)
(b) Upper limb muscles (Wall pushups 10 repetitions)
(c) Abdominal muscles (5-10 repetitions)
(d) Forward stepping (5 repetitions)
(e) Brisk walking for 30 minutes
(f) Cool down exercise as above Session 3: (5 days per week)
(g) Flexibility exercises (5 repetitions,15 second hold)
(h) Upper limb muscles (Wall pushup 10-15 repetitions)
(i) Abdominal muscles (10 repetitions)
(j) Brisk walking for 30 minutes
(k) Cool down exercise as above.

7. RESULTS

The present study comprised of 45 middle aged hypertensive adults, 15 in each group, all 45 subjects completed the study satisfactorily. Group A was given education for hypertension control and home exercise, Group B was given education for hypertension control and Group C was control group (no intervention).

Table 1: Mean difference in BMI between groups A, B & C

GROUP	BMI		H	p Value
	Mean	SD		
Group A	-0.5053	0.3596	25.92	<0.0001
Group B	-0.2813	0.1940		
Group C	0.2587	0.3507		

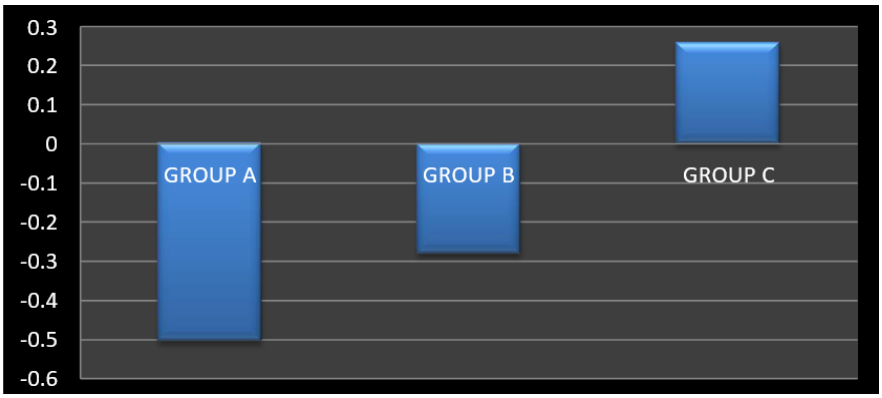

Fig. 6: Mean difference in BMI between groups A, B & C

Here Kruskal Wallis test was performed to compare difference in BMI value was found to be statistically significant at p<0.0001. Mean difference of Systolic BMI in Group A was found to be statistically more significant between 3 groups.

Table 2: Mean difference in HR between groups A, B & C

GROUP	HR		H	p Value
	Mean	SD		
Group A	2.4	4.421	4.517	0.1045
Group B	2.8	5.747		
Group C	-0.8	3.764		

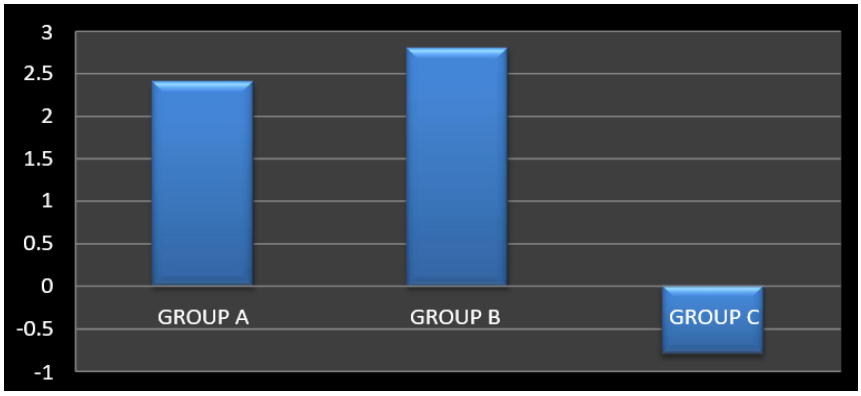

Fig. 7: Mean difference in HR between groups A, B & C

Here Kruskal Wallis test was performed, mean difference in HR was not significant at p= 0.1045

© 2020, www.IJARND.com All Rights Reserved

Table 3: Mean difference in Systolic BP between groups A, B & C

Group	Systolic BP		H	p Value
	Mean	SD		
Group A	-8.263	3.770	30.14	<0.0001
Group B	-7.467	2.875		
Group C	0.8000	1.014		

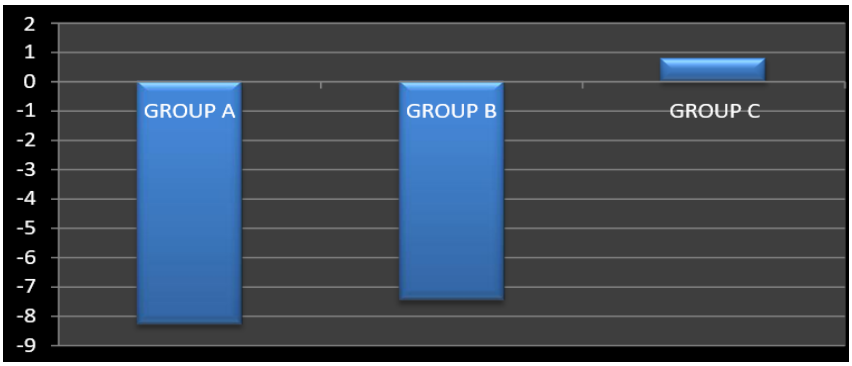

Fig. 8: Mean difference in Systolic BP between groups A, B & C

Here Kruskal Wallis test was performed. Mean difference in Systolic BP was found to be statistically significant at p<0.0001. Mean difference of Systolic BP in Group A was found to be statistically more significant between 3 groups.

Table 4: Mean difference in Diastolic BP between groups A, B & C

Group	Diastolic BP		H	p Value
	Mean	SD		
Group A	-4.000	4.000	18.83	<0.0001
Group B	-1.333	1.447		
Group C	0.8000	1.014		

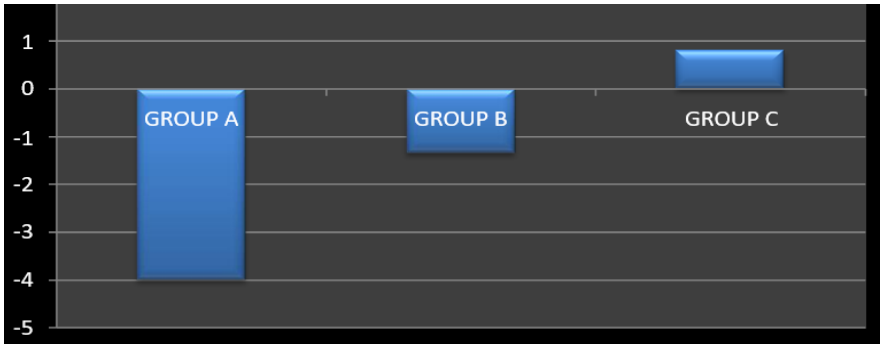

Fig. 9: Mean difference in Diastolic BP between groups A, B & C

Here Kruskal Wallis test was performed, mean difference in Diastolic BP was statistically significant at p<0.0001. Mean difference of Diastolic BP in Group A was found to be statistically more significant between 3 groups.

Table 5: Mean difference in PCS SCORE OF SF-3 between groups A, B & C

Group	PCS		t Value	p Value
	Mean	SD		
Group A	18.32	3.232	3.379	0.0045
Group B	13.96	4.034		
Group C	0.0	0.0		

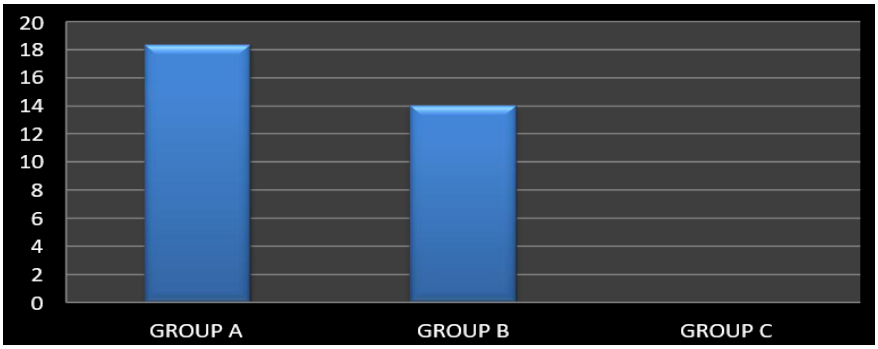

Fig. 10: Mean difference in PCS SCORE OF SF-3 between groups A, B & C

© 2020, www.IJARND.com All Rights Reserved

Here, paired t test was performed for analysis for mean difference in PCS score of SF-36 between groups A & B. t=3.379 and p=0.0045 was found statistically significant. Increase in PCS score of Group A was found to statistically more significant. There was no difference in PCS score of Group C (control group).

Table 6: Mean difference in MCS score of SF-36 between groups A, B & C

Group	MCS		t Value	p Value
	Mean	SD		
Group A	2.907	2.367	2.338	0.0248
Group B	1.340	1.169		
Group C	0.0	0.0		

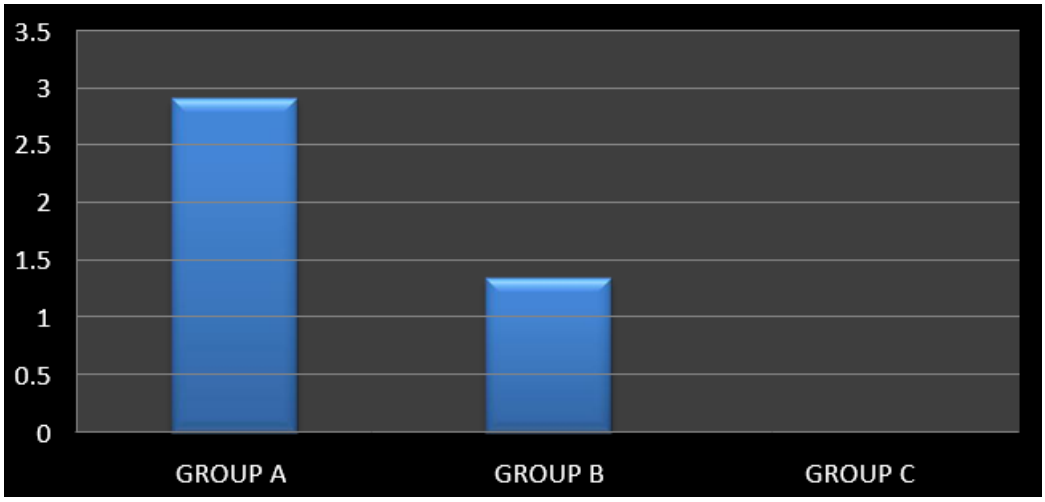

Fig. 11: Mean difference in MCS score of SF-36 between groups A, B & C

Here, paired t test was performed for analysis for mean difference in MCS score of SF-36 between groups A & B. t=2.338 and p=0.0248 was found statistically significant. Increase in MCS score of Group A was found to statistically more significant. There was no difference in MCS score of Group C (control group).

8. DISCUSSION

The present study was done to see the effect of education classes in addition to home exercise program in community based middle-aged hypertensive adults with mean age of 47.27±5.869 years in Group A, 44.87±3.720 years in Group B and 47.33±4.964 in Group. In the present study mean difference of HR (Group A t=2.103, p=0.0541, Group B t=1.887, p=0.0801 & Group C t=0.8231, p=0.4243) was not found to be statistically significant within 3 groups. Mean difference of HR (H=4.517, p=0.1045) was not found to be statistically significant between three group A, B and C.

In the present study mean difference of Systolic BP (t=8.493, p<0.0001), and Diastolic BP in Group A(t=3.873, p=0.0017) was found to be statistically significant. Mean difference of Systolic BP (H=30.14, p<0.0001) and Diastolic BP (H=18.83, p<0.0001), was found to be statistically significant between groups A, B and C.

Difference in PCS (Group A t=21.95, p<0.0001) and MCS (Group A t=4.475, p=0.0003) scores of SF-36 (QOL) within the group A was found to be statistically significant in the present study. Mean difference of PCS (t= 3.379, p= 0.0045) and MCS (t= 2.338, p= 0.0248) between groups A & B was also found to be statistically significant
Difference in means in Group C of BMI (t=), Systolic BP, Diastolic BP were increased and statistically significant. Difference in HR () was not found to be statistically significant. In Group C PCS (pre & post score=33.16) & MCS (Group C pre & post score=32.66) scores did not change pre & post intervention.

8.1 Limitations

- Long term follow-up was not taken
- Subjects were not under daily observation
- Some days were missed out by subjects during their exercise program

8.2 Future Study

The future study can be done with a larger sample size and for longer time duration.

8.3 Clinical Implication

Along with antihypertensives, middle aged adults with hypertension can be advised for the exercise and education programs.

9. CONCLUSION

Education classes in middle aged hypertensive subjects decreases BMI, BP and improves QOL. Education + Home Exercise Program for 6 weeks decreases BMI, BP & improves QOL in middle aged hypertensive subjects. Education + exercise is more effective than education alone in decreasing BMI, BP and improving QOL in middle aged hypertensive subjects. Education +

© 2020, www.IJARND.com All Rights Reserved

exercise and education alone has no effects on HR in middle aged hypertensive subjects.

t=14.10, p<0.0001 & Group B t=5.615, p<0.0001), Systolic BP (Group A t=8.493, p<0.0001 & Group B t=10.06, p<0.0001), Diastolic BP (Group A t=3.873, p=0.0017 & Group B t=3.568, p=0.0031) and PCS score (Group A t=21.95, p<0.0001 & Group B t=13.40, p<0.0001) and MCS score (Group A t=4.475, p=0.0003 & Group B t=4.439, p=0.0006) scores of SF-36 (QOL) questionnaire were found to be statistically significant within group A and group B using paired t-test. In Group C an increase in BMI (t=2.856, p=0.0284), HR (t=0.8231, p=0.4243) Systolic BP (t=3.055, p=0.0086) and Diastolic BP (t=3.055, p=0.0086) were found, which were statistically significant. There was no change in PCS (pre & post score=33.16) and MCS (pre & post score=32.66) scores of SF-36 in group C. The change in Heart Rate (Group A t=2.103, p=0.0541, Group B t=1.887, p=0.0801 & Group C HR t=0.8231, p=0.4243), was not significant in group A,B & C,

Validity of St. George's respiratory questionnaire in lung cancer population

Dr. Mohammedsohel Quadri[1], Dr. Hirenkumar Damor[2]

[1,2]Assistant Professor, Venus Institute of Physiotherapy, Swarrnim Startup and Innovation University, Gandhinagar, Gujarat

ABSTRACT

The main aim of this study is: to determine the concurrent validity of St. George Respiratory Questionnaire with Chronic Respiratory Questionnaire as a gold standard measure to measure health related quality of life in respiratory (chronic airflow limitation) diseases. The research was objected to check the validity of St. George Respiratory Questionnaire in lung cancer population. A Cross Sectional Study design was followed. As the result it was found out that there is high to moderate correlation between domains of SGRQ and CRQ & there is moderate correlation between domain of SGRQ and SF – 36. One way of capturing the personal and social context of patients is to use HRQoL measures. The inclusion of HRQoL in clinical investigations has increased significantly during the last two decades, as has the development of psychometrically sound HRQoL instruments to measure a variety of health conditions. In present study, Results indicate high correlation (r = -0.826, p<0.05) between SGRQ and CRQ and moderate correlation (r = -0.697, p<0.05) between SGRQ and SF-36, because SF-36 is generic health related questionnaire while CRQ is disease specific questionnaire. Our results suggest that the SGRQ is a valid measure to assess HRQOL in subject with Lung cancer. The SGRQ is valid and compares well with the CRQ and SF-36. There was an excellent concurrent validity for SGRQ and CRQ, moderate concurrent validity of SGRQ with SF-36 in lung cancer.

Keywords— *Health Related Quality of Life, Lung Cancer, St. George Respiratory Questionnaire (SGRQ), Chronic Respiratory Questionnaire(CRQ)*

1. INTRODUCTION

Cancer is the leading cause of death worldwide, it accounted for 7.4 million deaths (around 13% of all deaths) in 2004[1]. In 2005, cancer killed approximately 826,000 people in India[2].Lung cancer is among the five main types of cancer leading to overall cancer mortality contributing about 1.3 million deaths/year globally[1]. Lung cancer accounts for 7% of total cancer DALY (Disability Adjusted life years) in India[3]. Cancer is defined as abnormal and uncontrolled division of cells that then invade and destroy the surrounding tissues[4]. Lung cancer is defined as any cancer arises from air passages is called lung cancer[5] Pulmonary symptoms are Dysnea, cough, wheeze, blood stain sputum and hoarseness.[6,7] Dyspnoea, an uncomfortable awareness of breathing, is a very common symptom of patients with lung cancer. Shortness of breath greatly affects the quality of life of these patients.[8] Dyspnea predominant in 80% of lung cancer patients.[9] Dyspnea is a one of symptoms that causes greatest stress to caregivers.[9] Dyspnea causes loss of physical stamina, so that even activities of daily leaving (ADL) became difficult or even impossible.

Quality of life can be defined as a composite measure of physical and social wellbeing as perceived by each individual or by group of individual.[10] HRQOL refers to multidimensional assessments that include at least the physical, emotional (or psychological) and social domains, and may also include other domains such as cognitive functioning. HRQOL instrument require the little technical support and can be used in high resources and in low resources areas[12], but there is no disease specific instrument that has been validated for persons with lung cancer.

The St. George Respiratory Questionnaire (SGRQ) is an Index designed to measure and quantify health-related health status in patients with chronic airflow limitation.[11] SGRQ, an existing instrument that has been validated for use in patient with several types of lung diseases. I.e. COPD, cystic fibrosis, bronchial asthma and bronchiectasis[11] and pulmonary tuberculosis.[12] there is no study has been done to measure HRQoL by using SGRQ in lung cancer population.

The SGRQ divided into three sections component of "symptoms", "activity" and "impacts" Chronic Respiratory Questionnaire (CRQ) measures physical and emotional function divided into four dimensions: dyspnoea, fatigue, emotion, and mastery.

Medical Outcomes Short Form 36: is a generic health-related quality-of-life instrument, which has been used to assess quality of life in a variety of chronic medical conditions including COPD and asthma[35-36.]

© 2020, www.IJARND.com All Rights Reserved

Its validity, reproducibility, and responsiveness to changes over time have been well demonstrated. SGRQ is measures respiratory disease specific HRQOL and reliability and validity of this questionnaire is done in many of the respiratory diseases, till now no study has been done to measure HRQOL in Lung Cancer by using Respiratory disease specific Questionnaire. So, the purpose of this study is to find out the concurrent validity and measurement of Health related QOL in lung cancer patients by using St. George Respiratory Questionnaire.

2. AIMS AND OBJECTIVES

2.1 Aim

To determine the concurrent validity of St. George Respiratory Questionnaire with Chronic Respiratory Questionnaire as a gold standard measure to measure health related quality of life in respiratory (chronic airflow limitation) diseases.

2.2 Objective

Primary objective: To check the validity of St. George Respiratory Questionnaire in lung cancer population.
Secondary objective: To measure the health-related quality of life in lung cancer patients using self administered questionnaire.

3. METHODOLOGY

3.1 Study Design

Cross-sectional study design

3.2 Source of data

The participants with Lung Cancer of this study were recruited from the following hospital

- Gujarat cancer research institute, Ahmedabad.
- Vedant hospital, Ahmedabad.
- Apollo hospital, Ahmedabad.

Permission with the ethical clearance was obtained from the ethical committee of Srinivas College of Physiotherapy and Research Center and also from the above-mentioned hospitals.

3.3 Sampling Technique

Since the study was done on Lung cancer patients and subject were chosen based on the selectivity criteria. Hence purposive sampling was done.

3.4 Sample Size

A total 59 number of cancer subjects were selected for the study. Out of 59 subjects 34 included in study as 17 subjects were not willing to take participation and 8 did not meet the inclusion criteria

3.5 Criteria for selection

(a) Inclusion Criteria

- Patient with histopathologically diagnosed as lung cancer.
- Age more than eighteen years.

(b) Exclusion criteria

Subject with history of:

- Psychiatric disorders.
- Neurological impairments.
- Muscular dystrophies.
- Cognitive impairments.
- Pediatrics.
- Medically unstable.

4. PROCEDURE

The participants who meet the inclusion criteria were asked to sign an informed consent form approved by the institution. Pre participation data was taken for each subject prior to study which includes Name, Age, Sex, Socioeconomic status, Concurrent disease, and Type of Lung cancer. Subjects were asked to fill the questionnaire which was design to measure their level of health-related quality of life by using SGRQ, CRQ and SF-36 respectively. The participants, who do not know to read and write, were explained about the questionnaire in their mother tongue and response was noted by the person interviewing.

4.1 Data Recording and Tabulation

Data was collected in hard copies of all questionnaires, than the data for SGRQ was feeded in the SGRQ Microsoft Excel based calculator as recommended by the developer, while for the CRQ the scoring was done on a 7 point likert scale higher the score better the quality of life as suggested by developer and for SF – 36 the same Microsoft Excel based calculator as recommended by the developer**.**

4.2 Statistical Analysis

Basic characteristics of subjects age, gender, height, weight and BMI was analyzed by Descriptive statistics. Concurrent validity of SGRQ with CRQ and SF-36 was validated with Spearman's correlation test. Statistical analysis done by using SPSS Version 14.0.

© 2020, www.IJARND.com All Rights Reserved

5. RESULTS

Table 1: Descriptive data of total scores of SGRQ, CRQ and SF-36

	Mean	Standard Deviation
Total SGRQ	**54.2544**	**17.68**
Total CRQ	**75.2353**	**18.35**
Total SF-36	**46.5588**	**18.76**

Table 1 shows the descriptive statistics i.e. mean and Standard Deviation of SGRQ, CRQ and SF-36 score(x = 54.25 SD = 17.68, x = 75.23 SD =18.35 and x = 46.55 SD = 18.76 respectively).

Table 2: Descriptive data of Domains of SGRQ, CRQ and SF-36.

		Mean	Standard Deviation
SGRQ	Symptoms	65.5368	17.09
	Activity	59.0712	20.11
	Impact	47.6065	18.63
CRQ	Dysnea	20.8235	4.69
	Fatigue	14.9706	3.97
	Emotional Functioning	25.2941	6.96
	Mastery	14.5588	4.11
SF-36	Physical functioning	52.5000	20.53
	Role-Physical	36.0294	29.63
	Bodily-Pain	42.0294	18.60
	General Health	39.5000	15.95
	Physical health Component Score	42.8235	18.32
	Vitality	44.5588	17.89
	Social Function	52.0294	21.17
	Role Emotional	50.9706	36.08
	Mental Health	55.0588	19.39
	Mental health Component Score	48.2941	18.46

Table 2 describes the descriptive statistics for subjects age and all the domains of SGRQ, CRQ and SF-36.

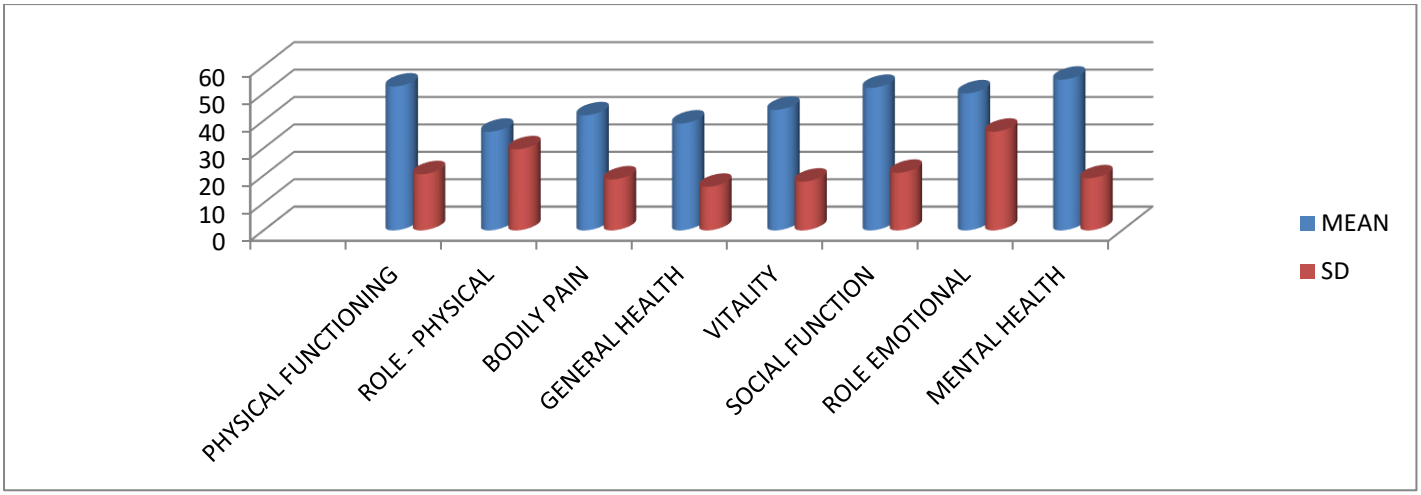

Fig. 1: Shows descriptive data of Domains of SF-36

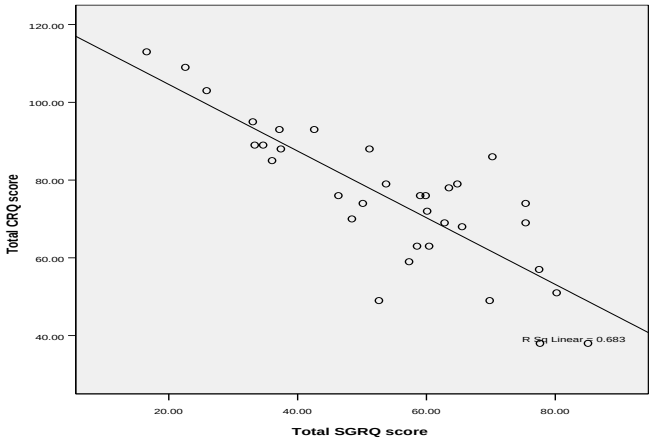

Fig. 2: Shows correlation between total score of SGRQ and total score of CRQ

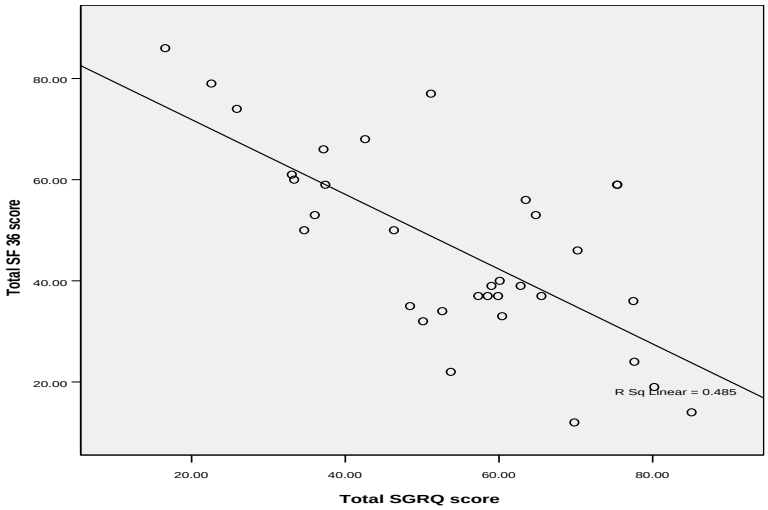

Fig. 3: Shows correlation between total score of SGRQ and total score of SF-36

Table 3: Correlations between the SGRQ domains and the CRQ

SGRQ Domains	CRQ Domains	Correlation(r)	Significance (p)
Symptoms	Dysnea	-0.396*	0.020
	Fatigue	-0.596**	0.0001
	Emotional function	-0.719**	0.0001
	Mastery	-0.751***	0.0001
Activity	Dysnea	-0.570**	0.0001
	Fatigue	-0.495*	0.0003
	Emotional function	-0.691**	0.0001
	Mastery	-0.619**	0.0001
Impacts	Dysnea	-0.609**	0.0001
	Fatigue	-0.460*	0.0006
	Emotional function	-0.711**	0.0001
	Mastery	-0.641**	0.0001
Total Score	Dysnea	-0.601**	0.0001
	Fatigue	-0.528**	0.001
	Emotional function	-0.757*	0.0001
	Mastery	-0.699**	0.0001

***= high correlation **=moderate correlation *=low correlation.

Table 3 shows correlation between domains of SGRQ and CRQ

Table 4: Correlations between the SGRQ domains and the SF-36.

SGRQ Domains	SF-36 Domains	Correlation(r)	Significance (p)
Symptoms	PCS score	-0.669**	0.0001
	MCS score	-0.541**	0.001
Activity	PCS score	-0.676**	0.0001
	MCS score	-0.586**	0.0001
Impacts	PCS score	-0.662**	0.0001
	MCS score	-0.636**	0.0001
Total Score	PCS score	-0.716**	0.0001
	MCS score	-0.646**	0.0001

***= high correlation **=moderate correlation *=low correlation.

Table 4 shows correlation between domains of SGRQ and SF-36.

6. DISCUSSION

The evaluation of lung function does not fully reflect the impact of the disease on a patient and, therefore, should be supplemented by using quality-of-life questionnaires.[15]One way of capturing the personal and social context of patients is to use HRQoL measures. The inclusion of HRQoL in clinical investigations has increased significantly during the last two decades, as has the development of psychometrically sound HRQoL instruments to measure a variety of health conditions.

In present study, Results indicate high correlation($r = -0.826$, $p<0.05$) between SGRQ and CRQ and moderate correlation($r = -0.697$, $p<0.05$) between SGRQ and SF-36, because SF-36 is generic health related questionnaire while CRQ is disease specific questionnaire.[13] Molken et al also found well correlation ($r = -0.725$; $P<0.001$ and our result is $r = -0.826$; $P<0.001$) between total of SGRQ and total score of CRQ. The total scores of both questionnaires (SGRQ and CRQ) correlated best with each other and with the each domain scores. [9] Even in our study also the total score of SGRQ correlated well with each domains.

© 2020, www.IJARND.com All Rights Reserved

Moderate to high significant correlation found between various domains of SGRQ and total score of CRQ ($p<0.05$) similarly same results were found by a previous study.[9]

Results of our study are supporting the results of studies[10, 11] being done previously to measure the correlation between SGRQ and SF-36 in different diseases. Moderate to high significant correlation was found between and total score of SGRQ and PCS and MCS score of SF-36. Carolyn BW et al[11] other two previous studies, [12,13] found overall, SGRQ scores were more strongly associated with the PCS than MCS of SF-36. In general, scores of SF-36 were better correlated with the Impact component of the SGRQ than the Symptoms or Activity component. These may be due to Impacts component contains similar aspects as in PCS and MCS components of SF-36.

We found moderate significant correlation found between various domains of SGRQ and total score of SF-36($p<0.05$) (table 5.7). So, SGRQ is valid tool to measures HRQOL in various Respiratory Diseases as same as the gold standard tool CRQ. Moreover, SGRQ measures larger aspects of HRQOL compare to CRQ thus provide better idea about HRQOL of subjects and allow clinician/physiotherapist to measure impact of a disease on a patient's daily life and they can be especially valuable in clinical trials design to access the benefits, side effects and cost of different treatments.

SGRQ is available in 48 languages including 11 Indian languages while CRQ is available in only 8 languages (no Indian language) so SGRQ is better applicable to measure HRQOL in disease specific conditions in Indian scenario.

7. LIMITATIONS

- Smaller sample size.
- To precisely know HRQOL, how long its impact remains longitudinal study should be done.

8. FURTHER RECOMMENDATIONS

- Further research should be focused on specific type of locally language adapted questionnaire.
- Further research should be done with Cancer specific questionnaire along with HRQOL questionnaire.
- The SGRQ emerges as an excellent discriminative and a good evaluative instrument for LC subjects, and its use should be encouraged in routine assessment of patients' health status.
- Psychometric properties of Questionnaire should be done in Lung cancer.

9. CONCLUSION

Our study leads to following conclusions:

- Our results suggest that the SGRQ is a valid measure to assess HRQOL in subject with Lung cancer.
- The SGRQ is valid and compares well with the CRQ and SF-36.
- There was an excellent concurrent validity for SGRQ and CRQ, moderate concurrent validity of SGRQ with SF-36 in lung cancer.
- There was moderate to high significant correlation found between the domains of SGRQ and CRQ, except there was low significant correlation between SGRQ domain symptoms and CRQ domain dysnea, SGRQ domain activity and CRQ domain fatigue and SGRQ domain impacts and CRQ domain fatigue.
- Similarly, moderate to high significant correlation was found between the total score of SGRQ and various domains of CRQ.
- Moderate to high significant correlation found between various domains of SGRQ and PCS and MCS score of SF-36, and total score of SGRQ and PCS and MCS score of SF-36.
- High significant correlation found between various domains of SGRQ and total score of CRQ.
- Moderate significant correlation found between various domains of SGRQ and total score of SF-36.
- The SGRQ emerges as an excellent discriminative and a good evaluative instrument for Lung cancer subjects, and its use should be encouraged in routine assessment of patients' health status.

TO SEE EFFECT OF PANCHAM KRIYA IN CHRONIC LOWER BACK PAIN

Dr. HEENABANU YUSUFBHAI SHEKH
Assistant Professor
Venus Institute of Physiotherapy, Swarnim Startup & Innovation University, Gandhinagar, Gujarat, India.

ABSTRACT

Objective

The aim of the study was to check the effect of *PANCHAM KRIYA* in chronic lower back pain.

Methodology

Total 10 subjects fulfilling selection criteria participated in the study. All of them were told about the procedure of study. All their queries were answered satisfactorily and informed consent was taken from them.*Pancham kriya* exercises were given to the participants. In the beginning of treatment, they were given VAS disability questionnaire.They were asked to fill these questionnaires. After 10 days of protocol of *Pancham kriya* exercises, they were again told to fill these outcome measures.

Result

It shows statistically significant improvement in Pre intervention or post intervention scores of VAS.

Discussion

It is important to note that *Pancham kriya* exercises are significant in the patients with low back pain than general exercises. There were greater improvements in the group that received this therapy. It is also discussed that transverse abdominal muscle, which was the focus of specific strengthening exercises programme for low back pain can significantly decrease the laxity of sacro -illiac joint.

Conclusion

Pancham kriya exercises were efficient in reducing pain and disability of low back pain patient.

Key words:- *Pancham kriya,* Low back pain, VAS.

INTRODUCTION

Low back pain is common,painful,irritative & unpleasant condition affecting the lower portion of the spine.it can be caused by injury to a muscle(strain) or ligament(sprain).common causes for low back pain include improper lifting,poor posture,lack of regular exercises,a fracture,ruptured disc or arthritis,it can be due to prolonged sitting and laying down in one position,sometimes lower back pain can be due to some other cause e.g. osteomyelitis,ankylosing spondylitis etc.

According to the NATIONAL INSTITUTE OF NEUROLOGICAL DISORDERS AND STROKE (NINDS) low back pain is the most common cause of job related disability. Over 80% of population suffer from lower back pain during their lives mainly because of adoption of bad posture while activities of daily living

PANCHAM KRIYA is sustained movements with co-ordination and regular simultaneous movements from distal to proximal direction in lower limbs to relieve chronic low back pain.In this treatment exercises were scheduled from ankle joint to lumbo-sacral joints.

Aim and Objective of the study:

The aim and objective of the study is to check the effect of core strengthening exercises in low back pain.

Hypothesis:

Experimental Hypothesis:

There is effect of ***PANCHAM KRIYA*** exercises in low back pain with visual analogue scale and questionnaire.

Null Hypothesis:

There was less effect of ***PANCHAM KRIYA*** exercise in low back pain with visual analogue scale questionnaire.

METHODOLOGY

For this study method sample selection was random in which 10 subjects were fulfilling the criteria for study with ***PANCHAM KRIYA*** exercises to relieve chronic low back pain in females age group 20-40 years. Pre and Post intervention were noted down to get proper results and conclusions.

Study design:
Experimental study design.

Sample:
Random Sampling
A total number of 10 subjects were included for the study.

Study center:
Merchant Physiotherapy college, Mehsana, HNGU(Patan)

Inclusion criteria:-

- ✓ Females of age group 20-40 yrs.
- ✓ Females having chronic low back pain

Exclusion criteria:-

- ✓ History of surgery of back
- ✓ History of recent fractures
- ✓ History of back deformity
- ✓ History of pathologies around knee/ankle
- ✓ History of trauma
- ✓ History of steroidal medication since last months.

Outcomes measures:-

- ✓ Visual analogue scale

Procedure: 10 subjects fulfilling selection criteria participated in the study. All of them were told about the procedure of study. All their queries were answered satisfactorily and informed consent was taken from them.***PANCHAM KRIYA*** exercises were given to the participants. In the beginning of treatment, they were given VAS disability questionnaire. They were asked to fill theis questionnaire. After 10 days of protocol of ***PANCHAM KRIYA*** exercises, they were again told to fill these outcome measures.

Pancham kriya is combined and simultaneous activities for lower spine as well as lower limbs from distal to proximal direction. Activities in ***pancham kriya*** should be given in following sequence are as under:-

(1) Ankle dorsiflexion-Planterflexion (ankle pump)
Exercises:-They were asked to lie down on back and asked to go for Dorsiflexion-Planterflexion at a time
Repetitions :-5-5 repetations and twice a day

(2) Knee flexion –extension
Exercises:- They were asked to lie down on back and asked to go for Knee flexion –extension B/L
Repetitions :- 5-5 repetations and twice a day

(3) Hip flexion-back to starting position
Exercises:- They were asked to lie down on back and asked to go for Hip flexion-back to starting position B/L
Repetitions :- 5-5 repetations and twice a day
(4) Knee to heel
Exercises:- They were asked to lie down on back and asked to flex both knees and asked to touch heels by opposite knees
Repetitions :- 5-5 repetations and twice a day

(5) Pelvic rotation
Exercises:- They were asked to lie down on back and asked to flex both knees and asked to go for pelvic rotation by turning both knees one side and head towards another side
Repetitions :-5-5 repetations both sides

The participants were selected for the inclusion and exclusion criteria of the study. The patient should be comfortable and relaxed.

DATA ANALYSIS

Variable	VAS
Mean	2.35
Standard Deviation	1.786
S.E	0.436
T value	4.161

Conclusion:- T-value is highly significant at 1% level
Pancham Kriya exercises are highly significant for chronic lower back pain.

RESULTS
It shows statistically significant improvement in:
Pre intervention or post intervention scores of VAS.

DISCUSSION
The results of this study supported hypothesis that ***PANCHAM KRIYA*** exercises were significant in the patients with low back pain than general exercises. There were greater improvements in the group that received ***PANCHAM KRIYA*** therapy. Using the criteria of **Ferreira PH, and Rackwitz B,** also reported that specific Progressive exercises was better than ordinary medical care and treatment by a general practitioner for reducing pain. ***PANCHAM KRIYA*** exercises were found very effective as part of yoga also,major effects on back muscles with help of simultaneous movements to lower limbs from distal to proximal without having any side effects.

Limitations: This study was characterized by some limitations . The first common limitation was that the findings were based on short data. Another limitation was that some article did not contain much sufficient information for evaluating the quality and clinical relevance of data.

CONCLUSION
PANCHAM KRIYA exercises were more efficient in reducing chronic low back pain and disability of low back pain of patient.

Validity of St. George's respiratory questionnaire in lung cancer population

Dr. Mohammedsohel Quadri[1], Dr. Hirenkumar Damor[2]

[1,2]Assistant Professor, Venus Institute of Physiotherapy, Swarrnim Startup and Innovation University, Gandhinagar, Gujarat

ABSTRACT

The main aim of this study is: to determine the concurrent validity of St. George Respiratory Questionnaire with Chronic Respiratory Questionnaire as a gold standard measure to measure health related quality of life in respiratory (chronic airflow limitation) diseases. The research was objected to check the validity of St. George Respiratory Questionnaire in lung cancer population. A Cross Sectional Study design was followed. As the result it was found out that there is high to moderate correlation between domains of SGRQ and CRQ & there is moderate correlation between domain of SGRQ and SF – 36. One way of capturing the personal and social context of patients is to use HRQoL measures. The inclusion of HRQoL in clinical investigations has increased significantly during the last two decades, as has the development of psychometrically sound HRQoL instruments to measure a variety of health conditions. In present study, Results indicate high correlation (r = -0.826, p<0.05) between SGRQ and CRQ and moderate correlation (r = -0.697, p<0.05) between SGRQ and SF-36, because SF-36 is generic health related questionnaire while CRQ is disease specific questionnaire. Our results suggest that the SGRQ is a valid measure to assess HRQOL in subject with Lung cancer. The SGRQ is valid and compares well with the CRQ and SF-36. There was an excellent concurrent validity for SGRQ and CRQ, moderate concurrent validity of SGRQ with SF-36 in lung cancer.

Keywords— *Health Related Quality of Life, Lung Cancer, St. George Respiratory Questionnaire (SGRQ), Chronic Respiratory Questionnaire(CRQ)*

1. INTRODUCTION

Cancer is the leading cause of death worldwide, it accounted for 7.4 million deaths (around 13% of all deaths) in 2004[1]. In 2005, cancer killed approximately 826,000 people in India[2].Lung cancer is among the five main types of cancer leading to overall cancer mortality contributing about 1.3 million deaths/year globally[1]. Lung cancer accounts for 7% of total cancer DALY (Disability Adjusted life years) in India[3]. Cancer is defined as abnormal and uncontrolled division of cells that then invade and destroy the surrounding tissues[4]. Lung cancer is defined as any cancer arises from air passages is called lung cancer[5] Pulmonary symptoms are Dysnea, cough, wheeze, blood stain sputum and hoarseness.[6,7] Dyspnoea, an uncomfortable awareness of breathing, is a very common symptom of patients with lung cancer. Shortness of breath greatly affects the quality of life of these patients.[8] Dyspnea predominant in 80% of lung cancer patients.[9] Dyspnea is a one of symptoms that causes greatest stress to caregivers.[9] Dyspnea causes loss of physical stamina, so that even activities of daily leaving (ADL) became difficult or even impossible.

Quality of life can be defined as a composite measure of physical and social wellbeing as perceived by each individual or by group of individual.[10] HRQOL refers to multidimensional assessments that include at least the physical, emotional (or psychological) and social domains, and may also include other domains such as cognitive functioning. HRQOL instrument require the little technical support and can be used in high resources and in low resources areas[12], but there is no disease specific instrument that has been validated for persons with lung cancer.

The St. George Respiratory Questionnaire (SGRQ) is an Index designed to measure and quantify health-related health status in patients with chronic airflow limitation.[11] SGRQ, an existing instrument that has been validated for use in patient with several types of lung diseases. I.e. COPD, cystic fibrosis, bronchial asthma and bronchiectasis[11] and pulmonary tuberculosis.[12] there is no study has been done to measure HRQoL by using SGRQ in lung cancer population.

The SGRQ divided into three sections component of "symptoms", "activity" and "impacts" Chronic Respiratory Questionnaire (CRQ) measures physical and emotional function divided into four dimensions: dyspnoea, fatigue, emotion, and mastery.

Medical Outcomes Short Form 36: is a generic health-related quality-of-life instrument, which has been used to assess quality of life in a variety of chronic medical conditions including COPD and asthma[35-36.]

© 2020, www.IJARND.com All Rights Reserved

Its validity, reproducibility, and responsiveness to changes over time have been well demonstrated. SGRQ is measures respiratory disease specific HRQOL and reliability and validity of this questionnaire is done in many of the respiratory diseases, till now no study has been done to measure HRQOL in Lung Cancer by using Respiratory disease specific Questionnaire. So, the purpose of this study is to find out the concurrent validity and measurement of Health related QOL in lung cancer patients by using St. George Respiratory Questionnaire.

2. AIMS AND OBJECTIVES

2.1 Aim

To determine the concurrent validity of St. George Respiratory Questionnaire with Chronic Respiratory Questionnaire as a gold standard measure to measure health related quality of life in respiratory (chronic airflow limitation) diseases.

2.2 Objective

Primary objective: To check the validity of St. George Respiratory Questionnaire in lung cancer population.
Secondary objective: To measure the health-related quality of life in lung cancer patients using self administered questionnaire.

3. METHODOLOGY

3.1 Study Design

Cross-sectional study design

3.2 Source of data

The participants with Lung Cancer of this study were recruited from the following hospital

- Gujarat cancer research institute, Ahmedabad.
- Vedant hospital, Ahmedabad.
- Apollo hospital, Ahmedabad.

Permission with the ethical clearance was obtained from the ethical committee of Srinivas College of Physiotherapy and Research Center and also from the above-mentioned hospitals.

3.3 Sampling Technique

Since the study was done on Lung cancer patients and subject were chosen based on the selectivity criteria. Hence purposive sampling was done.

3.4 Sample Size

A total 59 number of cancer subjects were selected for the study. Out of 59 subjects 34 included in study as 17 subjects were not willing to take participation and 8 did not meet the inclusion criteria

3.5 Criteria for selection

(a) Inclusion Criteria

- Patient with histopathologically diagnosed as lung cancer.
- Age more than eighteen years.

(b) Exclusion criteria

Subject with history of:

- Psychiatric disorders.
- Neurological impairments.
- Muscular dystrophies.
- Cognitive impairments.
- Pediatrics.
- Medically unstable.

4. PROCEDURE

The participants who meet the inclusion criteria were asked to sign an informed consent form approved by the institution. Pre participation data was taken for each subject prior to study which includes Name, Age, Sex, Socioeconomic status, Concurrent disease, and Type of Lung cancer. Subjects were asked to fill the questionnaire which was design to measure their level of health-related quality of life by using SGRQ, CRQ and SF-36 respectively. The participants, who do not know to read and write, were explained about the questionnaire in their mother tongue and response was noted by the person interviewing.

4.1 Data Recording and Tabulation

Data was collected in hard copies of all questionnaires, than the data for SGRQ was feeded in the SGRQ Microsoft Excel based calculator as recommended by the developer, while for the CRQ the scoring was done on a 7 point likert scale higher the score better the quality of life as suggested by developer and for SF – 36 the same Microsoft Excel based calculator as recommended by the developer**.**

4.2 Statistical Analysis

Basic characteristics of subjects age, gender, height, weight and BMI was analyzed by Descriptive statistics. Concurrent validity of SGRQ with CRQ and SF-36 was validated with Spearman's correlation test. Statistical analysis done by using SPSS Version 14.0.

© 2020, www.IJARND.com All Rights Reserved

5. RESULTS

Table 1: Descriptive data of total scores of SGRQ, CRQ and SF-36

	Mean	Standard Deviation
Total SGRQ	**54.2544**	**17.68**
Total CRQ	**75.2353**	**18.35**
Total SF-36	**46.5588**	**18.76**

Table 1 shows the descriptive statistics i.e. mean and Standard Deviation of SGRQ, CRQ and SF-36 score(x = 54.25 SD = 17.68, x = 75.23 SD =18.35 and x = 46.55 SD = 18.76 respectively).

Table 2: Descriptive data of Domains of SGRQ, CRQ and SF-36.

		Mean	Standard Deviation
SGRQ	Symptoms	65.5368	17.09
	Activity	59.0712	20.11
	Impact	47.6065	18.63
CRQ	Dysnea	20.8235	4.69
	Fatigue	14.9706	3.97
	Emotional Functioning	25.2941	6.96
	Mastery	14.5588	4.11
SF-36	Physical functioning	52.5000	20.53
	Role-Physical	36.0294	29.63

Table 4 shows correlation between domains of SGRQ and SF-36.

6. DISCUSSION

The evaluation of lung function does not fully reflect the impact of the disease on a patient and, therefore, should be supplemented by using quality-of-life questionnaires.[15]One way of capturing the personal and social context of patients is to use HRQoL measures. The inclusion of HRQoL in clinical investigations has increased significantly during the last two decades, as has the development of psychometrically sound HRQoL instruments to measure a variety of health conditions.

In present study, Results indicate high correlation($r = -0.826$, $p<0.05$) between SGRQ and CRQ and moderate correlation($r = -0.697$, $p<0.05$) between SGRQ and SF-36, because SF-36 is generic health related questionnaire while CRQ is disease specific questionnaire.[13] Molken et al also found well correlation ($r = -0.725$; $P<0.001$ and our result is $r = -0.826$; $P<0.001$) between total of SGRQ and total score of CRQ. The total scores of both questionnaires (SGRQ and CRQ) correlated best with each other and with the each domain scores. [9] Even in our study also the total score of SGRQ correlated well with each domains.

© 2020, www.IJARND.com All Rights Reserved

Moderate to high significant correlation found between various domains of SGRQ and total score of CRQ ($p<0.05$) similarly same results were found by a previous study.[9]

Results of our study are supporting the results of studies[10, 11] being done previously to measure the correlation between SGRQ and SF-36 in different diseases. Moderate to high significant correlation was found between and total score of SGRQ and PCS and MCS score of SF-36. Carolyn BW et al[11] other two previous studies, [12,13] found overall, SGRQ scores were more strongly associated with the PCS than MCS of SF-36. In general, scores of SF-36 were better correlated with the Impact component of the SGRQ than the Symptoms or Activity component. These may be due to Impacts component contains similar aspects as in PCS and MCS components of SF-36.

We found moderate significant correlation found between various domains of SGRQ and total score of SF-36($p<0.05$) (table 5.7). So, SGRQ is valid tool to measures HRQOL in various Respiratory Diseases as same as the gold standard tool CRQ. Moreover, SGRQ measures larger aspects of HRQOL compare to CRQ thus provide better idea about HRQOL of subjects and allow clinician/physiotherapist to measure impact of a disease on a patient's daily life and they can be especially valuable in clinical trials design to access the benefits, side effects and cost of different treatments.

SGRQ is available in 48 languages including 11 Indian languages while CRQ is available in only 8 languages (no Indian language) so SGRQ is better applicable to measure HRQOL in disease specific conditions in Indian scenario.

7. LIMITATIONS

- Smaller sample size.
- To precisely know HRQOL, how long its impact remains longitudinal study should be done.

8. FURTHER RECOMMENDATIONS

- Further research should be focused on specific type of locally language adapted questionnaire.
- Further research should be done with Cancer specific questionnaire along with HRQOL questionnaire.
- The SGRQ emerges as an excellent discriminative and a good evaluative instrument for LC subjects, and its use should be encouraged in routine assessment of patients' health status.
- Psychometric properties of Questionnaire should be done in Lung cancer.

9. CONCLUSION

Our study leads to following conclusions:

- Our results suggest that the SGRQ is a valid measure to assess HRQOL in subject with Lung cancer.
- The SGRQ is valid and compares well with the CRQ and SF-36.
- There was an excellent concurrent validity for SGRQ and CRQ, moderate concurrent validity of SGRQ with SF-36 in lung cancer.
- There was moderate to high significant correlation found between the domains of SGRQ and CRQ, except there was low significant correlation between SGRQ domain symptoms and CRQ domain dysnea, SGRQ domain activity and CRQ domain fatigue and SGRQ domain impacts and CRQ domain fatigue.
- Similarly, moderate to high significant correlation was found between the total score of SGRQ and various domains of CRQ.
- Moderate to high significant correlation found between various domains of SGRQ and PCS and MCS score of SF-36, and total score of SGRQ and PCS and MCS score of SF-36.
- High significant correlation found between various domains of SGRQ and total score of CRQ.
- Moderate significant correlation found between various domains of SGRQ and total score of SF-36.
- The SGRQ emerges as an excellent discriminative and a good evaluative instrument for Lung cancer subjects, and its use should be encouraged in routine assessment of patients' health status.

TO SEE EFFECT OF TADASANA(MOUNTAIN POSE) IN FLAT FOOT

Dr. HEENABANU YUSUFBHAI SHEKH

Assistant Professor

Venus Institute of Physiotherapy, Swarnim Startup & Innovation University, Gandhinagar, Gujarat, India.

ABSTRACT

Objective

The aim of the study was to check the effect of ***TADASANA*** in Flat Foot condition.

Methodology

Total 10 subjects fulfilling selection criteria participated in the study. All of them were told about the procedure of study. All their queries were answered satisfactorily and informed consent was taken from them.***TADASANA*** was given to the participants. In the beginning of treatment, they were given VAS disability questionnaire.They were asked to fill these questionnaires. After 10 days of protocol of ***TADASANA*** they were again told to fill these outcome measures.

Result

It shows statistically significant improvement in Pre intervention or post intervention scores of VAS.

Discussion

It is important to note that ***TADASANA*** is significant in the patients with Flat Foot than general exercises. There were greater improvements in the group that received this therapy. It is also discussed that Gastrocnameous & Hamstrings muscles, which were the focus of specific strengthening exercises programme for Flat Foot can significantly decrease the laxity of Knee joint & Ankle joint.

Conclusion

TADASANA is efficient in reducing pain due to Flat Foot and walking disability of lower limb in patient.

Key words:- ***TADASANA***, Hamstring, Gastrocnameous, VAS.

INTRODUCTION

Flat Foot is common,painful,irritative & unpleasant condition affecting the lower limb. it can be caused by sedentary life style, height more than normal parameters of WHO, poor posture, poor locomotion.common causes for Hamstring Tightness include ,poor posture,lack of regular exercises,a fracture, it can be due to prolonged sitting and laying down in one position,sometimes Hamstring Tightness can be due to some other cause e.g. Osteomyelitis, Rheumatoid arthritis, Osteoarthritis etc.

According to the NATIONAL INSTITUTE OF NEUROLOGICAL DISORDERS AND STROKE (NINDS) weak arches is the most common cause of above related disability. Over 53% of population suffer from planter surface and gastrocnameous pain during their lives mainly because of adoption of bad posture due to Flat Foot while activities of daily living.

TADASANA is sustained movements with co-ordination and simultaneous exercises from shoulder joint ankle joints and segment to relieve Hamstring Tightness and pain due to flat foot condition.

Aim and Objective of the study:

The aim and objective of the study is to check the effect of ***TADASANA*** **i**n Flat Foot.

Hypothesis:

Experimental Hypothesis:

There is effect of ***TADASANA*** in Flat Foot with VAS scale and questionnaire.

Null Hypothesis:

There was less effect of ***TADASANA*** in VAS with questionnaire.

METHODOLOGY

For this study method sample selection was random in which 10 subjects were fulfilling the criteria for study with TADASANA to relieve pain due to Flat Foot in females age group 20-40 years. Pre and Post intervention were noted down to get proper results and conclusions.

Study design:

Experimental study design.

Sample:

Random Sampling

A total number of 10 subjects were included for the study.

Study center:

YOG-NIKETAN Sankul, Maharaja Sayajirao University, Vadodara.

Inclusion criteria:-

- ✓ Females of age group 20-40 yrs.
- ✓ Females having Flat Foot.

Exclusion criteria:-

- ✓ History of surgery of lower limb and ankle region
- ✓ History of recent fractures
- ✓ History of Knee and ankle deformities
- ✓ History of pathologies around knee and ankle
- ✓ History of trauma
- ✓ History of steroidal medication since last months.

Outcomes measures:-

- ✓ VISUAL ANALOUGE SCALE for pain due to Flat Foot.

Procedure: 10 subjects fulfilling selection criteria participated in the study. All of them were told about the procedure of study. All their queries were answered satisfactorily and informed consent was taken from them.***TADASANA*** was given to the participants. In the beginning of treatment, they were given VAS scale questionnaire. They were asked to fill theis questionnaire. After 10 days of protocol of ***TADASANA*** was given, they were again told to fill these outcome measures.

Tadasana:-

This is "*Sanskrit*" word, which means "*samasthiti*"

"*Tad*" means "Mountain and "*Asana*" means "Position"

This asana is practiced in 4 stages:-

(1) Posture is entered by standing with the feet together.
(2) Groundly evenly through the feet and lifting up through the crown of the head.
(3) The thighs are lifted, the waist is lifted and the spine is elongated.
(4) It is important as it allows the body and consciousness to integrate the experience of the preceding *asana* and to prepare for the position.

The participants were selected for the inclusion and exclusion criteria of the study. The patient should be comfortable and relaxed.

DATA ANALYSIS

Variable	**FASH**
Mean	**5.35**
Standard Deviation	**3.786**
S.E	**0.793**
T value	**5.091**

Conclusion:- T-value is highly significant at 2% level

TADASANA highly significant for Flat Foot.

RESULTS:-

It shows statistically significant improvement in:

Pre intervention or post intervention scores of VAS scale.

DISCUSSION

The results of this study supported hypothesis that ***TADASANA*** is significant in the patients with Flat Foot than general exercises. There were greater improvements in the group that received ***TADASANA*** therapy. Using the criteria of **Ferreira PH, and Rackwitz B,** also reported that specific Progressive exercises was better than ordinary medical care and treatment by a general practitioner for reducing stretching pain. ***TADASANA*** was found very effective as part of yoga also,major effects on thigh,calf and planter surface muscles with help of simultaneous movements to lower limbs from distal to proximal without having any side effects.

Limitations: This study was characterized by some limitations . The first common limitation was that the findings were based on short data. Another limitation was that some article did not contain much sufficient information for evaluating the quality and clinical relevance of data.

CONCLUSION

TADASANA was more efficient in reducing Flat Foot pain and disability of lower limb of patient.

"PREVALENCE OF PROLAPSED INTERVERTEBRAL DISC (PIVD) IN CAB DRIVERS: A CROSS SECTIONAL STUDY"

1Dr Arvind Chauhan, 2Yash Sharma, 3Pruthviben Upadhyay
1PhD in Physiotherapy, 2BPT, 3BPT
1Swarrnim Startup and Innovation University,
2Swarrnim Startup and Innovation University,
3Swarrnim Startup and Innovation University

ABSTRACT:

TITLE:

Prevalence of Prolapsed Intervertebral Disc (PIVD) in Cab Drivers: A cross sectional study

BACKGROUND:

Low backpain is very common and usually occupation related. This study aimed at determining the prevalence of PIVD in cab drivers by seeing at the low back disability index due to bad posture of sitting and duration of driving in the cab drivers.

METHODOLOGY:

It is cross-sectional study in which 200 cab drivers has been screened for the presence of PIVD. 200 participants who were fulfilling the inclusive criteria has been taken. Then the researcher has explained about the research and the topic of research to the participants. Researchers has also explained about the PIVD, LBP which may further leads to PIVD and proper ergonomics while driving to prevent the PIVD. Participants with acute or sub-acute low back pain has been recruited. And their consent has been taken. SLR Special Test has been used to diagnose the PIVD. Then the researcher has explained about the special test and had

performed it on the participant. If the test of a participant has been positive, he has been advised further for the radiological investigations to check the severity of the bulge and further the physiotherapy treatment has been provided to the participant.

RESULT:

Total 200 patients were included in this study based on the inclusion and exclusion criteria. After filling the online consent form. Special test (SLR Test) is performed on the individual to diagnose the PIVD. Statistical analysis was done. All outcome measure(ODI) were analysed at the end of study. After doing the pivot study on the collected data we have found that around 41% of the cab drivers have radiating pain. among which 32% of drivers had moderate low back disability,7.5% had severe disability,1% were crippled and 0.5% had minimal low back disability resulting in hampering performance with the daily life activities and social life. Study identified the duration of driving and type of seating posture while driving as risk factors for low back pain which can further leads to PIVD among the participants.

CONCLUSIONS:

Study concludes that 41% drivers where having radiating pain among which 32% of drivers had moderate low back disability,7.5% had severe disability,1% were crippled and 0.5% had minimal low back disability resulting in hampering performance with the daily life activities and social life. Study identified the duration of driving and type of seating posture while driving as risk factors for low back pain which can further leads to PIVD among the participants.

KEYWORDS:

Low back pain, Cab drivers, Posture, Prolapsed Intervertebral Disc

INTRODUCTION

INTRODUCTION

Back pain is a very common malady next only to headache and affects nearly 80% of population. Low back pain is the pain which occurs at the lower back region due to muscle tension or stiffness. LBP is the most common problem and it is reported that more than 70% of people in developed countries suffers from LBP.[1]

Most common cause of back pain is bad posture which increases the strain on the Intervertebral disc and ligaments causing faster disc degeneration. Pain can arise from Intervertebral disc, ligaments, joints, muscles, nerves, etc. Other Causes of LBP- Muscles Strain or sprain, PIVD, disc degeneration, sciatica, spinal stenosis, spondylolisthesis, etc.[1]

Any abrupt, unbalanced and unwarranted movements upset the stabilizing function of the back muscles increasing the load on the disc. Hence bad posture, over loading and abrupt unbalanced movements are the cause of disc prolapsed or disc rupture.[1]

Mechanical LBP: 80% of LBP are due to mechanical cause like back muscle strain, ligament sprain and disc problems. Muscles strain and sprains are due to sudden unaccustomed activities and improper postures.[1]

There are 23 discs throughout the spine. It is thinnest in the thoracic region and thickest in the lumbar region. Each disc is interposed between the pair of vertebral bodies.[1]

Intervertebral disc in adults are avascular, the cells within it are sustained by diffusion of nutrients into the disc through the pores in the bodies.[1]

Degeneration of the disc may be prompted by changes in the permeability of cartilage end plate. Movement and weight bearing helps in diffusion of disc.[1]

Disc consist of two parts centrally it is nucleus pulposus and peripherally it has annulus fibrosis. It is thick anteriorly and thin posteriorly more so in the posterolateral aspect. Hence posterolateral disc prolapse is more common.[1]

With age, water content of the disc decreases fibrous tissue and cartilaginous cells increases and the nucleus becomes granular and friable. Disc apart from giving the spine its mobility, functions as a shock absorber.[1]

Non-mechanical LBP: It is defined as low back pain not attributable to a recognizable, known specific pathology e.g., Infections, Tumors, Osteoporosis, Spine fracture, Cauda equine syndrome.[1]

Heavy lifting, repetitive movements & sitting at a desk all day can take a troll on your back.[1]

Common cause of occupational LBP: natural curves, which exerting to much force on back can cause injury. Repeating certain movements can lead to muscle fatigue or injury. Slouching can lead to muscle fatigue & injury. Percentage of prevalence: 73.5% in drivers

Intervertebral disc is under constant pressure with degenerative changes and weak state of disc the annulus can bulge into the space containing the nerve root causing pain due to compression.[1]

Types of Disc Prolapse- Disc Protrusion, Disc Extrusion, Disc Sequestration. LBP (Low Back pain) is a serious occupation disease. Driving is the job causing occupational LBP. Occupational LBP: It is the largest single health problem related to work observation and the most common cause of incapacity among workers, younger than 45 years old world wide, 37% of LBP was attributed to occupation. Employees whose job involves lifting, bending, twisting or repetitive spinal movements are, most at risk for these injuries.

It has been pointed out that the factors leading to occupational LBP includes exposure to vibration, repeatedly lifting any heavy objects, strained posture and sitting or standing work for prolong period of time.[2]

Due to driving car for prolonged period of time and poor comfort the stress on the spine increase which further can result to back pain and then to severe conditions like, PIVD (prolapsed Intervertebral disc), musculoskeletal problems, spondylolisthesis, etc.[2]

Can drivers have been found to have high prevalence rates of back problems.[2]

Due to prolong sitting in particular position while driving car can cause stiffness in the back and also in legs and driving the car on rough roads without understanding proper ergonomics can lead to major problems.[2]

Due to uncomfortable seat and without knowing the proper ergonomics driving car for prolong period of time can cause major spine problems.[2]

Some studies have shown that driving professional is associated with the risk factors. Various environmental factors combine to overload the vertebral column and its supportive structures. During car driving excessive exposure to whole body vibration due to rough roads or potholes.[3]

Due to the rough & uneven roads as well as poor & prolonged sitting posture will create major stress on spinal area. Although, it is the major contributing factors for the higher onset & development of musculoskeletal conditions among professional cab or car drivers. [4]

Lesion in an Intervertebral disc are the most common cause of low back pain & sciatica. The annual incidence of low back pain is estimated at 5% but only 1% develops radiculopathy lumbar disc prolapsed is a disease most common between 30-50 years' age with a male preponderance as associated with repeated mechanical force. It may occur at any level but 95% of disc prolapse occur at L4-L5 or L5-S1.[4]

Symptoms of lumbar disc herniation are relatively common in the general population although the prevalence rates vary widely different studies symptoms severity also varies and in many patient pain

and loss of function may lead to disability and some measure spine problems. Physiotherapy treatment is choice in patient with symptoms caused by lumbar disc herniation.[4]

In clinical practice a broad range of physio therapeutic modalities such as TENS, ULTRASOUND, IFT, SWD, TRACTION and cryotherapy has been revealed to be helpful.[4]

Study aimed to investigate the prevalence of male cab drivers who operates cabs. Usual history of lumbar disc herniation is of repetitive LBP, radiating to the buttocks and decreased by rest.[5]

Pain is increased by flexion, sitting, straining, sneezing, coughing, etc. Pain is decreased by rest and in semi-fowler positions. Radiculopathy- This refers to pain in the distribution of the sciatica nerve and is invariably due to disc herniation this is called sciatica.[6]Nerve root compression about 95% of disc prolapse takes place through the L4-L5 region compressing the L5 nerve root. The other nerve roots commonly involved are L4 and S1 due to disc prolapsed between L3-L4 and L5-S1 respectively [7]

REVIEW OF LITERATURE

REVIWE OF LITRATURE:

1. **Occupational factors associated with low back pain in urban taxi drivers.**

   Jiu - Chiuan Chen, Wen – Ruey and David Christiani (2005)[8]

A cross- sectional data was collected from the taxi drivers. Health study standardized instrument were used to collect the information on personal factors, work related, physical & psychosocial factors and driving time profiles LBP prevalence was assessed using the modified Nordic Musculoskeletal Questionnaire. The results show that of 1242 drivers, 5% reported LBP in the past 12 months they found that driving time >4hrs/day, frequently bending / twisting activities while driving are the major occupational factors significantly associated with higher LBP prevalence in taxi drivers. ($p<0.001$)

2. **Low back pain disorders in agricultural tractor drivers exposed to whole- body vibration and postural stress.**

   Massimo Bovenzi, Alberto Betta (1994)[9]

Occurrence of LBP was investigated in a population of 1155 tractor drivers exposed to whole body vibration & postural stress (response rate 91.2%) & in a control group of 220 office worker (response rate 92.2%) subjects were questioned about several types pf low back symptoms and various work & individual related risk factors, by using a standard questionnaire. Prevalence of LBP was found to be greater in the tractor drivers. LBP were found to be significantly associated with both vibration and postural loads. Prolong sitting or standing in one position and due to poor posture the stress on the spine increases which can leads to musculoskeletal problems & may further lead to PIVD. More exposure data are needed in order to improve the knowledge of relationship between whole body vibration exposure & LBP among professional drivers. ($p<0.05$)

3. **Manual Therapy for Management of Lumbar PIVD- an Innovative Approach.**

   P P Mohanty, Monalisa Pattnaik (2015)[10]

Disc Prolapse mainly occurs in L4-L5 or L5-S1 and these is most common in 30-50-year age group peoples. In this study 75 subjects with acute or sub-acute LBP due to PIVD were recruited &randomly distributed in one of the three groups. Outcome measures: pain by visual analog scale (VAS) & functional outcome measures by Oswestry disability index (ODI). Result of the study shows significant change in pain & function for all the groups after 4 weeks of treatment. At the end of treatment there was significant difference between the groups for functions.

4. Driving of motor vehicles as a risk factor for acute herniated lumbar intervertebral disc.

Jennifer L. Kelsey and Robert J. Hardy (1975)[11]

In this study of the epidemiology of the acute herniated lumbar intervertebral disc in New Haven, connected area it was found that driving a motor vehicles was associated with an (increased) risk for developing herniated disc. In this study the participants are divided into the two group and diagnosed by the examiner with the special test by the SLR & x-ray. The study shows that the men who spend half or more of their job a motor vehicles are about three times as likely to develop acute herniated lumbar disc those who do not hold such jobs. Some of the limitation of the study such as disappointing response rate (78%), the lack of control group of general population, small sample size.

5. Prevalence of low back pain in car drivers and non-drivers.

Lenka Gallais (2008)[12]

This study investigated whether there is evidence of an associated between car driving and LBP & evidence that whole body vibration contributes to LBP in car drivers. There are many limitations that arise from factors such as the study design choice of study population, sample size, response rate and the large number of factors that can influence back pain. Some studies have reported (increased)

driving, but number study has shown that the risk of LBP is greater with increased exposure to the whole body vibration from car driving further studies are needed to verify the relationship between risk factor & LBP in car divers.

6. **Therapeutic effects of selective nerve root block in case of lumbar PIVD- A prospective study.**

   Sanjiv Kumar, Reetu Verma, Gaurav Chahal, Ashish Kumar, Shah Walliulah (2019)[13]

This prospective analytic study was designed to assess the efficacy of selective nerve root block with corticosteroids in the management of pain associated with PIVD that didn't get relief from non-surgical pharmacological treatment. In this study 40 known cases of lumbar PIVD not responding to the pharmacological treatment were given guided root & results were evaluated using VAS, ODI & SLR test over the period of 1,3,6 & 12 months. Result show that the lifetime prevalence of lumbar radiculopathy has been reported to be 5.3% in men and 3.7% in women.5, 6 Lumbar radiculopathies due to a prolapsed disc resolves spontaneously in 23-48% of patients, but up to 30% will still have pronounced symptoms after one year, 20% will be out of work, and 5-15% will undergo surgery.

7. **Health survey of professional drivers.**

   Backman AL (1983)[14]

In Finland an investigation carried out in 1979- 1980 included both a health screening and an inquiry about the work conditions of active drivers. A cross-sectional health survey comprising of 633 male drivers showed that the, frequencies of complaints, for instance pain in the back, shoulder & neck increased in old age groups. The study showed that the most common health problem was back pain & shoulder pain. About 70% of drivers had suffered from the back pain & shoulder pain during the last month ergonomic factors concerning work posture & movements will probably explain the high frequencies of back & shoulder.

8. Drivers of international variation in prevalence of disabling low back pain.

D. Coggon et.al. (2018)[15]

This study investigated the prevalence of disabling LBP among working population is not explained by known risk factors. Baseline information about musculoskeletal pain and risk factors was elicited from 11710 participants aged 20-59 years. Who were sampled from 45 occupation groups in 18 countries. After allowance for other known and suspected risk factors, pain propensity showed the strongest association with disabling LBP. The findings indicate that difference in general propensity to musculoskeletal pain are a major driver of large international variation in the prevalence of disabling LBP among people of working age.

9. A Comparison between the low back pain scales for patients with lumbar disc herniation: validity, reliability, and responsiveness

Min Yao at.al (2020)[16]

Study aimed to compare the following scales ODI, NPRS, SF-36, RMDQ, JOABPEQ in lumbar disc herniation patients receiving conservative treatment to select the better option to assess the severity of disease. Total 353 LDH patients were enrolled for this study. The relationship of these scales were evaluated by the person correlation coefficient the results shown that the NPRS, ODI or RMDQ is recommended in studies related to LDH patients. While if the quality of life also is needed to observe, the NPRS & JOABPEQ would be the more appropriate rather than SF-36.

10. The Sensitivity and Specificity of the Slump and the Straight Leg Rising Tests in Patients with Lumbar Disc Herniation

Javid Majlesi, Halit Togay, Halil Unalan, Sadik Topark (2008)[17]

Study aimed to measure the sensitivity & specificity of the slump test and compare it with SLR test in patient with & without lumbar disc herniation. 75 patients with complaints suggestive of lumbar disc herniation were enrolled both slump and SLR test were performed on the patients. Result shown that the slump test was more sensitive than SLR in the patient with lumbar disc herniation however, the SLR was found to be slightly move specific test than slump test

NEED OF STUDY

NEED OF THE STUDY

To investigate the prevalence of PIVD and its risk factors among cab drivers.

There are so many studies have been provided the information regarding the relation of LBP with various spinal conditions. Also some articles gave the information about prevalence of LBP in various workers. But no study has been done on cab drivers, so this study will provide proper prevalence of PIVD in cab drivers.

To improve knowledge of cab drivers by making them understanding about the proper ergonomics which reduces the risk of PIVD.

OBJECTIVES OF THE STUDY

OBJECTIVE OF THE STUDY

To determine whether the PIVD is more prevalent in car drivers.

To improve knowledge of cab drivers by making them understand about the proper ergonomics.

To improve understanding of the risk factors which may contribute to the development or progression of the symptoms of PIVD.

HYPOTHESIS

HYPOTHESIS

Null hypothesis: There is no correlation between lumbar PIVD and cab drivers.

Research hypothesis: There is correlation between lumbar PIVD and cab drivers.

MATERIALS AND METHODS

MATERIALS AND METHODS

STUDY DESIGN: A cross sectional study

SOURCE OF DATA: Cab drivers from Ahmedabad (Gujarat)

POPULATION: PIVD (age: 25- 60years)

METHOD OF COLLECTION OF DATA: Convenient Method

SAMPLE SIZE: 200

DURATION OF STUDY: 6 Months

MATERIALS AND TOOLS

Mat: For performing the special test on participant to diagnose PIVD participant had lie down on the mat

Pen: For writing the details of participants

Paper: To write the details of participants

Scales: To measure the outcomes

METHOD OF COLLECTION OF DATA

INCLUSION CRITERIA:

1. Patient complaining of low back pain along with or without radiculopathy in one leg or both the legs.
2. Time duration of car driving is 4-5hrs/day.
3. Acute or sub-acute low back pain which is not chronic.
4. Limited straight leg rise(SLR) 30°-70° or positive sciatica syndrome. (sciatica syndrome- sciatic nerve becomes pinched, usually by a herniated disk in your spine or overgrowth of bone on your vertebrae)
5. Lumbar flexion, extension and side flexion to the painful side will produce original symptom**.** Numbness in genital area, Pain behind the shoulder blade or in buttocks, Tingling in one or both arms or legs, Loss of control of bladder/ bowels.

EXCLUSION CRITERIA:

1. Patient /Cab driver who don't have any symptoms of back pain and leg pain.
2. The exclusion criteria included:
3. patients with prior back surgery
4. impending Cauda equine syndrome or with Cauda equine syndrome
5. back or leg pain due to other etiologies.

OUTCOME MEASURES

- **Oswestry disability index (ODI):** The Oswestry disability index is an index derived from the Oswestry Low Back Pain Questionnaire used by clinicians and researchers to quantify disability for low back pain.

METHODOLOGY

METHODOLOGY

1. It is cross-sectional study in which 200 cab drivers has been screened for the presence of PIVD.
2. 200 participants who will fulfilling the inclusive criteria has been taken.
3. Then the researcher has explained about the research and the topic of research to the participants.
4. Researchers has also explained about the PIVD, LBP which may further leads to PIVD and proper ergonomics while driving to prevent the PIVD.
5. Participants with acute or sub-acute low back pain has been recruited.
6. And their consent has been taken.

Examination of the Back –

1- Inspection (Note any postural defect)

2- Palpation – Tenderness

- Movements (All the movements of spine has been tested)

3- Evaluation of neurological system:

- Dermatomal and myotomal distribution are carefully analyzed to detect the level of lesion

4- Clinical Test: Test are based on stretching of the sciatica nerve over the prolapsed disc.

a) Forward bending to touch the toes.
b) Sitting and alternatively extending one leg and then the other.
c) Slump test: Sitting bent forward and extending one leg and then the other.
d) Straight Leg Raising Test (SLRT): Participant is in supine position. the examiner raises the leg of the patient straight one after the other. Up to 30° nerve is not put under stretch between 30°-70° nerve comes into contact with the prolapsed disc and the participant complains of pain. Beyond 70° if participant complains of pain it is usually not due to disc prolapsed but could be due to sacroiliac joint involvement

7. SLR Special Test has been used to diagnose the PIVD.
8. Then the researcher has explained about the special test and had performed it on the participant.
9. If the test of a participant has been positive, he has been advised further for the radiological investigations to check the severity of the bulge and further the physiotherapy treatment has been provided to the participant.
10. Researcher has explained about the proper sitting ergonomics while driving to prevent the PIVD.
11. Back Ergonomics: This is an extremely important aspect of back pain management as it helps in preventing recurrence. It consists of:

a) Proper postural habit

b) Proper work environment

c) Back exercises

d) Modifications of Daily routine activities

a) Sit close the steering wheel as is comfortable.
b) Place a small pillow beneath the lumbar curvature to preserve the normal lordosis.
c) Use the rear view mirror frequently and do not turn back those the vehicles.
d) Keep the knee bent.
e) Avoid stress in life by proper planning and meditation.

FLOW CHART:

Participants has been selected by the inclusive and exclusive criteria.

↓

Subjects has been selected by the convenience sampling method.

↓

Participants with LBP has been selected.

↓

Participants consent has been taken.

↓

Special test had been performed to diagnose the prevalence of PIVD.

↓

Outcome measures has been taken.

↓

Participants with PIVD has been selected for this study.

↓

Statistical Data analysis has been done.

RESULT

RESULT:

Total 200 patients were included in this study based on the inclusion and exclusion criteria. After filling the online consent form. Special test (SLR Test) is performed on the individual to diagnose the PIVD.

Statistical analysis was done. All outcome measure(ODI) were analysed at the end of study.

.

DISCUSSION

DISCUSSION

In our study, prevalence rate of radiating pain was 41% among which 32% of cab drivers are having moderate disability it shows there is relation between cab drivers and PIVD the risk was identified among cab drivers on an average whose duration of driving was 8 hours or more than 8 hours and those who are driving from last 8-10years on an average.

In our study 51% of cab drivers were driving in daytime and 49% of cab drivers were driving during day and night both.

40% of drivers have travel difficulties due to pain,64% of drivers have sleep disturbances due to pain.

Almost all men in occupation involving professional driving had a statistically significant elevated risk of PIVD.

There are many limitations arise from factors such as the study design, the choice of sample population, sample size, type of question, response rate and large number of factors that can influence the backpain.

The reviewed studies mostly conclude that car driving is associated with increased risk of low backpain. Some studies have reported increased risk of low backpain with increased driving but no study shown that the risk of low backpain is greater with increased exposure to whole body vibrations from car driving.

In these cross sectional baseline study,45% of taxi drivers,53% of police drivers and 46% of police non-drivers reported experiencing low backpain for at least one day during the past

12 months (chi square test; p=0.09)

Chen JC et.al in this study the cross sectional analyses of data suggested that the urban taxi drivers were at high risk group for work related low backpain they observed association between long duration of car driving and low backpain conforms to previous studies on other occupational groups

often operating small auto mobiles. Found that driving a car or van for >4h/day was associated with a high prevalence of low backpain in past 12 months.[1]

27% of drivers has slouching back posture and 41% have forward head posture which further leads low backpain and neck pain respectively. Sitting for prolonged period of time can be major cause of backpain, because Sitting for prolonged periods of time can be a major cause of backpain, because increased stress of the back, neck, arms and legs and can add a tremendous amount of pressure to the back muscles and spinal discs. Additionally, sitting in a slouched position can overstretch the spinal ligaments and strain the spinal discs. When seated with a lumbar support, the intrinsic and abdominal muscles are no longer active. They cease to support your spine as it rests. Weight on each disc becomes uneven, and disc bulge occurs. The extrinsic and intrinsic muscles (which are smaller and shorter) become weaker and overstretched. Using the lumbar support found in all seats also reduces circulation to these muscles as person lay against them. Most of the people do not use seats upright properly, and over time, may slouch while seated. Here the pelvis develops a posterior tilt, leading to greater disc imbalance and risk or injury.

Placing arms and hands steering wheel, allows us to relax the upper body further. Relaxing exacerbates the curve in spine. Our natural and balanced lumbar S-shaped curve becomes a C-shaped curve. Other muscles like the abdominals and the transverse abdominals relax, resulting in less support. Hamstring and quadriceps muscles become progressively shorter (and weaker). The progression causes them to pull on the pelvis during activity, thereby reducing our pelvic mobility. The progression causes them to pull on the pelvis during

activity, thereby reducing our pelvic mobility. The inclination of the seat back to an angle of 100-110 is preferred as, this angle decreases the pressure on the discs in the low back. And in our study 61% of drivers was having difficulties while walking and 79% of them were having difficulties while lifting. The extensor muscles are attached to back of the spine. They enable standing and lifting objects. These muscles include the large paired muscles in the lower back, called erector spine, which help hold up the spine, and gluteal muscles. The flexor muscles are attached to the front of the spine and enable flexing, bending forward, lifting, and arching the lower back. The oblique

muscles are attached to the sides of the spine and help rotate the spine and maintain proper posture. Overusing, bad posture leads to malalignment of muscles which leads to inflammation in the muscle and then pain. Which results in activity limitations such as lifting heavy objects and walking. And 62% of drivers have pain on prolonged standing. The extensor muscles are attached to back of the spine. They enable standing and lifting objects. These muscles include the large paired muscles in the lower back, called erector spine, which help hold up the spine, and gluteal muscles. The flexor muscles are attached to the front of the spine and enable flexing, bending forward, lifting, and arching the lower back. The oblique muscles are attached to the sides of the spine and help rotate the spine and maintain proper posture. Overusing, bad posture leads to malalignment of muscles which leads to inflammation in the muscle and then pain. Which results in activity limitations such as lifting heavy objects and walking. The association between bending, twisting movements while behind the wheel and higher prevalence of LBP is also supported by recent reports from biomechanical experiments. Because LBP is such a common musculoskeletal disorder, it is possible that prolonged driving may not be an etiological factor but an occupational factor related to progression or recurrence of

existing LBP symptoms. High LBP frequency in taxi drivers was associated with prolonged driving time frequent bending, twisting activities while driving.

In this study Bovenzi et.al. a significant trend of increasing occurrence of disc protrusion was threefold higher among the tractor drivers compared with the controls. It has been reported that the professional drivers have an excess risk of herniated disc or rupture of annulus fibrosus.[2]

LBP has been identified as one of the costliest disorder in the worldwide population and activities such as sitting, whole body vibration and awkward postures have been associated with the risk of developing LBP. Uncomfortable seats, back support and gear level were observed to be associated with the higher prevalence of LBP.

Previous studies show that some type of car seats contribute to the development of LBP, particularly in people who drive for prolong period of time. The car seat and its backrest usually keeps the drivers hip in an angle of 90° or less, thus predisposing the lower lumbar disc to a great pressure: the

resultant forces subsequently contributes to injury of the low back and degeneration of lumbar spine. Additionally, sitting in a slouched position can overstretch the spinal ligaments and strain the spinal disc.

Study identified the duration of driving, type of seating posture, radiating pain and pain while doing any ADL (Activity of Daily Living) while driving as risk factors for PIVD among the cab drivers. Thus, our aim of study was to find out is there any relation between PIVD and cab drivers in Indian Cab Drivers. And our objective of the research which to analyses the prevalence of PIVD in cab drivers with LBP concludes that 41% of drivers had radiating pain among which 32% had moderate disability,7.5% had severe disability,1% were crippled and 0.5% had minimal disability.

CONCLUSION AND SUMMARY

CONCLUSION: Study concludes that 41% drivers where having radiating pain among which 32% of drivers had moderate low back disability,7.5% had severe disability,1% were crippled and 0.5% had minimal low back disability resulting in hampering performance with the daily life activities and social life. Study identified the duration of driving and type of seating posture while driving as risk factors for low back pain which can further leads to PIVD among the participants.

SUMMARY:

TITLE: Prevalence of Prolapsed Intervertebral Disc (PIVD) in Cab Drivers: A cross sectional study

AIMS & OBJECTIVES: To determine whether the PIVD is more prevalent in car drivers. To improve knowledge of cab drivers by making them understand about the proper ergonomics. To improve understanding of the risk factors which may contribute to the development or progression of the symptoms of PIVD.

BACKGROUND: Low backpain is very common and usually occupation related. This study aimed at determining the prevalence of PIVD in cab drivers by seeing at the low back disability index due to bad posture of sitting and duration of driving in the cab drivers.

METHODOLOGY: It is cross-sectional study in which 200 cab drivers has been screened for the presence of PIVD. 200 participants who was fulfilling the inclusive criteria has been taken. Then the researcher has explained about the research and the topic of research to the participants. Researchers has also explained about the PIVD, LBP which may further leads to PIVD and proper ergonomics while driving to prevent the PIVD. Participants with acute or sub-acute low back pain has been recruited. And their consent has been taken.SLR Special Test has been used to diagnose the PIVD. Then the researcher has explained about the special test and had performed it on the participant. If the test of a participant has been positive, he has been advised further for the radiological investigations to check the severity of the bulge and further the physiotherapy treatment has been provided to the participant.

RESULT: Total 200 patients were included in this study based on the inclusion and exclusion criteria. After filling the online consent form. Special test (SLR Test) is performed on the individual to diagnose the PIVD. Statistical analysis was done. All outcome measure(ODI) were analyzed at the end of study. After doing the pivot study on the collected data. We have found that around 41% of the cab drivers have radiating pain among which 32% of drivers had moderate low back disability,7.5% had severe disability,1% were crippled and 0.5% had minimal low back disability resulting in hampering performance with the daily life activities and social life. Study identified the duration of driving and type of seating posture while driving as risk factors for low back pain which can further leads to PIVD among the participants.

KEYWORDS: Low back pain, Cab drivers, Posture, Prolapsed Intervertebral Disc

LIMITATIONS

LIMITATIONS:

-Small sample size

-Only done in the particular area

FUTURE RECOMMENDATIONS:

Future research should replicate these findings in other large samples, area and investigate between the other musculoskeletal problems related with driving.

- I can look after myself normally without Causing extra pain
- I can look after myself normally but it causes extra pain
- It is painful to look after myself and I am slow and careful
- I need some help but manage most of my personal care
- I need help every day in most aspects of self-care
- I do not get dressed, I was with difficulty and stay in bed

Q.8 Sitting

- I can sit in any chair as long as I like
- I can only sit in my favorite chair as long as I like
- Pain prevents me sitting more than 1 hours

- Pain prevents me from sitting more than 30 minutes
- Pain prevents me from sitting more than 10 minutes
- Pain prevents me from sitting at all

Q.9 Walking

- Pain does not prevent me walking any distance
- Pain prevents me from walking more than 5 minutes
- Pain prevents me from walking more than 10 minutes
- Pain prevents me from walking more than 15 minutes
- I can only walk using a stick or crutches
- I am in bed most of the time

Q.10 Standing

- I can stand as long as I want without extra pain
- I can stand as long as I want but it gives me extra pain
- Pain prevents me from standing for more than 1 hours
- Pain prevents me from standing for more than 30 minutes
- Pain prevents me from standing for more than 10 minutes
- Pain prevents me from standing at all

Q.11 Lifting

- I can lift heavy weights without extra pain
- I can lift heavy weights but it gives extra pain
- Pain prevents me from lifting heavy weights off the floor, but I can manage if they are conveniently placed eg. On a table

- Pain prevents me from lifting heavy weights, but I can manage light to medium weights if they are conveniently positioned
- I can lift very light weights
- I cannot lift or carry anything at all

Q.12 Sleeping

- My sleep is never disturbed by pain
- My sleep is occasionally disturbed by pain
- Because of pain I have less than 6 hours sleep
- Because of pain I have less than 4 hours sleep
- Because of pain I have less than 2 hours sleep
- Pain prevents me from sleeping at all

Q.13 Travelling

- I can travel anywhere without pain
- I can travel anywhere but it gives me extra pain
- Pain is bad but I manage journeys over 2 hours
- Pain restricts me to journeys of less than 1 hours
- Pain restricts me to short necessary journeys under 30 minutes
- Pain prevents me from travelling except to receive treatment

CONSENT FORM

Subject's Name:

Age:

Address of the subject:

Investigators: YASH SHARMA

PRUTHVIBEN UPADHYAY

I have been explained regarding the research project entitled "PREVALENCE OF PROLAPSED INTERVERTEBRAL DISC (PIVD) IN CAB DRIVERS: A CROSS SECTIONAL STUDY" have been explained in details about the therapy which were given to me. I understand that my participation in the study is voluntary and that I am free to withdraw at any time, without giving any reason, without my medical care or legal right being affected. I understand that the data obtained through the study may be used for research paper publication and I also understand that my identity will not be revealed in any information released to third parties or published. I agree to take part in the above study.

Signature of the subject: ----------

Investigator Sign: ----------

Date: ----------

SCALE

Oswestry Low Back Pain Disability Questionnaire

Section 1- Pain Intensity

- No pain
- Mild
- Moderate
- Severe
- Very severe
- Worst

Section 2- Personal Care (washing, dressing etc.)

- I can look after myself normally without Causing extra pain
- I can look after myself normally but it causes extra pain
- It is painful to look after myself and I am slow and careful
- I need some help but manage most of my personal care
- I need help every day in most aspects of self-care
- I do not get dressed, I was with difficulty and stay in bed

Section 3- Lifting

- I can lift heavy weights without extra pain
- I can lift heavy weights but it gives extra pain
- Pain prevents me from lifting heavy weights off the floor, but I can manage if they are conveniently placed eg. On a table
- Pain prevents me from lifting heavy weights, but I can manage light to medium weights if they are conveniently positioned
- I can lift very light weights
- I cannot lift or carry anything at all

Section 4- Walking

- Pain does not prevent me walking any distance
- Pain prevents me from walking more than 5 minutes
- Pain prevents me from walking more than 10 minutes
- Pain prevents me from walking more than 15 minutes
- I can only walk using a stick or crutches
- I am in bed most of the time

Section 5- Sitting

- I can sit in any chair as long as I like
- I can only sit in my favorite chair as long as I like
- Pain prevents me sitting more than 1 hours
- Pain prevents me from sitting more than 30 minutes
- Pain prevents me from sitting more than 10 minutes
- Pain prevents me from sitting at all

Section 6- Standing

- I can stand as long as I want without extra pain
- I can stand as long as I want but it gives me extra pain
- Pain prevents me from standing for more than 1 hours
- Pain prevents me from standing for more than 30 minutes
- Pain prevents me from standing for more than 10 minutes
- Pain prevents me from standing at all

Section 7- Sleeping

- My sleep is never disturbed by pain
- My sleep is occasionally disturbed by pain
- Because of pain I have less than 6 hours sleep
- Because of pain I have less than 4 hours sleep
- Because of pain I have less than 2 hours sleep
- Pain prevents me from sleeping at all

Section 8- Travelling

- I can travel anywhere without pain
- I can travel anywhere but it gives me extra pain
- Pain is bad but I manage journeys over 2 hours
- Pain restricts me to journeys of less than 1 hours
- Pain restricts me to short necessary journeys under 30 minutes
- Pain prevents me from travelling except to receive treatment

ABSTRACT

Background: Pulmonary function test is the most common test to check the function of lungs in normal healthy, sedentary or diseased person. Pulmonary function testing is often considered the basis for diagnosis in many categories of pulmonary disease. Although most of the testing methodologies are well established and widely employed, there are still many questions regarding how tests should be performed, how to ensure that reliable data are produced, what reference values and rules should be used, and how pulmonary tests (PFTs) function should be interpreted to best support clinical decision making. Sedentary behaviour (SB), defined as sitting (no exercising), reclining, and lying down (posture), or by low energy expenditure, is a public health risk independent to physical activity.

Methodology: This study included 30 participants who were of the age group 18-25 and the study was conducted online through ZOOM video calls where everyone was asked to keep their camera on for monitoring them. The participants were divided in 2 groups; Pranayama (yoga) and Breathing Exercise.

Result: Statistically significant improvements were seen in FVC of group pranayama (P=0.0002), FEV1of group pranayama (P=0.0002), FVC of group breathing exercise (P=0.0001), FEV1 of group breathing exercise (P=0.0003); whereas there was no statistical significance in FEV1/FVC% of group pranayama (P=0.2655) and FEV1/FVC% of group breathing exercises (P=0.8839).

Conclusions: The current study strongly support that both pranayama (yoga) improves FEV1 (P=0.0002) whereas breathing exercises improve FVC (P=0.0001) in sedentary people.

Keywords: Pulmonary function test, sedentary people, sedentary lifestyle, pranayama, yoga, spirometry, breathing exercises, physiotherapy

INTRODUCTION

Pulmonary function measures reflect the normal and pathological state of the lungs.[1] Lung function, specifically forced vital capacity (FVC) and forced expiratory volume in 1 second (FEV1), are objectively measurable quantitative parameters of respiratory health. It is an early indicator of respiratory and systematic inflammation, and associated with cardiorespiratory morbidity and mortality. [2]

Pulmonary function test (PFT) is a useful tool for objective assessment of respiratory impairement.[3] PFT results depend on patient efforts. Normal ranges are related to patient's sex, age, race, and body size.[4] It is of great value in early diagnosis, severity classification, disease progression and evaluation of curative effect of respiratory diseases.[5] The most basic and useful PFT is spirometry.[6] Pulmonary function testing (PFT) is a complete evaluation of the respiratory system including patient history, physical examinations, and tests of pulmonary function. [7]

Spirometry includes tests of pulmonary mechanics – measurements of FVC, FEV1, FEF values, forced inspiratory flow rates (FIFs), and MVV. Measuring pulmonary mechanics assesses the ability of the lungs to move huge volumes of air quickly through the airways to identify airway obstruction.[7]

There are four lung volumes and four lung capacities. A lung's capacity consists of two or more lung volumes. The lung volumes are tidal volume (VT), inspiratory reserve volume (IRV), expiratory reserve volume (ERV), and residual volume (RV). The four lung capacities are total lung capacity (TLC), inspiratory capacity (IC), functional residual capacity (FRC) and vital capacity (VC).[8]

PFTs, measure how well the lungs work. For some of the test measurements, the client can breathe normally and quietly. Other tests require forced inhalation or exhalation after a deep breath. Sometimes, they will be asked to inhale a different gas or a medicine to see how it changes test results.[9]

Table 1.1: Pulmonary Function Test

Pulmonary function test	Instrument	Measures	Function
Spirometry	Spirometer	Forced vital capacity (FVC)	Volume of air that is exhaled after maximum inhalation
		Forced expiratory volume (FEV)	Volume of air exhaled in one breath
		Forced expiratory flow, 25–75 percent	Air flow in the middle of exhalation
		Peak expiratory flow (PEF)	Rate of exhalation
		Maximum voluntary ventilation (MVV)	Volume of air that can be inspired and expired in 1 minute
		Slow vital capacity (SVC)	Volume of air that can be slowly exhaled after inhaling past the tidal volume
		Total lung capacity (TLC)	Volume of air in the lungs after maximum inhalation
		Functional residual capacity (FRC)	Volume of air left in the lungs after normal expiration
		Residual volume (RV)	Volume of air in the lungs after maximum exhalation
		Total lung capacity (TLC)	Maximum volume of air that the lungs can hold
		Expiratory reserve volume (ERV)	The volume of air that can be exhaled beyond normal exhalation
Gas diffusion	Blood gas analyzer	Arterial blood gases	Concentration of oxygen and carbon dioxide in the blood

Spirometry Measures the rate of air flow and estimates lung size. For this test, client will breathe multiple times, with regular and maximal effort, through a tube that is connected to a computer. Some people feel lightheaded or tired from the required breathing effort.[10]

If breathing is taken seriously and done with utter care and consciousness it can benefit the body and can increase the efficiency of everyday life and process. Breathing is a workout in itself for the body.[11]

Human life relies on the process of breathing. Breathing is the basic living process on which life depends. It is important to understand the significance of the process of breathing. With breathing, we inhale air and that is circulated throughout the body so it matters, what are we breathing and how are we breathing. Yet with time and lifestyle, people have forgotten how to breathe properly.[12]

When you have healthy lungs, breathing is natural and easy. You breathe in and out with your diaphragm doing about 80 percent of the work to fill your lungs with a mixture of oxygen and other gases, and then to send the waste gas out. Lung Helpline respiratory therapist Mark Courtney compares the process to a screen door with a spring, opening and shutting on its own. "Our lungs are springy, like the door.[13]

Over time, stale air builds up, leaving less room for the diaphragm to contract and bring in fresh oxygen.[14] With the diaphragm not working to full capacity, the body starts to use other muscles in the neck, back and chest for breathing. This translates into lower oxygen levels, and less reserve for exercise and activity. If practiced regularly, breathing exercises can help rid the lungs of accumulated stale air, increase oxygen levels and get the diaphragm to return to its job of helping you breathe.[15]

Breathing exercise (BE) has been an essential part of a comprehensive pulmonary rehabilitation program. Many types of BE such as slow and deep breathing, active expiration, pursed-lip breathing (PLB), relaxation breathing, diaphragmatic breathing (DBE), and ventilatory feedback (VF) training, have been prescribed to decrease lung hyperventilation, enhance respiratory muscle function, exercise tolerance, and QoL.[16] These BEs have been used individually, or in combination of different types of BE.[16]

A person may not be able to change how much oxygen their lungs can hold. However, breathing exercises can help reduce shortness of breath caused by limited lung function.[17]

Some people find it especially beneficial to focus on time, for example by breathing in for 5 seconds and breathing out for 10 seconds. It can help to keep a clock that shows the second's nearby.[18] For people who are not very physically active and may not be exercising their breathing muscles frequently, pursed lip breathing may have particular benefits. Deep breathing exercises may help increase lung capacity. For instance, the British Lung Foundation say that deep breathing can help clear mucus from the lungs after pneumonia, allowing more air to circulate.[17]

Other exercises, such as pursed lip breathing, can help manage breathlessness during respiratory illness. According to the National Institute for Health and Care Excellence, this may help with breathlessness caused by COVID-19.[19]

Although the terms breathing control and diaphragmatic breathing are often used synonymously, unlike breathing control, diaphragmatic breathing exercises encourage abdominal movement and contraction. Levensen (1992) describes diaphragmatic breathing as a breathing exercise which improves diaphragmatic recruitment. Excursion during inspiration and expiration. Although no studies to date have investigated the effect of breathing control on ventilation, it may be appropriate to extrapolate from the findings of research based on diaphragmatic breathing exercises.[20]

Pranayama is the yogic practice of focusing on breath. In Sanskrit, prana means "vital life force", and yama means to gain control.[21] In yoga, breath is associated with the prana, thus, pranayama is a means to elevate the prana shakti, or life energies. Pranayama is described in Hindu texts like the Bhagavad Gita and the Yoga Sutras of Patanjali. Later in Hatha yoga texts, it meant the complete suspension of breathing.[22]

Pranayama, the practice of controlled breathing, can be found as a part of many types of yoga's. This practice is believed to help encourage relaxation and improve breathing.[22, 23, 24] Although limited in nature, research studies on a small group of subjects indicate pranayama to have a positive impact on lung function and lung parameter as an adjunctive treatment. Long term and large-scale studies would be needed in order to validate the research and confirm the effects of pranayama and reach global acceptance pranayama.[24]

Pranayama improves overall performance of the body.[25] The regular practice of pranayama increases chest wall expansion and almost all lung functions. The beneficial effect of different pranayama is well reported and has sound scientific basis. Pranayama makes efficient use of abdominal and diaphragmatic muscles and improves the respiratory apparatus. Yoga strengthens the respiratory musculature due to which chest and lungs inflate and deflate to fullest possible extent and muscles are made to work to maximal extent .[25, 26]

Yoga originated in ancient India and denotes union between the individual self and the transcendental self. Pranayama is an important aspect of yoga that mainly deals with the relationship between breathing pattern and emotional states.[26] It can assume more complex forms of breathing, but the essence of its practice remains slow and fast breathing. Regular practice of pranayama improves cardiovascular and respiratory functions, improves cognitive function, decreases the effect of stress and strain on the body and hence improves the physical and mental health of an individual. The Bhramari Pranayama (Bhr.P), in specific, is one such ancient yogic breathing practice that not only includes a unique breathing technique but also is associated with concurrent generation of a constant humming sound during the phase of expiration thus placing the body in the state of relaxation. Studies done by Jain et al. and Rampalliwar et al. have concluded that regular practice of Bhr.P reduces the cardiovascular reactivity to stress (cold pressor test) by inducing parasympathetic predominance and cortico-hypothalamo medullary inhibition. Immediately after the practice of Bhr.P, there is a reduction in heart rate, blood pressure and improvement in the cognition in healthy subjects.[27]

Pranayama is an ancient yoga technique. The regular practice of Pranayama integrates the mind and the body. It differs from other forms of exercises as it mainly focuses on the sensations in the body.[28] Pranayama thus acts directly on the various functions of the body and affords benefits in a positive way. The following may be the reasons for this:

- Regular, slow and forceful inspiration and expiration for a longer duration during the pranayama practice, leading to strengthening of the respiratory muscles.[28]
- Pranayama training causes improvement in the expiratory power and decreases the resistance to the air flow in the lungs. [28]
- Pranayama training causes an increase in the voluntary breath holding time. This may be due to acclimatization of the chemoreceptors to hypercapnoea. [28]

Pranayama breathing may prevent serious cardio-respiratory complications by emphasizing optimal physical and mental conditioning. It also helps in tranquilizing the mind and as a result patient feel.[29]

REVIEW OF LITERATURE

1. **Breathing exercises and pranayama to decrease perceived exertion during breath-holding while locked-down due to COVID19 online randomized study. Mayank Shukla, et al. (2020)**30

Aim of the study was to compare the anulom vilom pranayama (AVP), kapal bhati pranayama (KBP), diaphragmatic breathing exercise (DBE), and pursed lip breathing (PLB), for breath holding time (BHT) and rate of perceived exertion (RPE). It was concluded that KBP and PLB did not decreased RPE as compared to AVP and DBE (p.0.05). DBE increased BHT more than KBP and PLB interventions (p 0.05). Study concluded that AVP is best among studied interventions for increasing relaxation during breath holding and DBE increases breathe holding time maximally.

2. **Pulmonary function tests. Harpreet Ranu, et al. (2011)**31

The study concluded that pulmonary function tests are an important tool in the assessment of patients with suspected or known respiratory disease. They are also important in the evaluation of patients prior to major surgery. Interpretation of the tests, which requires knowledge of normal values and appearance of flow volume curves, must be combined with the patient's clinical history and presentation.

3. **Pulmonary function tests for the generalist: A brief review. Timothy M. Dempsey, et al. (2018)**32

The study concluded that PFT's are essential to the diagnosis of many lung conditions and help to identify numerous non pulmonary disease processes. Understanding the basic interpretation of the components of this valuable test is crucial for primary care physicians to aid in the diagnosis of patients with respiratory symptoms.

4. **Lung function in obese children and adolescents without respiratory disease: a systematic review. Mariana Simoes Ferreira, et al. (2020)**33

The objective of the study was to perform a systematic review to assess lung function in children and adolescents affected by obesity and to verify the presence of pulmonary changes due to obesity in individuals without previous or current respiratory diseases. Articles from 18 countries were included. Spirometry was the most widely used tool to assess lung function. There was a high variability in lung function values with a trend towards reduced lung function markers (FEV1/FVC, FRC, ERV and RV) in obese children and adolescents.

5. **Effects of Diaphragmatic breathing on health: A narrative review. Hidetaka Hamasaki. (2020)**34

This review consists of a total of 10 systemic reviews and 15 random controlled trials. DB appears to be effective for improving the exercise capacity and respiratory function in patients with chronic obstructive pulmonary disease. Based on this narrative review the exact usefulness of diaphragmatic breathing in clinical practice is unclear due to poor quality of studies. However, it may be feasible and practical treatment method of various disorders.

6. **The short-term effect of pranayama on the lung parameters. Shankarappa V., et al. (2020)**35

An evaluation of a non-controlled study with 50 adult subjects was undertaken to study the effect of 6 weeks of pranayama on the lung parameters. After 6 weeks of pranayama it was noted that pulmonary function parameters FVC, FEV1, PEFR, FEF 25-75% and breath holding time (BHT) increased significantly.

7. **Effect of bhramari pranayama practice on pulmonary function in healthy adolescents: a randomized controlled study. Maheshkumar Kuppusamy, et al. (2017)**36

The study was conducted to find the effects of bhramari pranayama practice on pulmonary function in healthy adolescents. A significant ($P<0.05$) improvement in all pulmonary function parameters; FVC, FEV1, FEV1/FVC ratio, FEF 25% - 75% and PEFR was seen in the bhramari group then the control group adolescents. Slow vital capacity (SVC) and maximum voluntary volume (MVV) also showed significant improvement in the pranayama group.

8. **Exploring the therapeutic benefits of pranayama (yogic breathing): a systematic review. Ranil Jayawardena, et al. (2020)**37

The aim of the study was to perform a systematic review about the beneficial health effects of pranayama. Available evidence on pranayama indicates physiological benefits. Beneficial effects were mostly observed in patients with respiratory diseases such as bronchial asthma. It also helped those with cancer and cardiovascular disease.

9. **The comparison of the pulmonary functions of the individuals having regular exercises and sedentary individuals. Irfan Marangoz, et al. (2016)**38

The objective of the study was to determine the differences between the pulmonary functions of individuals having regular exercises and long-term exercises, and sedentary individuals. When the results of the study were evaluated, it was found out that no difference is present between FEV1 and PEF ($p>0.05$) values of individuals having long term and regular exercises, and sedentary individuals; however, there is a significant difference among MVV, FVC and VC values ($p<0.05$). Therefore, it has been found out that the pulmonary capacities (MVV, FVC, and VC) of individuals having regular exercises have improved better than that of sedentary individuals.

10. **Pulmonary functions in yogic and sedentary population. Shobha Rani Vedala, et al. (2014)**39

Pulmonary functions were compared between the yoga practitioners and sedentary group. Yoga exercise significantly increased chest wall expansion as observed by higher values of pulmonary functions compared with sedentary controls. Regular yoga practice increases the vital capacity, timed vital capacity, maximum voluntary ventilation, breath holding time and maximal inspiratory and expiratory pressures.

11. **A comparative study of the effects of yoga and swimming on pulmonary functions in sedentary subjects. Shilpa S Gupta, et al. (2012)** [40]

The aim of the study was, designed to assess and compare the effects of yogic training and swimming on pulmonary functions in normal healthy young volunteers.100 volunteers were inducted into the study and randomly divided into two groups: One group underwent 12 weeks training for yogic exercises and other for swimming. The training and data acquisition was done in small cohorts of 10 subjects each. The subjects were assessed by studying their anthropometric parameters and pulmonary function parameters (FVC, FEV1/FVC ratio, PEFR, FEF25-75%, FEF 0.2-1.2 l and MVV) both before and after training. All parameters showed statistically significant improvements after both yoga and swimming. Comparison of these improvements for different

parameters statistically analysed by unpaired t test or Mann Whitney U test depicted a statistically better improvement in FVC, FEF25-75% and MVV with swimming as compared to yogic exercises.

12. Effect of short-term yoga practice on pulmonary function tests. Vinayak P Doijad, et al. 2012[41]

This work was done to find effects of short-term Yoga practice on pulmonary function tests. The study was conducted on 60subjects, (40males and 20females) who came voluntarily as subjects for the project with written consent. It was a cohort study on I MBBS students, 60 in number (40 boys and 20 girls). Their age ranged between 18 to 20 years. Various Pulmonary function tests were measured. The instrument used was Medspiror Pneumotachometer (manufactured by MED SYSTEMS PVT. LTD. CHANDIGARH). FVC, FEV 1%, MVV and PEFR were found to be increased in both male and female subjects in result of the study. From this study we conclude that yoga practice can be advocated to improve respiratory efficiency for healthy individuals as well as an alternative therapy or as adjunct to conventional therapy in respiratory diseases.

13. **Effects of slow breathing exercise on cardiovascular functions, pulmonary functions & galvanic skin resistance in healthy human volunteers-a pilot study. AV Turankar, et al. 2013.**42

In this study eleven normal healthy volunteers were randomized into Pranayama group (n= 6) and a non-Pranayama control group (n= 5); the pranayama volunteers were trained in pranayama, the technique being Anuloma-Viloma pranayama with Kumbhak. Pulse, GSR, blood pressure (BP) and pulmonary function tests (PFT) were measured before and after the 7-day programme in all the volunteers.

While no significant changes were observed in BP and PFT, an overall reduction in pulse rate was observed in all the eleven volunteers; this reduction might have resulted from the relaxation and the environment. Statistically significant changes were observed in the Pranayama group volunteers in the GSR values during standing phases indicating that regular practice of Pranayama causes a reduction in the sympathetic tone within a period as short as 7 days. On the basis of results the study concluded that beneficial effects of pranayama started appearing within a week of regular practice, and the first change appeared to be a reduction in sympathetic tone.

14. An Approach to Interpreting Spirometry. Timothy J. Barreiro, et al. 2004.[43]

According to this study spirometry is a powerful tool that can be used to detect, follow, and manage patients with lung disorders. Technology advancements have made spirometry much more reliable and relatively simple to incorporate into a routine office visit. However, interpreting spirometry results can be challenging because the quality of the test is largely dependent on patient effort and cooperation, and the interpreter's knowledge of appropriate reference values. A simplified and stepwise method is key to interpreting spirometry. The first step is determining the validity of the test. Next, the determination of an obstructive or restrictive ventilatory pattern is made. If a ventilatory pattern is identified, its severity is graded.

15. Spirometry in the lung health study. Paul L Enright, et al.1991[44]

In this study Data were obtained from four surveys and included 3,598 subjects aged 4–80 years. The original analyses were sex specific and limited to non-Hispanic white subjects. An extension of the LMS (lambda, mu, and sigma) method, widely used to construct growth reference charts, was applied. The study concluded that the modelling technique provides an elegant solution to a complex and longstanding problem. Furthermore, it provides a biologically plausible and statistically robust means of developing continuous reference ranges from early childhood to old age. These dynamic models provide a platform from which future studies can be developed to continue to improve the accuracy of reference data for pulmonary function tests.

NEED OF STUDY

This study is required to determine the significance of pranayama (yoga) and breathing exercise in increasing or changing the lung volume or its capacity in sedentary people. With increasing popularity and demand of yoga it is important to have the knowledge about its effect on pulmonary function in comparison to breathing exercise, to determine if they both have same effect or if one type is superior to other.

AIM AND OBJECTIVES OF THE STUDY

AIM OF THE RESEARCH:

To see the difference in effects of pranayama (yoga) and breathing exercise on vital capacity in sedentary people.

OBJECTIVE OF THE RESEARCH:

To assess the effectiveness of pranayama (yoga) and breathing exercise on vital capacity in sedentary people.

HYPOTHESIS

NULL HYPOTHESIS:

There will be no significant difference in effects of pranayama (yoga) or breathing exercises on vital capacity in subjects with sedentary lifestyle.

ALTERNATE HYPOTHESIS:

There will be significant difference in effects of pranayama (yoga) or breathing exercises on vital capacity in subjects with sedentary lifestyle.

METHODOLOGY

Study design: Experimental

Study setting: Community

Sampling method: Purposive

Sample size: 30

Inclusion criteria:

a) Age group – 18 to 25 years

b) Subjects with sedentary lifestyle

Exclusion criteria:

a) Age group that does not match the inclusive criteria

b) Subjects who are physically active and not sedentary

c) Subjects having allergic disorders or respiratory disorders

d) Systemic diseases like hypertension, diabetes

Data collection tool:

a) International Physical Activity Questionnaire

b) Pulmonary Function Test

Procedure:

Identification of subjects were done according to the inclusion criteria. Each of them was explained about the study and its benefits and written consent form was obtained from each subject.

Subjects who fulfilled the inclusion and exclusion criteria along with MET scoring were recruited and assigned into one of the two groups: Pranayama (yoga) and Breathing exercise.

Each individual's height, weight and spirometry score were recorded before and after the intervention procedure.

GROUP 1: Pranayama (yoga) group

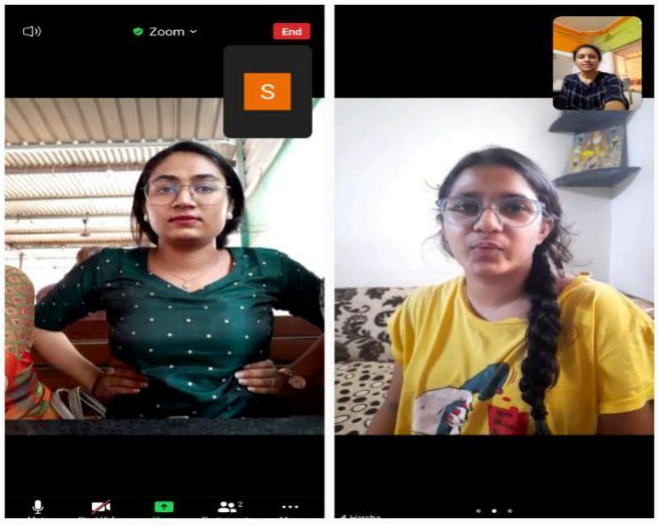
15 subjects were taken in the group who were treated with pranayama (yoga) which included anuloma viloma, kapal bhati, Bhramari.

10 repetition of each exercise was done for 5 sessions per week for 4 weeks.

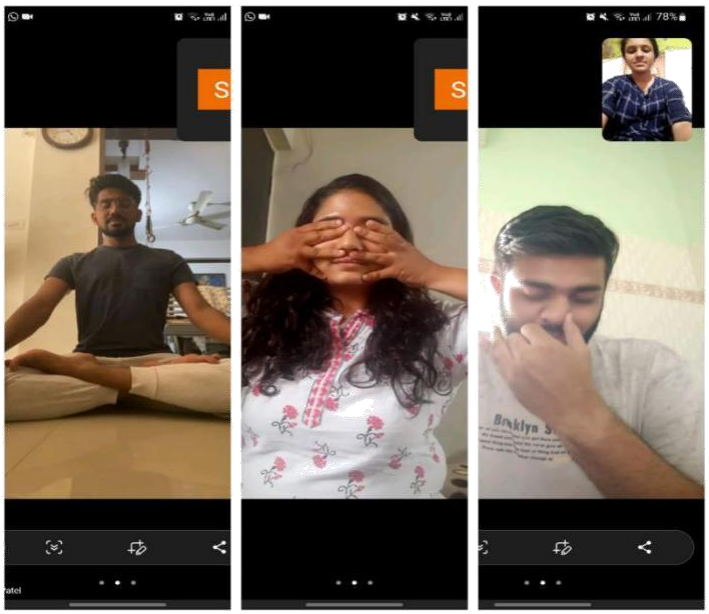
GROUP 2: Breathing exercise group

15 subjects were taken in the group who were treated with breathing exercises which included diaphragmatic breathing, pursed lip breathing, segmental breathing.

10 repetition of each exercise was done for 5 sessions per week for 4 weeks.



Photograph 6.1: Subjects performing Breathing exercises



Photograph 6.2: Subjects performing pranayama (yoga)

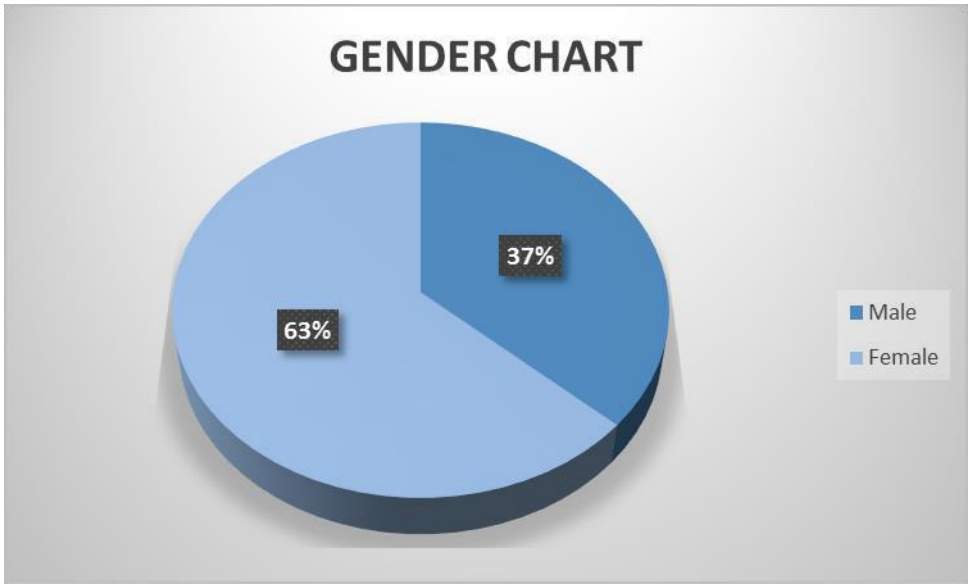
Photograph 6.3: Subjects performing Spirometry

RESULT

Demographic Profile:

1. GENDER DISTRIBUTION:

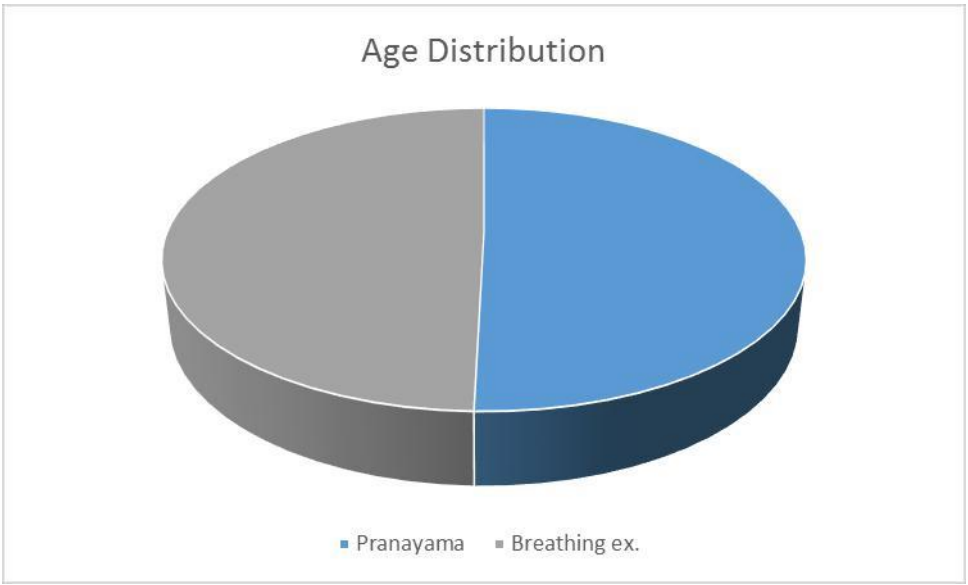
There were total 30 participant taken after matching the inclusion and exclusion criteria in which 19 were Females and 11 were Males.



Graph 7.1: Gender Distribution

2. AGE DISTRIBUTION

The mean age of participants of both groups are 20.8 and 20.46 respectively for group Pranayama (yoga) and Breathing exercise.



Graph 7.2: Age Distribution

Table 7.1: Mean Of Age Distribution

MEASURES	MEAN
PRANAYAMA (YOGA)	20.8
BREATHING EXERCISE	20.46

Clinical Parameters:

The participants in both groups shows significant result in increasing FVC and FEV1 whereas there were no significant changes in FEV1/FVC Ratio.

3. PULMONARY FUNCTION TEST

PFT recordings were done in both groups pre and post intervention for FVC, FEV1 and FEV1/FVC Ratio.

3.1 FVC in Pranayama (yoga) Group and Breathing exercise Group

In Pranayama (yoga) group, the treatment was given for 4 weeks and its pre and post treatment difference is -0.8500.

In Breathing exercise group, the treatment was given for 4 weeks and its pre and post treatment difference is -0.8353.

Table 7.2: FVC Pre And Post

MEASURES	FVC		DIFFERENCE	T VALUE	P VALUE
	PRE	POST			
PRANAYAMA	2.29±0.128	3.14±0.147	-0.85	4.3447	0.0002
BREATHING EX.	2.38±0.116	3.22±0.136	-0.835	4.6424	<0.0001

3.2 FEV1 in Pranayama (yoga) group and Breathing exercise Group

In Pranayama (yoga) group, the treatment was given for 4 weeks and its pre and post treatment difference is -0.7573.
In Breathing exercise group, the treatment was given for 4 weeks and its pre and post treatment difference is -0.7000.

Table 7.3: FEV1 Pre And Post

MEASURES	FEV1		DIFFERENCE	T VALUE	P VALUE
	PRE	POST			
PRANAYAMA	1.948±0.120	2.706±0.128	-0.7573	4.312	0.0002
BREATHING EX.	2.046±0.113	2..746±0.125	-0.7	4.137	0.0003

3.3 FEV1/FVC in Pranayama (yoga) group and Breathing exercise Group

In Pranayama (yoga) group, the treatment was given for 4 weeks and its pre and post treatment difference is -1.4467.

In Breathing exercise group, the treatment was given for 4 weeks and its pre and post treatment difference is 0.2160.

Table 7.4: FEV1/FVC Pre And Post

MEASURES	FEV1/FVC		DIFFERENCE	T VALUE	P VALUE
	PRE	POST			
PRANAYAMA	84.58±0.88	86.03±0.91	-1.446	1.136	0.265
BREATHING EX.	85.43±0.91	85.215±1.14	0.216	0.147	0.8839

DISCUSSION

It is seen in many studies done in past that sedentary lifestyle is one of the causes of reduced lung capacity and volume. It is known that sedentary lifestyle is a risk factor for reduced lung volumes and lung capacity. Reduction in these can cause many obstructive or restrictive lung diseases in healthy as well as sedentary population. Also, current study found out that participant's with lower MET showed comparatively lower lung volume and capacity this indicates that sedentary lifestyle and reduced lung volume are correlated and directly proportional. Many researches have also shown improvement in lung volumes and capacity through pranayama or breathing exercise in diseased individuals but the intervention procedure might take longer duration to show significant results. This research presents an experimental study of Pranayama (yoga) and Breathing exercise in sedentary people.

A study done by Irfan Marangoz, et al. (2016) to determine the differences between the pulmonary functions of individuals having regular exercises and long-term exercises, and sedentary individuals showed that there was a significant difference among MVV, FVC and VC values ($p<0.05$) in individuals doing regular exercise, and sedentary individual. Therefore, it has been found out that the pulmonary capacities (MVV, FVC, and VC) of individuals having regular exercises have improved better than that of sedentary individuals. Similarly, although our study didn't find any statistically significant change in FEV1/FVC but there was statistically significant improvement seen in both FVC and FEV1.

Current findings suggest that participants who were having high more sedentary lifestyle i.e. lower MET value were having comparatively lower lung volume and capacity, this indicates that sedentary lifestyle and reduced lung volume are correlated and directly proportional. We collected 30 samples from which females were 19 and males were 11.

CONCLUSION & SUMMARY

Conclusion

The current study strongly supports that both pranayama (yoga) and breathing exercises improve FVC and FEV1 in sedentary people.

Summary

This study is comparing the effects of pranayama (yoga) and breathing exercise on sedentary people, 30 participants were taken and their MET was calculated using IPAQ. Spirometry was done before and post the intervention procedure. It is seen that both pranayama (yoga) and breathing exercises help increase FVC and FEV1 in sedentary people.

LIMITATIONS

Limitations

Limitations of the study included the conduction of the study which was done online on zoom call because of outrage of cases of COVID-19.
Small sample size (30 participants).
Limited age group of 18-25 years.

Future recommendation

Offline study conduction can help monitor the participants well rather than contacting them online.
Increasing sample size can help in making sure that data obtained is statistically correct.
Increasing age group range.

Abstract

Background:
Pain and Functional activity limitations are the most common complaints of the women after caesarean section. Progressive muscle relaxation has been shown to relieve pain and improve Functional activity in post caesarean section women. We designed this study to examine if PMR reduces Pain and improve Functional activity.

Methodology:
We included 30 participants with the age of 20 to 45 years. Participants were randomly assigned into two groups i.e. PMR in addition with conventional therapy and Conventional Therapy (Control group).

Result:
After the intervention, both groups showed significant improvement ($p<0.05$) in measures of NPRS and Patient Specific Functional Activity scale.

Conclusion:
These data suggest that incorporating PMR in post C-section physical therapy session is effective in reducing pain and improving Functional activity.

Keywords:
C-section, Progressive muscle relaxation technique, Physical activity, Pain.

INTRODUCTION

Lower segment caesarean section is procedure where the making of incision is on the lower abdomen to the deliver the baby.[1]

There are many advantages of the caesarean section i.e. Post-operative comfort is more, Less chances of the wound dehiscence, Less chances of the incisional hernia, Reduced risk of perineal vaginal injury, Obstetric shock, Early postpartum haemorrhage.[2,3,4,5,6,7]

However there are some disadvantages of Caesarean section i.e. neonatal intensive care unit admission, longer hospital stays, Risk of the anaesthesia, Post-operative pain.[4]

Women with C - section surgery has both physical and psychological problems. Physical problems include: incision pain, limitation of the doing activity, gastrointestinal Disturbance, Anaesthesia complication. Psychological problems include: anxiety, depression, loss of the control, disturbed body image .caesarean pain affects the daily activity performance and it contribute to persistent post-operative pain. Caesarean pain characterized as acute and similarly connected the damage caused to the inflammatory reaction derived from traumatic operation.[6]

Progressive muscle relaxation technique was developed by Edmund Jacobson in the literatures science 1938. This technique is used to induce a state of deep relaxation through involving a systemic sequential muscle tension for 5-7 seconds followed by relaxation. During the intervention of the therapy it was instructed to take the deep breath and hold it for 5 to 10 seconds and then exhale the breathe slowly by lips, which will help to get the relaxation state and get the benefits of the deep breathing exercise. Progressive muscle relaxation technique is one of the non-pharmaceutical method used to treat the post-operative pain and increase the physical activity after the caesarean section surgery.[7]

However the few articles Progressive muscle relaxation technique relieve the pain and improve physical activity. Therefore the aim of the study was determine to Progressive muscle relaxation technique can reduce pain and improve physical activity in Post - Caesarean section women.

The purpose of this RCT was to examine the effects of Progressive muscle relaxation technique on Pain and Functional Activity in comparison with conventional therapy.

METHODOLOGY

Study Design: Randomized Controlled Trial

Sampling Method: Randomized Block Technique

Sample Size: 30

Inclusion criteria

- Age: 20 to 45
- Patients who are willingly to participants in study.
- Those who are primary of repeat caesarean section.
- Early post caesarean patients.

Exclusion criteria

- Women who have developed major complication in post caesarean such as severe anaemia ,heart disease, post-partum haemorrhage, severe pregnancy, hypertension, Eclampsia, postpartum psychosis, musculoskeletal problem or urinary infection.
- Multiple births
- Delivery with operative complication.
- Psychiatric disorder such as depression or anxiety.

Each of them was explained about the study and its benefits and written consent was obtained from every Women. Pain and Functional Activity was assessed by using Numeric Pain Rating Scale (NPRS) & Patient Specific Functional Activity Scale (PSFA-S) respectively. The Participants were then randomly divided in 2 groups:

Group A - Progressive Muscle Relaxation

Group B - Conventional therapy

Progressive Muscle Relaxation (Group A):

- Begin with deep breathing exercise. Then slowly exhale out with mouth, the navel pulling in towards the spine. Repeated 3-5 cycles of deep breathing.
- Tense and release muscles.
- Starts with feet clenching toe and press heels towards the ground. Squeeze tightly for 10 seconds and the release it.
- Then flex feet in pointing toes up towards the head, hold it for 10 seconds and then slowly release while counting 1 to 10.
- Work on the right leg squeeze thigh muscle hold it for 10 seconds then slowly release it.
- Repeat on the left leg, after that squeeze the buttocks muscles hold it for 10 seconds and then release it.
- After that squeeze abdomen muscles hold it for 10 seconds and then slowly release it.
- Tensing the chest muscles by taking deep breathing, hold it for 10 seconds and then slowly release it.
- Open mouth widely enough to stretch the hinges of jaw, hold it for 10 seconds, and then release it.
- Clench eyes tightly hold it for 10 seconds and then release it.
- Raise eyebrows and tight the forehead, hold it for 10 seconds then release it.
- End up with few deep breaths.

Technique was used after the effects of anaesthesia are decrease and women on her conscious state of mind. Pre and Post – Therapy NPRS and Patient Specific Functional Activity scale was taken.

Duration: 30 minutes - Thrice a day for 3 days.

In addition with PMR, Conventional therapy were given to Group A.

Conventional therapy (Group B):

- Starts with deep breathing exercise for 3 repetitions.
- After deep breathing 10 repetitions of thoracic expansion, huffing technique and splinted coughing.
- 10 repetition of knee bending and leg bracing.
- End up the session with breathing exercise.

Technique was used after the effects of anaesthesia are decrease and women on her conscious state of mind. Pre and Post – Therapy NPRS and Patient Specific Functional Activity scale was taken.

Duration: 30 minutes - Thrice a day for 3 days.

DATA ANALYSIS

Data were analysed using SPSS statistical software using an intention-to-treat approach. Prior to all hypothesis testing, independent sample t-tests were conducted to examine whether significant mean differences existed in demographic, NPRS and Functional activity variables among the two groups at baseline. We examined whether outcomes changed differentially from baseline to post intervention.

RESULT:

All the patients completed the treatment session without interruption and having no other complication were observed during the treatment session.

Table no.1: The Mean values of Group A and Group B according to pre and post NPRS Scale

Group	Pre/Post NPRS Scale	Mean	Number	Std. Deviation
Group A	Pre	9.53	**15**	**0.61**
	Post	3.86	15	1.14
Group B	Pre	9.4	15	0.61
	Post	6.26	15	1.34

N=number, PRE=Pre NPRS Scale, Post=Post NPRS

Table no.2: The Mean value of Group A and Group B according to Pre and Post patient-Specific Functional Scale.

Group	Pre-Post PSF Scale	Mean	No	Std. Deviation
Group A	Pre	9.13	15	0.95
	Post	4	15	1.15
Group B	Pre	9	15	0.96
	Post	5.8	15	1.46

Table No.3: The Pre and Post values of between group Comparisons: Average improvement in T-Value and P-value.

Group	Pre-Post Comparison	Average Improvement	T-Value	P-Value	Result
Group A	Pre-Post	5.67	8.37	0.00	P<0.05 SIG
Group A	Pre-Post	5.13	3.15	0.1	P<0.05 SIG
Group B	Pre-Post	3.14	1.17	0.00	P<0.05 SIG
Group B	Pre-Post	3.2	2.14	0.1	P<0.05 SIG

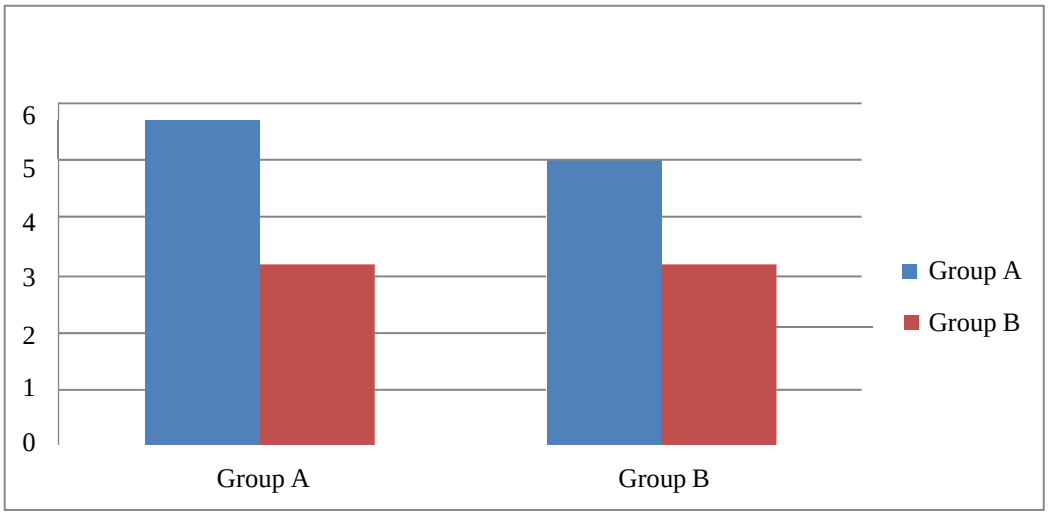

Fig.No.1: Average improvement in T-Value and P-value between groups

However, statistically significant result were noticed in both the groups, clinically it was observed and also observed that PMR technique had greater effects than conventional therapy.

DISCUSSION

The result of the present study is in line with at least four studies. First, Devmurari and Nagrale (2018) who studied "Effectiveness of Jacobson's PMR technique for pain management in post-caesarean women". They found that 100% of experimental group after intervention had pain ranging from 0 to 5 compared to 17.6% of control group. There is significant difference in mean values between pain scores of control and experimental group on VAS score. They further concluded that the pain is more reduced in experimental than control group.[8] Second, Devi et al (2017) who studied " Effect of PMR on post-operative analgesia" among patients with abdominal surgery in India during the first two days post-operative. They reported that PMR was very effective in pain relieve among study group compared to control group. They further added that PMR helped their patients to overcome the distressing feelings during post-operative period and improve their quality of life.[9] Third, Gupta et al (2016) who studied "Effectiveness of PMR technique on physical symptoms among patients receiving chemotherapy". They elaborated that around two thirds (63.3%) among their study participant had only mild pain post intervention compared to non-before it. They further added that none of their study group complained from severe pain post intervention compared to 100% before intervention[10]. Fourth, Paula et al (2002) who studied "the use of PMR technique for pain relief in gynecology and obstetrics". Their subjects were patients with abdominal surgery for obstetrics or gynecologic reason. They concluded that PMR significantly decreased pain perception among study group compared to control group. They further recommended that health care team should prepare their patients to apply PMR during the preoperative period to be used as a pain control method during the post-operative period.[11]

The result of the current study is also in line with relevant literatures. PMR may work to decrease post Cs pain through numerous mechanisms. First, PMR is effective in decreasing stress and consequently stress hormones (cortisol, epinephrine, catecholamines). Second, it can inhibit sympathetic and stimulate the parasympathetic nerves by blocking the feedback pathway from the mind to muscles and consequently prevent the biological response to pain. So, it may lower blood pressure, heart rate and metabolic rate (Avianti et al, 2016 & Topcu and Findik, 2012). Third, PMR may manipulate the hypothalamus by concentration on the positive sensation of deep relaxation state during the intervention so, the stress impulses from the hypothalamus is decreased or even inhibited.[7] Fourth the deep breathing technique during the intervention can increase oxygen

saturation, decrease the oxidative factors and consequently, pain. Fifth, PMR may help the secretion of endogenous endorphins, decrease the secretion of adrenal hormones, and improve blood circulation (Peciuliene et al 2015).[12]

It is expected that all the above mentioned mechanism of PMR over the course of the 3 days post C-section is likely to have resulted in decreasing pain and improving functional gains reported in this study.

CONCLUSION

Based, on the results of the current study, it is concluded that progressive muscle relaxation techniques have significant effects in reducing pain and improving Functional activity of the women who has undergone Caesarean section.

FUTURE RECOMMENDATION

- Based on the findings of the current study Progressive muscle relaxation technique is easy to learn and there is no side effects of therapy , therefore these technique should be involved in the treatment protocol management after caesarean section.
- Patient's education about PMR technique should be implemented with all post caesarean women to help relieve pain.

FUTURE RESEARCHES:

- Replication of the study using a large probability sample from a broad geographical area to allow greater generalization of the results.
- Exploration of the effect of PMR on stress, fatigue, and quality of life during postpartum

[2]Venus Institute of Physiotherapy – Swarrnim Startup & Innovation University, Gandhinagar, Gujarat

Abstract

Introduction: Maximum Oxygen Uptake (VO2max) reflects Physical Fitness of individual. Decreased Cardiorespiratory Fitness due to lack of regular Physical Activity in young adults have forced them to become the victims of Cardiovascular co morbidities in their later stage.

Method: A Total 40 young adult male and female undergraduate College going student age group between 18 to 23 years were recruited by convenient sampling. Data was collected by assessment and International Physical Activity Questionnaire and QCST.

Result: Mean value of VO2max for males was 46.45 $\pm$ 15.9790711 ml/kg/min and for females was 40.780 $\pm$ 4.107005078 ml/kg/min. The Mean and SD values were found to be significantly higher in the males than in females. The VO2max values obtained in males were found to be closer to the normal predicted values than the values obtained in females.

Conclusion: After analyzing the results it is concluded from this study that overall Physical performance of males was higher than the female students.

Keywords: Physical Fitness, Queen's College Step Test, VO2Max, International Physical Activity Questionnaire.

INTRODUCTION

Transition to College is characterized by change, ambiguity, and adjustment compared to the previous lifestyle before entering college. Time spent in university represents a period of transition and may be an appropriate time to promote physical activity among young adults. Transitioning to College life could be stressful due to an increased pressure to focus on academic performance and having a new social life, as well as in some instances moving away from home for the first time. College students are vulnerable to experiencing tension, stress, and anxiety, and exercise could be used as an excellent method to manage these conditions. Moreover, university students are at risk for weight gain 5.5 times more than the general population. They are also at risk of developing high blood pressure and high serum cholesterol. Therefore, exercise is not only helpful in managing psychological stress reactions that students can experience, but it also has a positive effect on mood and self-esteem, physical and mental health, and the student's quality of life.[1]

However, now a day's increasing dependence on mechanical devices in daily life and reduction in work-related and leisure-time physical activities is rendering life style of both males and females sedentary.[2]

PHYSICAL ACTIVITY

Regular physical activity and health related physical fitness are key indicators of health outcomes. Bodies are recognizing that physical activity and exercise are integral to professional practice and core contributors to health along with reducing the risk of developing diabetes, hypertension, osteoporosis and cardiovascular disease, primary and secondary prevention of cancer. Physical activity also improves emotion and stress control. Promoting physical activity in undergraduate college group students is a sensible strategy likely to help reduce physical activity levels. An associated disease in the future generation a decline physical activity levels among young adults so there was a need to evaluate the physical activity level of the students and to determine their physical fitness level.[3]

Physical activity Maintain healthy bone and muscle, reduce obesity, reduce stress and anxiety, depression, enhanced cognitive function, positive mental health and promote Well Being and healthy lifestyle[4]. Young adults are exposed to a number of academic, physical, emotional and social changes which coupled with changes in independence and living situation among some students may influence key health behaviour such as Smoking, alcohol use, poor nutrition and physical activity.[5]

The International Physical Activity Questioner Measure all physical activity for use with individual adult patients aged 15 to 69 years old. The International Physical Activity Questioner can be used clinically and in population research that compare physical activity level between populations internationally[6]. The measure Assess the type of intensity of physical activity and sitting time that people do as part of their daily lives are considered to estimate total physical activity in MET minute per week and time spent sitting.[7]

FACTORS AFFECTING PHYSICAL ACTIVITY

Several Social and Environmental Factors have systematically emerged as determinants of physical activity in adults. In ethnic minorities, the removal of barriers such as unaffordable facilities and unavailable childcare, high crime rates, fear for personal safety and culturally inappropriate activities are of primary importance. Social support from family, peers, communities and healthcare providers has resulted in modest improvements across cultures, ages and genders in selected settings, but the definition of specific interventions and their outcomes deserve additional attention.[8]

PHYSICAL FITNESS

Being physically fit has been defined as the ability to carry out daily tasks with vigour and alertness without undue fatigue and with ample energy to enjoy leisure time pursuit and to meet unforeseen emergencies[9].The health-related components of physical fitness are cardio respiratory endurance, muscular endurance, muscular strength, body composition and flexibility.[10] Physical fitness is a measure of body's ability to function effectively and efficiently or can be defined as state of health and wellbeing of a person fitness can be achieved through proper nutrition, exercise, rest and moderate to vigorous physical activity.[11] Physical fitness is a multidimensional concept that evolves with age and involves muscles, skeleton, heart and mind related activities that enhance physical, intellectual, psychological, emotional and social development. The lifestyle change diminishes level of physical activity as well as increasing various sickness caused by the lack of movement.[12]

PHYSICAL ACTIVITY AND PHYSICAL FITNESS

The Objectives of the Study are to find the level of the physical activity and compare physical fitness parameters in undergraduate college going student's age group between 18-23 years by evaluating Aerobic Capacity and Endurance and body composition in different level of physical activity.[13] There is consensus that regular physical activity (PA) can improve physical fitness (PF) and health and assist in the prevention of disease. Physically active adults are healthier and have a higher PF than inactive adults. Physical activity is therefore promoted as part of a healthy lifestyle. PA can influence fitness and health and that the relationships are also reciprocal.

BMI

Body Mass Index (BMI) is a value derived from the mass (weight) and height of a person. The BMI is defined as the body mass divided by the square of the body height, and is expressed in units of kg/m2, resulting from mass in kilograms and height in meters.

BMI AND PHYSICAL ACTIVITY

Obesity is an excessive fat accumulation in adipose tissues and is defined by a Body Mass Index (BMI) of 30 kg/m2 and above. Individuals in the BMI range of 25 to 30 kg/m2 are categorized as overweight while a BMI of 40 kg/m2 and above is regarded as morbid obesity. Obesity correlates with an individual's increased risk of cancers, stroke, metabolic disease, heart failure, and other cardiovascular conditions, highlighting the need to reduce the incidence and prevalence of obesity[14]. Inactivity or low level of physical activity combined with changes in eating habits are believed to be the main reasons for the increased prevalence of overweight/obesity among adolescents and adult. The genetic differences in weight gain among them also make them vulnerable to overweight. As physical activity is an important component in weight control and also associated with other major health benefits its role in youth health is fundamental. Physical activity measured as number of steps per day was inversely correlated to percentage body fat as well as to Body Mass Index (BMI) in adults. It is therefore difficult to know whether inactivity causes obesity or obesity leads to inactivity. Guidelines for physical activity levels in adolescents and adult recommend at least 60 minutes of accumulated moderate to vigorous physical activity per day. Many other factors besides individual level of daily physical

activity for a healthy lifestyle are cultural, social, and personal. Data on the inter-relationship between BMI and physical activity are limited.[15]

VO2max

VO2max is the maximum amount of oxygen can take in and utilize. Not all air taken in is used by the body. The more cardiovascular conditioned are, the higher VO2max will be, thus the more oxygen will be able to utilize with each breath. Finding VO2max is among the best measures of cardiorespiratory fitness. Each litre of oxygen utilized burns about 5 Kcals so the higher the VO2max, the more energy will require to exercise meaning can burn more calories and get better more intense workouts. Striving for a higher VO2max is one of the best ways to improve all cardiovascular functions in the body which will improve your overall fitness level.[16]

FACTOR AFFECTING VO2MAX

VO2max level depends on body build and composition and is affected by the following factors:

- Sex - Comparatively, the typical female will have a lower VO2max than the typical male.
- Age - Maximal Oxygen Uptake (VO2max) decreases by 10% per decade in men and women regardless of age and exercise activity.
- Size – Maximal Oxygen Uptake is directly proportional to height and body surface area.
- Weight - Maximal Oxygen Uptake is proportional to a weight.
- Lean body mass - VO2max correlates 0.63 with body mass, 0.85 with fat-free body mass, and 0.91 with active muscle tissue.
- Bed rest - Enforced bed rest of 3 weeks reduces maximal oxygen uptake by approximately 17%.[17]

MET

Meta Equivalent represent the amount of energy expended carrying out physical activity. A Meta Equivalent is a multiple of estimated resting energy expenditure. To get a continuous variable score from the International Physical Activity Questioner we will consider walking to be 3.3 METs, moderate physical activity to be 4 METs and vigorous physical activity to be 8 METs.[18] Increasing energy expenditure can help reduce excess adipose tissue and obesity. The current guidelines put out by the American College of Sports Medicine (ACSM) include either aerobic or anaerobic exercise. Aerobic exercise (i.e., running, cycling, rowing, etc.) is an exercise that exhausts the oxygen in the muscles, but oxygen consumption is sufficient to supply the energy demands placed on the muscles and does not need to derive energy from another source. On the other hand, anaerobic exercise (or resistance exercise, i.e., weight lifting) is oxygen consumption that is not sufficient to supply the energy demands placed on the muscles, and muscles must break down other energy supplies, such as sugars, to produce energy and lactic acid.[19]

VO2max and METs

Metabolic Equivalents (METs) refers to the ratio between the energy expended during physical activity and the energy expended while at rest. Finding a person's MET involves measuring how much oxygen their body uses at rest[20]. At rest, oxygen utilization is about 3.5mL · kg-1 · min-1 and is known as a ―Metabolic Equivalent of Tasks‖ or MET. 1 MET is also known as VO2rest. Normal healthy individuals typically have as VO2max of 25-80 or 7.1 to 22.9 METs.

FACTORS AFFECTING HEART RATE DURING EXERCISE

These factors play a role in directly affecting heart rate while running or walking:

- Emotions and anxiety can raise heart rate.
- Body Temperature: If become too hot or too cold body senses a thermal stress load. Blood is sent to skin to enhance heat dissipation to cool or increases blood flow to warm.
- Apparent temperatures (which account for humidity or wind chill) above 70 degrees (F) and below 35 degrees (F) will increase heart rate at least 2-4 beats per minute. Over 90% humidity can equal as much as a10 beats increase in heart rate. 1.0 Walk or run uphill and HR increases - Walk or run downhill and HR decreases.
- Wind - Walking or running with the wind at back is easy, therefore HR decreases. Walking or running into the wind is more difficult: HR increases.
- Dehydration - As become increasingly dehydrated during a long walk, hike, or run blood becomes thicker and waste products build up in bloodstream heart will work harder to maintain constant cardiac output. A fluid loss of 3% of body weight increases pulse rate because of decrease in circulating blood volume.
- Insufficient nutrition - HR increases.
- Insufficient sleep - HR increases.

METHODOLOGY

Study design: Observational study

Source of data: Civil hospital gandhinagar.

Sampling method: convenient sampling method.

Duration: 4 months

Sample size: 40, group a male – 21, group b female - 19

Inclusion criteria

- Age: 18 to 23 years
- Healthy Male and female college going students

Exclusion criteria

- Age: below 18 years
- Above 23 years neurological disorders cardiorespiratory disorders musculoskeletal disorders
- Students who have recently undergone any surgical procedure students making any history of acute or chronic medical illness**.**

Materials and tools required:

- Google form
- Consent form
- Pen , pencil , paper

Data collection tool:

- Borg Rating of Perceived Exertion (RPE)
- Queen's college step test

DATA ANALYSIS

- Descriptive analysis was done for demographic details.
- Correlation between VO2Max values obtained of male and female.
- Correlation between VO2Max values obtained of the students and their HR.

RESULT:

- 40 young Male (n = 21) and Female (n =19) undergraduate college going students aged between 18 to 23 years participated in the study.
- The mean age obtained of the total participants was 19.95 + 1.72388946 years. The mean values obtained for the height and weight of the participants was 164.13 + 8.63486044 cm and 57.1325 + 13.36431121 kg respectively. The max and min values obtained for height and weight were 182.88 cm, 148 cm and 96 kg, 40 kg respectively.
- The mean BMI recorded was 21.115 + 4.511668632 kg/m2 also the max values found was 34.8 kg/m2 and min value found was 13.5 kg/m2. Out of 40 students that had participated for the test 13 students were underweight, 19 were into the normal category, 6 were found to be overweight and 2 were found to be obese class 1 category.
- Mean value of VO2max for males was 46.45 + 15.9790711 ml/kg/min and that for the females was 40.780 + 4.107005078 ml/kg/min. The mean and SD values were found to be significantly higher in males than in females. The VO2max values obtained in males were found to be closer to the normal predicted value than the values obtained in females.

Variables	Mean	SD	Max	Min
Age(years)	19.95	±1.72	23	18
Height(cm)	164.13	±8.63	182.88	148
Weight(kg)	57.1325	±13.36	96	40
BMI (kg/m^2)	21.115	±4.51	34.8	13.5
HR (bpm) (After Ex.)	143.9	±32.41	220	96

DISCUSSION

At present, physical exercise is promoted as an important aspect of general health, and the transition from high school to college will pronounce lifestyle changes that can severely challenge a student's health status[1]. Queen's college step test used to assess the VO2Max of young male and female using heart rate after the participants stepped on a 41.3cm stool at the rate of [female=22 steps/min] and [male=24 steps/min]. Test re-test reliability for recovery heart rate has been measured as r = 0.92. Correlation between recovery heart rate and VO2max has been measured as r = -0.75[21]. 40 young male [n=21] and female [n=19] college going students aged between 18-23 years participated in our study. The result of the present study showed that the mean value of Vo2Max for males was 46.45+15.97 ml/kg/min and that for the females was 40.78+4.1ml/kg/min. On comparing both the mean values it is clearly seen that the aerobic capacity of male students is significantly higher than the female students. It also gives an idea about the level of physical fitness of both the gender. Comparison between the heart rate after exercise and VO2Max values, we found that the students with a high VO2max values were able to gain a lower heart rate and inverse scenario was seen with those who showcased low VO2max. We also found that when compared the BMI and heart rate values of the participants classified according to the standard BMI classification, the students coming under OBESE category had a higher HR and the students coming under the UNDERWEIGHT category also showed and average HR values while some of the students coming under the NORMAL category showed a relatively lower HR somewhere up to the mark. Obesity and Overweight in our participants could also be the reason for a decreased in aerobic capacity. The results of our study also suggested that the female students were into a level of low physical activity when compared with male students. On comparison of the VO2max values of our subjects according to the standard VO2max classifications, the majority numbers of female students n= 6 fitted in the category of AVERAGE and ABOVE AVERAGE, whereas the BELOW AVERAGE and GOOD categories had 5 & 2 females respectively. On the other side maximum numbers of male students n= 6 were found to be falling into the EXCELLENT category. The male students falling into VERY POOR, POOR, BELOW AVERAGE, AVERAGE, ABOVE AVERAGE & GOOD category were 2, 5,1,2,4 & 1 respectively. We also found that out of the total 40 participants who were asked to fill out the physical activity questionnaire, majority students n= 25 were found to be minimally active as they spent 20 to 30 minutes of regular exercise sessions and n= 12 students were found to be inactive and did not spare any time for routine exercise. Lastly 3 students were found to be highly active.

CONCLUSION

This research provides a baseline marker for physical activity levels and sedentary behaviour among college going students, which will be useful for future monitoring and evaluation of interventions. Low to moderate level of physical activity was found among college going students, and there is a difference in aerobic capacity in students who were physically active in their routine life and thus better physical fitness.

FUTURE RECOMMENDATION

- Sample size was small to generalize the result of study.
- IPAQ difficult to provide exact hours and minutes for sitting and walking time.

FUTURE RESEARCHES:

- Further this study can be used to find out the physical fitness index of the individual subjects.
- This study can be extended further by including a detailed measurement of the cardiac function in order to assess whether any cardiac impairment persists or not.

ABSTRACT

Background: Primary Dysmenorrhoea is a difficult menstrual flow in the absence of any pelvic pathology where pain is spasmodic in character and felt mainly in the lower abdomen. Women that participated in sports experienced fewer occurrences of symptoms of dysmenorrhea.

Aim: To assess the effect of one term of stretching exercise on primary dysmenorrhea in adolescent girls.

Materials and Methods: 30 girls aged between 18-28 years with mild to severe primary dysmenorrhea were selected; the girls were non-athletes and volunteered for the study. The participants were randomly divided into 2 groups: an exercise group (n=15) and a control group (n=15). In the intervention group, the subjects were requested to complete an active stretching for 12 weeks (4 days per week, 1 time per day, 10 minutes, and post test was examined 12 weeks later.

Results: After the intervention, however, a significant difference was found between the two groups regarding the mean intensity of dysmenorrhea in the first and second menstrual cycles. Also, a significant difference was observed between the stretching group and the control group. However, no such difference was observed in control group.

Conclusions: Stretching exercises are effective in reducing pain intensity, pain duration, and the amount of absenteeism in schools and colleges due to having pain during menstruation.

Key Words: Dysmenorrhoea, Adolescent girls, Stretching, Exercise, Physiotherapy

INTRODUCTION

Dysmenorrhea literally means painful menstruation but more realistic and practical definition includes cases of painful menstruation of sufficient magnitude so as to incapacitate day to day activities. [1]

It is commonly classified into primary dysmenorrhea when there is no co- existent pathology and secondary dysmenorrhea where there is an identifiable pathological condition. About 40-70% of women of reproductive age suffer with dysmenorrhoea. [2]

Primary dysmenorrhea begins when young girls first experience the ovulatory cycles and its prevalence increases during adolescence (15-17) years and decreases progressively then after. In dysmenorrhea pain begins few hours before or after the onset of menstruation and lasts for 24-48 hours. The pain is more in the first day and rarely continues to next day. [3]

Primary dysmenorrhea is commonly seen only in ovulatory cycles, usually developing within 6 to 12 months of menarche and is characterized by lower abdominal sharp pain that may radiate to the back and upper thighs. The pain of primary dysmenorrhea starts with the onset of menstrual flow or a few hours after the onset and may last for a few hours up to 2 days. The pain of secondary dysmenorrhea usually begins few days before the start of menstrual flow and may be present during much of the menstrual cycle. Pain that occurs with the first menses or after the age of 25 or is associated with an ovulatory cycles is more likely to be secondary dysmenorrhea. [4]

It is characterized by lower abdominal pain that potentially could radiate to the back and thigh regions. The pain may be associated with headache, fatigue, nervousness, nausea, vomiting, mood swings.

Primary dysmenorrhea most likely caused by increased prostaglandin production within the uterus and associated uterine hyper- contractility. [5]

In primary dysmenorrhea pain is spasmodic in character and felt mainly in the lower abdomen, but it may radiate to the back and along the thighs. There may be associated systemic symptoms like nausea, vomiting, diarrhea, and headache. [6]

Despite the widespread use of stretch in physical rehabilitation, considerable uncertainty remains surrounding its lasting effects. There is little doubt that stretch induces immediate increases in muscle extensibility due to the viscoelastic nature of soft tissues. [8] However, these effects are transient and quickly dissipate. The lasting effects of stretch are more controversial but arguably of more importance, particularly for individuals with chronic pain.

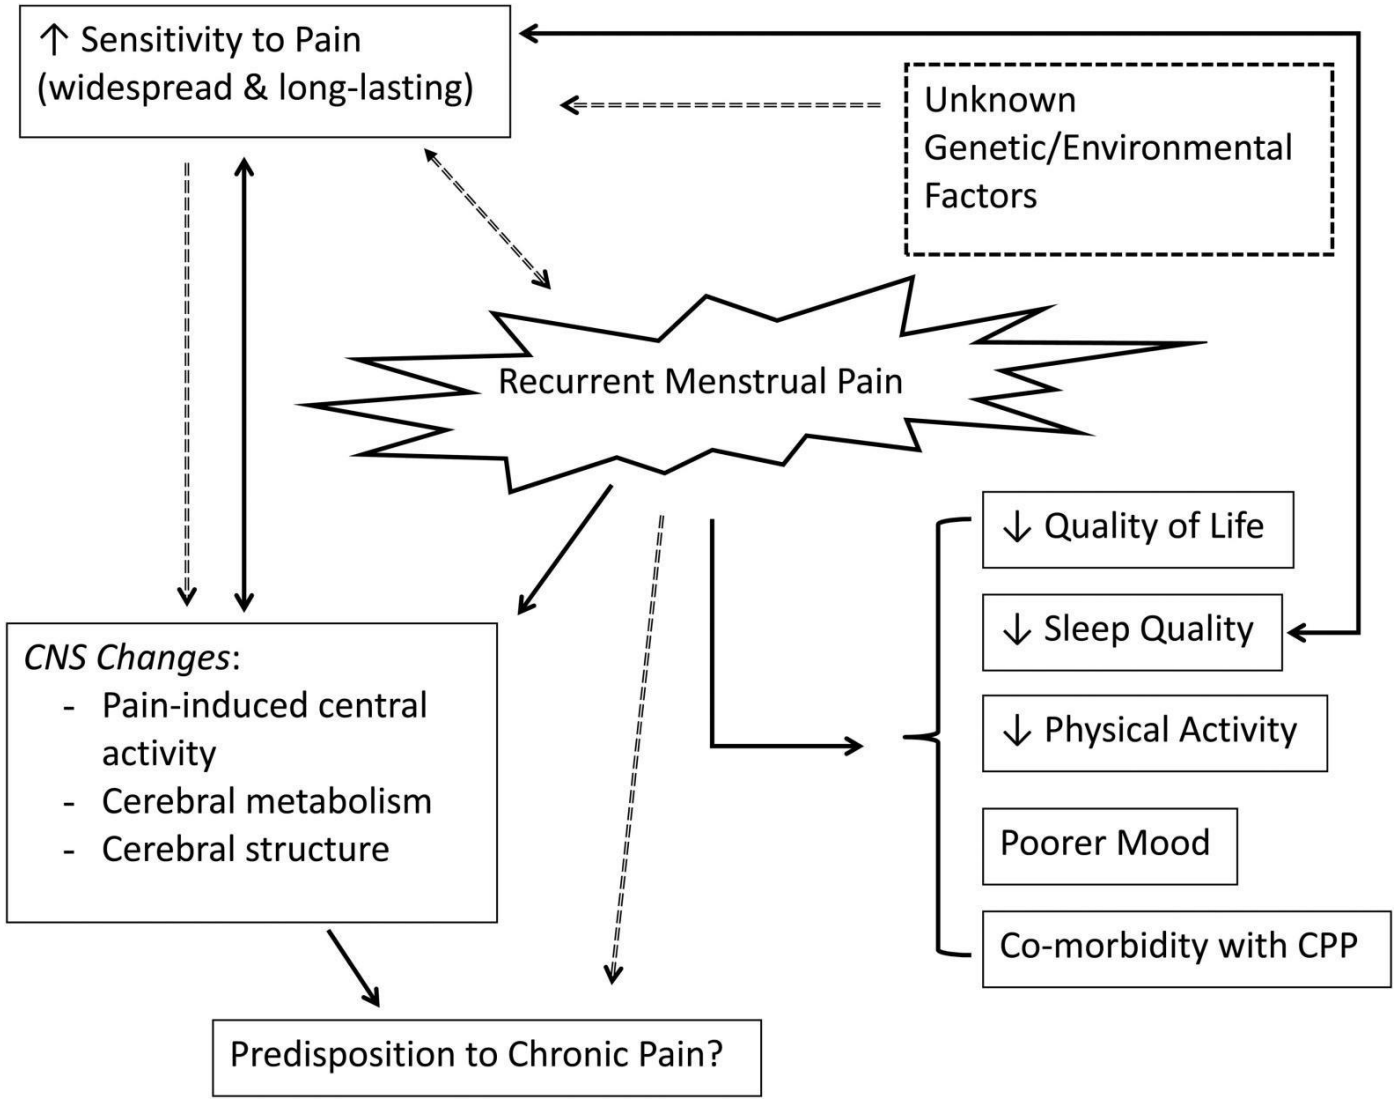

Figure.1 A schematic representation of the proposed (dotted lines) and known (solid lines) effects of recurrent dysmenorrheal pain [7]

The controversy arises from the discrepancy between strong anecdotal evidence and evidence from studies of animals [9] supporting the effectiveness of stretch and high-quality randomized controlled trials indicating otherwise. Studies of animals showed that soft tissues are adaptable and undergo structural remodelling in response to stretch. On the other hand, results of studies of humans are less consistent. In this article, improvements in extensibility refer to an increase in joint ROM when repeat measurements are taken with the same testing torque (torque is the product of applied force and moment arm or the tendency of a force to cause rotation).

Some investigators contend that what appear to be lasting changes in extensibility are in fact changes in people's willingness to tolerate the discomfort associated with stretch over time. For example, following a hamstring muscle stretch program, an individual may touch his or her toes more easily. This patient outcome may not be due to any underlying change in muscle extensibility, but may instead be due to the direct relationship between applied stretch torque and resultant joint ROM. That is, the harder an individual

leans forward (ie, the stretch torque), the further he or she can reach down toward the toes (ie, the joint ROM). The ability to reach further is due to altered perceptions and increased willingness to tolerate the discomfort associated with stretch [10]

The causes of primary dysmenorrhea are still unclear, but one of the most accepted explanations is increased synthesis of prostaglandins, of which types E2 and F2α play a significant role in the development of ischemia and hypoxia, resulting in dysrhythmia uterine contractions and decreased blood flow. [11]

Drug therapies and complementary medicine are often used to treat dysmenorrhea. [12] According to the literature, NSAIDs and OCPs rank among the most frequently used medications. These drugs reduce pain by inhibiting the production and release of prostaglandins. However, long-term use of NSAIDs has been associated with side effects such as headache, dizziness, drowsiness, loss of appetite, nausea, vomiting, gastrointestinal bleeding, increased acute asthma, dysuria, and acne. [13]

OCPs inhibit ovulation, reduce endometrial proliferation, and create an endocrine environment that mimics the early stages of the proliferative phase of the menstrual cycle, in which prostaglandin levels are at theirlowest. Lower prostaglandin levels lead to fewer uterine cramps. In the realm of complementary medicine, methods resorting to herbs, yoga, relaxation, psychotherapy, massage, hypnosis, vitamins (E, B, C), and supplements (calcium and magnesium) as well as acupressure and acupuncture have been used. The herbs used more commonly to treat dysmenorrhea are chamomile, ginger, fennel, cinnamon, and aloe Vera. [14] Common treatments for dysmenorrhea are extensive and in some cases subject to restrictions. For example, NSAIDs are contraindicated for patients with digestive problems, while medicinal plants are not always readily available. This research aimed to investigate the effects of a set of stretching exercises on reducing the pain of dysmenorrhea.

REVIEW OF LITERATURE

1. **An epidemiological study of young women with dysmenorrhoea[15] : B Andersch et al. (1982)**

   The study was conducted in 1982**,** The prevalence of dysmenorrhoea was studied in a random sample of 19 year old women from an Urban-Swedish population, dysmenorrhoea was reported by 72% of the women 15% suffered from dysmenorrhoea which limited daily activity and was unimproved by analgesics.

2. **Prevalence of dysmenorrhea and its effects on quality of life among a group of female university students.[16] : A Unsal et al. (2009)**

   This cross-sectional study was conducted between 15 march and 15 April 2009. The study group included 623 female students. The severity of dysmenorrhea was determined with 10-point visual analog scale. The average age of the study groups was 17-30 years. They concluded that prevalence of dysmenorrhea was found to be 72.7% and it was significantly higher in coffee consumers, females with

menstrual bleeding duration 7 days, and those who had a positive history of dysmenorrhea when compared to the others.

3. **Association of psychologic and nonpsychologic factor with primary dysmenorrhea.[17] : M Faramarzi et al. (2014)**

   This study was conducted in Aug 2014, in this study 180 females with dysmenorrhea and 180 females without dysmenorrhea were enrolled. Psychological risk factors were evaluated in four domains including affects, social support, personality, and alexithymia. The data was collected by using questionnaires and they concluded and high caffeine diet are important risk factors risk factors for women with primary dysmenorrhea.

4. **Comparing the effects of aerobic and stretching exercises on the intensity of primary dysmenorrhea in the students of universities of busher[18]: F Vaziri et al. (2015)**

   The study was conducted in March, 2015. This randomized clinical trial was conducted on 105 females who were suffering from primary dysmenorrhea. The participants were divided into aerobic, stretching and control groups. The 2 groups performed exercise three times a week for 8 weeks. Then after the intensity of dysmenorrhea was determined using several modified questionnaires that assessed several symptoms of dysmenorrhea. After all, the data was compared between and within groups through analysis of variance. They concluded the aerobic and stretching exercises are effective in reducing Severity of dysmenorrhea.

5. **Primary dysmenorrhea and its effects on quality of life in young girls.[19]: T Joshi et al. (2015)**

   The study was conducted in March 2015, A cross sectional study and data were collected among 310 young girls on presence and absence of dysmenorrhea, premenstrual symptoms, dietary habits using questionnaire and they concluded that concluded that dysmenorrhea is a leading causes of a absenteeism in colleges and has an adverse effects on the quality of young girls.

6. **Effects of different exercise techniques on primary dysmenorrhea among higher secondary school girls. [20]: D Khare et al. (2016)**

   The study was conducted in 2016, to study the effectiveness of isometric exercises and variousstretching techniques used as a treatment protocol for primary dysmenorrhea. The students were divided into control and experimental groups, both groups performed set protocol from fourth day of menstrual cycle. They concluded that isometric and stretching both exercise has a positive effects on treatments of primary dysmenorrhea in school girls.

7. **Effects of exercises on primary dysmenorrhea in young females.[21]S Shah et al. (2016)**

This study was conducted in year 2016, A convenient sample was taken of 40 participants, randomly and equally divided into 2 groups. Groups A received stretching exercises and group B was control groups. Participants in group A completed an active stretching exercise program for 6 active stretching exercises in the abdominal, pelvic and groin regions for 8 weeks, group B was control group. All the participants were examined for pain intensity with VAS and VMSS. After the research they concluded that stretching exercises are effective in reducing pain in young females with primary dysmenorrhea.

8. **Effects of selected muscle stretching exercise on primary dysmenorrhea among studentnurses.[22]: B Gomathi et al. (2017)**

This study was conducted in July 2017, To assess the effectiveness of selected muscle stretching exercise on primary dysmenorrhea. 67 student nurses with primary dysmenorrhea were selected from college by using non probability purposive sampling technique and they were randomly assigned into experimental group and control group. Muscle stretching exercise taught to the experimental group and practiced for 8 weeks. Pain intensity was assisted by using numerical pain rating scale and they concluded that selective muscle stretching exercise are effective in reducing pain in dysmenorrhea.

9. **What we know about primary dysmenorrhea today: a critical review[23]S Lacovides et al. (2015)**

Comprehensive literature searches on primary dysmenorrhea were performed using the electronic databases PubMed, Google Scholar and the Cochrane Library. Full-text manuscripts published between the years 1944 and 2015 were reviewed for relevancy and reference lists were cross-checked for additional relevant studies. In combination with the word „dysmenorrhea" one or more of the following search terms were used to obtain articles published in peer-reviewed journals only: pain, risk factors, etiology, experimental pain, clinical pain, adenomyosis, chronic pain, women, menstrual cycle, hyperalgesia, pain threshold, pain tolerance, pain sensitivity, pain reactivity, pain perception, central sensitization, quality of life, sleep, treatment, non-steroidal anti-inflammatory drugs.

NEED OF STUDY

Dysmenorrhea pain is associated with restriction of activities and it is considered as the leading cause of absenteeism from work place and colleges in young girls. Dysmenorrhea is the most commonly relieved by medication ranging for commercially available formulas to contraceptive. The side effects from such medication are well known (nausea, breast tenderness, and drowsiness, hearing and visual disturbances).
Despite the widespread belief that exercise can reduce dysmenorrhea, evidence based studies are limited. Several observational studies reported that physical exercise was associated with reduce prevalence of dysmenorrhea, although numerous other studies found no significant association between outcomesevidence

from controlled trials suggests that exercises can reduce dysmenorrhea and associated symptoms. Hence this study is designed to determine the value of stretching exercise weather it is helpful in reducingthe symptoms of primary dysmenorrhea or not.

OBJECTIVE OF THE STUDY

1) **Aims:** To check the effects of stretching exercises on reducing the symptoms of primary dysmenorrhea in adolescent girls.
2) **Objectives of the studies:** To find out effects of stretching exercise on primary dysmenorrhea in adolescent girls.

HYPOTHESIS

1) **NULL HYPOTHESIS**

   There will be no significant effects of stretching exercise on reducing the symptoms of primary dysmenorrhea in adolescent girls.

2) **EXPERIMENTAL HYPOTHESIS**

   There will be significant effects of stretching exercise on reducing the symptoms of primary dysmenorrhea in adolescent girls

METHODOLOGY

Materials and Methods:

- **Study design:** Randomized control trial
- **Source of data:** Nearby colleges and working girls through online question forms
- **Population:** All subjects are adolescent girls that are having symptoms of primary dysmenorrhea
- **Sampling method:** Purposive sampling
- **Sample size:** 30 subjects
- **Duration of study:** 3 months

All the data were collected by general assessment form, questionnaires regarding menstrual characteristics and dysmenorrhea, Numerical rating scale and verbal rating were used for assessment of intensity of pain. The general assessment form and questionnaires were distributed to all the girls who agreed to participatein

the study.

Then participants were explained the procedure and purpose of the study and consent was taken in an understandable language.

Then after participants was randomly divided into 2 groups, Group A: Stretching exercise group, Group B: Control group. Severity of the pain was measured by using Numerical rating scale and Verbal pain rating scale for pretreatment and post treatment.

Group A participants was asked to perform 5 self- stretching exercises in the back, thigh and pelvic regions for 8 weeks (4 days per week). Also they were asked to avoid performing stretching exercise during the menstrual cycle and group B participants were asked not to perform any kind of exercise on daily basis.

The exercises are as follows:

1. **Double Knee Chest**

First you have to lie down on a mat then bring one knee towards the chest then the other one, clasp the hands around the thighs and pull them to the chest, elevating the lower back part off the mat, you should not grasp over the knee part but end area of the thigh. Do it for 20 seconds and 5 times.[This exercise will stretch the lumbar spine muscle and tissues posterior to the spine]

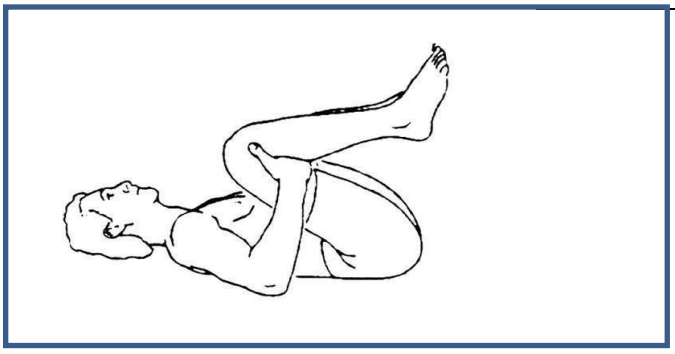

Figure.2 Double knee chest

2. **Gluteal Muscle Stretch**

Knee to chest: Pull your left knee towards your chest while lying on the ground , focus on placing your lower back flat on the ground while breathing long and deep, hold the stretch for 20 seconds and 5 times. Then perform this same on the right side of knee for 20 seconds 5 times.[This exercise will stretch the gluteal muscles , hamstrings and lower back muscles]

Figure.3 Gluteal muscle stretch

3. Child's Pose

Go on all 4 limbs and with both arms reach as far as possible with your elbows locked and your arms straight. Then lean back with your shoulders relaxed.

The stretch should be felt in the lower back and shoulders. Focus on breathing deeply with your long breaths (20 seconds 5 times) [This exercise will stretch the lumbar spine muscle , gluteal Maximus , quadriceps femoris and shoulderextensor muscle].

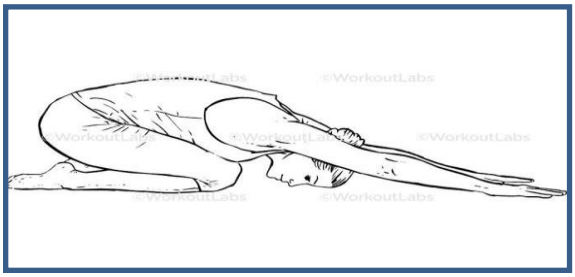

Figure.4 Childs pose

4. Cobra Pose

Lay down on your stomach then place your hands by your sides at chest level and push up while leaving your waist on the floor. Try to relax your back and waist and allow the stretch in your stomach and lower back. Focus on breathing deeply and increase movement in the spine.(20 seconds 5 times) [This exercise will stretch the soft tissues anterior to the lumbar spine and hip joints].

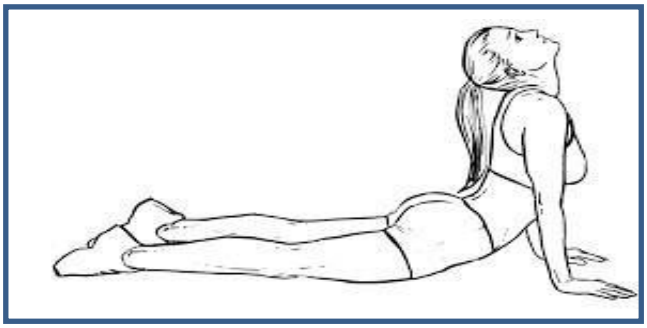

Figure.5 Cobra pose

5. Quadratus Lumborum Stretch

Lay down the ground and pull the left leg over the right side, try to leave the same side of shoulder on thefloor while you are holding the stretch. To increase the intensity of stretch extend your leg and pull the leg closer to your chest, keep inmind that do not stretch beyond your limits. (20 seconds 5times) [This exercise will stretch the quadratus lumborum muscle]

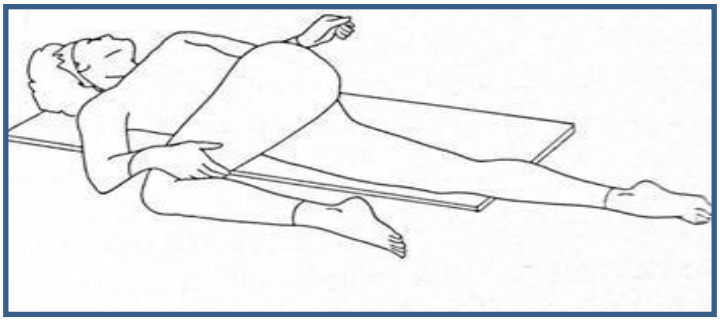

Figure.6 QL stretch

- Then same perform to the right side (20 seconds 5 times)
- Group B will be Control Group and will be asked not to perform any type of exercise during this time of study. Again data will be collected, that includes their menstrual pain before study and menstrual pain after 8 weeks, from both the group. Data will be compared and conclusion will be made on results

- Scales that were used for pain assessment of girls are as follow

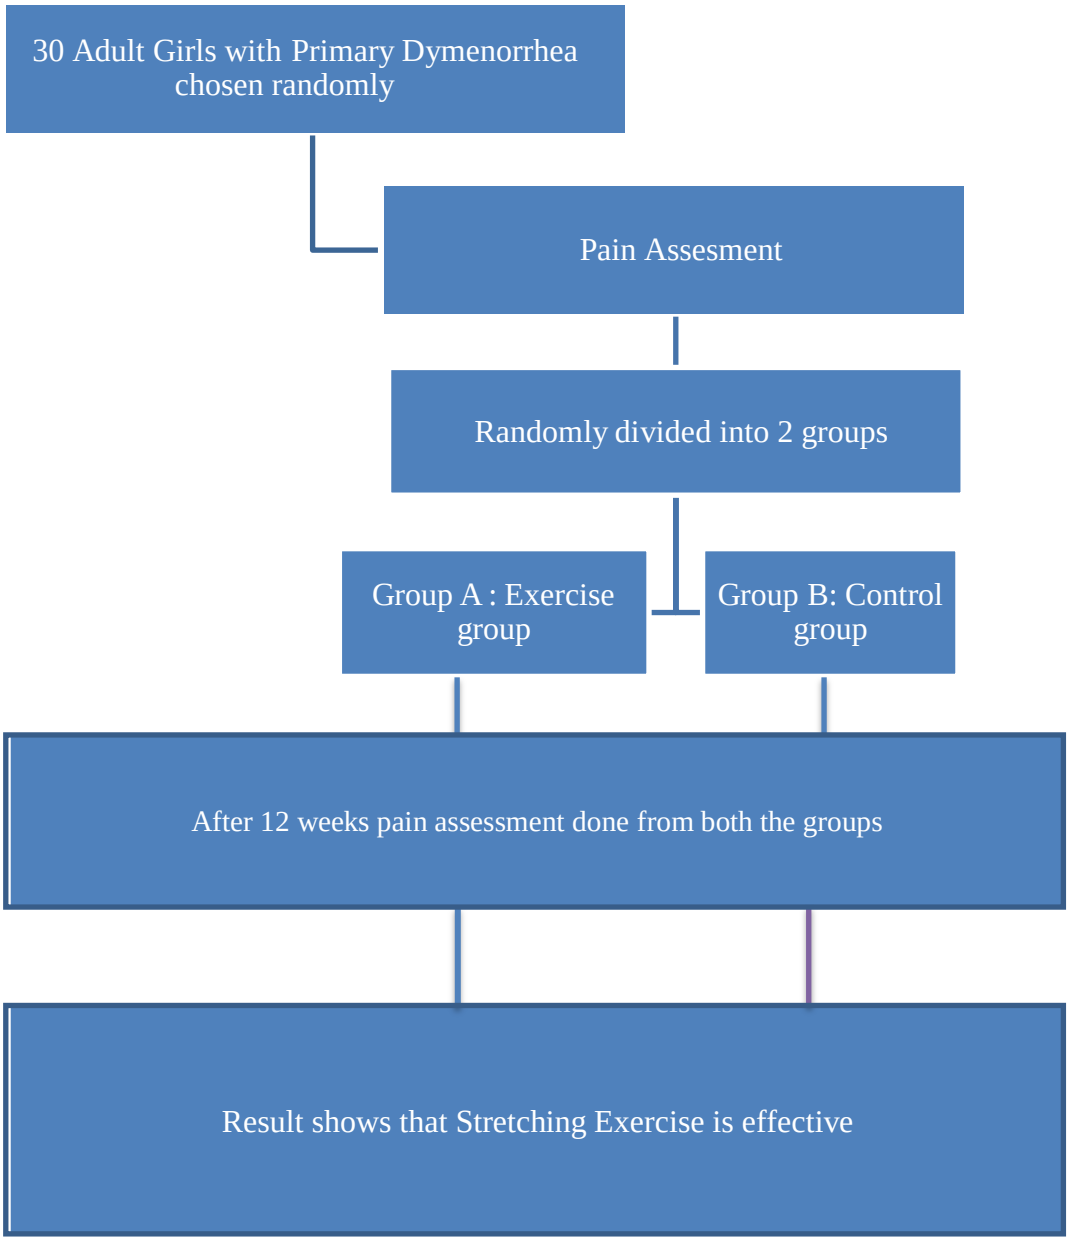
1) Numerical pain rating scale
2) Verbal pain rating scale

. Numerical pain rating scale

0 1 2 3 4 5 6 7 8 9 10

. Verbal pain rating scale

- None
- Mild
- Moderate
- Severe



RESULT

In present study 30 subjects with the age of 18-28 years were selected and divided into two groups:

- Group A – Exercise group
- Group B - Control group

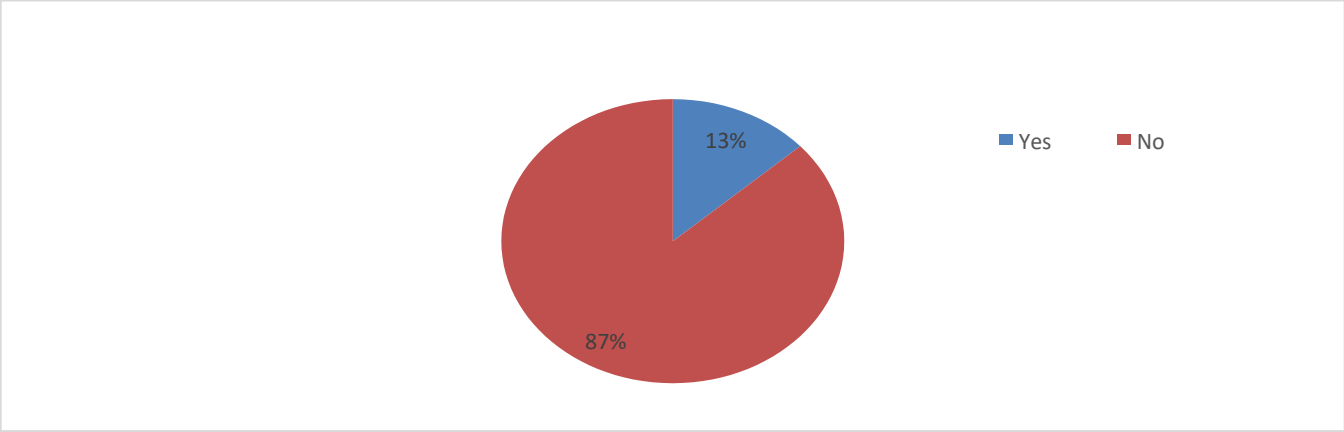
30 individuals completed the study program without any complications. The data obtained in both the groups are as follows.

Table 1 Medication taken by patients

Medicines (pain relief)	NO. of Patients
YES	4
NO	26
Total	30

Interpretation: The above table shows the no. of patients that took medication for pain relief in both the groups

Graph.1



Interpretation: Above graph shows no. of patients who respond yes and no to the medication

Table 2: Pain and any other symptoms

Pain and symptoms	No. of patients
Yes	20
Sometimes	10
Total	30

Interpretation: The above table shows the no. of patients having pain or any other symptoms

DISCUSSION

The present study was conducted to see the effect of stretching exercises on the pain intensity of primary dysmenorrhea. In present study, pain has reduced in primary dysmenorrhea more in stretching exercise group than in control group.

This improvement may be due to the increase in the blood flow and metabolism of the uterus during exercise which may be effective in the reduction of dysmenorrheal symptoms. A study done by Izzo and Labriola (1991) [26] has shown that improved metabolism is a factor in the reduction of symptoms. It is also suggested that increased menstrual pain by uterine muscle contraction is derived from a nervous system that is innervated by the sympathetic nerve hence; stress through hyperactivity of sympathetic nerve system via the increase contractibility of uterine muscles may lead to menstruation symptoms. A study done by Dawood MY (2006) [27] has shown that therapeutic exercise can increase the secretion of endorphins from the brain, and these materials in turn raise the pain threshold of the body. Daley AJ (2009) [28] believed that contracted ligamentous bands in the abdominal region were the causative factor for physical compression of nerve pathways and their irritation, so the proposed series of stretching exercise was considered very effective.

Pain in general has disabling nature and makes dysmenorrhea stressful and it can become important irritating factor in the life of lots of women, particularly who are self-financing. Some women are completely prostrated and cramped to bed, whereas others are able to remain in the works with the support of analgesics. So, many studies were done to replace medication by physical exercises in management of primary. The present study was conducted to see effect of stretching exercises in relieving pain of primary dysmenorrhea. In this study, treated females reported a significant reduction in menstrual pain within an average of 8 weeks of exercises (Group A).

Since time ago, Israel et al. [29] found that after 12 weeks of aerobic training, the intensity of symptoms decreased and Golub et al. [30]expressed that dysmenorrhea in high school girls who were involved in sports and physical activities were less than non-exercise group. In present study, pain of primary dysmenorrhea has reduced in exercise group than in control group as regard intensity and duration. These findings are similar to those of lots of authors who studied the effects of exercises on primary dysmenorrhea. Abbaspour et al. [31] and Shahr-jerdy et al. [32] proved that stretching exercises are effective in reducing pain intensity, pain duration, and the amount of painkillers used by girls with primary dysmenorrhea. Onur et al. [33] studied the impact of home-based exercise on quality of life of women with primary dysmenorrhea and concluded that there is evidence that exercise has a positive effect in the treatment of dysmenorrhea.This improvement may be due to the increase in the blood flow and metabolism of the uterus during exercise which may be effective in the reduction of dysmenorrheal symptoms. Stress tends to enhance sympathetic activity and may increase menstrual pain by exacerbating uterine contraction. Exercise may decrease this sympathetic activity and relief the stress through release of endorphins, substances produced by the brain that raise the pain threshold, so reducing symptoms. [34] Dawood [35] has shown that therapeutic exercise can increase the secretion of endorphins from the

brain, and these materials in turn raise the pain threshold of the body. Daley [36] believed that contracted ligamentous bands in the abdominal region were the causative factor for physical compression of nerve pathways and their irritation, so the proposed series of stretching exercise was considered very effective. Golomb et al. [37] concluded that exercise is widely accepted as a mean of moderating stress and biochemical changes in the immune system. A mechanism by which exercise may improve the symptoms of dysmenorrhea (reducing stress) has been articulated so, findings of different studies have shown that therapeutic exercise and physical activity was related with reduced incidence of dysmenorrhea**.**

CONCLUSION:

Stretching exercises are effective in reducing pain intensity and improve the quality of life and also it helps in reducing the amount of pain killers taken by young girls which might have bad long term effects on their health and it is also shown that the productivity has also increased for those days as having less pain among the girls with primary dysmenorrhea.

SUMMARY:

The study was conducted to find out the effects of stretching exercise in reducing pain symptoms among the adult girls that were having primary dysmenorrhea. 30 girls are voluntarily participated in the study, after that pain assessment and data was collected through assessment form and girls were randomly divided into two groups (A: exercise group, B: control group). After that exercise groups was given a set of exercises to practice for 12 weeks (4 days per week) meanwhile control group was asked not to perform any exercise on daily basis. After the study duration pain assessment was taken from both the groups and compared to find out the effects. Results are seen that stretching exercises are effective in reducing pain in the girls of group A while girls of group B did not felt any change in their pain after 12 weeks.

LIMITATIONS:

There are some drawbacks of this study, such as

This study was conducted through online modes so there are some chances of faulty postures of candidates while doing the exercises which can affect the final results of the exercises.

FUTURE RECOMMENDATIONS;

- Study can be done among various other types of exercise forms which could be effective in reducingthe pain intensity of primary dysmenorrhea.

"PREVALENCE OF IRREGULAR MENSTRUATION INFEMALES OF AHMEDABAD CITY- A CROSS- SECTIONAL STUDY."

[1]Dr. Arvind Kumar Chauhan [2]Dave Yashvi Sunil,

[1]M.P.T. (Musculoskeletal Conditions and Sports), Assistant Professor, VenusInstitute of Physiotherapy, Swarrnim Startup & Innovation University, Gandhinagar

[2]M.P.T., Ph.D., Musculoskeletal Conditions, Principal and Professor, VenusInstitute of Physiotherapy,

ABSTRACT

BACKGROUND: A natural process in which the blood is discharged through the vagina from the uterus, mainly occurs monthly at regular intervals in every women is known as menstruation. Menstrual abnormalities have the potential to have an impact on women's health and can be an indication. Therefore, awareness about this diseases can make the precautionary measurements a lot more easier.

AIM: To find the prevalence of Irregular menstruation in females of Ahmedabad city.

MATERIAL AND METHODS: This cross-sectional study was carried out within period of six months to study various menstrual problems experienced by the females. A questionnaire was designed and 500 females were asked to partake by answering questions regarding their menses. After that, their data as collected for analysis.

RESULTS: Result shows that most of the population had regular menstruation cycle. Under closure analysis, it was found that 59 percent of females had medium bleeding flow and 64 percent had a painful menstrual cycle. However, 18 percent of which are taking treatment for the same.

CONCLUSIONS: This study's findings depicts about how the population is unaware of menstrual disorders and its impact on a women's life as only fewer subjects had intended to take treatment. Therefore, proper education must be gained by the females to maintain their health and thereby prevent these disorders. Moreover, attention

should be drawn towards it.
KEYWORDS: Prevalence, Irregular menstruation, Menstrual disorders

INTRODUCTION

Menstruation is the visible manifestation of cyclic physiologic uterine bleeding due to shedding of the endometrium. The period extending from the beginning of a period (mens) to the beginning of the next one is called menstrual cycle.[1]

Menstrual cycle starts at the age of 12 to 15 years, which marks the onset of puberty. The commencement of menstrual cycle is called menarche. Menstrual cycle ceases at the age of 45 to 50 years. Permanent cessation of menstrual cycle in old age is called menopause.[2]

The four basic stages of the menstrual cycle are: Menstruation, the follicular stage, ovulation, theluteal stage. During menstruation, the thickened outside layer of the uterus is disposed of fromthe body through vagina. Blood cells from the coating of the uterus and bodily liquid form the menstrual fluid. During the initial stages of cycle, the level of estrogen begins to rise, coating of the uterus grows and thickens due to the rise in the levels of estrogen.[3]

Normal menstrual cycle in females represents the complex interplay of hormones such as estrogen and progesterone. Regular menstrual cycle occurs every 28-35 days ± 2-3 days in whichthe menstrual flow lasts for 3-5 days with an average loss of 30-80 ml of blood.[4]

Menstrual cycle pattern changes with age. Overall cycle variations are common at menarche and perimenopause. A menstrual disorder is an abnormal condition in women's menstrual cycle.

Menstrual disorder may present as abnormal uterine bleeding, dysmenorrhea, premenstrual syndrome and premenstrual dysphoric disorder.[5]

Normal menstrual cycle is the indication of functioning of hormones in a proper manner, whichis significant of a healthy hypothalamo-pituitary axis with a normal uterus. Nevertheless, a number of conditions such sudden over-exercising, weight loss, medical conditions such as Polycystic ovarian disease, and even stress can have unpleasant effects on a woman's ability to experience a normal menstrual cycle. From most of the existing literature, it is evident that both longer duration of menstrual bleeding and irregular cycles are associated with major depression.[6]Life of adolescents is majorly affected by menstrual disorders. Among these are women who are affected by dysmenorrhea and heavy menstruation. The WHO reports that 18 million women aged 30 - 55 years identify their menstrual bleeding to be extreme.[3]

Menstrual patterns can be affected by a number of factors, including age, ethnicity, family history, smoking, physical activity, and dietary habits. Stress can be a major contributor to, or cause of menstrual irregularities. In addition, a high incidence of menstrual problems has been observed in students studying medicine and health sciences.[7]

Irregular menstruation can have various health implications, and is an indicator of health in women. The prevalence of irregular menstruation varies from 5% to 35.6% depending on age, occupation, and the country of residence.[8]

Abnormal menstrual cycle is any deviation from the normal cycle. Menstrual disorders prevailing in adolescent girls, including dysmenorrhea, amenorrhea, menorrhagia, hypomenorrhea, polymenorrhea, oligomenorrhea, and premenstrual syndrome.[4]

Menstrual irregularity results from various causes such as endometriosis, PCOS, type-2 diabetes mellitus, depression, hormonal imbalances, stress, underweight or obesity, smoking habit, etc.[8] The menstrual problems are not always problems but bodily reactions to various changes inside.Most of the women have some symptoms or a combination of a few or all of them, which may beeither physical or emotional. Insomnia or change in appetite is also a part of menstrual cycle.[4] There is a lack of information about the awareness and behaviors of adolescents

towardsmenstruation. Mostly girls have little knowledge about regular menstruation and about theirirregularities. Their only source of information is from their mothers or peers. Girls are interestedin knowing more about normal and abnormal menstruation. Having knowledge of thesedisorders, helped them to get medical advice as and when required.[3]

Some women experience backache, headache, or abdominal pain during their menstrual cycle.Pain around the breasts, swelling, soreness, or heaviness also occurs during menstruation.

Abdominal cramps are the worst among the menstrual pains that really bother all activities. These are caused by the involuntary contraction of the uterine muscles. Knowledge of the complications that are caused by these menstrual disorders in the general population may help to inform women when they should consult primary care and aid the appropriate referral of women for investigation of malignancy.[9]

REVIEW OF LITERATURE

1. Pattern and prevalence of menstrual disorders in adolescents.[3] Zafar M et al (2018):

This study was conducted in the year 2018, that depicts about adolescent menstrual disorders which are exceptionally not unusual, study reported higher than predicted incidence of menstrual issues. Expertise regarding the factors influencing menstrual symptoms is critical as a way to manage it correctly and assist the girls to make up the days less troublesome and tolerable. A selection of factors is recognized to affect menstrual behaviors, the most influential ones being economic popularity. Absenteeism from the school changed into the impact of menstruation related problems on their each day recurring. Dysmenorrhea and premenstrual symptoms had been perceived as maximum distressing symptoms leading to school absenteeism and of days off work. Women with premenstrual signs and symptoms have suggested a greater number of days with impairment in recurring work, school and household activities.

2. Prevalence of Menstrual Disorders and Their Association with Physical Activity in Adolescent Girls of Aligarh City. [4] Kulshrestha S. et al (2019):

This cross-sectional descriptive study was conducted in 2019 to assess the prevalence of menstrual disorders and their association with physical activity among 320 adolescent girls aged between 14 to17 years in Aligarh city. Data regarding age of menarche, menstrual cycle interval, menstrual flow length and period pain was contained. Physical activity was assessed by the Physical activity questionnaire scale (PAQ-A). The overall prevalence of menstrual disorders was reported by 76.9%. Dysmenorrhea and PMS were found to be highly prevalent among girls in Aligarh. It was found that PMS was the commonest menstrual disorder that interfered with the daily routine of the school girls.

3. Prevalence of Menstrual Disorders in Woman of Reproductive AgeGroup. [5] Farhan I. et al (2020):

This study was conducted in 2020 which showed that menstrual disorders are prevalent in Pakistan. Management of these disorders should be paid more attention within the available reproductive health care programs. Further research into prevalence of and risk factors for menstrual disorders and their morbidity is endorsed. Appropriate health education measures should be promoted to influence females to seek medical management leading to early diagnosis and precautionary treatment.

4. Association of Menstrual Patterns with Perceived Stress Score in College Going Female Students of a South Indian Town.[6] Periasamy P. et al (2021):

This study was conducted in 2021, stated an association between high stress levels in students (PSS >20) and menstrual pattern could not be established notably. However, there was association established between high stress levels (PSS >20) and menorrhagia (heavy menstrual bleeds). Consequently, despite high levels of stress in

undergraduate students, other factors can also play a significant role in maintaining their menstrual cycle. Therefore, other causes must also be looked for among the young females complaining of menstrual problems before concluding them because of stress.

5. Prevalence of menstrual problems and their association with psychological stress in young female students studying health sciences.[7] Rafique N. et al (2018):

This study conducted in 2018 concluded that the prevalence of menstrual problems and stress is quite high in young, Saudi, female health sciences students. In addition, a strong positive association between psychological stress and amenorrhea, dysmenorrhea, and premenstrual symptoms was identified. It is recommended that all health sciences students should be provided with short courses on stress management techniques as part of their curriculum. Moreover, allhealth sciences colleges should make arrangements for early identification of students with menstrual problems, as these conditions can not only affect the academic performance of the students, but can also have negative effects on their psychological and reproductive health. The students identified should be provided with timely psychological and gynecological counselling, as well as instructions and strategies for preventing future complications.

6. Prevalence of irregular menstruation according to socioeconomic status: A population-based nationwide cross-sectional study.[8] Kwak Y. et al (2019):

This cross-sectional study conducted in the year 2019, observed a higher prevalence of irregular menstruation among women with higher incomes and lowereducational levels. Public health professionals should recognize the need for early education, detection, and intervention for at-risk populations and stress the importance of building a multidimensional understanding of irregularmenstruation.

7. Prevalence of irregular menstruation among homemakers and workingwomen.[9] Sharon V. et al (2019):

This study was conducted in 2019 which described about the development of the symptoms of menstrual loss among women in the community is common, in contrast to the rarity of gynecological malignancy. That raised concern about the usefulness of the current guidelines, based on symptoms, advising women when to consult, and for the early awareness of gynecological malignancy in the community and primary care.

8. Pattern of menstrual irregularities amongst women presenting to gynaecological outpatient department. Journal of Islamabad Medical & Dental College (JIMDC). [10] Mahmood M. et al (2013):

This study conducted in the year 2013 depicted about how most of thepatients are unaware about what represents normal menstrual pattern. Therefore, it is important to educate patients regarding range of normal cycle length. It isequally important for the clinicians to have an understanding of bleeding patterns and ability to differentiate between normal and abnormal conditions. Menstrual cycle as an additional vital sign adds a powerful tool for the assessment of normal development and exclusion of pathological conditions.

9. Prevalence and pattern of menstrual disorders among Lebanese nursing students.[11] Karout N. et al (2012):

This study conducted in 2012 found a higher percentage of different menstrual disorders among young female students in Lebanon. These disorders are not only likely to affect the quality of life and future productivity of women but may also be indicators of underlying problems that can become serious in thefuture and this is an important concern for reproductive health policy-makers. Health education on menstrual problems targeting female students

and their parents, and including education on reproductive health in the school curriculum may assist in early diagnosis of these disorders.

10. Factors associated with menstrual cycle irregularity and menopause.[12]Bae J. et al (2018):

This study conducted in the year 2018, results showed the importance of healthier behavioral practices to maintain menstrual cycle regularity, especially when considering that smoking may be associated with the occurrence of early menopause. Given the association between early menopause or irregular menstruation and women's health, improvements in health behaviors should be emphasized inview of public health.

NEED OF STUDY

Irregular menstruation is an important indicator and mediator of various health problems among women. The study focuses on women experiencing irregular menstruation cycle are somehow not aware about the future health issues. Therefore, the study is necessary to measure the awareness level and prevalence of

the irregular menstruation among women. The results obtained will be helpful increating strategies for improving psychological and reproductive health.

OBJECTIVE OF THE STUDY

1) AIMS: To find the prevalence of Irregular menstruation in females ofAhmedabad city.

2) OBJECTIVE OF THE STUDY: To assess the menstrual health in females of18-30 age groups in Ahmedabad city using a questionnaire.

To measure the awareness level of the causes of irregular menstruation inAhmedabad city.

METHODOLOGY

This was a cross-sectional study of six month duration (2021), in which 500 females (aged between 18 and 30 years) of Ahmedabad city were invited toparticipate.

The questionnaire was designed by the author, based on some previous similar studies and was regarding menstrual characteristics, and multiple choice questions were used for assessment of intensity of pain.

The subjects were asked to complete a menstrual problem identification questionnaire anonymously. The questionnaire included items relating to the participants' demographic details, and concerned their menstrual pattern (menarcheage, cycle length in days, duration of flowing days, menstrual regularity).

Furthermore, all the data were collected by sending the questionnaire form to the females who agreed to participate in the survey.

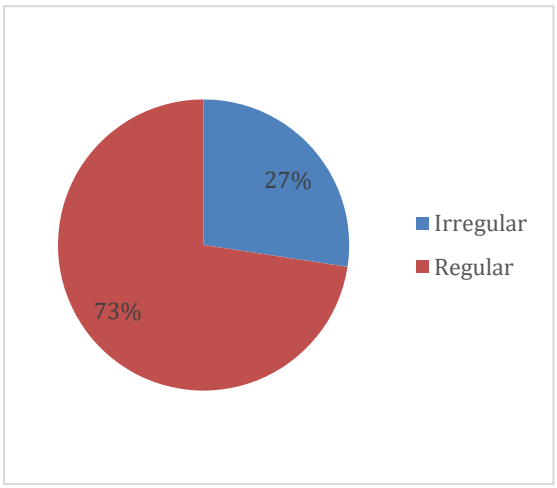
In addition to that, the participants were given brief about the procedure and purpose of the study and thereby the consent was contained in an understandable language and all the participants were assured that their personal informationwould be kept confidential.

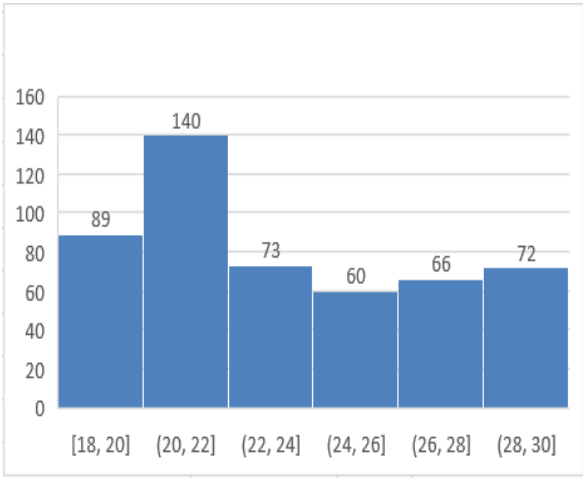
After that, the result was shown with statistical analysis which included proper graphs and charts that provided detailed information of the numbered characteristics.

RESULT

In this cross-sectional study of 500 subjects among females aged between 18 to 30 years, irregular menstrual cycle was noticeably lesser than the regular menstrual cycle. Under thorough observation, plethora of questions were asked and analyzed accordingly [Graph 2].

Irregular menstruation was observed to be about 27% while the regular menstruation stated about 73% overall [Graph 1].



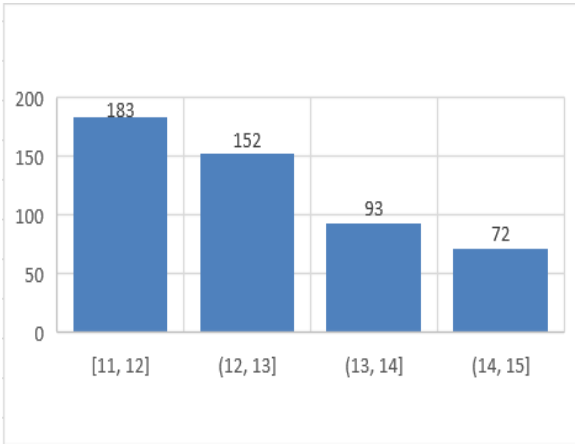


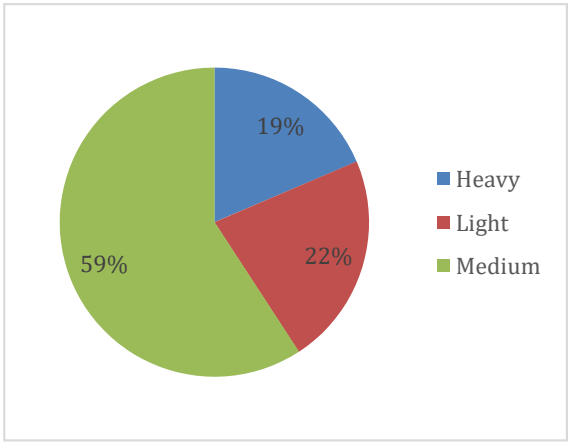
Graph 1: Menstrual period

Graph 2: Age

The females who participated in the study had their menarche age from 11 to 15 years. Moreover, the average value suspected was 13 years of age [Graph 3].

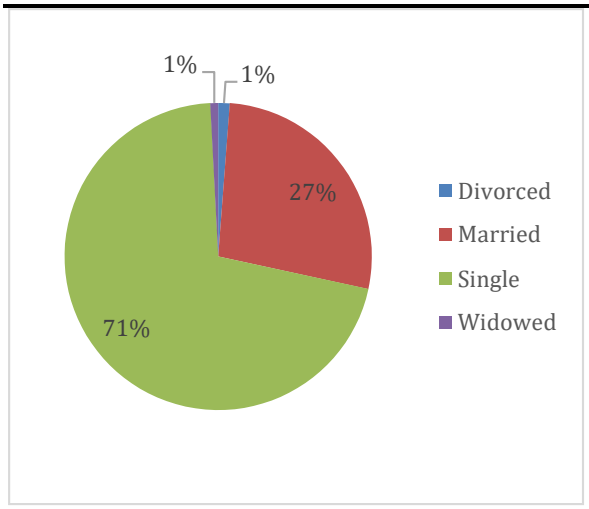
When the females were asked about the bleeding, around 59% of the females were observed medium flow, and the heavy flow was observed in nearly 19% of females. While 22% observed light flow [Graph 4].



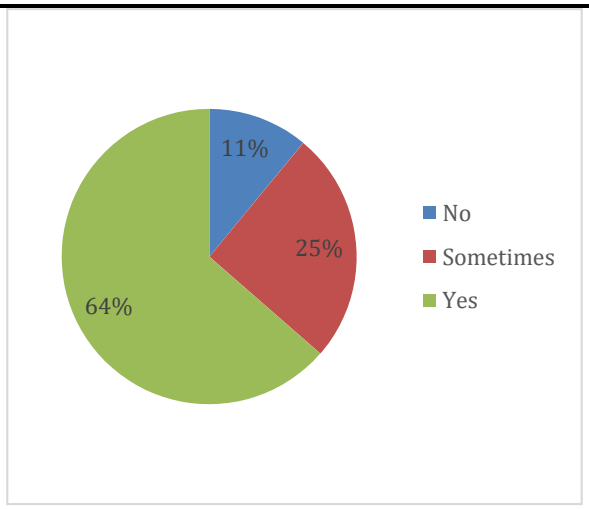


Graph 3: Age of menarche

Graph 4: Bleeding

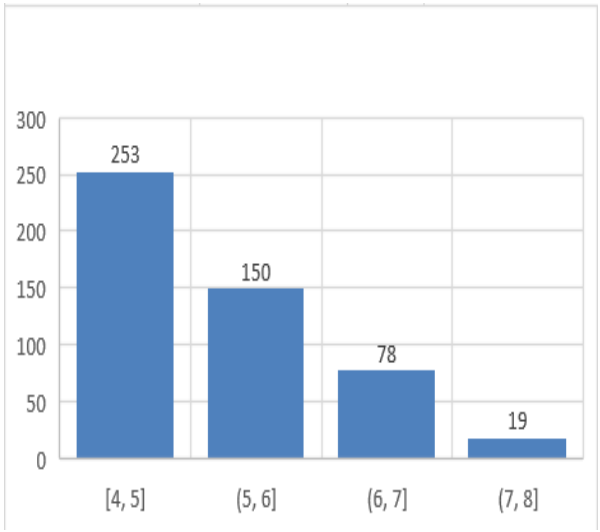


Graph 5: Marital status

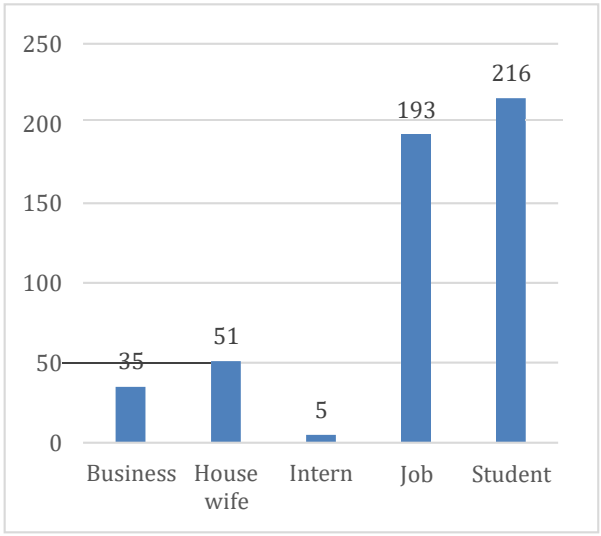


Graph 6: Pain during menstrual period

Besides that, the highest subjected females were single as amounted to 71% , and 27% married women being the second highest. Whereas, the other two categories had remarkably as low as 1% individually [Graph 5].
Menstrual cramp or pain is the most common remark presented as well as observedin the population. 64% of the women had experienced pain during their mensesand 25% of which had experienced it sometimes. The women who did not go through menstrual cramps were around 11% [Graph 6].

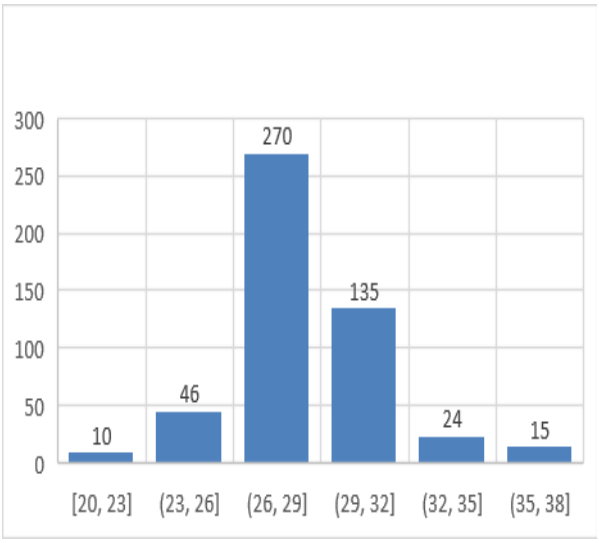


Graph 7: Menses period

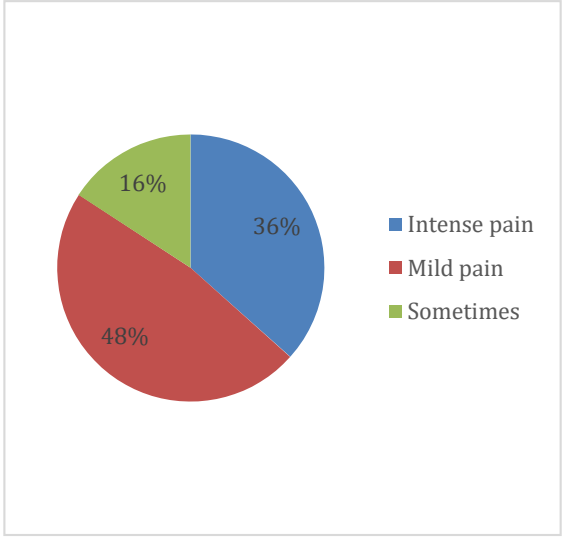


Graph 8: Occupation

Most of the females, that is about 253 females had their menses for about four to five days, and the least score was 19 females who had their period for seven to eight days. The other 228 subjected females were experiencing 5 to 7 days of menstrual cycle [Graph 7].
In this study, the subjected females were from various sectors such as student, job, housewife, business, intern. All of this details are kept in descending order according to the outcome [Graph 8].



Graph 9: Days of menstrual cycle



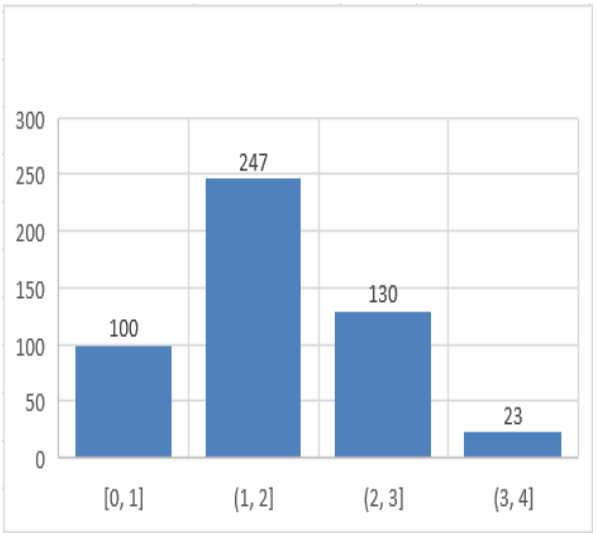
Graph 10: Stomach pain

When asked about their days of menstrual cycle, however, the range was from 20 days to 38 days, but 270 females had nearly 26 to 29 days during their menstrual cycle which states that huge amount of females had normal menstrual cycle [Graph9].

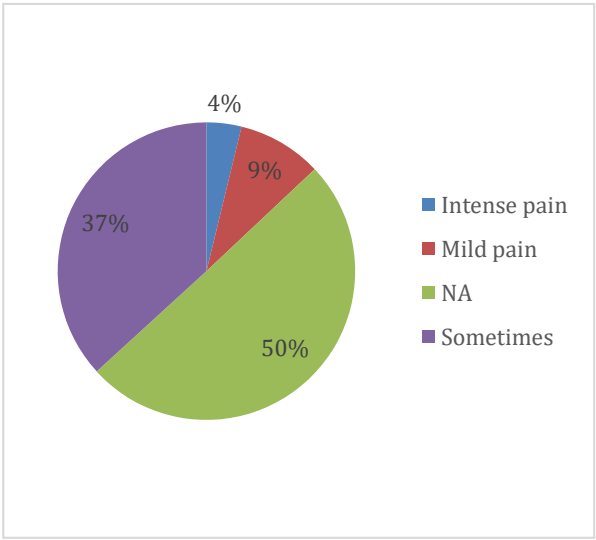
In addition to this, menstrual pain can be seen in various parts of the body, stomachpain has relatively higher remarks in that. 48% of women were having mild pain symptom. Whereas, the other women had experienced sometimes and intense pain amounting to 16% and 36% respectively [Graph 10].

Other than that, the severity of pain was experienced highest on the first two days as claimed by 247 females. While the intensity of pain on 3rd and 4th day wasquite low [Graph 11].

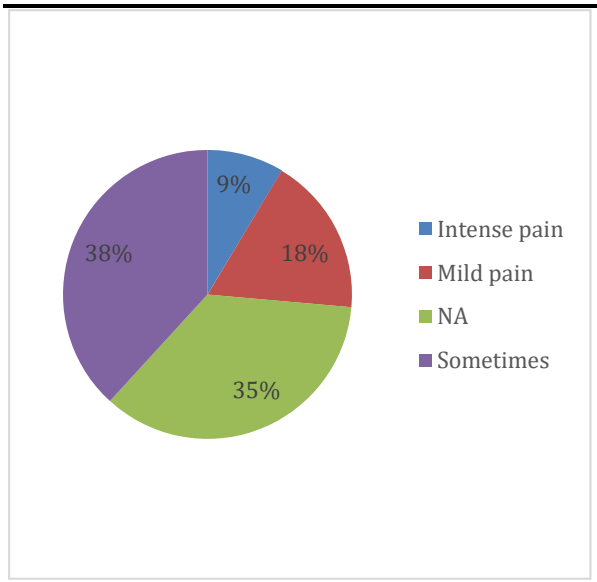
When asked about chest pain, 50% of the females had no experience as such while the other 50 percent of women had experienced mild pain (9%), intense pain (4%), sometimes (37%) [Graph 12].



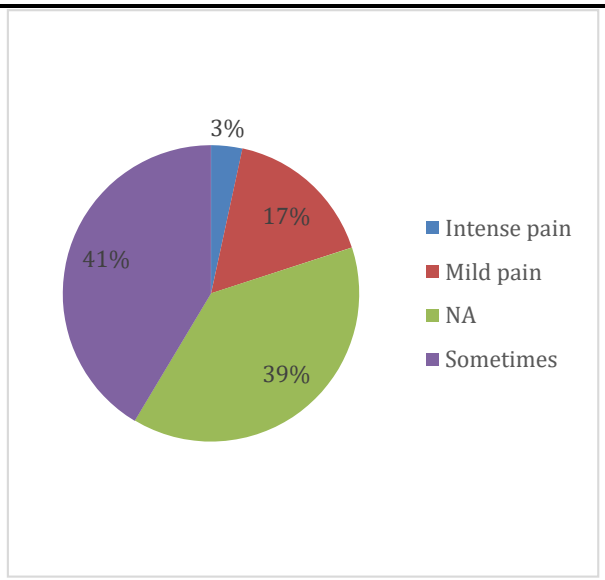
Graph 11: Days of severe pain



Graph 12: Chest pain

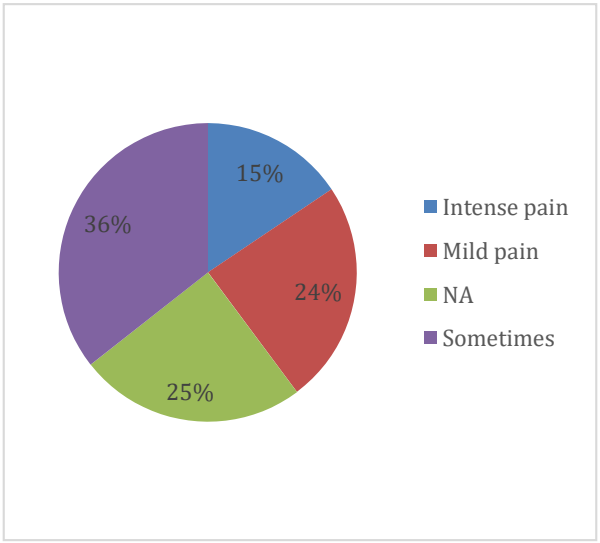


Graph 13: Pain in the hip

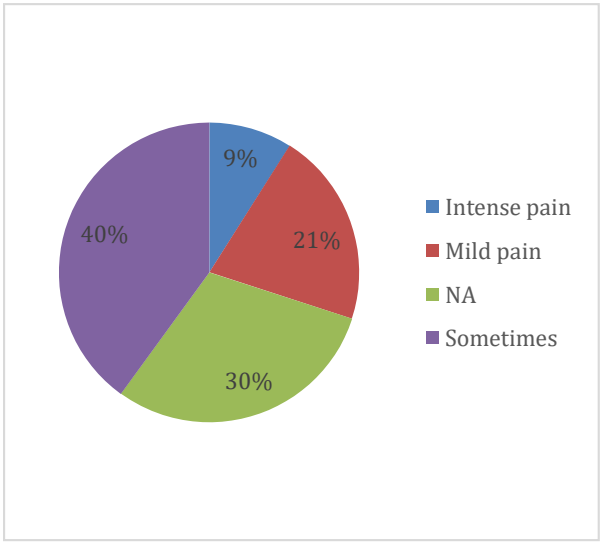


Graph 14: Pain in the arms

Further when questioned about pain in the hip, 38 percent of females had pain sometimes, and 35 percent of them had responded to no, whereas, 18 and 9 percenthad experienced mild and intense pain respectively [Graph 13].
Next question was about pain in the arms, as low as 3% of which had experienced intense pain and 17% females had experienced mild pain. On the other hand, 41% females had responded sometimes [Graph 14].

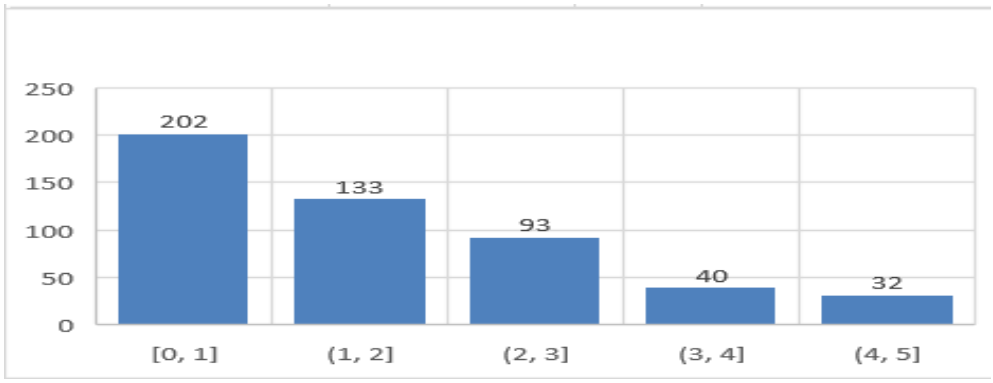


Graph 15: Pain in the legs



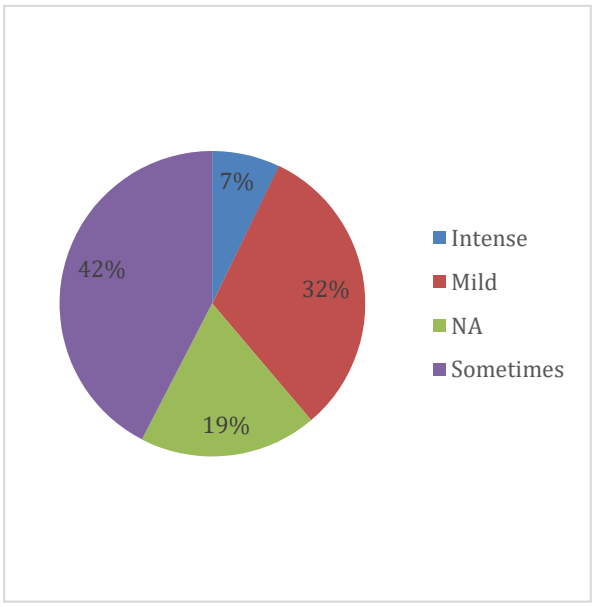
Graph 16: Pain in the joints

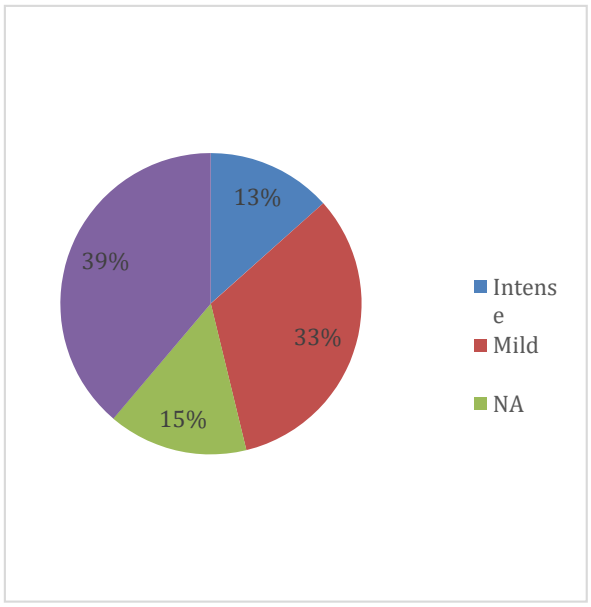
When asked about pain in the legs, 15 percent of females had intense pain and 36 percent of which had experienced pain sometimes. The females had responded to no pain as well as mild pain of about 25% and 24% respectively [Graph 15].
After that, a question about pain in joints was observed to have responded sometimes (40%), no pain (30%), mild pain (21%), intense pain (9%) in the same manner [Graph 16].



Graph 17: Number of irregularities in a year

The majority of the population, that is, 202 females experienced to 0 to 1 irregularities in a year. While 133 females claimed it to have extended up to 1 to 2 irregularities. On the other hand, some females around 32 of them had respondedto have 4 to 5 menstrual irregularities in a year [Graph 17].





Graph 18: Headache

Graph 19: Fatigue

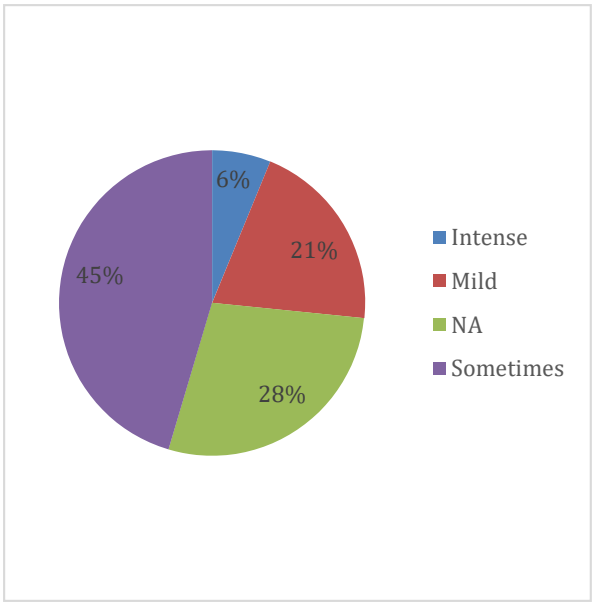
Headache was observed to be at peak about 42% with sometimes response, whereas, mild headache was noted to be around 32%, and significant aching in 7%of females [Graph 18].

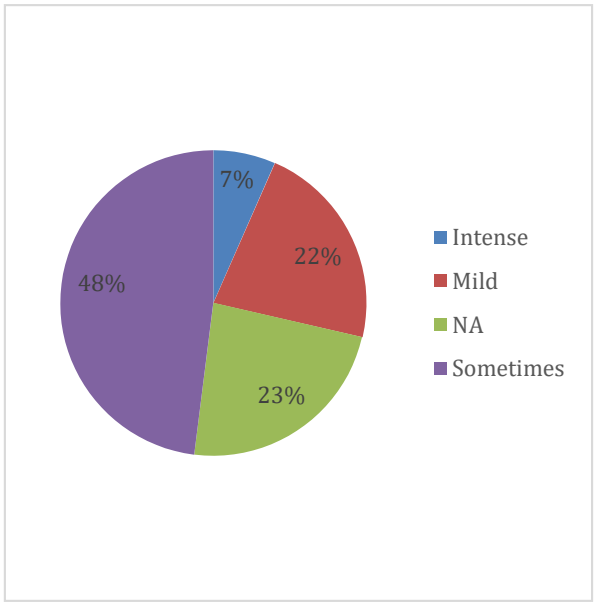
Among 39% of females, fatigue or tiredness was experienced sometimes. Whilethe mild and intense tiredness along with no response was observed to be 33%,13% and 15% respectively in females [Graph19].

Nausea was experienced sometimes for about 45% of females, while mild (21%) and intense (6%) nausea was

answered by females. Of which, 28% had no response at all [Graph 20].

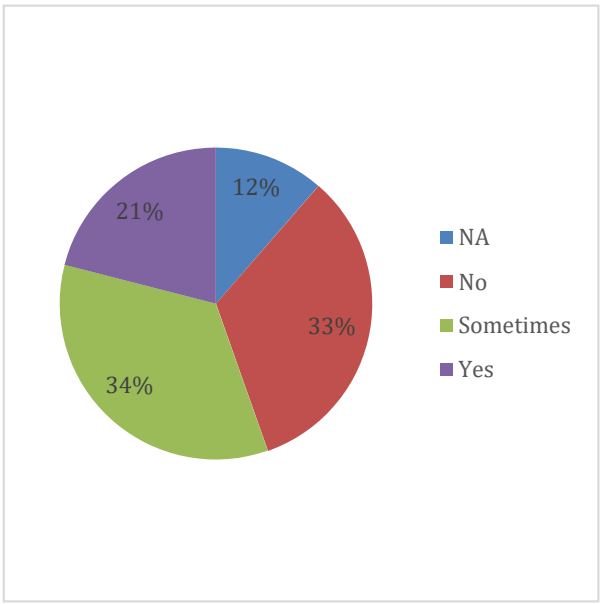
Almost around 48 percent of females answered sometimes when asked aboutdizziness. Whereas, the mild and intense response was noted to be around 22 and 7percent individually [Graph 21].

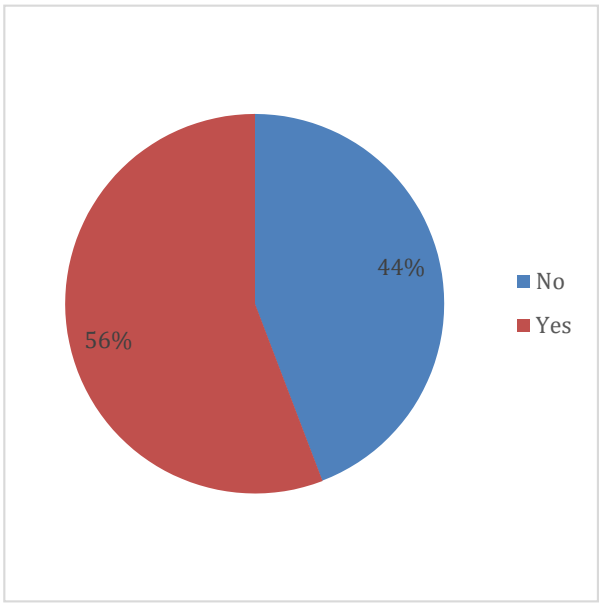




Graph 20: Nausea

Graph 21: Dizziness





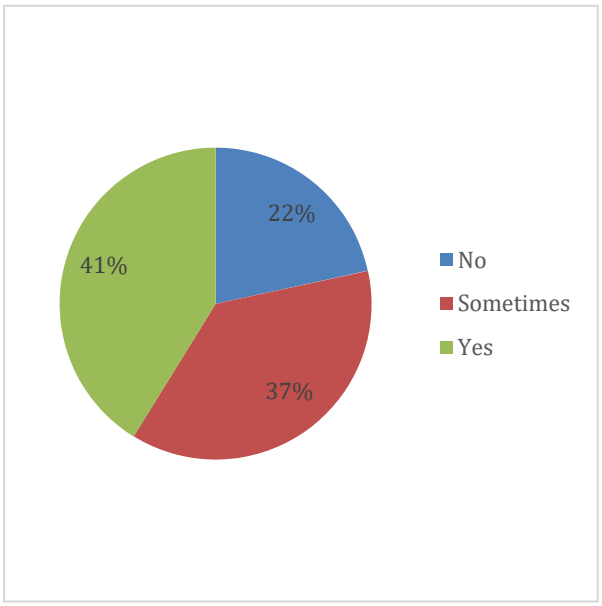
Graph 22: Anxiety

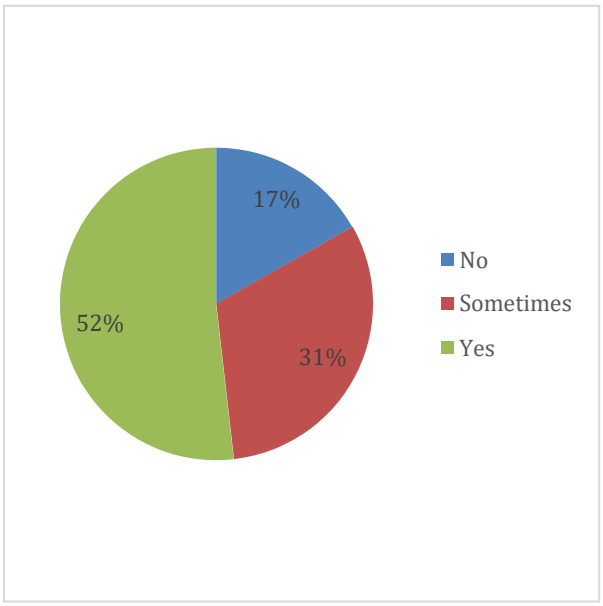
Graph 23: Increased appetite

When enquired about the anxiety level during their menstrual period, 34 % of themhad answered sometimes, while 21% answered yes , 33% answered no and 12% had no response as such during their menses [Graph 22].

Among 56% of females felt that their appetite had increased during their menses while the other 44% of them had

felt the literal opposite of it [Graph 23].





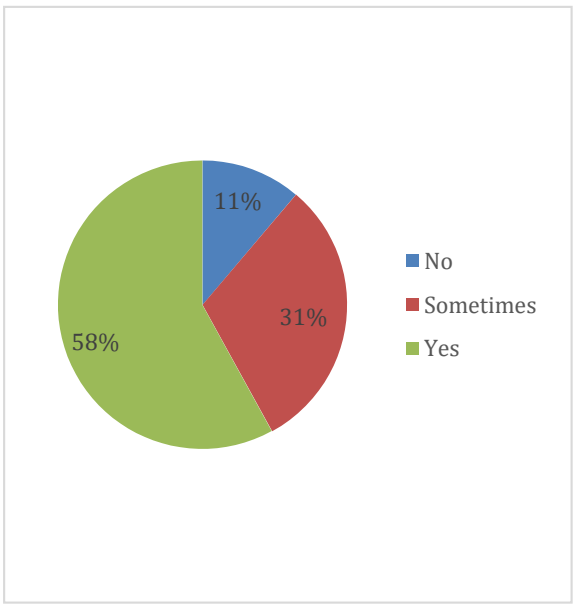
Graph 24: Difficulty in concentrating **Graph 25:** Irritability

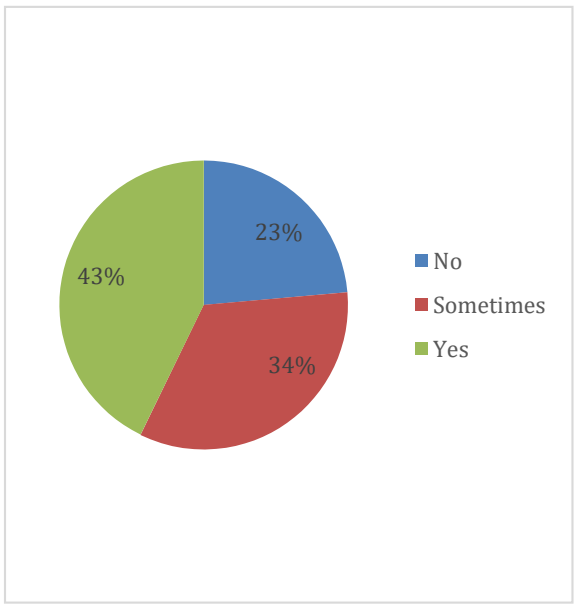
Almost 41% of the females had faced lack of concentration during their menstrual period while 22% of which had no difficulty in concentrating. Whereas, 37% of them had experienced it sometimes [Graph 24].

Irritability during the menses was noticeable as 52% of females answered yes, the other 31% of them answered sometimes, and 17% of females answered no [Graph 25].

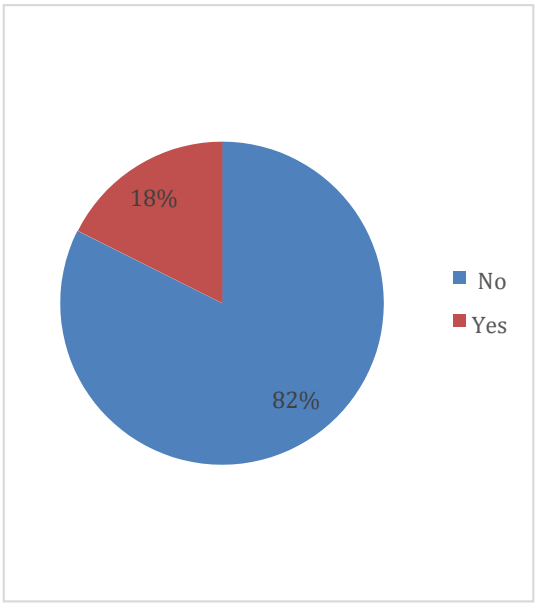
Among 58% of females had experienced mood swings, whereas, some females answered no (11%) along with sometimes (31%) during their menstrual cycle [Graph 26].

Anger issues were observed in 43% of females, 23% of them had no such feelings while the other 34% of females were experiencing anger problems sometimes during their menstrual period [Graph 27].

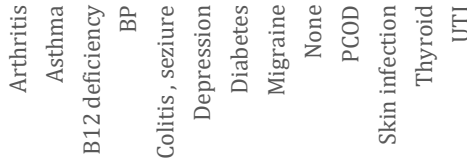




Graph 26: Mood swings **Graph 27:** Anger



Graph 28: Taking treatment



Graph 29: Any other major diseases

When questioned about taking any precautionary treatment, only 18% of femalesagreed to it while the other 82% of females answered no [Graph 28].
Majorly diabetes (7 females), asthma (6 females), arthritis (6 females) and PCOD

(6 females) were listed when question was raised regarding diseases. Other diseases listed had a very miniscule amount as 459 females in particular werecompletely healthy [Graph 29].

DISCUSSION

Menstrual cycle being irregular mainly affects women health as they are not aware of it causes. The present study shows that most of the population had regular menstruation cycle. Under closure analysis, it was found out that 59 percent of females had medium bleeding flow and 64 percent had a painful menstrual cycle. However, 18 percent of which are taking treatment for the same.

Sharon V et al. in their survey reported that 33.4% of homemakers had experiencedhip pain sometimes, 46.6% responded to yes, and 20% responded to no.[6]

This study depicts that around 270 respondents had a normal length cycle, and 10 respondents had a shorter cycle. These variations in cycle length and duration are consistent with other finding from Rafique and Alshiekh, where they found 13% of their participants had a short cycle with only 5% reporting long menstrual periods.[11]

According to the World Health Organization International and Multicenter study of3073 girls, the median length of the first cycle after menarche was 34 days with 38% of cycle lengths exceeding 40 days. Hence, the irregular menstrual cycle in young girls may not be taken in account since they vary from 34 days.[13]

The survey in Tiruchirappalli district shows that 68.6% of women experience pain during their cycle, intense stomach pain (23.8%), intense hip pain (25.7%), and intense leg pain (23.3%). 80% of respondents have no headache, 94.8% have no chest pain, and 84.3% have no pain in joints.

Pitts et al. have reported high rates of pelvic pain in Australian women. Among 4366 women, 15% of them reported severe pain with dysmenorrheal, 7.3% women with dyspareunia, and 20% of women with chronic pelvic pain.[14]

Agarwal and Agarwal reported in their survey that dysmenorrhea is a very commonproblem among adolescent girls and they experience a number of physical and emotional symptoms associated with increased intensity of pain.[15]

CONCLUSION

This study's findings depicts about how the population is unaware of menstrual disorders and its impact on a women's life as only fewer subjects had intended to take treatment. Therefore, proper education must be gained by the females to maintain their health and thereby prevent these disorders. Moreover, attentionshould be drawn towards it.

SUMMARY

A cross-sectional study was contained among 500 females of Ahmedabad city regarding their menstrual cycle. To assess, the subjected females were asked to answer different questions about their menstrual period. After that their data was collected to analyze and find out the prevalence of irregular menstruation among these women. The end result showed that only fewer population are experiencing

irregular menses but somehow only half of these females are taking proper carewhich briefs out about their lack of knowledge towards it.

LIMITATIONS:

The sample size was limited due to study conducted in Ahmedabad cityonly.

FUTURE RECOMMENDATIONS:

The future study can involve effects of various exercises on irregularmenstruation.

Abstract : Sujok is a simple, easy and effective way to heal oneself. In Sujok therapy, the palms and feet represent all of the organs and meridians in the body. Sujok can be done in addition to other therapies and it has no side effects. By stimulating points on the hands and feet, this therapy can help cure various ailments throughout the body. Physiotherapists help people with injuries, illnesses or disabilities by providing movement and exercise, manual therapy, education and advice. They provide health care for people of all ages, helping patients manage pain and prevent disease. Physiotherapy is a science-based profession that takes a holistic approach to health and wellbeing, including considering a patient's overall lifestyle. An experimental study was conducted using convenient sampling from the physiotherapy clinics situated in the area of Gandhinagar and Ahmedabad of Gujarat state among 90 adult patients of knee OA aged between 18 to 60 years. Data was collected in the period of April and May 2022. There is a significant difference before and after physiotherapy, Sujok and Sujok + Physiotherapy sessions on all 7 consecutive days. There was a significant decrease in the pains of the patients after 3rd day, irrespective of treatment taken by patient. Significant difference was found between physiotherapy and Sujok treatments after day 5. Physiotherapy and Sujok treatments do differ significantly. But there is no benefit

I. INTRODUCTION

Pain disrupts people's lives, and the ability to recognize and understand pain is an early sign of disease states (1), illness, bodily injury (2), and serious or minor health problems (3). One definition of pain is: An unpleasant sensory and emotional experience associated with, or resembling that associated with, actual or potential tissue damage (4). Several literature reviews indicate that there are two types of pain management strategies: multimodal or multidisciplinary (5) and non-multidisciplinary. Multimodal strategies are commonly referred to as "programs". The non-multidisciplinary program is his second strategy for pain relief. This method includes medical treatment and alternative therapy, usually applied in one treatment. Several studies have shown that Su Jok can be used to treat fatigue and weakness (6), elbow eczema (7), migraines (8), asthma (9), and stroke rehabilitation (10). Su Jok for pain relief can also be used for heel spur pain (11). Su Jok Therapy is a complementary and alternative therapy developed in 1987 by his Professor Park Jae Woo in South Korea. Su Jok can provide fast and meaningful results (12). The term Su Jok is of Korean origin. Su means hand, Jok means foot, and Su Jok functions as a therapeutic group for managing health (12). The Su Jok method of treatment is done by stimulating the hands and feet (13). Because they have many similarities with the human body (12). Stimulate the limbs by massaging, applying paint to the skin, moxibustion, placing seeds, magnets, needles, etc. in specific locations. Su-Jok therapy is considered an easier and cheaper treatment than most alternative therapies, and results are generally quicker.

Su Jok Therapy's view of the healing process is based on the concept that the human body is a living organism subject to various factors and has causal relationships with all the energies of the universe. All changes in the human body must obey universal laws of interaction, so that a person's health is determined not only by individual characteristics, but also by environmental forces (14). The aim of this current study was to assess the effects of Sujok therapy, physiotherapy and Sujok + physiotherapy on patients with knee OA.

II. MATERIALS AND METHODOLOGY

An experimental study was conducted using convenient sampling from the physiotherapy clinics situated in the area of Gandhinagar and Ahmedabad of Gujarat state among 90 adult patients of knee OA aged between 18 to 60years. Data was collected in the period of April and May 2022.

Data was collected for the pain and its intensity. Then the patients were divided in to 3 groups -Group A: Patients will be treated by physiotherapy treatment and Sujok therapy. Group B: Patients will be only treated by Sujok therapy. Group C: Patients will be only treated by physiotherapy. In Sujok therapy patients will be diagnosed by probe and then after finding point on hand. Using Su Jok theory, the first thing to do is to find the corresponding areas of the knee on the hand, and then stimulate those points. The most painful points were found on one or several of the areas on Middle or on ring finger and then massaging those areas. Next stage is to massage areas on the fingers (phalanxes of fingers) corresponding to your knee using a Sujok ring or massage ring. The next step

is heating up these areas with Moxa. After that we will apply seeds to the area corresponding to the knee either on the left or right hand. Patients will be examined by VAS (Visual Analog Scale). The visual analog scale (VAS) is a validated, subjective measure for acute and chronic pain. Scores are recorded by making a handwritten mark on a 10-cm line that represents a continuum between "no pain" and "worst pain." for checking the effect of Sujok therapy. Physiotherapy treatment will include the following: - 1. Quadriceps setting, 2. Quadriceps Strengthening, 3. Hamstring Stretch.

The Study was approved by Institutional Ethical Committee, on 25th February 2021 with the outward number VIP/2021/EC/95.

III. RESULTS AND DISCUSSION

Table I: Descriptive Statistics

		Frequency	Percentage
Gender	**Female**	44	48.9%
	Male	46	51.1%
Treatment Given	**Physiotherapy**	30	33.3%
	Sujok + Physiotherapy	30	33.3%
	Sujok Therapy	30	33.3%

In this study, a total of 90 respondents in this study comprised of 46 males and 44 females. All the 90 respondents were divided equally among all the three treatments. The type of therapy can be seen from Table I.

Table II: Statistical Significant difference between pains in patients before and after physiotherapy sessions

Paired Samples Test							
		Paired Differences			t statistic	df	P-Value
		Mean	Std. Deviation	Std. Error Mean			
Pair 1	**b_day 1 - a_day 1**	0.567	0.568	0.104	5.461	29	0.000
Pair 2	**b_day 2 - a_day 2**	0.567	0.568	0.104	5.461	29	0.000
Pair 3	**b_day 3 - a_day 3**	0.667	0.547	0.100	6.679	29	0.000
Pair 4	**b_day 4 - a_day 4**	0.833	0.461	0.084	9.898	29	0.000
Pair 5	**b_day 5 - a_day 5**	0.833	0.379	0.069	12.042	29	0.000
Pair 6	**b_day 6 - a_day 6**	0.900	0.403	0.074	12.245	29	0.000
Pair 7	**b_day 7 - a_day 7**	0.833	0.379	0.069	12.042	29	0.000

Significant differences before and after Physiotherapy, Sujok and Sujok + Physiotherapy sessions were calculated using t-test on SPSS 20.0 software at 5% level of significance. From the table II it can be concluded that there is a significant difference before and after physiotherapy treatment on day 1, 2, 3, 4, 5, 6, 7 as p-value was found to be 0.000 < 0.05 at 5 % level of significance.

Table III: Statistical Significant difference between pains in patients before and after Sujok sessions + Physiotherapy

Paired Samples Test							
		Paired Differences			t statistic	df	P-value
		Mean	Std. Deviation	Std. Error Mean			
Pair 1	b_day 1 - a_day 1	0.933	0.691	0.126	7.393	29	0.000
Pair 2	b_day 2 - a_day 2	0.867	0.434	0.079	10.933	29	0.000

Pain after _day 4	Physiotherapy	30	4.97	1.066	2.453	0.092
	Sujok	30	4.43	0.858		
	Sujok + Physiotherapy	30	4.50	1.106		
	Total	90	4.63	1.033		
Pain after _day 5	Physiotherapy	30	4.70	1.119	4.2	0.018
	Sujok	30	3.90	0.803		
	Sujok + Physiotherapy	30	4.33	1.241		
	Total	90	4.31	1.108		
Pain after _day 6	Physiotherapy	30	4.47	1.042	4.698	0.012
	Sujok	30	3.67	0.758		
	Sujok + Physiotherapy	30	4.03	1.189		
	Total	90	4.06	1.053		
Pain after_day 7	Physiotherapy	30	4.37	1.033	5.676	0.005
	Sujok	30	3.57	0.774		
	Sujok + Physiotherapy	30	3.77	1.040		
	Total	90	3.90	1.006		

To test the significant difference between the pains pertaining to patients after giving physiotherapy session, Sujok session and Sujok + physiotherapy session, ANOVA test was applied at 5% level of significance using SPSS 20.0 software. Following results were concluded from Table V:

After applying all the sessions to respective patients, the significant difference between the after therapy, pain of all the three groups on day 1 and day 2, was not found significant, with P-value > 0.05 at 5% level of significance. In other words, there is no significant difference in therapies after day 1 and day 2.

The significant difference between the after therapy, pain of all the three groups on day 3 was found significant, with P-value 0.003 > 0.05 at 5% level of significance. In other words, there is a significant difference in therapies after day 3. Physiotherapy was found least effective with average VAS for pain (5.30), Sujok + Physiotherapy was found second highest with average VAS for pain (4.90) after Sujok and Sujok was highest effective among all the three with average VAS for pain (4.73).

The significant difference between the after therapy pain of all the three groups on day 4 was not found significant, with P-value 0.092 > 0.05 at 5% level of significance. In other words, there is no significant difference in therapies after day 4, though the effectiveness of the therapies remained same as that on day 3 i.e. Physiotherapy was least effective with average VAS for pain (4.97), Sujok + Physiotherapy less than only Sujok with average VAS for pain (4.50) and Sujok was found highest effective with average VAS for pain (4.43).

The significant difference between the after therapy pain of all the three groups on day 5 was found significant, with P-value 0.018 < 0.05 at 5% level of significance. In other words, there is a significant difference in therapies after day 5. Physiotherapy was found least effective with average VAS for pain (4.70), Sujok + Physiotherapy was found second highest with with average VAS for pain (4.33) after Sujok and Sujok was highest effective among all the three with with average VAS for pain (3.90).

The significant difference between the after therapy pain of all the three groups on day 6 was found significant, with P-value 0.012 < 0.05 at 5% level of significance. In other words, there is a significant difference in therapies after day 6. Physiotherapy was found least effective with average VAS for pain (4.47), Sujok + Physiotherapy was found second highest with average VAS for pain (4.03) after Sujok and Sujok was highest effective among all the three with with average VAS for pain (3.67).

The significant difference between the after therapy pain of all the three groups on day 7 was found significant, with P-value 0.005 < 0.05 at 5% level of significance. In other words, there is a significant difference in therapies after day 7.

In two pooled studies (15), (16), the reduction in the VAS pain score from treatment with physiotherapeutic modalities in combination with stretching exercises was statistically superior to treatment with physiotherapeutic modalities alone. (WMD 0.56; 95% CI 0.20 to 0.92; $I^2 = 0\%$; $P < 0.05$; n = 102 pooled sample size). A similar result was obtained from studies (17), (15), using the KOOS pain scale. (WMD 7.52; 95% CI 4.05 to 10.98; $I^2 = 0\%$; $P < 0.05$; n = 76 pooled sample size).

Fitzgerald et al. (18) evaluated these techniques separately, and found no significant evidence that these exercises improve pain and muscle strength in OA patients. This finding does not corroborate the study by Diracoglu et al., (19) who compared kinesthesia and balance exercises or only strengthening exercises in women with knee OA, obtaining positive outcomes on muscle strength, quality of life, and the physical function scale, according to the WOMAC questionnaire.

In the Chen, HL. Et. al (2022)'s study, functional status was primarily assessed using the WOMAC scale, and significant improvements with the implementation of IFC were observed in short-term assessment but not in long-term follow-up. We also discovered that the results for walk tests (short- and long-term) and stiffness scores (short-term) did not favor IFC use over control treatment. The WOMAC scale evaluates activities of daily living, functional mobility, gait, general health, and quality of life in knee osteoarthritis patients (21). It consists of 24 questions that can be divided into the subscales of pain, physical function, and stiffness. The outlier data of one study were removed in sensitivity testing because we observed high heterogeneity, which could be attributed to the study's inadequate blinding of participants and its small sample size (22). The significance of our meta-analysis findings persisted after sensitivity testing, indicating that the outcomes were reliable.

We found many studies pertaining to knee pain treatments, but no study came to our knowledge in regard to Sujok therapy on knee osteoarthritis patients. In our study overall, Physiotherapy was found least effective with average VAS for pain (4.37), Sujok + Physiotherapy was found second highest with average VAS for pain (3.77) after Sujok and Sujok was highest effective (pain relieving technique) among all the three with average VAS for pain (3.57).

IV. CONCLUSION

There are many ways to manage pain, including traditional and unconventional treatments. The development of pain management research continues, and easier, less expensive therapeutic approaches that produce quicker pain relief are still being sought after. In this retrospective study, Su Jok is one of the complementary therapies for pain, offers a successful method of pain relief and highest effective when compared to that of physiotherapy for patients with Knee osteoarthritis. However, future studies must be conducted using stricter procedures, large sample and with more precise standards for pain management.

V. LIMITATIONS OF THE STUDY

Due to low sample size, Su Jok treatment in combination with Physiotherapy doesn't show more effectiveness compared to solely Physiotherapy treatment. So, further research must be conducted using large sample size.

VI. DECLARATION OF COMPETING INTEREST

There is no conflict of interest in this publication.

[1]Swarrnim Startup & Innovation University, Gandhinagar, India

ABSTRACT

Background:

Physical exposure during mobile phone use results repetitive movement of thumb and hand causes multiple symptoms. The term SMS Thumb is most common among them. Aim is to find out the prevalence rate of SMS Thumb among smartphone users in school going students

Methodology:

A cross sectional study was conducted by convenient sampling technique. A total 300 participants who is school going students both boys and girls at age group of 13-18 years using a smartphone minimum 1 hourper day. Participants were asked to fill a Proforma containing Cornell Hand Discomfort Questionnaire (CHDQ) & Numerical Pain Rating Scale (NPRS).

Result:

It is shown that there is 28% prevalence of SMS thumb pain is shown among teenagers who use smartphones.

Conclusion:

The prevalence rate of SMS thumb among smartphone users in teenagers has been established in this study. Musculoskeletal problems may be short term initially but can develop into long term disabilities if proper caution is not taken.

Keywords:

Pain, Smartphone, SMS Thumb

INTRODUCTION

A Smartphone is the most popular gadget among the adolescent population nowadays foe sharing information, using the internet, watching videos, using social media, gaming and many other daily activities. (1)

There is a relation between mobile design and anthropometry of the user in causing discomfort and fatigue in hand, elbow and shoulder while using the hand-held device (HHD).(2) Type of Posture(sitting or standing) and the type of mobile phone task (holding the phone versus texting)have an effect on muscles activity and thumb positions. The thumb is placed in abductionand flexion during texting compared to adduction and extension when making phone calls with its range of moment differing according to the size of the phone and orientation of the keys. Females compared to males had higher muscle activity in extensor digitorium muscle and the abductor policies longus muscle when entering SMS messages and tended to have greater thumb abduction, higher thumb movement velocities and fewer pauses in thumb movements. (3) Long-term repetitive movements of the thumb and fingers are the main identified risk factor for disorder of thumb and its musculature. (1)

This has led to coining of various phrasesto describe musculoskeletal disorders due to use of mobile phones such as "SMS Thumb", "iPod finger", "blackberry thumb" etc. [4][5]

Continuous repetitive movements with the thumb and fingers may lead to disorders of the thumb and its musculature like tendinosis of the extensor pollicislongus or myofacial pain syndrome in the hand. [6]

The term "Text neck syndrome" was first coined by Dr. Dean L. Fishman as an overuse injury.The injury may be due to poor posture because, during smartphone use, the neck goes into forward flexion and the normal curvature of the cervical spine is flattened and stretched on theneck musculature. The poor posture of the head and neck has been correlated with chronic musculoskeletal pain of the cervical spine and upper back, tightness, and spasm in the upper extremity muscles.

Several studies have reported a significant increase in the number of adolescent smartphones. Users and its association with musculoskeletal discomfort in recent years, which is becoming agrowing problem and has large impact globally.

NEED OF STUDY

SMS Thumb is associated with restricted movement of thumb and fingers most commonly seen in teenagers who uses smart phones for very long time. This study is to find out the prevalence of SMS thumb among teenage students who use smart phones.

AIM

- Aim of study was to find out the prevalence rate of SMS Thumb among smartphone users incollege going students.

OBJECTIVE

- To assess Pain and Discomfort using NPRS scale in teenagers who use smart phones.
- To assess Pain and Discomfort using Cornell Hand Discomfort Questionnairein teenagers who usesmart phones.

HYPOTHESIS

1) NULL HYPOTHESIS

There will be no significant relation of SMS Thumb among teenagers who usesmartphone very long time.

2) EXPERIMENTAL HYPOTHESIS

There will be significant relation of SMS Thumb among teenagers who use smartphonevery long time.

METHODOLOGY

- Study Design: Cross Sectional Study
- Source of Data: Schools of Ahmedabad
- Population - students of Age 13-18 years
- Sampling Method - Convenient Sampling
- Sample Size - 300 subjects
- Duration of the Study - 1 years

Materials and Tools Used:

- Numerical Pain Rating Scale
- Cornell Hand Discomfort Questionnaire
- Pen

- Pencil
- Rubber
- Scale

Inclusion Criteria:

- School - going students
- Age 13 - 18 years
- Using smart phone for a period minimum 1 year
- Minimum duration of smart phone use of ≥1 hour per day
- Able to understand and fill in the questionnaire in English
- Willing to participate in the study.

Exclusion Criteria:

- Any known condition which could lead to pain in the upper limb
- Any traumatic injury to the upper limb.
- History of hand surgery
- Neurological problems of upper limb

Outcome Measures:

1.Numerical Pain Rating Seale (NPRS): The NPRS is an 11- point scale consisting of integers from 0 through10; 0 representing "NoPain" and 10 representing "Worst imaginable pain". Respondents select the single number that best represents their pain intensity.

2.Cornell hand discomfort questionnaire (CHDQ): It is a 6-item questionnaire containing a hand map diagram showing 6 shaded areas of thehand and questions about

1. Prevalence of Musculoskeletal pain,
2. Discomfort,
3. Interference with work, during the previous week.

Total discomfort score will be calculated by using the following formula: Frequency x discomfort x interference, where higher the score indicated more discomfort. Maximumscoring for each are is 90, and the total scoring for 6 areas is 560.

Procedure:

- Participants were recruited from various schools in Ahmedabad, Gujarat.
- Study participates will be recruited according to their academic year (8th - 12th), andan equal percentage will be obtained from each class, Boys and girls will be divided equality among the academic year groups.
- The nature and purpose the study will be explained by the researcher and informedconsent will be taken from the participants.
- A structured questionnaire containing Demographics (Name, Age, Gender, Height, Weight & duration of smartphone use), Numerical Pain Rating Scales(NPRS), Cornell Hand Discomfort Questionnaires (CHDQ) will be used to collect thedata.

RESULT

In present Study 300 participants with 13 -18 years were selected and divided in five groups.300individuals have been filled a proforma digitally.

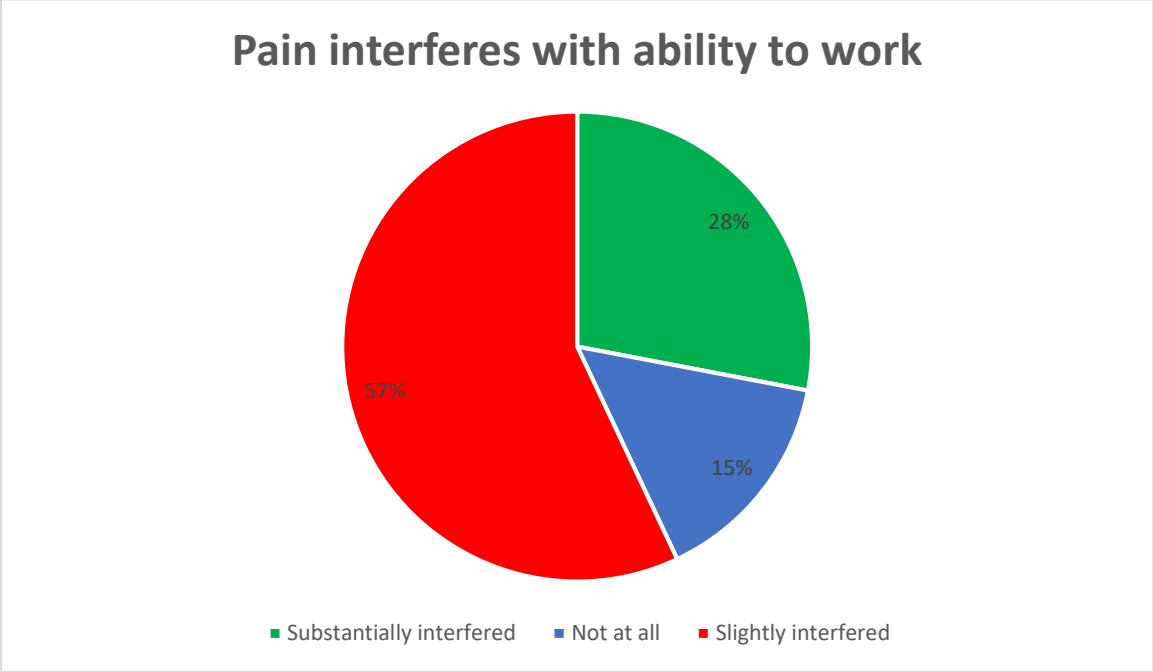

Figure 1: Pain interferes with ability to work

As per the figure 1, 15% subjects have no pain that interferes with their ability to work. 57% were slightly interference and 28% have substantially interference with ability to wok. Among them 57% have slight discomfortness, 27% have moderately uncomfortnesss and 15% have very uncomfortnessdue to pain while using smartphone. This shows that 85% subjects have some affection due to use ofsmartphones.

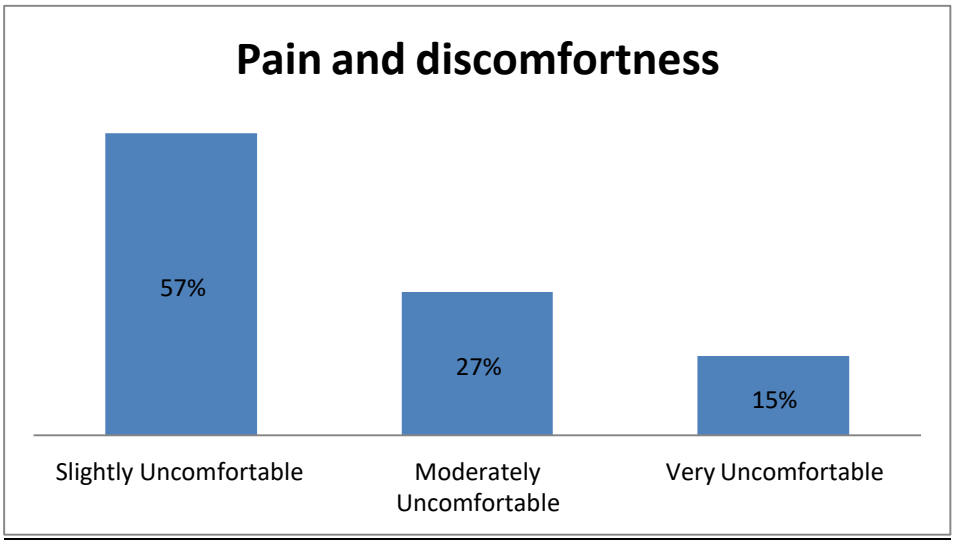

Figure 2: Pain and discomfortness

Among the population affected 5% have pain experienced several times per day, 11% have affection onceevery day, 21% have 3-4 times per week , 54% have 1-2 times per day and 9% have experienced no pain.

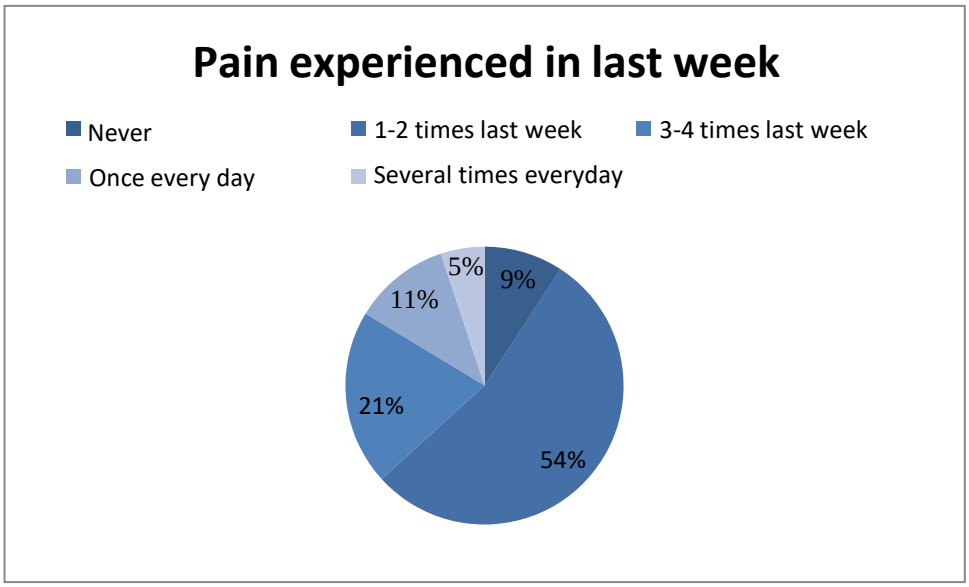

Figure 3: Pain experienced in last week

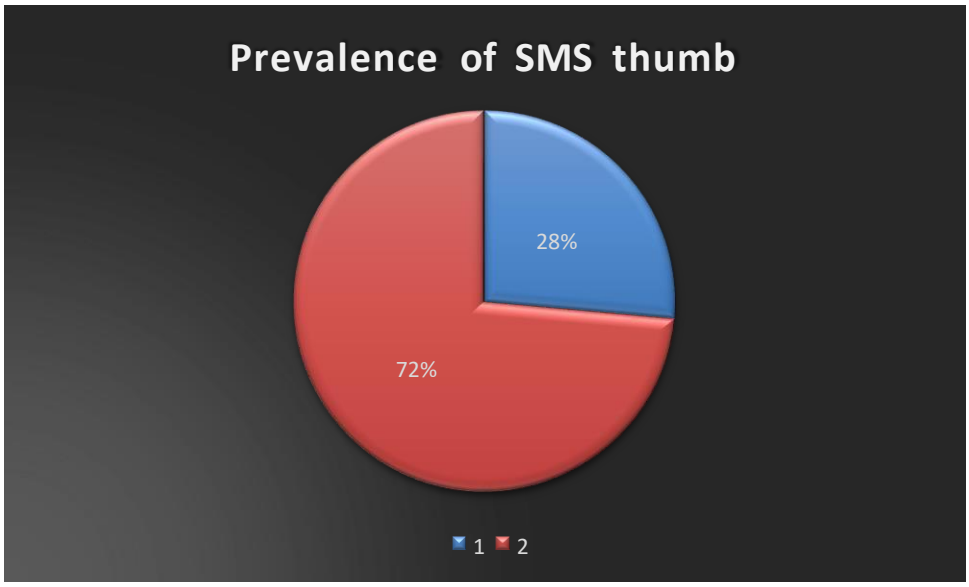

Figure 4: Prevalence of SMS Thumb

So, it is concluded that 28% population is affected by SMS thumb and it is shown in figure 6. 72%population is remained unaffected.

DISCUSSION

In this study, the prevalence of SMS Thumb among teenagers who use smartphone was reported. During message typing, the thumb and palm muscles are used extensively. Sustained gripping and repetitive movements of the fingers and thumb are main key factor that might lead to the associated syndrome.

For texting, the thumb is adducted on the key pad of mobile device and high force is used to type. Studies reported that tendonitis in extensor pollicis longus, adductor pollicis, wrist tendonitis, and deQuervain's syndrome are associated with text messaging. Excessive texting might also lead to carpometacarpal joint arthritis.

Various factor affect the cause of SMS thumb. The contributing factors might be the small spacing on keyboard, mobile size, phone keypad, posture of thumb, etc. the static loading during text messaging on a hand-held device for a long duration can be hazardous for the body posture and overuse of the hand muscle, which might lead to pain in the hand, forearm, neck and upper back muscles.

Long durations of use of mobile phones could adversely affect the musculoskeletal system of hand. Long durations off computer use might increase the risk of neck and shoulder pain.

Text neck syndrome and SMS thumb are repetitive stress injuries that could be prevented by taking some preventive measures and controlling the use of smart phones. Simple life style changes like maintaining correct posture during smart phone use and avoiding long-term use of smart phones could prevent the development of neck pain and SMS thumb.

This study would be helpful to inform smart phone users about the alarming rise of negative consequences of smart phone addiction and long-term smart phone use.

The various biases of this cross-sectional survey, such as selection bias, non-response bias and ascertainment bias, were eliminated by using some strategies as follows. By using pre-fixed inclusion and exclusion criteria, the ascertainment bias was eliminated. Selection bias and non-response bias were eliminated by using a random sampling method. The sample size used in this study was small.

CONCLUSION

The prevalence rate of SMS thumb among smartphone users in teenagers has been established in this study. It is shown that there is 28% prevalence of SMS thumb pain is shown among teenagers who use smartphones. The musculoskeletal problems may be short term initially but can develop into long term disabilities if proper caution is not taken.

Reliability and Validity of Gujarati Version of Tinetti Assessment Tool: Validation Study

[1]Dr. Jaynesh Vandra, [2]Dr. Arvind Kumar Chauhan, [3]Disha J. Patel

[1]Assistant Professor (Master of Physiotherapy in Musculoskeletal And Sports, PhD Scholar ,
[2]Principal and Professor (PhD Physiotherapy) ,
[3]Bachelor of Physiotherapy
[1]Venus Institute of Physiotherapy – Swarrnim Startup & Innovation University ,
[2]Venus Institute of Physiotherapy – Swarrnim Startup & Innovation University ,
[3]Venus Institute of Physiotherapy – Swarrnim Startup & Innovation University

Abstract:

Background: The Tinetti Assessment Tool is a valid and reliable self-reporting Tool evaluating the patient's problems toward the effect of their activities of daily living (ADLs) and works on their balance and gait disorder. Till the date it was translated into various languages but is not available in Gujarati language. This study aimed to translate Tinetti Assessment Tool into Gujarati and to study reliability and validity of Gujarati version**.**

Methodology: Translation and cross culture adaptation were performed according to the guidelines. Content validation was executed by the panel of 6 members who were experts in using Gujarati and English. They were completed the content validity .The psychometric properties were tested by administering the tool to 60 samples (40 to 70 years) was recruited by Purposive sampling. For test-retest reliability, people with Balance Gait disorder were tested after a week by Intra-class correlation coefficient (ICC) and internal consistency was assessed by Cronbach's alpha (α).

Result : The content validity of Gujarati translated Tinetti Assessment Tool by a panel of 6 experts were found to be, I-CVI of individual items of Gujarati version of Tinetti Assessment Tool ≥ 0.93 and the overall S-CVI for idiomatic equivalence (S-CVI =0.89) semantic equivalence (S-CVI=0.91) and content relevance(S-CVI=0.92). The test-retest reliability of Gujarati version Tinetti Assessment Tool was good (ICC (2,1) = 0.986 and 0.977). Internal consistency was found to be good (Cronbach's alpha = 0.993 and0.988).

Conclusion : The Gujarati version of Tinetti Assessment Tool was cross-culturally adapted and validated can be use patient with balance and gait disorder in the Gujarati-speaking populations.

Keywords : Cross cultural adaption, Tinetti Assessment Tool, Reliability, Validity , Balance and Gait disorder

INTRODUCTION

Balance and gait disorders are among the most common causes of falls in older adults.[1] more than one third of persons 65 years of age or older fall each year, and in half of such cases the falls are recurrent. Approximately 1 in 10 falls results in a serious injury, such as hip fracture, other fracture, ,subdural hematoma, other serious soft-tissue injury, or head injury.[2] Chronic diseases and aging can affect the balance ability of older people; therefore, an assessment of balance ability is valuable predicting and preventing falls and a reduction in independent living in older people. [3]

Balance is required for maintaining static posture, stabilizing dynamic movements, performing daily activities and moving around the community.[3] The loss of balance response and increased incidence of falls is of concern to physical therapists. Improvement of the balance may be a desired functional outcome for many patients. Balance function has been reported to decline with age, as evidenced by increased postural sway and decreased stability.[4]

Balance difficulties are reported by 13% of patients at age 65,35%at age 75, and 46% at age 85. Gait impairment has been estimated to occur in 8% to 19% of elderly individual living in the community.[5]

Balance can be affected in various ways which include joint motion limitation, weakness, altered muscular tone, sensory deficits, anomalous postural reactions and cognitive problems.[6] Most of changes in gait that occur in older are related to underlying medical conditions, particularly as condition increase in severity, and should not be viewed as merely an inevitable consequence of aging.[1]

Other causes of balance is the dizziness, vertigo, neurological disorder, vestibular migraine and vestibular neuritis. Balance disorders are recognized risk factors for falls. especially in the elderly with high associated morbidity, mortality, and economic cost.[7] Only few studies describe the distribution of gait disorders. Obviously, the spectrum of underlying illnesses will depend on the population under consideration and the assessment technique. Within a relatively healthy subgroup of 153 community residents aged 88 years and older, about 61% reported distinct diseases as a cause of gait impairment.[0] Non-neurological disorders were the leading causes of gait impairment, in particular joint pain (52 of 87 people), whereas many others had multiple causes for their gait impairment.[8]

Non-neurological disorders were the leading causes of gait impairment, in particular joint pain (52 of 87 people), whereas many others had multiple causes for their gait impairment. Stroke was the most common neurological cause. In another study of 120 elderly outpatients seen in a neurological reference practice, the most common causes for gait disorders were sensory ataxia (18%), myelopathy (17%), multiple strokes (15%), and parkinsonism (12%).2 Largely the same causes dominated in a series of 493 neurological inpatients, 60% of whom had a gait disorder.[8]

Determining that a gait is abnormal can be challenging, because there are no clearly accepted standards to define a normal gait in an older adult.10 Studies comparing healthy persons in their 70s with healthy persons in their 20s demonstrate a 10 to 20 percent reduction in gait velocity and stride length in the older population.18,19 Other characteristics of gait that commonly change with aging include an increased stance width, increased time spent in the double support phase, bent posture, and less vigorous force development at the moment of push off. These changes may represent adaptations to alterations in sensory or motor systems to produce a safer and more stable gait pattern.[1]

They may contribute to gait and balance disorders for a variety of reasons, such as causing pain, dyspnea, imbalance, diminished strength, limited range of motion, poor posture, decreased sensory perception, fatigue, deformity, and decreased awareness of and ability to adapt to and traverse through possibly hazardous surroundings.[1]

In addition, recent surgery or hospitalization and other acute medical illnesses may lead to gait and balance disorders. The use of multiple medications, as well as specific classes of medications, can lead to gait disorders and an increased rate of falls.[00] Although data are limited, surgery may improve gait for patients with cervical spondylotic myelopathy,51 lumbar spinal stenosis,52 normal-pressure hydrocephalus,53 or arthritis of the knee or hip.[1]

In many studies ,risk factor for falls have been determined. These are classified as intrinsic and extrinsic factors. Muscular weakness of the Lower extremities ,decreased grip force, impaired postural balance, Functional and cognitive disorders, and visual problems constitute Intrinsic factors ,while extrinsic factors include environmental factors Such as inadequate illumination, slippery floors and lack of safety equipments in bathrooms. Besides, a decrease in the ability to perform daily living activities and usage of walking aids contribute to the frequency of falls.[9,10]

Tests and functional scales used in proportion to variation in risk factors for falls, and excess number of components of postural control are also numerous.[9] One of these scale tinetti balance was developed by mary tinneti 1986 so as determine as risk falls.[9]

One of the most widely used version of the Tinetti Assessment of Balance and Gait scale. It is composed of two separate categories as balance and gait tests. Balance and gait are evaluated with nine and eight items, respectively. Total score of balance category consists of sitting balance, balance on arising to stand, immediate standing balance (within first 5s), standing balance, maintenance of balance when the subject turns 360 degree around him /herself, and tries to sit down from standing position is 16 points. Total score of the gait category which evaluates initiation of gait, step length and height , step symmetry and continuity deviation from a specified path, sways of patient's trunk and the position of heels while walking is 28 points. As a result, the total score of the amounts to 28 points. The highest score indicates the best performance.[9]

REVIEW OF LITERATURE

1. **Jinse Park. Seong-Beom Koh, Hee Jin Kim, Eungseok Oh, Joong-Seok Kim, Ji Young Yun, Do-Young Kwon, Younsoo Kim, Ji Seon Kim, Kyum-Yil Kwon, Jeong-Ho Park, Jinyoung Youn, and Wooyoung Jang. (2018)[10] :-** ·Validity and Reliability Study of the Korean Tineti Mobility Test for Parkinson's Disease**.:-** Twenty-four patients diagnosed with PD were enrolled in this study. For the interrater reliability test, thirteen clinicians scored the TMT after watching a video clip. We also used the test-retest method to determine intrarater reliability. The interrater reliability and intrarater reliability of the Korean Tinetti balance scale were 0.97 and 0.98, respectively. The interrater reliability and intra-rater reliability of the Korean Tinetti gait scale were 0.94 and 0.96, respectively. The Korean TMT scores were significantly correlated with the other clinical scales and three-dimensional motion capture. The cutoff values for predicting falling were 14 points (balance subscale) and 10 points (gait subscale).
2.
3. **Seung-Heon An, Dong-Geon Lee, PT, Yun-Bok Lee, Gyu-Chang. (2014)[11]**. Inter –rater ? absolute Reliability and Concurrent Validity of Tinetti – gait Scale (Korean version) in stroke patients**. :-** The purpose of this study was to investigate the inter-rater absolute reliability and the concurrent validity of the Tinetti-gait scale that was translated into Korean for chronic stroke patients. Fifty-two with post-stroke participated in this study. Results was The inter-rater reliability of the Tinetti-gait scale was high; ICC(3,1)=.91 ICC(3,1)=.91 (95% CI=.85~.95) (very reliable), the range of Kappa coefficient were .73~.92 (substantial~good). The inter-rater agreement of the each item in Tinetti-gait scale ranged from .74 to .92 (95 % CI=.59~.95) (reliable~very reliable). The SEM and MDC were .56 and 1.55, respectively. In the results of concurrent validity, there were moderate positive correlation between Tinetti-gait scale and DGI (r=.78), 10WT (r=.74), OLST (r=.65~.73), FM-LE (r=67). And there was moderate negative

correlation between Tinetti-gait scale and STS (r=-79) (p<.01). The Tinetti-gait scale(Korean version) was a reliable and valid tool to measure gait ability in stroke patient.

4. **Serap D. Yücel & Füsun Şahin & Beril Doğu & Tülay Şahin, Banu Kuran & Sevda Gürsakal.(2012)[9].** Reliability and Validity of the Turkish version of the Performance- Oriented Mobility Assessment 1. **:-** The aim of this study was translate POMA-l to Turkish and to assess its reliability and validity people with amputated lower extremities. Eighty participants enrolled in the study with a mean age of 76.5 ± 6.75 years.The turkih version of POMA were ICC(0.70)and cronbach's alpha(0.72,0.83,0.88). In the reliability evaluation of the scale in validation study POMA total score had a strong positive correlation with BBS total score ($r = 0.86, p < 0.0001$), and also a negative correlation with TUG ($r = - 0.75, p < 0.0001$). According to the results of this study, the Turkish version of the POMA-l scale has been found to be a reliable and a valid scale for elderly Turkish peopl

5. **Camila Rodriez Guevara. Luz Helena Lugo. (2012)[12] .** Validity and reliability of Tinetti Scale for Colombian people :- A validity study was conducted in 2012 to a validate the Tinetti Scale for its use in Colombian populations. The Spanish version of Tinetti scale was applied by two evaluators to elderly persons with different degress of gait and balance functionally. Results of this study was the The content validity suggests the re-structuring of the items in the domain of equilibrium with a Cronbach's alpha of 0.948 and a variance of 13,894, in the construct validity, 46 of the 48 responses of the scale differences statistically significant in the ability to detect changes in a group without alterations in gait and balance (healthy) and a group with these conditions (sick); the concurrent validity had a high correlation r = -0.82 with Timed up and go. The inter and intra- rater reliability was between 0.4 to 0.6 and 0.6 to 0.8, respectively. The Cronbach's alpha was 0.91 so the scale was valid and reliable.

6. **Huma Parveen. Majumi M. Noohu.(2016)[13].** Evaluation of Psychometric properties of Tinetti Performance-Oriented Mobility Assessment Scale In Subjects with Knee Osteoarthritis :- The objective of this study was to determine the psychometric properties of the (POMA) scale to measure balance and gait impairments in individuals with (OA).A convenient sample of 25 individuals with bilateral OA knee were recruited. The Results Score of BBS was significantly correlated with POMA-B scores, $r_s = 0.63$, $p = 0.001$, whereas TUGT showed a negative correlation with POMA-G, $r_s = -0.481$, $p = 0.020$, showing moderate convergent validity. ICC results of the total POMA scale (POMA-T), POMA-B, and POMA-G were 0.96, 0.93, and 0.96, respectively, indicating high test retest reliability. SEM, for POMA-T, POMA-B, and POMA-G was 0.35, 0.27, and 0.35, respectively; MDC values were 0.97 for POMA-T, 0.75 for POMA-B, and 0.63 for POMA-G. The findings indicate that the POMA is a valid and reliable tool to assess balance and gait impairments in people with OA knee.

7. **Anne D Kloos, Deb A. Kegelmeyer ,Gregory S. Young, Sandra K Kostyk.(2010)[14].**Fall risk assessment using the Tinetti mobility test in individuals with Huntington's disease. :- The Tinetti Mobility Test (TMT) is a clinical balance and gait test that predicts fall risk in the elderly. This study examined the concurrent validity, usefulness of the TMT as a fall risk screening tool, and the potential ability of the TMT to predict falls in individuals with Huntington's disease (HD). Data from a retrospective review of 94 patient records were used. TMT scores were correlated with Unified Huntington Disease Rating Scale motor scores. The ability of the TMT to accurately assess fall risk was determined using validity index measures. Logistic regression was used to assess the ability of the TMT to predict falls. TMT scores correlated with motor scores ($r_s = -0.751$, $P < 0.0001$). Using a cutoff value of 21, the TMT had a sensitivity of 74% and a specificity of 60% to identify fallers. Lower TMT scores and younger age were significant predictors of falls. The TMT is a for assessing balance and gait status and fall risk of individual with HD.

8. **Anne D. Kloos.Nora E. Fritz, Sandra K. Kostyk, Gregory S, Deb A. Kegelmeye Young. (2014)[15].**Clinimetric properties of the Tinetti Mobility Test, Four Square Step Test , Activities-Specific Balance Confidence Scale, and spatiotemporal gait measures in individuals with Huntington's disease:- This study examined the reliability and concurrent validity of spatiotemporal gait measures, the TMT, FSST and ABC scale in individuals with HD. Results of this study was participants Spatiotemporal gait measures, the TMT total and the FSST showed good to excellent test–retest reliability (ICC > 0.75). MDC values were 0.30 m/s and 0.17 m/s for velocity in forward and backward walking respectively, four points for the TMT, and 3 s for the FSST. The TMT and FSST were highly correlated with most spatiotemporal measures. The ABC Scale demonstrated lower reliability and less concurrent validity than other measures. The high test–retest reliability over a six week period and concurrent validity between the TMT, FSST, and spatiotemporal gait measures suggest that the TMT and FSST may be useful outcome measures for future intervention studies in ambulatory individuals with HD.

9. **Lorenzo Panella, Tinelli Carmine, Buizza Angelo, Lombardi Remo, Gandolfi Roberto.(2008)[16].** Towards objective evaluation of balance in the elderly: validityand reliability of measurement instrument applied to the tinetti test **:-** The aim of present study was the validation of an instrument for evaluating balance, applied Tinetti test. Trunk inclination was measured by inclinometers during thr Tinetti test in 163 healthy participants. Reliability was evaluated by cronbach;s alpha and its validity by itemscale correlation, discriminant validity and concurrent validity. Influence of age and gender was assessed by regression model. Repeatable and distribution consistent measurement were obtained (cronbach;s alpha=0.88). parameter distribution was significantly different in control and patients ($p<0.001$). optimal threshold fpr discriminating between normal and abnormal performance (153.9/200) corresponded to sensitivity of 84.7% and area under the receiver operating characteristics curve of 93.

10. **Cipriany-Dacko LM, Dana Innerst, Joann Johannsen, Vicki Rude.(1997)[17].** Interrater reliability of the tinetti balance scores in novice and experienced physical therapy clinicians:- A reliability design was used to assess the interrater agreement and consistency of the BPOMA scores in an elderly population. Twenty-six residents of a skilled nursing home, ranging in age from 66 to 90yrs ($\bar{x}$ = 80.4, SD = 6.8), participated in Phase 1. Twenty-four hospital inpatients and five residents of a skilled nursing home, ranging in age from 60 to 92yrs ($\bar{x}$ = 74.7, SD = 7.9), participated in Phase 2.Phase 1 demonstrated fair to excellent κ coefficients (.40–1.00) in all maneuvers across all raters. The ORs had higher agreement compared with the AR, ranging from good to excellent (.75–1.00). Phase 2 demonstrated fair to good κ coefficients (.40–.75) in 5 of 8 maneuvers across all nine raters. When comparing proportion of observed agreement to evaluate the years of experience on rater agreement, there was no significant difference between clinician groups.Fair to good reliability of BPOMA scores occurred across many raters of varied experience with a small amount of BPOMA scores occurred across many raters of varied experience with a small amount of training..

11. **Bahman Moulodi., Akram Azad, Ghorban Taghizadeh, Mahtab Roohi-Azizi, Parvaneh Mohammadi.(2020)[18].**Reliability and Validity of Persian Version of Performance Oriented Mobility Assessment (POMA) in Community- dwelling Iranian older adults:- This study aimed at investigating the construct validity, factor analysis, internal consistency, test-retest and inter-rater reliability, and ceiling/floor effects of the Persian version of Performance-oriented Mobility Assessment (POMA) in community-dwelling elderly**.** One hundred and forty-five older adults aged 65 years and older were recruited from daily care centers of Tehran by convenience sampling method. Timed Up and Go (TUG) test and Berg Balance Scale (BBS) were used to investigate the construct validity of the POMA. Test-retest (7-14 days with interval) and inter-rater reliability of the gait and balance subscales and the total score of the POMA were moderate to very high correlation ($r= 0.67-0.9$, $P\leq 0.05$) was found between the total score of the POMA and BBS, Fullerton Advanced Balance Scale, step test (right and left), TUG, Dynamic Gait index, and walking speed, whereas the correlation between the total score of the POMA and step length was poor ($r= 0.39$, $P\leq 0.05$). The results of confirmatory factor analysis showed a poor goodness-of-fit of POMA with the two-factor

model (balance and gait) in community-dwelling elderly. Internal consistency (Cronbach's alpha= 0.94), test-retest reliability (ICC = 0.97), as well as inter-rater reliability (ICC = 0.92) of the POMA were excellent. The results revealed no floor effect for the total score of the POMA; however, its ceiling effect was 3.44%.The Persian version of POMA showed excellent psychometric properties for evaluating different aspects of balance in community-dwelling

NEED OF STUDY

Tinetti Assessment Tool is one of the most common Tool that has been used by physiotherapist all over the world. Also it is already translated in many language like Turkish,[9] Korean[10], Spanish[12], persian[18] etc. I want to translate this scale in my mother language i.e. Gujarati because it will be more beneficial for patients to understand the scale in Gujarati and it will be helpful to physiotherapists also who are from Gujarat.

OBJECTIVE OF THE STUDY

- To translate Tinetti Assessment Tool in to Gujarati language.
- To find out test-retest reliability and internal consistency of Gujarati version
- Tinetti Assessment Tool.
- To find out face and contact validity of the Gujarati version Tinetti Assessment Tool.

HYPOTHESIS

- NULL HYPOTHESIS : Tinetti Assessment Tool for balance and gait will be not reliable and valid on Gujarati population.
- RESEARCH HYPOTHESIS : Tinetti Assessment Tool for balance and gait will be reliable and valid on Gujarati population.

METHODOLOGY

The study was carried out on elderly people aged 40 to 70 years in Gujarat, India. Those peoples who have balance and gait disorder.

INCLUSION CRITERIA

1) Patients who can write , reading and understand Gujarati language
2) Age group 40 – 70 years
3) Patient who is having problems with balance and gait

EXCLUSION CRITERIA

1) Subjects who don't know Gujarati
2) Subjects who had fracture within 6 months
3) Patient with neurological and psychological problem

The Tineeti Balance Scale had been cross-culturally adapted into Gujarati version of Tinetti Assessment Tool in following eight steps:

1. Initial translation to Gujarati language/ forward translation: The translation of Tinetti Assessment Tool in Gujarati language was performed by two individuals whose native language is Gujarati.

2. Synthesis: After discussion, the 2 translators produced a consensus version of the Tinetti Assessment Tool

3. Back translation: Back translation of preliminary Tinetti Assessment Tool into English was conducted by two native English speakers who were fluent in both English and Gujarati. The two translators were neither aware nor be informed of the concepts explored, and they had no medical background.

4. Reviewer's committee: An expert committee comprising of panel of 6 members performed cross-cultural adaption and validation. After back translation, the Scale were forwarded to back translators. They reviewed all translation and developed the
Pre-final version of Tinetti Assessment Tool with emphasis on semantic, idiomatic, experimental and conceptual equivalence in relation to original back- translated Tinetti Balance Scale versions. Then the Scale was content validation by the expert committee.

5. Content validation: Content validation was excuted by the panel of 6 pre-identified members who experts in using Gujarati and English. They were provided with five options, "agree", "strongly agree", "neutral", "disagree", and "strongly disagree". For providing their valuable opinion regarding Gujarati version of Tinetti Assessment Tool.. Eighty percent consensus of agreement among the experts were required to validate the translated version of Tinetti Assessment Tool .Eighty percent of agreement between the experts were fixed in recommendation by Lynn to yield the item-level content validation index (I-CVI) of 0.93. According to Lynn's (1986) criteria a minimum I-CVI of 0.78 for 6 to 10 experts is required to validate each item in a scale.[19] Hence, we have used an expert panel with 6 members to validate the Gujarati translated content of Tinetti Assessment Tool .They were provided with options, agree, strongly agree, neutral, disagree and strongly disagree in a five point likert scale with Gujarati translated content of Tinetti Balance Scale Neural, disagree and strongly disagree were considered as negative response while agree and strongly agree was considered as positive. Content validation of Tinetti Assessment Tool was performed until the overall scale-level content validation index (S-CVI) reaches SCVI/Ave $\geq$ 0.90.[19]

6. Pretesting: According to inclusion and exclusion criteria, the pre-final Scale was administered to 10 balance and gait disorder patients. The interviewer reported on each respondents understanding the Scale items and making decision on them. As no further adaptation is indicated, the pre-final and final Tinetti Assessment Tool is identical. The objective was to assess whether the translated Scale was understandable, the vocabulary was appropriate and also the expression was relevant for Gujarati culture

7. Validation study: Face validity and Content validity was obtained by the Experts and the translators.

i. Test-retest reliability: The recruited patients with balance and gait disorder were asked to fill Gujarati version of Tinetti Assessment Tool by themselves twice with minimum gap of one week duration. So that person may not copy the same data as well as he/she will not forgot.[19] The readings were recorded to report test-retest reliability.

ii. Internal consistency: Internal consistency was measured with Cronbach's alpha (α), a statistic which was calculated from the pair wise correlations measured between paired readings of Gujarati version of Tinetti Assessment Tool.

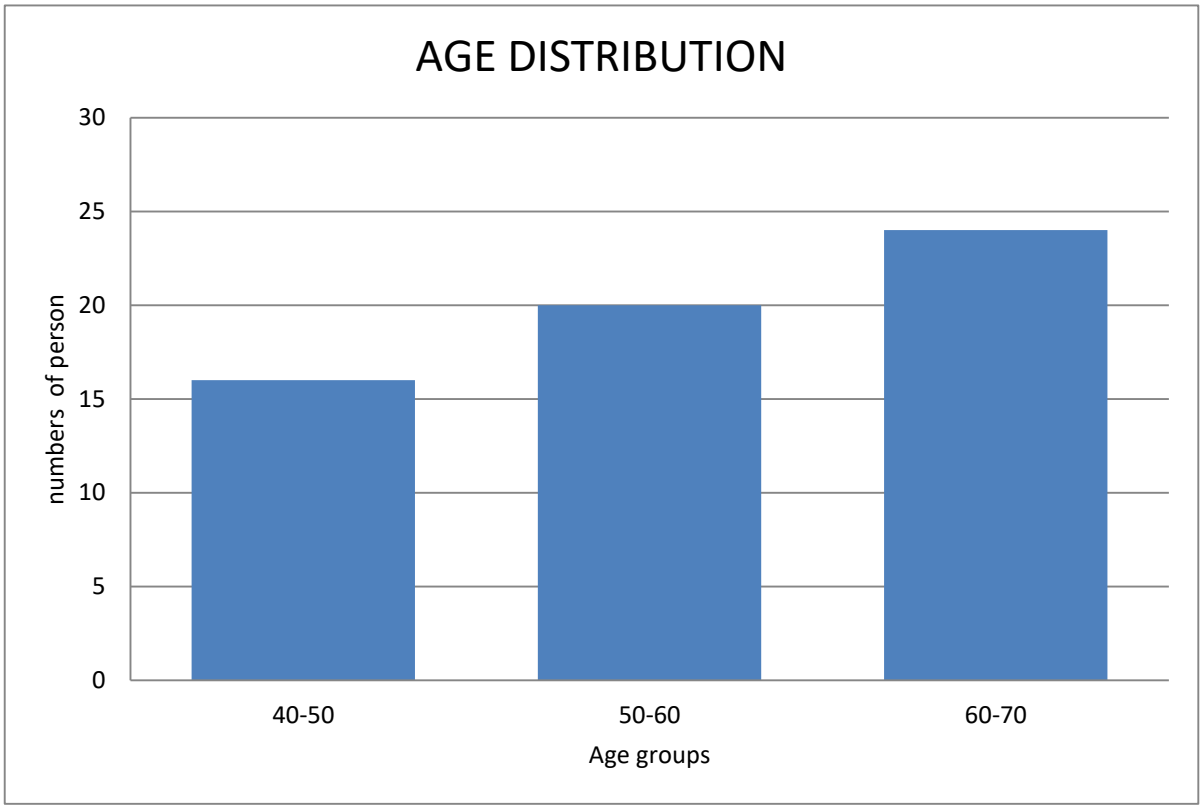
RESULT

1. Age distribution

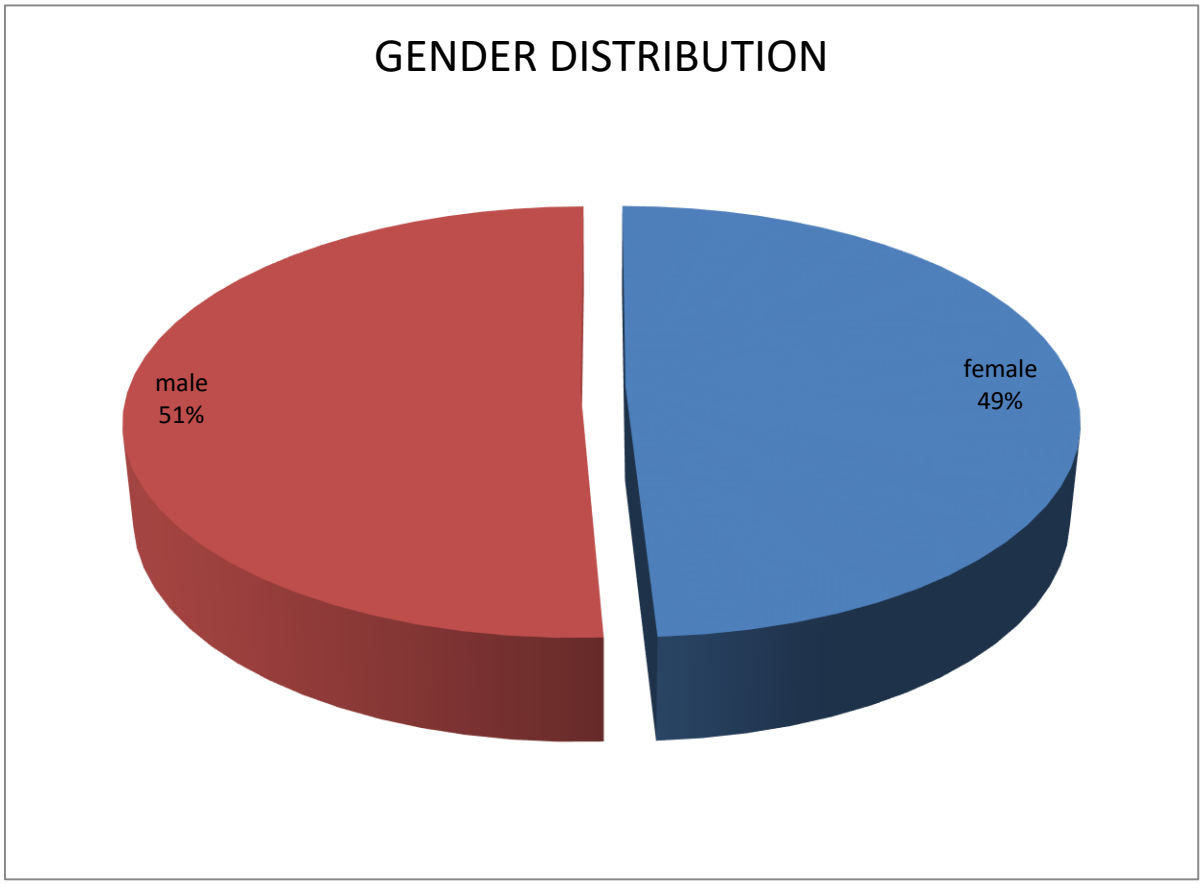
The research was performed on 60 patient with Balance and Gait disorder between the age of 40-70. There were 14 patients between the ages of 40 to 50, 20 patients between the ages 50 to 60, and 24 patients between the ages of 60 to 70. The Mean of age was 20.



GRAPH 7.1 :- AGE DISTRIBUTION CHART

2. Gender distribution

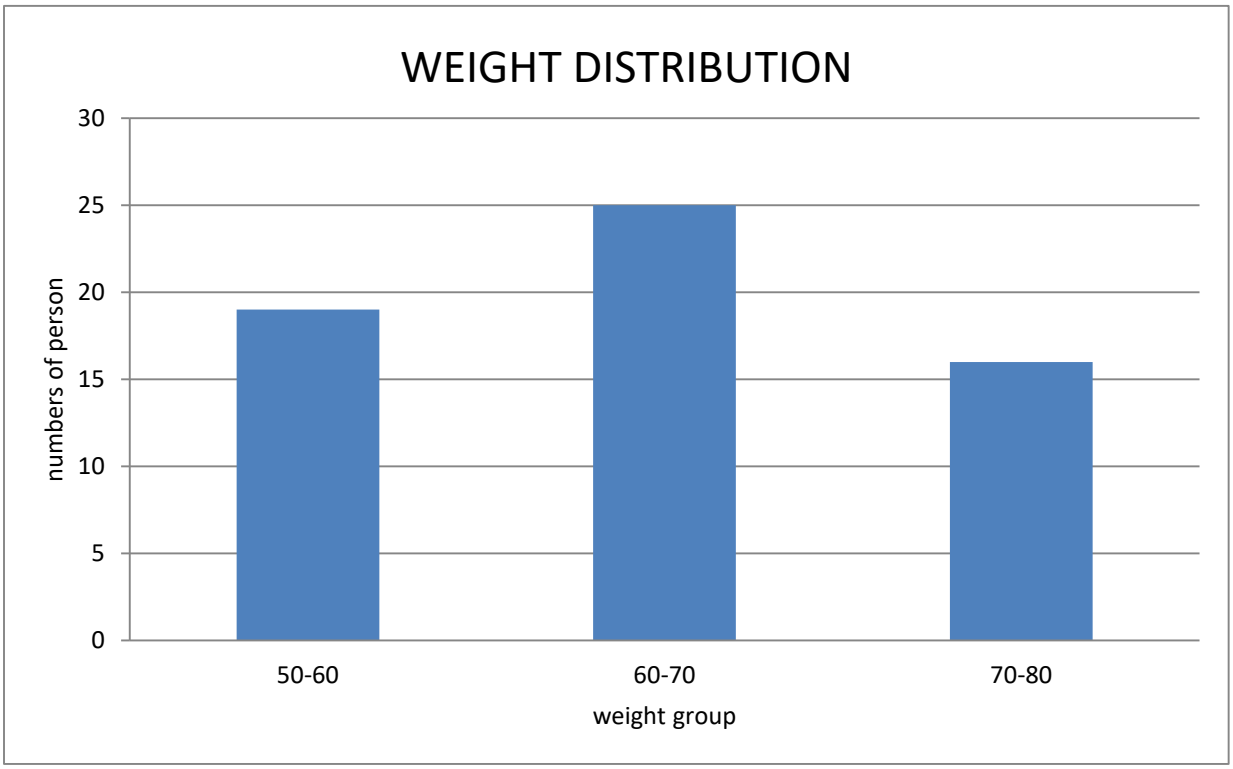
The research was performed on 60 patient with Balance and Gait disorder. In which 30 are Females and 31 are Males. The Mean of gender was 30.5



GRAPH 7.2 :- WEIGHT DISTRIBUTION CHART

3. Weight Distribution

The research was performed on 60 patient with Balance and Gait disorder There were 19 patients between the weight of 50 to 60, 25 patients between the weight of 60 to 70 and 16 patients between the weight 60 to 70 . The Mean of weight was 20.



GRAPH 7.3 :- WEIGHT DISTRIBUTION CHART

The content validity of Gujarati translated Tinetti Assessment Tool by a 6 experts were found to be, I-CVI of individual items Tinetti Assessment Tool of ≥ 0.93 and overall S-CVI for idiomatic equivalence, semantic equivalence and content relevance ≥ 0.90. For content validity equivalence all 6 experts answers were located between mostly agree and strongly agree of Gujarati version of Tinetti Assessment Tool for idiomatic equivalence (average= 0.89) semantic equivalence(average = 0.91) and content relevance (average= 0.92). Test-retest reliability (n=60) was tested by using the intraclass correlation coefficient, ICC (2,1) and Internal consistency (n=60) was reported in terms of cronbach's α measured in two session after 1 week is reported in Table 2.

Tinetti Balance Scale	Session 1	session 2	Cronbach's alpha	ICC	P- value
BALANCE SECTION	10.71±6.34	10.88±6.20	.993	.986	0.980
GAIT SECTION	8.60±3.29	8.41±3.40	.988	.977	0.959

DISCUSSION

Many elderly people has Balance and Gait disorder caused by neurological disorder, Parkinson, stroke, poor posture, ataxia , myelopathy. They causing pain, dyspnea, imbalance, diminished strength, limited range of motion, poor posture, fatigue. In our study first report of the reliability and validity of the Tinetti Assessment Tool for evaluating patient with Balance and Gait disorder.

In this study 60 patients participated. Gujarati version of Tinetti Assessment Tool was given twice with 1-week interval to measure the test- retest reliability and to validity. The results of the study showed good

correlation Balance scale and Gait scale(ICC= .986,and .977) (P<0.01) and internal consistency (cronbach's alpha = . 993 and .986).

For content validity equivalence all 6 experts answer were located between mostly agree and strongly agree of Gujarati version of Tinetti Assement Tool for idiomatic equivalence (average= 0.89) semantic equivalence (average = 0.91) and content relevance (average= 0.92). Thus, Gujarati version of Tinetti Balance Scale was content validated for idiomatic equivalence, semantic equivalence , content relevance.

In previous studies, interrater reliability and intrarater reliability of the Korean Tinetti balance scale were(ICC =(0.97 and 0.98) respectively. The interrater reliability and intrarater reliability of the Korean Tinetti balance scale were(ICC =0.94 and 0.96). reliability and validity for gait and balance had high sensitivity and specificity for predicting falls among the patient with PD.[10] In Spanish version the concurrent validity had a high correlation (r = 0.74- 0.93). and inter and intra- rater reliability was between 0.4 to 0.6 and 0.6 to 0.8 The tinetti scale is valid and reliable for Colombian population.[12]

Turkish version of the scale was applied on the participants at 2 week intervals. Test-retest shown good reliability (ICC= 0.94) . interrater and intrarater reliability (ICC=0.86 And 0.90).[9] Turkish version of the POMA-1 scale has been found be a reliable and valid.In Persian version of POMA was applied 7-14 days intervals. Internal consistency (cronbach's alpha= 0.94). test-retest reliability (ICC=0.97). inter-rater reliability (ICC=0.92). Persian shown excellent psychometric properties

It was found Gujarati version of Tinetti Assessment Tool items equivalent to those in original version which is intended by translators involve in this study. The results showed that it was translate this scale into other languags without losing psychometric properties of the original English version

CONCLUSION

The Gujarati version of Tinetti Assessment Tool was cross-culturally adapted and validated for use among the Gujarati-speaking populations. The translated version has acceptable reliability and internal consistency.

SUMMARY

The study is find out the reliability and validity of the Tinetti Assessment Tool in Gujarati language on the elderly people with Balance and Gait disorder in Gujarat. 40 people were chosen with the 40-70 age group participated in the study and they were given Tinetti Assessment Tool was given twice with 1 week interval to measure test-retest reliability and to measure validity. The results showed good correlation and internal consistency and content validity

CHRONIC NECK PAIN AMONG COLLEGE STUDENTS A CROSS-SECTIONAL STUDY

[1]Dr. JAYNESH VANDRA, [2]FORAM SOLANKI, [3]Dr. ARVINDKUMAR CHAUHAN

[1]Assistant Professor (MPT in Musculoskeletal and Sports, PhD Scholar), [2]Bachelor of Physiotherapy, [3]Principal and Professor
[1,2,3]Venus Institute of Physiotherapy,
[1,2,3]Swarrnim Startup & Innovation University, Gandhinagar, Gujarat, India.

ABSTRACT :

Chronic neck pain is most common problem in people nowadays. Chronic neck pain can have causes such as working for hours over computer and mobile phones which eventually causes muscle strains.

BACKGROUND:

To find prevelance, determinants and consequences of chronic neck pain among college going students.

METHODOLOGY:

STEP 1: Selection of suitable participants.

STEP 2: Sending the consent form through e-mail.

STEP 3: Sending the link of questionnaire through e-mail.

STEP 4: Collection of data.

STEP 5: Analysis of the survey.

STEP 6: Statistical Analysis

STEP 7: Result

RESULT: Most of the patient did not had any pain or had miled pain during personel care, lifting heavy weights, reading, headaches, Concentration inactivities, work, driving, Sleeping and Recreational activities.

CONCLUSIONS: From the results it can be concluded that more than half of the population had no pain or mild pain and they didn't feel any issues in dealing with personal care lifting heavy weights reading headaches concentration work driving sleeping and Recreation

KEYWORDS: Chronic neck pain, VAS scale, NDI scale, college students

I. INTRODUCTION

Chronic neck pain is most common problem in people nowadays.1,2The chronic neck pain seems to a have large impact on people's health and hinders with an Individual's day to day activity and work.2

Symptoms

- Pain that's often worsened by holding your head in one place for long periods, such as when driving or working at a computer.
- Muscle tightness and spasms.
- Decreased ability to move your head.
- Headache.
- Neck pain is typically classified as chronic when it persists or regularly recurs for at least 3 months.

Causes of neck pain and problems may include:

- Injury (damage to the muscles, tendons, or ligaments) Herniated disk in the neck.
- Arthritis (such as osteoarthritis, rheumatoid arthritis) Cervical (neck) disk degeneration.
- Congenital (present at birth) abnormalities of the vertebrae and bones.
- Tumors.

Your neck is flexible and supports the weight of your head, so it can be vulnerable to injuries and conditions that cause pain and restrict motion. Neck pain causes include:

- Muscle strain : Overuse, such as too many hours hunched over your computer or smartphone, often triggers muscle strains. Even minor things, such as reading in bed or gritting your teeth, can strain neck muscles.
- Worn joints : Just like the other joints in your body, your neck joints tend to wear down with age. Osteoarthritis causes the cushions (cartilage) between your bones (vertebrae) to deteriorate. Your body then forms bone spurs that affect joint motion and cause pain.

- Nerve compression : Herniated disks or bone spurs in the vertebrae of your neck can press on the nerves branching out from the spinal cord.
- Injuries : Rear-end auto collisions often result in whiplash injury, which occurs when the head is jerked backward and then forward, straining the soft tissues of the neck.
- Diseases : Certain diseases, such as rheumatoid arthritis, meningitis or cancer, can cause neck pain.

Neck pain can cause reduced range of motion due to movement restriction muscles of the neck can become strained due to bad posture habits such as spending excessive time on computer and mobile phones where the neck remains continuously in the same position for a prolonged period of time. Pain in the neck most of the time goes away within a few weeks that being said pain that persist for months could be a sign of underlying problem that needs Observation.4 Chronic Neck pain can have causes such as working for hours over computer and mobile phones which eventually causes muscle strains. Whiplash injuries where the head is forced backward and forward and diseases like cancer.4

REVIEW OF LITERATURE

1. Prevalence , determinants and consequences of chronic neck pain in Finland, By Matti Makela, Markku Heliovaara, Kai Sievers, Olli Impivaara, Paul Knekt, Arpo Aromaa , in 1991.

The distribution, determinants, and consequences of chronic neck pain have hitherto been described inadequately. In the Mini-Finland Health Survey, a representative population sample of 8,000 Finns aged ≥30 years was invited to participate in a comprehensive health examination comprising an interview and a clinical examination; 90.2% complied. Predetermined criteria were used to diagnose major cardiovascular, musculoskeletal, respiratory, mental, and other disorders, regardless of other simultaneous disorders. Chronic neck syndrome was diagnosed in 9.5% of the men and 13.5% of the women. When adjusted for age and sex, the prevalence of the neck syndrome was associated with a history of injury to the back, neck, or shoulder and with mental and physical stress at work. Among those aged 30 to 64 years, overweight and parity were also significant determinants. Other musculoskeletal and mental disorders were associated with neck syndrome, and the association persisted after working conditions, injuries, overweight, and parity were adjusted for. There was some independent association between neck syndrome and disabilities, use of physician services, and use of pain killers.

2. Neck pain among undergraduate medical students in a premier institute of central India: A cross-sectional study of prevalence and associated factors,By Prateek Behera, Anindo Majumdar, G Revadi, John Ashutosh Santoshi, Vivek Nagar, Nitu Mishra in 2020 .

This study aimed to evaluate the prevalence of neck pain and the associated factors including gadget use among undergraduate medical students of a premier medical college in central India.

3. Prevalence of neck pain among under graduate student of Lahore, By Ayesha Malik , M.Umer Pasha , Sadia khalid , Ashfaq ahmad , Syed Amir Gilani , 2017 .

The main intent of this study was to find out the prevalence of neck pain in undergraduates Students. A cross sectional study was conducted which was not derived from experiments. A survey was conducted from the undergraduate students of main universities in lahore city named as Punjab university of Lahore and University of Lahore descriptive statistics focused on bar charts histograms and pie charts were Used. Results concluded that out of 402 respondents (56.7%) were suffering with neck pain while (43.3%) respondents were not having neck pain. No association was found between gender and neck pain (p-value 0.351) additionally, there was weaker relation between age and neck pain (p-value 0.785).Neck pain occurring. In students was mainly sudden in onset & intensity was mild to moderate of the neck pain. Mostly students were taking medications & physiotherapy treatment for reducing the neck pain.

4. Improving knowledge of Text Neck and Neck Pain Using Interactive Smartphone Application for Undergraduate Students in Universiti Sains Malaysia, By Jasni Dolah, Joey Loh Jo Yie, Lilian Lee Shiau Gee , In 2020.

The objective of this study is to determine the level of knowledge and awareness of the text neck among undergraduate students of University Sains Malaysia (USM) and to create an interactive mobile application to reduce the prevalence. The app is ARbased neck exercise gamification that alerts incorrect posture using a smartphone front camera and a built-in sensor. The proposed study will enable people who are suffering from, or at risk of, text neck to have more pleasant and engaging neck exercise experience with a better exercise impact, and may promote regular breakaway from the wrong posture.

5. Effects of neck exercise on sitting posture in patients with chronic neck pain , By Deborah Falla, Gwendolen Jull, Trevor Russell, Bill Vicenzino,Paul Hodges , 2007

This study had 2 purposes: (1) to compare change in cervical and thoracic posture during a distracting task between subjects with chronic neck pain and control subjects and (2) to comparethe effects of 2 different neck exercise regimens on the ability of people with neck pain to maintain an upright cervical and thoracic posture during this task. Fifty-eight subjects with chronic, nonsevere neck pain and 10 control subjects participated in the study.

6. Responses to Vignettes about Students with Chronic Pain in K-12 Public Schools Provide by Current Principals and Assistant Principal BY Kimberly S Payne , In 2020.

This dissertation study addresses a gap in the literature in K-12 public education regarding students who experience chronic pain (CP). While awareness and understanding about the plight of children and adolescents with CP are prevalent in the healthcare and medical realms, evidence of how public schools respond to students' pain

complications as they apply to their education, both in the K-12 setting andbeyond, is scant. Despite this, consequences of ignoring or misunderstanding CP instudents by K-12 schools could be significant: Studies from the healthcare realm indicate that students with CP often become caught in a "downward spiral" of chronic pain-invoked absenteeism resulting in falling behind in academics and low school functioning, thus placing them at risk of poorer eventual outcomes in life. Likewise, family members and school personnel become frustrated by lack of information, communication problems, and the inability to attend to students' needs. Additionally, matters are complicated when K-12 school administrators are required to work within fixed legal frameworks that are not necessarily sensitive to CP issues.

7. Active neck muscle training in the treatment of chronic neck pain in women a Randomized Controlled trial, by Jari Ylinen , Esa-Pekka Takala , Matti Nykänen , in 2003

Patients were randomly assigned to either 2 training groups or to a control group, with 60 patients in each group. The endurance training group performed dynamic neck exercises,which included lifting the head up from the supine and prone positions. The strength training group performed high-intensity isometric neck strengthening and stabilization exercises with an elastic band. Both training groups performed dynamic exercises for the shoulders and upper extremities with dumbbells. All groups were advised to do aerobic and stretching exercises regularly 3 times a week

8. A systematic review of the impact of chronic pain on adolescents' school functioning School personnel responses to managing pain in the schools By Fatimah Alsaggaf, Imelda Coyne , In 2020.

To critically synthesize empirical studies on the impact of chronic pain on adolescents' school functioning and school personnel responses to managing pain in schools.

9. Physical exercises and functional rehabilitation for the management of chronic neck Pain , By Jari Ylinen , in 2007

The aim of this review was to reassess the effectiveness of different exercise methods in relieving pain and improving disability in patients with chronic nonspecific neck pain. Ten andomized controlled or comparative high-quality trials were included in a more detailed analysis using patient oriented primary outcome measures (e.g., patient's rated pain and Disability) as well as pressure pain threshold and functional outcomes (neck strength and range of motion). Findings revealed moderate evidence supporting the effectiveness of both long-term dynamic as well as isometric resistance exercises of the neck and shoulder musculature for chronic or frequent neck disorders. Findings revealed no evidence supporting the long-term effectiveness of postural and proprioceptive exercises or other very low intensity exercises. Clinicians are encouraged to consider these findings and incorporate them into their practice when planning the treatment of patients with chronic neck disorders.

NEED OF STUDY

Currently there are many studies done on chronic neck pain but there is limited research on prevalence ,determinants and consequences of chronic neck pain among college going students. Need for study arises to understand the determinants and prevalence of chronic neck pain in college going students as their neck remains in the same position continuously for longer time while studying and using mobile phones as well as laptops.

OBJECTIVE OF THE STUDY

- To find out whether Myofacial Release (MFR) Technique or Active Release Technique is more effective in treating chronic low back pain.
- To find out whether Myofacial Release (MFR) Technique is superior for treating chronic low back pain.
- To find out whether Active Release Technique is superior for treating chronic low back pain.

HYPOTHESIS

H0 : There is no association between pain and personal care, lifting heavy weights, reading, headaches, concentration in activities, work, driving, sleeping, recreational activities.

H1: There is association between pain and personal care, lifting heavy weights, reading, headaches, concentration in activities, work, driving, sleeping, recreational activities.

METHODOLOGY

STEP 1: Selection of suitable participants.

STEP 2: Sending the consent form through e-mail.

STEP 3: Sending the link of questionnaire through e-mail.

STEP 4: Collection of data.

STEP 5: Analysis of the survey.

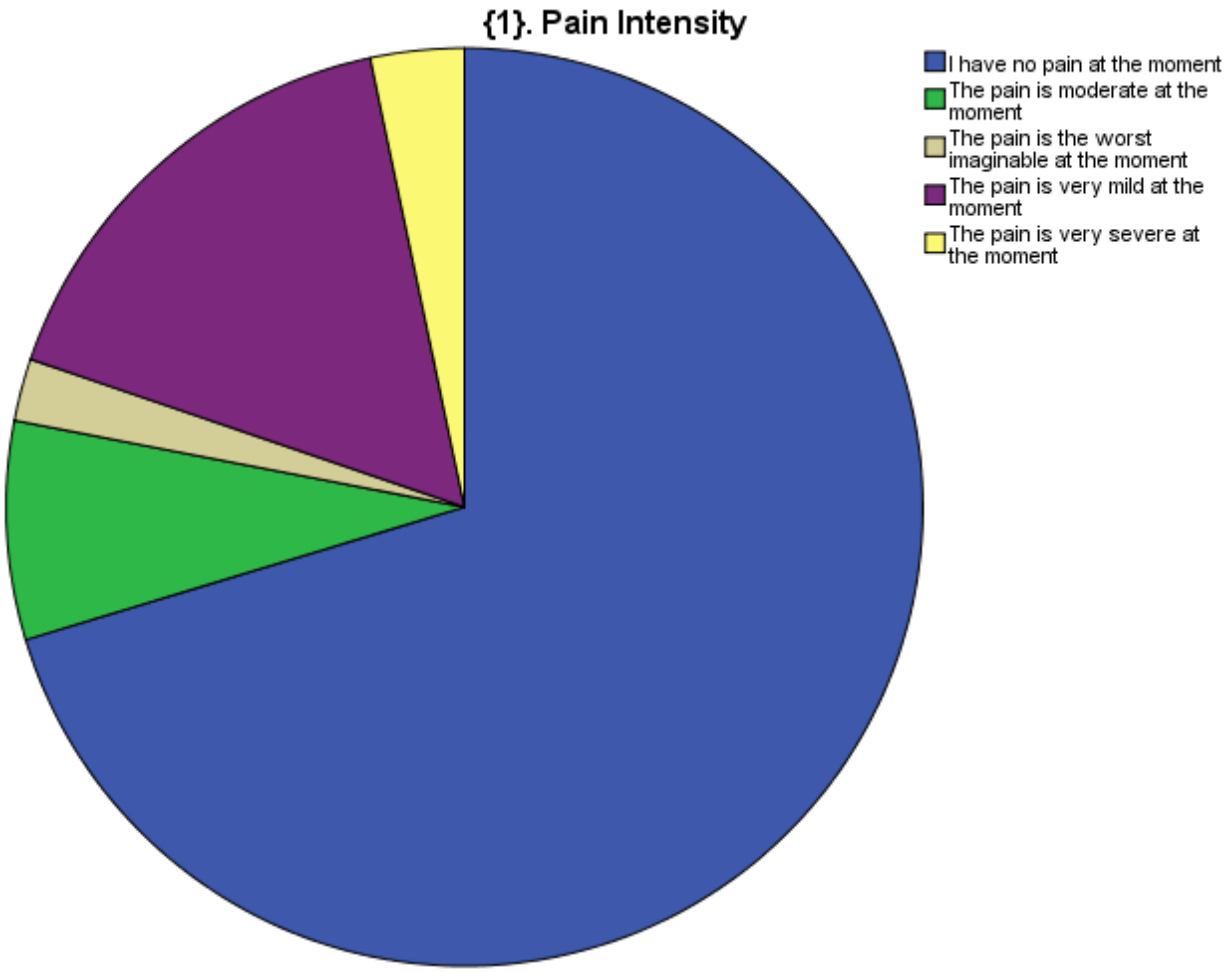
STEP 6: Statistical Analysis

STEP 7: Results

Result

{1}. Pain Intensity

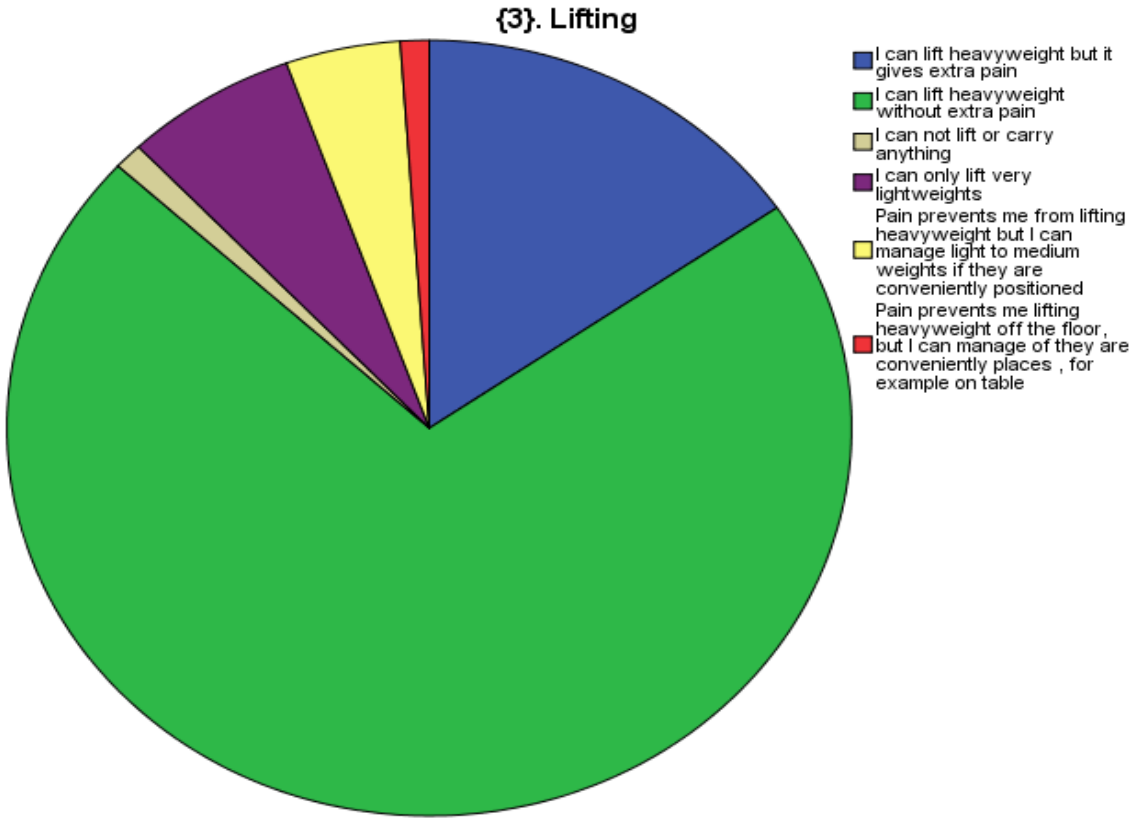
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	I have no pain at the moment	64	70.3	70.3	70.3
	The pain is moderate at the moment	7	7.7	7.7	78.0
	The pain is the worst imaginable at the moment	2	2.2	2.2	80.2
	The pain is very mild at the moment	15	16.5	16.5	96.7
	The pain is very severe at the moment	3	3.3	3.3	100.0
	Total	91	100.0	100.0	



{2}. Personal Care [Washing, Dressing, etc]

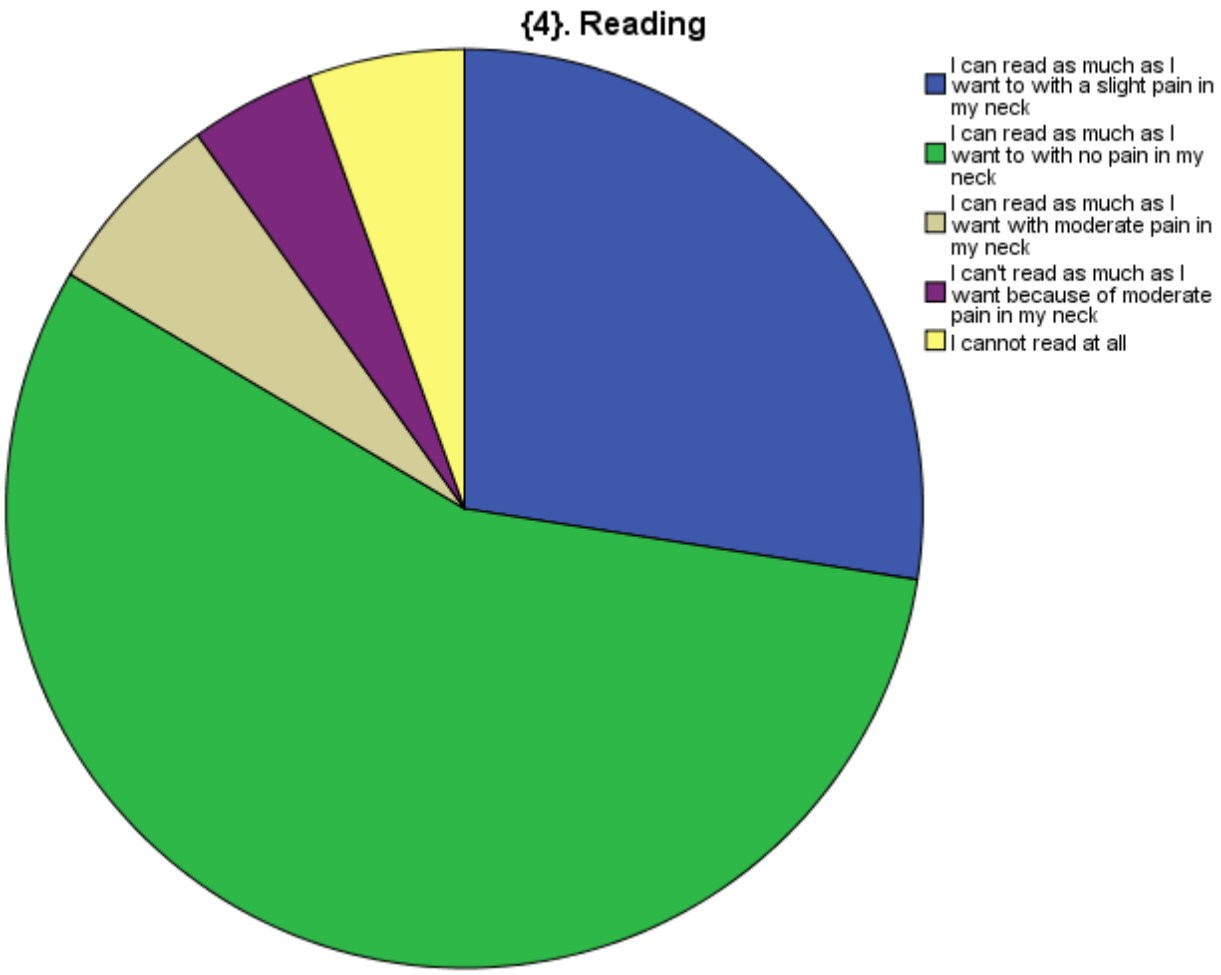
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	I can look after myself normally but it causes extra pain	8	8.8	8.8	8.8
	I can look after myself normally without causing extra pain	76	83.5	83.5	92.3
	I do not get dressed , i wash with difficulty and stay in bad	1	1.1	1.1	93.4
	I need some help but can manage most of my personal care	5	5.5	5.5	98.9
	It is pain full to look after myself and I am slow and careful	1	1.1	1.1	100.0
	Total	91	100.0	100.0	

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	I can lift heavyweight but it gives extra pain	14	15.4	15.4	15.4
	I can lift heavyweight without extra pain	65	71.4	71.4	86.8
	I can not lift or carry anything	1	1.1	1.1	87.9
	I can only lift very lightweights	6	6.6	6.6	94.5
	Pain prevents me from lifting heavyweight but I can manage light to medium weights if they are conveniently positioned	4	4.4	4.4	98.9
	Pain prevents me lifting heavyweight off the floor, but I can manage of they are conveniently places , for example on table	1	1.1	1.1	100.0
	Total	91	100.0	100.0	



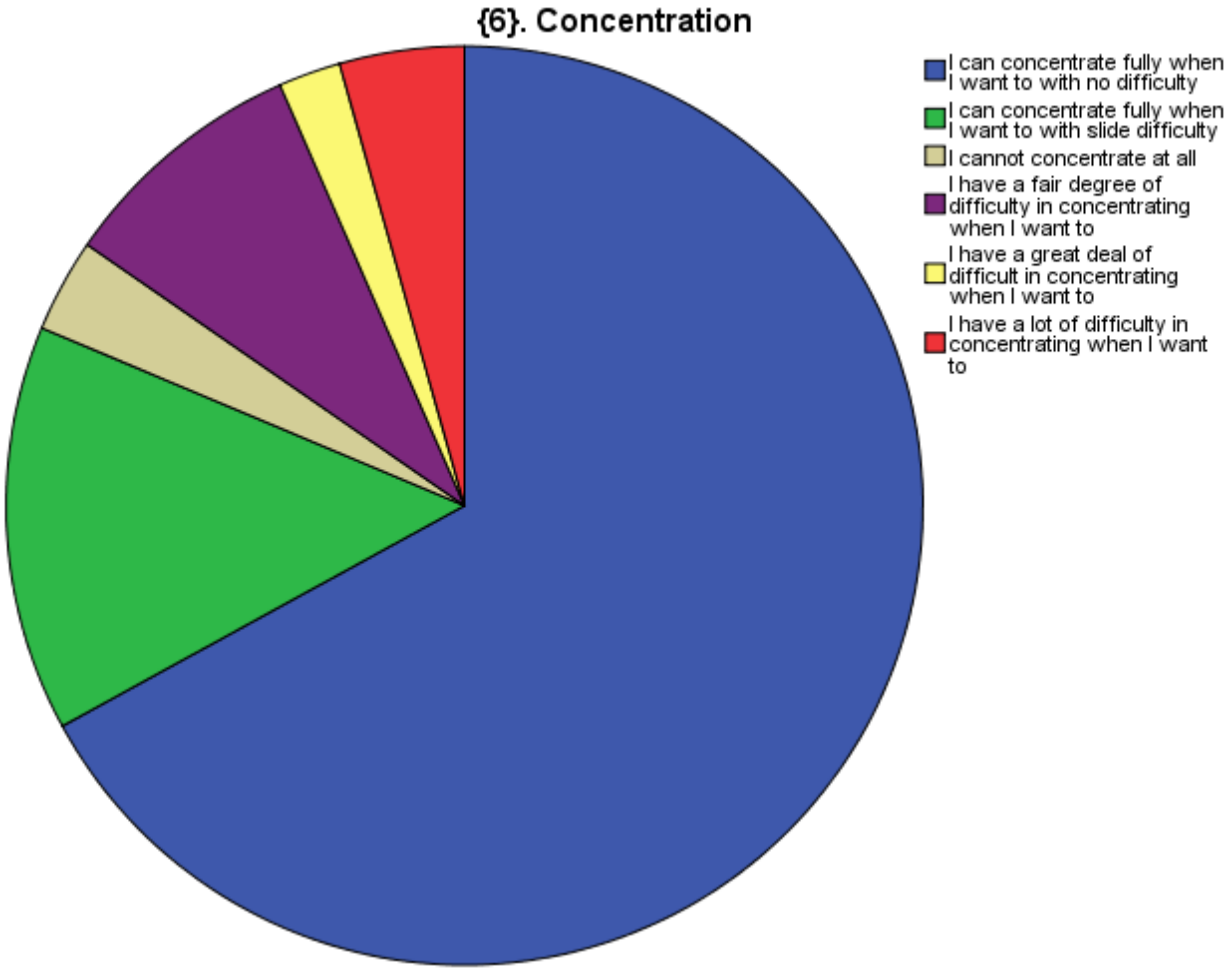
{4}. Reading

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	I can read as much as I want to with a slight pain in my neck	25	27.5	27.5	27.5
	I can read as much as I want to with no pain in my neck	51	56.0	56.0	83.5
	I can read as much as I want with moderate pain in my neck	6	6.6	6.6	90.1
	I can't read as much as I want because of moderate pain in my neck	4	4.4	4.4	94.5
	I cannot read at all	5	5.5	5.5	100.0
	Total	91	100.0	100.0	



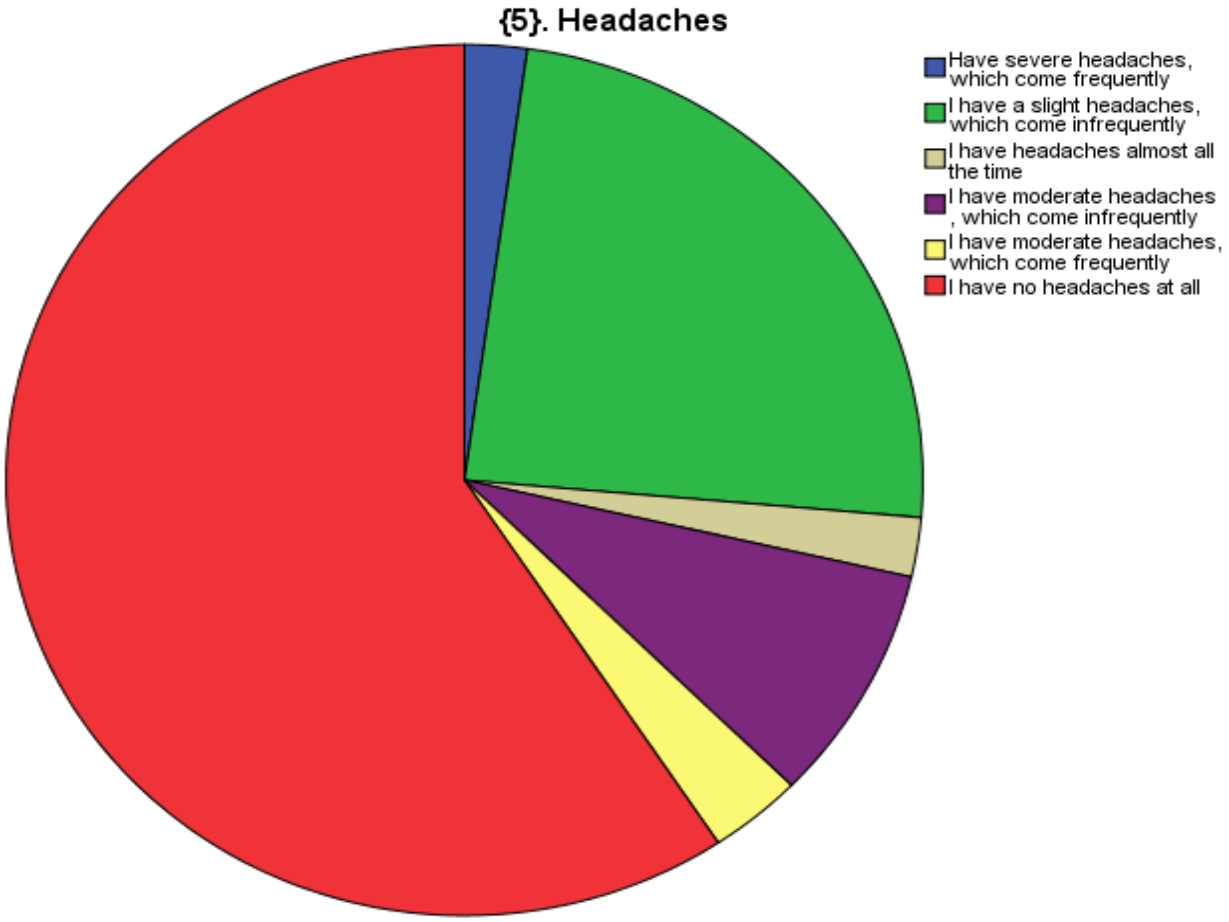
{5}. Headaches

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Have severe headaches, which come frequently	2	2.2	2.2	2.2
	I have a slight headaches, which come infrequently	22	24.2	24.2	26.4
	I have headaches almost all the time	2	2.2	2.2	28.6
	I have moderate headaches , which come infrequently	8	8.8	8.8	37.4
	I have moderate headaches, which come frequently	3	3.3	3.3	40.7
	I have no headaches at all	54	59.3	59.3	100.0
	Total	91	100.0	100.0	



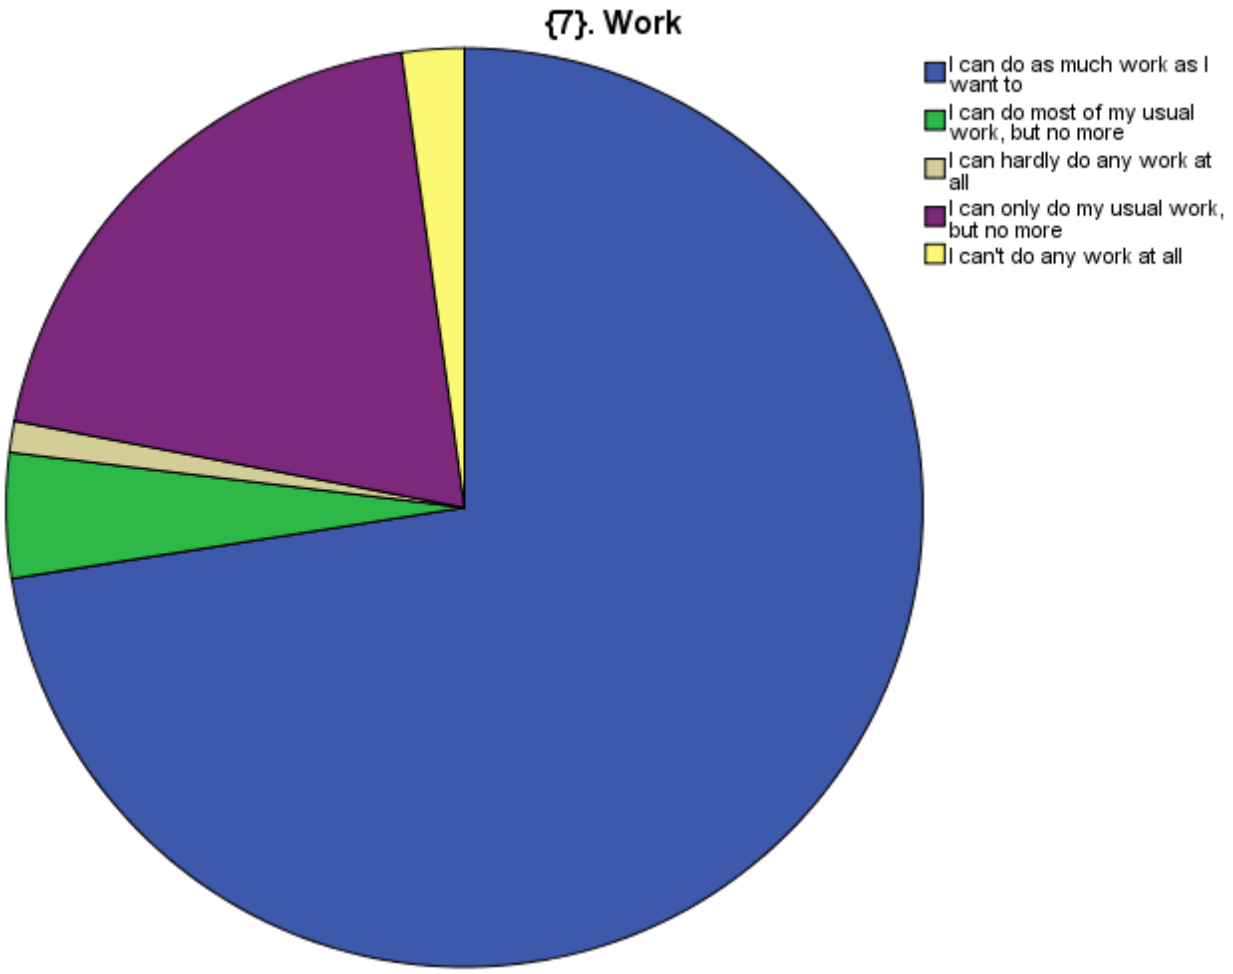
{6}. Concentration

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	I can concentrate fully when I want to with no difficulty	61	67.0	67.0	67.0
	I can concentrate fully when I want to with slide difficulty	13	14.3	14.3	81.3
	I cannot concentrate at all	3	3.3	3.3	84.6
	I have a fair degree of difficulty in concentrating when I want to	8	8.8	8.8	93.4
	I have a great deal of difficult in concentrating when I want to	2	2.2	2.2	95.6
	I have a lot of difficulty in concentrating when I want to	4	4.4	4.4	100.0
	Total	91	100.0	100.0	



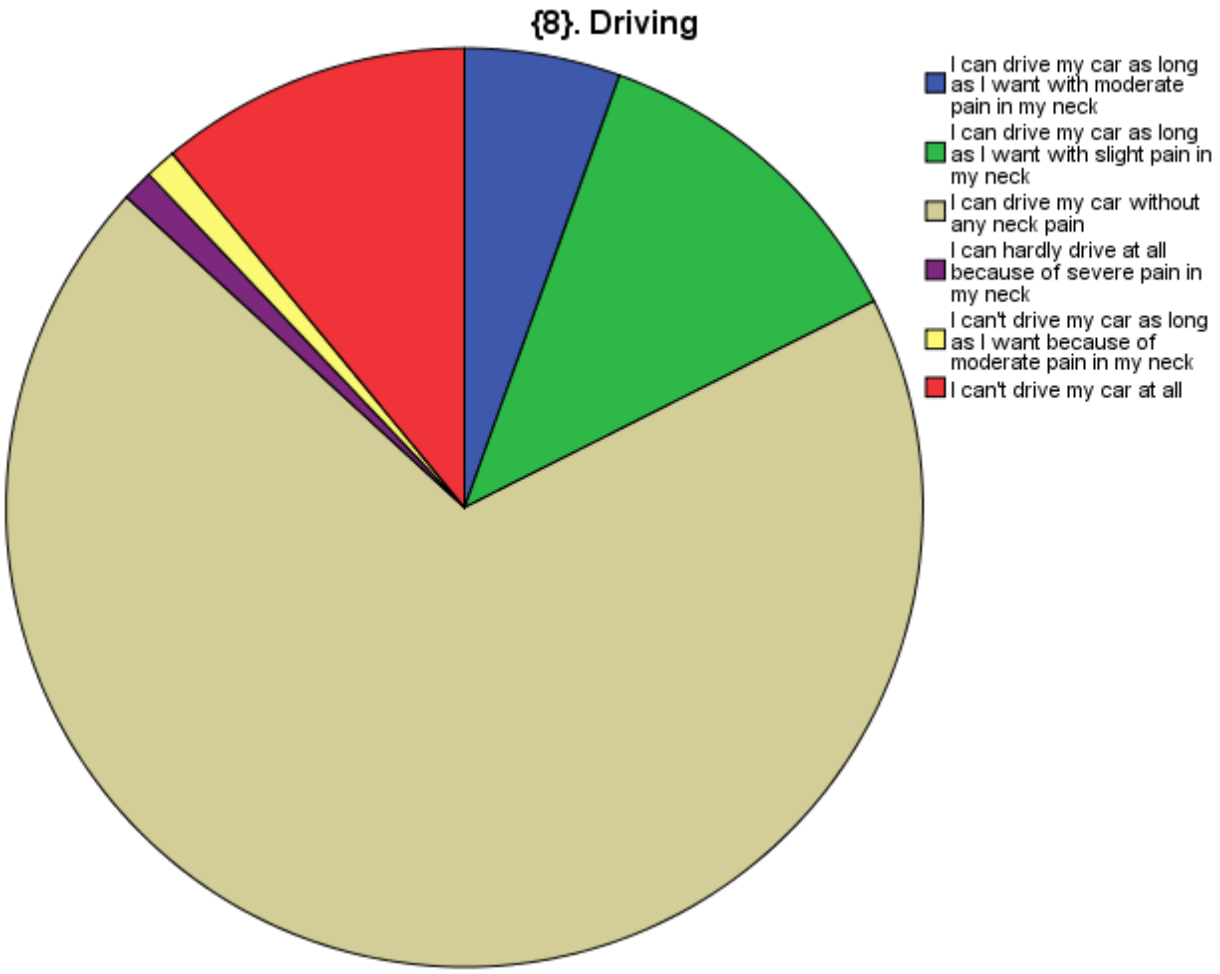
{7}. Work

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	I can do as much work as I want to	66	72.5	72.5	72.5
	I can do most of my usual work, but no more	4	4.4	4.4	76.9
	I can hardly do any work at all	1	1.1	1.1	78.0
	I can only do my usual work, but no more	18	19.8	19.8	97.8
	I can't do any work at all	2	2.2	2.2	100.0
	Total	91	100.0	100.0	



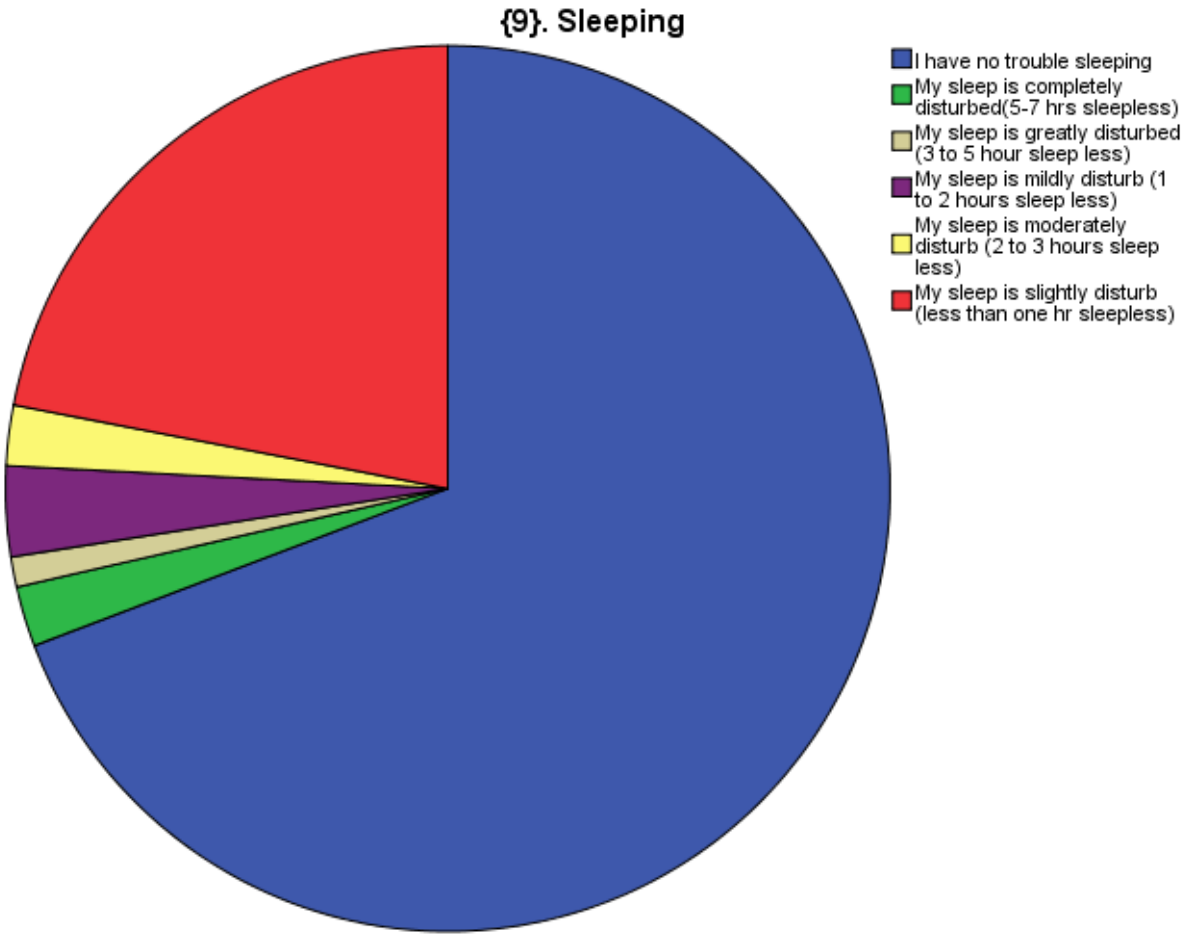
{8}. Driving

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	I can drive my car as long as I want with moderate pain in my neck	5	5.5	5.5	5.5
	I can drive my car as long as I want with slight pain in my neck	11	12.1	12.1	17.6
	I can drive my car without any neck pain	63	69.2	69.2	86.8
	I can hardly drive at all because of severe pain in my neck	1	1.1	1.1	87.9
	I can't drive my car as long as I want because of moderate pain in my neck	1	1.1	1.1	89.0
	I can't drive my car at all	10	11.0	11.0	100.0
	Total	91	100.0	100.0	



{9}. Sleeping

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	I have no trouble sleeping	63	69.2	69.2	69.2
	My sleep is completely disturbed(5-7 hrs sleepless)	2	2.2	2.2	71.4
	My sleep is greatly disturbed (3 to 5 hour sleep less)	1	1.1	1.1	72.5
	My sleep is mildly disturb (1 to 2 hours sleep less)	3	3.3	3.3	75.8
	My sleep is moderately disturb (2 to 3 hours sleep less)	2	2.2	2.2	78.0
	My sleep is slightly disturb (less than one hr sleepless)	20	22.0	22.0	100.0
	Total	91	100.0	100.0	



{10}. Recreation

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	I am able to engage in all my recreation activities with no neck pain at all	68	74.7	74.7	74.7
	I am able to engage in all my recreation activities, with some ne pain in my neck	17	18.7	18.7	93.4
	I am able to engage in most common but not all of my usual recreation activities because of pain in my neck	2	2.2	2.2	95.6
	I can't do any recreation activities at all	4	4.4	4.4	100.0
	Total	91	100.0	100.0

I HAVE NO PAIN AT THE MOMENT
THE PAIN IS VERY MILD AT THE MOMENT
THE PAIN IS MODERATE AT THE MOMENT
THE PAIN IS VERY SEVERE AT THE MOMENT
THE PAIN IS THE WORST IMAGINABLE AT THE MOMENT

Results

Using the graphs the following results were obtained:

1. Most of the patients did not had any pain or had mild pain during personal care (washing, dressing, etc).
2. Most of the patients did not had any pain or had mild pain during Lifting heavy weights.
3. Most of the patients did not had any pain or had mild pain during Reading.
4. Most of the patients did not had any pain or had mild pain during slight headaches, which come infrequently.
5. Most of the patients did not had any pain or had mild pain and so they can concentrate in their day to day activities with no/less difficulty.
6. Most of the patients did not had any pain or had mild pain while doing work.
7. Most of the patients did not had any pain or had mild pain while driving.
8. Most of the patients did not had any pain or had mild pain while sleeping or had no trouble sleeping.
9. Most of the patients did not had any pain or had mild pain and so they were able to engage in all their recreational activities with no/mild neck pain.

DISCUSSION

Neck pain can have causes that aren't due to underlying disease. Examples include prolonged straining (looking up or down), sleeping in an uncomfortable position, stress, chiropractic manipulation or wearing heavy necklaces. Chronic neck pain can range from an achy annoyance to shock-like pain that goes into the arm and becomes debilitating. Neck pain is typically classified as chronic when it persists or regularly recurs for at least 3 months.

Drs Ylinen and Häkkinen,Dr Takala ,Dr Nykänen,Dr Mälkiä,Dr Pohjolainen and Ms Karppi,Dr Airaksinen did research in Active neck muscle training in the treatment of chronic neck pain in women: a randomized controlled trial , the results show that the Both strength and endurance training for 12 months were effective methods for decreasing pain and disability in women with chronic, nonspecific neck pain. Stretching and fitness training are commonly advised for patients with chronic neck pain, but stretching and aerobic exercising alone proved to be a much less effective form of training than strength training. [6]

Author Deborah Falla, Gwendolen Jull, Trevor Russell, Bill Vicenzino, Paul Hodges did research in Effect of neck exercise on sitting posture in patients with chronic neck pain, the results show that the This study showed that people with chronic neck pain demonstrate a reduced ability to maintain an upright posture when distracted. Following intervention with an exercise program targeted at training the craniocervical flexor muscles, subjects with neck pain demonstrated an improved ability to maintain a neutral cervical posture during prolonged sitting. [4]

When Jari Ylinen did research in Physical exercises and functional rehabilitation for the management of chronic neck pain ,the results show that Specific moderate and highintensity neck muscle training can reduce neck pain. A decrease in neck pain is associated with reduced pressure pain sensitivity in neck muscles. Intensive regular training will increase neck muscle strength and range of motion, leading to improved function and less disability in patients with chronic neck pain. Training for a few months is commonly recommended, but it has beenshown to produce only transitory improvements. Long-term progressive resistance training for neck and shoulder muscles is therefore recommended. Moreover, effective training can be performed at home with low-cost training equipment.[8]

In this cross - sectional research chronic neck pain among college going students on 90 students from age 18-24 . In this research NDI scale and VAS scale were used to measure pain and disability of students. My research concluded that the there is no disability among college going students.

I did this research because I observed that college going students have to keep their neck constantly in one position whether it was for attending lectures or working on their desk so I wanted to know if they were experiencing any kind of chronic neck pain in their day to day life.

CONCLUSION

From the results it can be concluded that more than half of the population had no pain or mild pain and they didn't feel any issues in dealing with personal care lifting heavy weights reading headaches concentration work driving sleeping and recreation.

SUMMARY

From the results it can be concluded that more than half of the population had no pain or mild pain and they didn't feel any issues in dealing with personal care lifting heavy weights reading headaches concentration work driving sleeping and recreation.

Limitations

- Smallsamplesize.
- Limitedagegroupof18-24years.
- Neckpainprolongedmorethan12weeks.

ABSTRACT

BACKGROUND : Polycystic means many cysts. Polycystic ovarian Disease is a complex disorder of chronic oligoanovulation or oligomenorrhoea and clinical or biochemical hyperandrogegism. Genetic and environmental factors may contribute to this disorder and may affect 14-44 year age of women . This is one of the main reason for infertility. Women affected with this syndrome often have ovulatory dysfunction hormonal disbalance, hyperandrogenemia, obesity and hyper insulinemia.

METHODOLOGY: They were subjected to Yoga therapy for 30-45 mins /day for 3 months with a break after every 6 days. Treatment duration was 3 months. Pre and post outcome measures were taken.

RESULT: . Data was considered statistically significant with $P<0.05$ and highly significant at $p<0.01$. Pre and post mean difference of BMI shows 33.28 ± 26.64 in pre date collection and 28.36 ± 21.77 in post data collection. As $p<0.05$ there is significant difference between groups. Pre and post mean difference values of VMSS shows 2.33 ± 14.67 and 0.93 ± 23.87. This shows a significant difference between two groups.

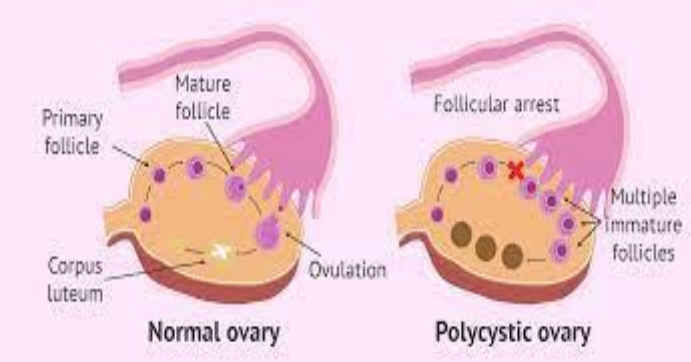
CONCLUSIONS: Daily yoga for 30 minutes with 5 Asanas along with meditation and Shavasana helps in weight reduction and stress management which ultimately stabilize the normal function of hypothalmo-pituitary–ovarian axis and cure PCOD.

KEYWORDS: polycystic ovarian disease, yoga, obesity, Body Mass Index , infertility.

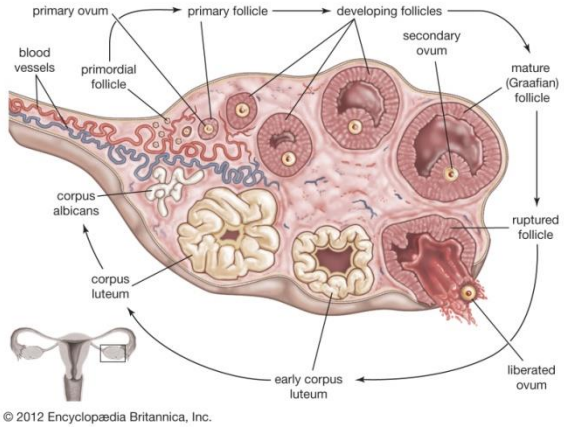
INTRODUCTION

Polycystic means many cysts. Polycystic ovarian Disease is a complex disorder of chronic oligoanovula-tion or oligomenorrhoea and clinical or biochemical hyperandrogegism. Genetic and environ-mental fac-tors may contribute to this disorder and may affect 14-34 age of women .This is one of the main reason for infertility. Women affected with this syndrome often have ovulatory dysfunction hormonal disbalan-ce, hyperandrogenemia, obesity and hyper insulinemia. PCOD has life-long implications with in-creased risk for infertility, metabolic syndrome, type 2 diabetes mellitus, cardiovascular disease and endometrial carcinoma. [1]

Polycystic ovary Disease (PCOD) is a very common endocrine disorder, of uncertain aetiology, that affects an estimated 5–10% of women of reproductive age. PCOD typically presents during adolescence and is a heterogeneous syndrome that classically is characterized by features of an ovulation (amenorrh-ea, oligomenorrhoea) combined with symptoms of androgen excess (Hirsutism, acne, alopecia). [2]



PHOTOGRAPH: 1 NORMAL OVARIES VS PCOD OVARI



PHOTOGRAPH: 2 OVULATION

Polycystic ovary disease (PCOD) is an endocrine disorder associated with metabolic change in women of reproductive age. It is the most common cause of infertility with physical, mental and hormonal imbalances. The prevalence rate of polycystic ovary disease (PCOD) in India is 9.13%.[3]

It is characterized by irregular, short menstruation, depression, obesity, acne, hair fall, cystic ovary, blood sugar imbalance, etc. Various factors responsible for polycystic ovary disease, but also stress and lack of exercise are the most important factor for exaggerating polycystic ovary disease. [3]

Clinical signs of PCOD include elevated luteinizing hormone (LH) and gonadotropin–releasing hormone (GnRH) levels, whereas follicular-stimulating hormone (FSH) levels are muted or unchanged. As a result of the increase in GnRH, stimulation of the ovarian thecal cells, in turn, produces more androgens.[4]

The word yoga is derived from the Sanskrit root yuj, which means to join or yoke. Philosophically, yoga refers to the connection of the individual self with the universal self. Yoga is one of the six branches of classical Indian philosophy and has been practiced for thousands of years.[5]

Yoga is an ancient discipline designed to bring balance and health to the physical, mental, emotional, and spiri- tual dimensions of the individual. Yoga is often depicted metaphorically as a tree and comprises eight aspects, or ‘‘limbs:’’ yama (universal ethics), niyama (individual ethics), asana (physical postures), pranayama (breath control), pratya- hara (control of the senses), dharana (concentration), dyana (meditation), and samadhi (bliss). Long a popular practice in India, yoga has become increasingly more common in Wes- tern society. In a national, population-based telephone survey (n 1⁄4 2055), 3.8% of respondents reported using yoga in the previous year and cited wellness (64%) and specific health conditions (48%) as the motivation for doing yoga.[6]

Yoga is the union of individual self, jeevatma, with the universal self, paramatma. It is the communion of the human soul with the divinity. Simple meaning of Yoga is union. Yoga is the integration and harmony between thoughts, words, and deeds or integration between head, heart and hands. [7]

NEED *OF STUDY*

Many researchers have studied the individual effect of Suryanamaskar and pelvic opening yoga among with diet and life style mordification but there is no research done without a combination of these two and any diet and lifestyle changes. Thus, it is necessary to conduct the study on Effect of Yoga on PCOD.

AIM AND OBJECTIVES OF THE STUDY

AIM OF STUDY:

To evaluate effect of yoga in PCOD.

OBJECTIVES OF STUDY:

1. To assess and compare the changes in BMI in PCOD before & after 3 months of Yoga.
2. To assess and compare the Oligomenorrhea (irregular menstruation) in PCOD. Before and after 3 months of yoga
3. To assess and compare yoga therapy in PCOD before and after 3 months of Yoga therapy.

HYPOTHESIS

1. **Null hypothesis:**
   There will be no significant impact of yoga in management of symptoms of PCOD.

2. **Research hypothesis:**
   There will be significant impact of yoga in management of symptoms of PCOD.

MATERIALS AND METHODS

STUDY DESIGN - A Quasi- experimental one- way study
SOURCE OF DATA - Hospitals (Ahmedabad)
POPULATION - 18-30 adolescent girls
SAMPLING METHOD- convenient sampling
SAMPLE SIZE - 30
DURATION OF THE STUDY - 3 months
TRETMENT DURETION - 6 session per week for 3 months

METHOD OF COLLECTION OF DATA

1.Inclusion criteria:

- Age limitation 18 to 30
- Menstrual irregular symptoms with PCOD
- Dysmenorrhea
- Obesity with symptoms with PCOD

2.Exclusion criteria :

- PCOS
- Infertility
- Patient takes any treatment or therapy

MATERIALS AND TOOLS USED

- Yoga Mats
- Pillow
- Blocks
- Mobile phones

OUTCOME MEASURES

BMI (Body Mass Index)

- It is a measure of body fat based on your weight in relation to your height. It is more of an indicator than a direct measurement of a person's total body fat. As the BMI score increases, so does the
- person's total body fat increases.
- Formula to check BMI is BMI= weight/ [height (m2)
- BMI weight ranges: Less than 18.5 = Underweight , Between 18.5 - 24.9 = Healthy Weight, Between 25 - 29.9 = Overweight, Over 30 = Obese.

VMSS (verbal multimensiona scoring system) [8]

- The Verbal Multidimensional Scoring System (VMDS) measures both pain and related systemic signs and symptoms, while the Visual Analogue Scale measures only pain. Hence, primary dysmenorrhea was measured in different degrees of severity in different studies. Dysmenorrhea or pain during menstruation is commonly seen in young women and largely impacts their quality of life. Pain medications are largely used to tackle this situation; however, they have side effects with regular use.

METHODOLOGY

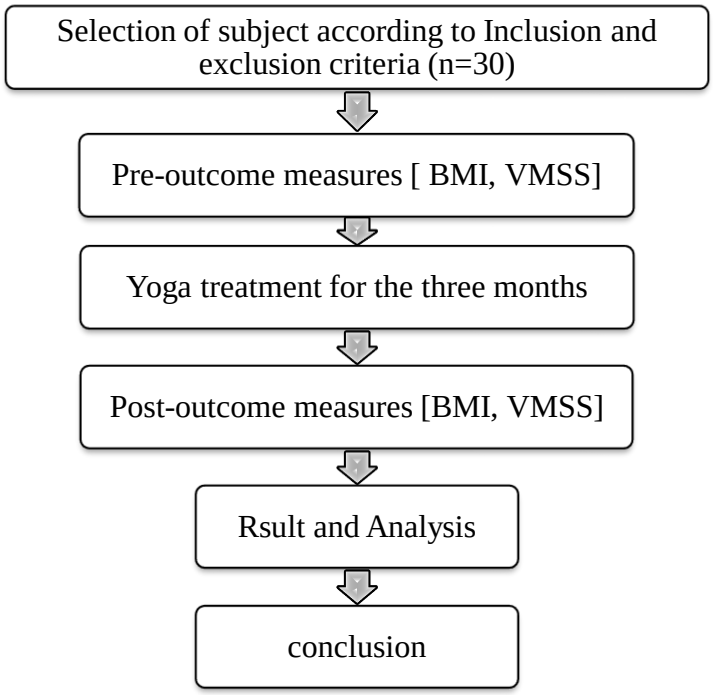


CHART 1: CHART OF STUDY PROCEDURE

The study a quasi -experimental one way study was undertaken by collecting data by convenient sampling of 18-30 age adolescent girls. First of all 30 patients will be selected according to the inclusion and exclusion criteria from the hospitals. Newly diagnosed and a case of PCOD but not under treatment. The patients have already diagnosed dysmenorrhoea severity. All of that patients presenting with complaints of weight gain, irregular periods from several years, lethargy, increased appetite and heaviness in the body.

At the second stage Informed consent was obtained from all the participants. Following which the study was initiated a thorough history was collected using questionnaire in favor of pre outcome measurement.

From all the participants including personal details such as name, age, address and phone number, medical history of any menstrual irregularities (Amenorrhoeal Oligmenorrhoea /menorrhagia) Hyperandrogenism features like (Hirsutism, Acne, Alopecia), history of other exclusion features were collected in detail. As well the Physical examination must be taken in this General examination was done

Height in inch's and weight in kilograms were measured and Body Mass Index (BMI) was calculated as weight/height in meter square; additionally VMSS (verbal multidimensional scoring sysrem) to assessment as concerns to dysmenorrhoea severity. All of that patients presenting with complaints of weight gain, irregular periods from several years , lethargy, increased appetite and heaviness in the body .

After the second stage, all participants will be asked to sign a consent with clear information about the research which will provide a clear understanding of the research project , procedure or treatment and clinical trial. It also includes information of possible risks and benefits, including what the researcher is doing in the field. If a person chooses to take part in the treatment, procedure, trial, or testing, she needs to signs the form to give official consent.

Next stage would be yoga therapy (yoga specific for PCOD along with weight loss) .Therefore for the management of obesity physical exercise, fat reducing medicine and diet is necessary. In this case only Yogasanas were advised without any medicinal treatment and diet management.

Patient prescribes Surya Namaskar, along with pelvic opening asanas. In these yoga package these asanas will include: Suryanamaskar (start with 5 rounds and then slowly increasing the number), Baddhakonasana, Supta baddhakonasana, Ustrasana, Shalabhasana (with 7 repetition) .

These Asanas practiced early in the morning with empty stomach for 45 mins to one hour per day for 3 months. Prior to therapy 6 days of training was given to participant. Participant didn't had any previous experience of yoga practice. Total duration of each asanas during six days training period for three months. While doing these asanas abdomen, thighs and spine are stretched. Stretching helps to reduce extra fat which is accumulated over abdomen, thighs. That's why these Asanas were selected for the study.

PHOTOGRAPH: 3 PATIENTS PERFORMING YOGASANAS

PHOTOGRAPH: 4 PATIENTS PERFORMING YOGASANAS

When patient start practicing yoga, patient was made to perform for 35 mins for seven days of training according to the schedule given in table number 1.

After 7 days yogasana training, duration of asanas was increased. This was followed for 1 hour 15min daily in the morning with empty stomach. Schedule of Yoga therapy practiced for three months by patient as shown in table number 2.

Sr.No.	Yogasanas	Duration	repetition	Rest	Total duration
1	Suryanamaskar	10 min	5	-	10 min
2	Baddhakonasana	30 sec	5	30 sec	3 min
3	Suptabaddhakonasana	30 sec	5	30 sec	3 min
4	Ustrasana	30 sec	5	30 sec	3 min
5	Shalabhasana	30 sec	5	30 sec	3 min

TABLE: 1 YOGA TERAPY FOR SEVEN DAYS

Sr.No.	Yogasanas	Duration	repetition	Rest	Total duration
1	Suryanamaskar	10 min	7	-	10 min
2	Baddhakonasana	30 sec	7	1min	7 min
3	Suptabaddhakonasana	30 sec	7	1min	7 min
4	Ustrasana	30 sec	7	1min	7 min
5	Shalabhasana	30 sec	7	1min	7 min

TABLE: 2 YOGA TERAPY FOR THREE MONTH

In last stage After three months of regular yoga practice history was collected using questionnaire in favor of post outcome measurement from all the participants including personal details such as medical history of any menstrual irregularities (Amenorrhoeal Oligmenorrhoea /menorrhagia). Hyperandrogenism features like (Hirsutism, Acne, Alopecia), history of other exclusion features were collected in detail. In General examination, height and weight were measured in inches and kilograms respectively. In addition physical examination should must be taken and Body Mass Index (BMI) was calculated as weight/height in meter square; additionally VMSS (verbal multidimensional scoring system) to assessment as concerns to dysmenorrheal severity .

RESULT

Study variables were done before starting physiotherapy sessions on group and at the end of the study, study variables include BMI and VMSS.

Data analysis:

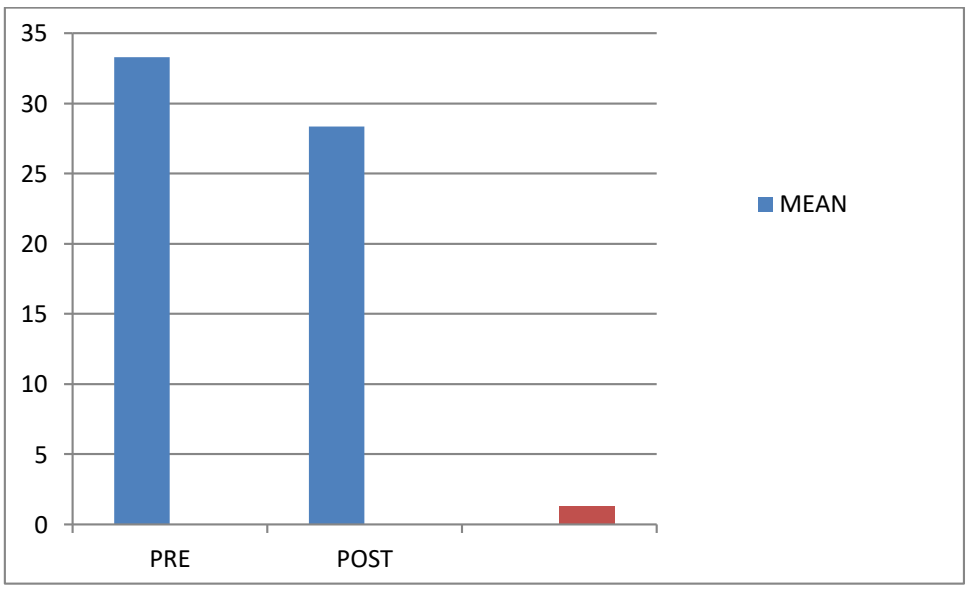
Statistical analysis was performed on the data obtained from 30 patients. Data was analyzed using Social Science statistics. It was a website which working with statistics. Descriptive statistics for all outcome measures were expressed as mean, standard deviations and test of significance such as paired‘t’ test used for comparing within group and comparing between the groups. Data was considered statistically significant with $P<0.05$ and highly significant at $p<0.01$. Pre and post mean difference of BMI shows 33.28 ± 26.64 in pre date collection and 28.36 ± 21.77 in post data collection. As $p<0.05$ there is significant difference between group. Pre and post mean difference values of VMSS shows 2.33 ± 14.67 and 0.93 ± 23.87. This shows a significant difference between two groups.

Group	Mean	Mean Difference	Standard Deviation	"t" Value	"p" Value
Pre Test	33.28	4.29	26.64	4.29812	P<0.05
Post Test	28.36	4.29	21.77		P<0.05

TABLE 3: PAIRED "T" TEST VALUES FOR BMI

Group	Mean	Mean Difference	Standard Deviation	"t" Value	"p" Value
Pre Test	2.33	1.4	14.67	-6.65226	P<0.05
Post Test	0.93	1.4	23.87		P<0.05

TABLE 4: PAIRED "T" TEST VALUES FOR VMSS



GRAPH 1: MEAN VALEUE FOR BMI

Outcome Measures	"t" Value	"p" Value
BMI	4.29812	P<0.05
VMSS	-6.65226	P>0.05

TABLE 5: INDEPENDENT "T" TEST VALUES

DISCUSSION

Obesity, hormonal imbalance, mental health problems such as depression, anxiety, stress, etc are among the most common reasons for individuals to seek treatment with Yoga, Asanas and Pranayama. Yoga encourages one to relax, ease the breath and focus on the present,shifting the balance from the sympathetic nervous system and the flight-or-fight response to the parasympathetic system and the relaxation response. It effects are mainly calming and restorative; it lowers breathing and heart rate, decreases blood pressure, lowers cortisol levels, and increases blood flow to the intestines and vital organs.[9]

Yoga calmness of the mind and create a sense of well-being, feelings of relaxation, improved self-confidence, improved efficiency, increased attentiveness, lowered irritability, and an optimistic outlook on life, it also help us treating the symptoms of PCOD such as obesity, stress and hormonal imbalance. It optimizes the body's sympathetic responses to stressful stimuli and restores autonomic regulatory reflex mechanisms associated with stress. The regular practice of Yoga results in lower anxiety, heart rate, respiratory rate, blood pressure, and cardiac output in students practicing yoga and meditation. Consistent yoga practice improves depression and can lead to significant increases in serotonin levels coupled with decreases in the levels of monamine oxidase, an enzyme that breaks down neurotransmitters and cortisol.[9]

Yoga increases blood flow and levels of hemoglobin and red blood cells which allows for more oxygen to reach the body cells, enhancing their function and reducing stress and improving metabolism.Many yoga asanas and postures lowers the resting heart rate, increases endurance, and can improve the maximum uptake and utilization of oxygen during exercise.[9]

The significant positive effects of yoga in reducing stress, anxiety, and depression have been confirmed.

CONCLUSION

Daily yoga for 30 minutes with 5 Asanas along with meditation and Shavasana helps in weight reduction and stress management which ultimately stabilize the normal function of hypothalmo-pituitary–ovarian axis and cure PCOD.

SUMMARY

A study was conducted to evaluate the effect of Yoga therapy on autonomic function and adrenal fatigue in patients with polycystic ovarian disease. 30 PCOD patients were participated in the study & they were given Yoga therapy for 45mins to one hour per day for 3months with 6 days for week. Before and after the therapy, subjects underwent pre and post outcome measurement. The results showed not only a significant reduction in BMI but also regular period cycle per month.

LIMITATION

- Small sample size
- Age group is limited in 18-30 years

FUTURE RECOMMENDATION

Further research can replicate these findings in other variation such as large group or large age group. In addition, comparison between two groups as well as comparison between exercises and yoga. Lastly, yoga therapy with diet plan.

"EFFECTS OF YOGA THERAPY ON PHYSICAL AND PSYCHOLOGICAL QUALITIES OF LIFE IN PERIMENOPAUSAL WOMENS- AN EXPERIMENTAL STUDY"

[1] Dr. Arvind Kumar, [2]Dr. Rima Pandya, [3] Priyanka Chaudhary

[1] Principal (Ph.D, Musculoskeletal), [2] Assistant Professor [MPT (Musculoskeletal)], [3]Bachelor of Physiotherapy
[1]Venus Institute of Physiotherapy,
[1]Swarrnim Startup & Innovation University, Gandhinagar, India

ABSTRACT

Background: Perimenopausal period is characterized by a continuous decline in ovarian function due to which women are vulnerable to various physical and psychological symptoms affecting quality of life. Currently these symptoms are managed by hormone replacement therapy. However, hormonal therapy can cause complications including malignancy which has resulted in search for various alternative therapies to improve the quality of life (QOL). Yoga is one such alternative therapy shown to enhance the QOL at all stages of human life associated with the chronic illness. There are very few scientific studies regarding the effect of yoga on perimenopause and in this study, we investigated the effects of yoga therapy on physical and psychological symptoms using the standardized questionnaire.

Objective: To study the effect of yoga therapy on physical and psychological symptoms of perimenopause.

Materials and Methods: It is a prospective non-randomized control study of 56 perimenopausal women with 12 weeks of intervention. The subjects were divided in two groups with either yoga therapy [n = 28] or exercise [n = 28] as the interventional tool. The symptoms control and QOL before and after intervention in both the groups were assessed by using the MENQOL which is standardized questionnaire.

Results: The perimenopausal symptoms in all domains were improved by yoga therapy, thus significantly improving the overall QOL compared to the control group.

Conclusion: This study clearly demonstrates the effectiveness of yoga therapy in managing the distressing perimenopausal symptoms. It is easy, safe, non-expensive alternative therapy helping the well-being of perimenopausal women and must be encouraged in the regular management of perimenopausal symptoms.

Key Words: MENQOL questionnaire, perimenopausal QOL, yoga therapy.

INTRODUCTION

Menopause is an important event in the life of a women when reproductive capacity ceases. During this transitional phase, woman exhibits severe and multiple symptoms. Frequently reported symptoms fall into several categories, including physical disturbances such as hot flushes, psychological complaints such as mood swings, and other changes that may impair personal or social interactions and diminish the overall quality of life.[1] It was seen that in 1990, there were an

estimated 467 million women in this state and this number is expected to increase to 1,200 million by the year 2030. [2]

According to the Indian Menopause Society [3] there will be a large increase in the perimenopausal women in India also. Most women in India over the age of 45 years do not understand the changes taking place in their bodies and spend their valuable years of life battling problems and diseases associated with perimenopause. Hence it becomes very important to develop methods and treatment plans to control perimenopausal symptoms and thereby to improve the quality of life of this large group of women.

DIFFERENCE BETWEEN PERIMENOPAUSE AND MENOPAUSE: Perimenopause is the period of a woman's life shortly before the occurrence of menopause. A women's body will begging the process of menopause meaning the hormone production from the ovaries is beginning to decline.

SYMPTOMS: The common symptoms include

- Irregular menses - As ova production in ovary reduces oestrogen production becomes erratic leading to Irregular menses
- Hot Flashes - Due to blood vessels dilation near the skin as a result of reduced estrogen
- Night sweats - Due to hot flashes
- Weight gain - oestrogen deficiency leads to weight gain
- Mood swings - Perimenopause has increased risk of depression
- Breast tenderness - Due to oestrogen induced water retention
- Alteration of blood cholesterol - Elevated oestrogen favours high density lipoprotein which reduces blood cholesterol
- Low bone density - oestrogen is involved in maintaining equilibrium of calcium in bone

BENEFITS OF YOGA IN PERIMENOPAUSAL WOMEN:

1. It relieves stress: yoga can also help women better manage and support Overall mood
2. A consistent practice may reduce blood pressure: Some research shows blood pressure may increase after menopause due in great part to the hormonal changes that take place in the body. Fortunately, yoga is a traditionally utilized antidote. A consistent practice may help promote better oxygenation and blood circulation throughout the body.
3. Yoga promotes good joint health: Research shows a frequent, and consistent yoga practice may help relieve joint pain Not all menopausal women have arthritis, but the condition does increase with age.
4. Yoga may help lead to fewer hot flashes.

NEED OF STUDY

Yoga, the traditional Indian body-mind science has been used effectively in various health disorders affecting almost all the major organ system including cardiovascular, respiratory, neuroendocrine, gastrointestinal and musculoskeletal system. [12-15] Since perimenopause also affects several organ systems, this study is conducted to evaluate the effects of yoga therapy on menopausal symptoms.

AIM

- To study the effects of Yoga Therapy on Physical and Psychological Quality of Perimenopausal Women

OBJECTIVE

- To study the effects of Yoga Therapy on Physical Quality of Perimenopausal Women
- To study the effects of Yoga Therapy on Psychological Quality of Perimenopausal Women

HYPOTHESIS

1) NULL HYPOTHESIS

There are no significant effects of Yoga Therapy on Physical and Psychological Quality of life Perimenopausal Women.

2) EXPERIMENTAL HYPOTHESIS

There are significant effects of Yoga Therapy on Physical and Psychological Quality of life Perimenopausal Women.

METHODOLOGY

Study Design: An Experimental Study
Source Of Data: Near Ahmedabad
Population: Perimenopausal Women
Sampling Method: Random Sampling
Duration Of Study: 3 Months
Sample Size: 56

Materials and Tools Used:

1. Consent form
2. Pen,
3. Pencil
4. Paper
5. Plinth and
6. Pillow
7. Assessment form

Inclusion Criteria:

1. Aged between 40-50 years,
2. Subjects willing to participate,
3. Subjects able to practice yoga or exercise protocols and,
4. Subjects who are having perimenopausal symptoms.

Exclusion Criteria:

1. Women who were already practicing yoga for a month or more,
2. Women with surgical menopause and receiving any kind of hormone therapy and
3. Active psychological disorders or any other medical disorders.

Outcome Measures:

MENOPAUSE-SPECIFIC QUALITY OF LIFE QUESTIONNAIRE (MENQOL) [13]

The self-administered questionnaire utilized in this study included socio-demographic information with menstrual history and the menopause-specific quality of life questionnaire (MENQOL). MENQOL is a self-administered, 'scaled' 29-item survey questionnaire, designed to measure quality of life in menopausal women and also to measure the extent to which an individual is affected by menopausal symptoms. It comprises the four domains, Vasomotor, Psychosocial, Physical and Sexual, which are graded separately.

Procedure:

This interventional study included 56 perimenopausal women divided into two groups. One group practiced yoga therapy (test group, n = 28) and the other practiced a set of physical exercise (control group, n = 28).

The subjects were from local community and recruited through personal contacts with various women's organizations, clubs and self-help groups. The informed oral consent was obtained from the subjects before starting the intervention.

After taking informed consent patients were divided into 2 groups by simple random sampling method and treatment was given for 3 months.

Group A: Subjects of these group received Yoga therapy.

Group B: Subjects of these group received conventional treatment (Exercise Program).

The intervention program in both groups were started by collecting the baseline data, teaching and practicing the respective protocols for 45 minutes every day, follow-ups and collection of post-interventional data after 12 weeks of practice.

FLOW CHART OF THE STUDY PROCEDURE

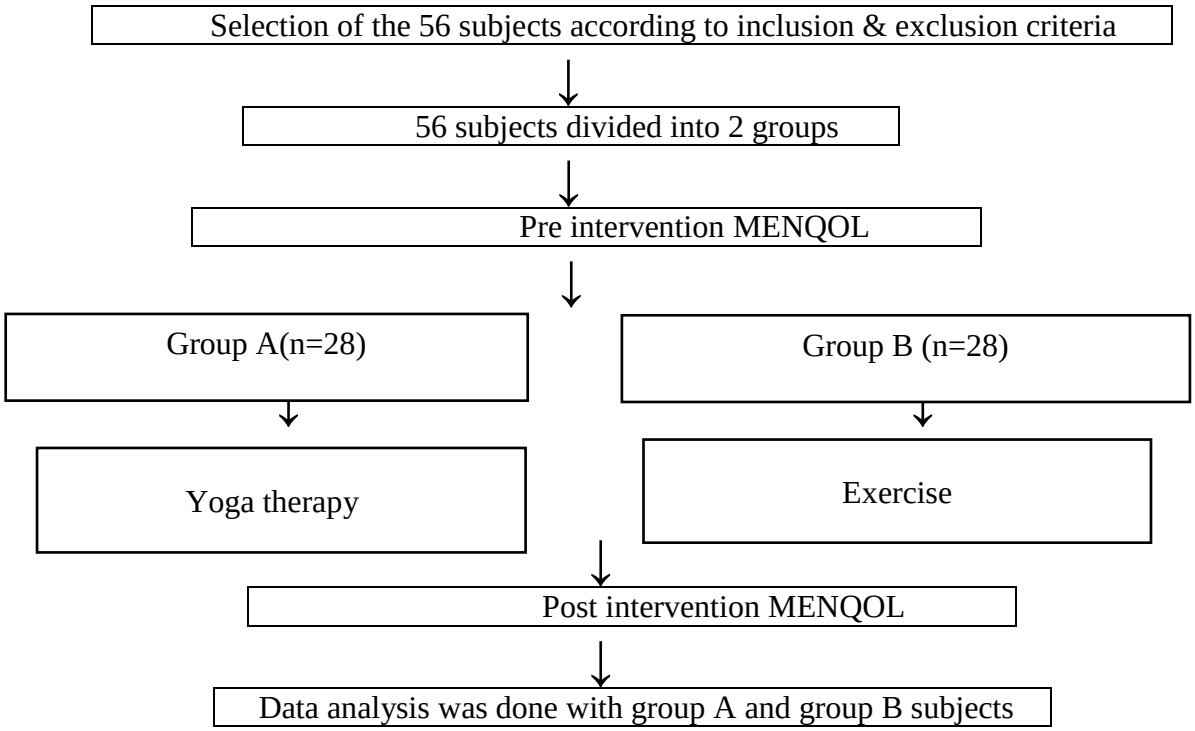

Figure 1: Flow chart of study Procedure

The yoga therapy module used was developed on the basis of Patanjali yoga [16] and Hatha yoga [17] to address the physical, psychological and emotional symptoms with suitable practice of asanas, pranayama and dhyana to result in improvement of overall quality of life. The control group practiced a set of exercise program.[18]

GROUP A: YOGA THERAPY (TEST GROUP)

1. ASANAS (Body postures)

- Sitting: Vajrasana, supta vajrasana Pascimottanasana, Poorvatanasana, Janusirsasana, Upavistakonasana, Baddhakonasana, Vakrasana, Ashvinimudra.
- Standing: Tadasana, Trikonasana, Parshvakonasana.
- Lying on the back (supine): Pavanamuktasana, Padottanasana.
- Lying on the stomach (Prone): Bhujangasana, Shalabhasana, Dhanurasana, Paryankasana.

Figure 2: Asanas

2. PRANAYAMA (Breathing practices)
    - Anuloma-viloma (alternative nostril),
    - Surya bhedana (right nostril),
    - Chandrabhedana (left nostril),
    - Sheetali (through tongue) and
    - Bhramari (honey bee sound during exhalation).

3. Relaxation: Deep relaxation in shavasana (corpse pose).

4. Meditation: 'So Ham' dhyana sitting in meditative postures like swastikasana

GROUP B: EXERCISE INTERVENTION (CONTROL GROUP)

1. Loosening exercises:
    - Sitting: Passive rotation of toes, Toe bending, Ankle bending, Ankle rotation, Knee bending, Knee rotation, Knee cap tightening, Half butterfly, Full butterfly, Neck bending, Neck rotation.
    - Standing: Waist rotation, Wrist rotation, Shoulder rotation.
    - Each one repeated for 10 rounds or 10 rotations.
2. Strengthening exercises (While standing/ Sitting).
    - Wrist — Stretching arms straight in front, make the tight fist, palm facing down, move the fist up and down vigorously from the wrist-10 times.
    - Palms — Holding near the chest bending at the elbow, spread the fingers, and move palms up and down vigorously from the wrist.
    - Fingers — Throwing out the arms in front, give the fingers of both the arms the shape of the hood of cobra, stiffen the entire length of the arms from the shoulder joints to the finger tips till they start trembling-5 times.
    - Elbows — Stretch the arms straight down beside the body, make the tight fist of the palms, and raise the fists forward up to the level of the shoulder with a jerk-10 times.
    - Arms — Make the fists of hands with thumb tucked in, bend the elbow and raise the forearms till they parallel to the ground, push both the arms forward forcefully and vigorously to the level of the shoulder-10 times.

Figure 3: Strengthening Exercise of wrist

- Back — Spreading the legs apart as far as possible, place the hands on the hips bend backward from the waist as far as possible and then forward without bending the knees till head reaches the ground-5 times.
- Thighs — Stretch out the arms facing down straight in front at the shoulder heights, inhaling bend the knees till thighs come parallel to the ground, and then come up exhaling-5 times.
- Calves — Stretch out the arms facing down straight in front at the shoulder heights, inhaling squat and go down as far as possible-5 times. Supine rest 5 to 10 minutes.

RESULT

Statistical analysis

All pre and post data were analyzed by using SPSS Version 16. The individual variables were evaluated to determine the changes in two groups after 12 weeks. The pre and post data of MENQOL questionnaire was analyzed.

The effectiveness was calculated as 'within the group' (yoga and control group), 'between the groups' (yoga vs. control).

Sr. No.	Variables	Yoga	Control
1	Age	47.03 ± 2.56	47.54 ± 2.17
2	BMI	26.08 ± 3.07	26.89 ± 3.45
3	Menstruation regular	6	8
4	Menstruation irregular	13	11
5	No Menstruation	9	9

Table 1: Demographic Data

The largest categories of women were between 46 and 50 years of age. No significant difference was observed between the groups regarding body mass index and menstrual history is shown in Table 1. There was no significant difference between the groups ($P > 0.05$). In the psychosocial domain, large number of women from both the groups (72% to 79%) complained experiencing poor memory as the most prevalent symptom followed by feeling of anxiety, loneliness, depression and impatience. Two of the questions in this domain that is being dissatisfied with personal life and accomplishing less what I used to do were recorded more significantly by control group compared to the yoga group ($P < 0.05$) while other attributes from this domain were all comparable ($P > 0.05$). All the symptoms in the physical domain except for flatulence and muscles and joint pains were comparable in both groups without any significant difference.

Groups	Within group analysis	Mean Difference	Standard Deviation	"t" Value	"p" Value
Group A	Pre-Test Post Test	-1.59	0.64	-8.9	P<0.05
Group B	Pre-Test Post Test	-0.68	0.18	-7.09	P<0.05

Table 2: Paired "t" test values for MENQOL

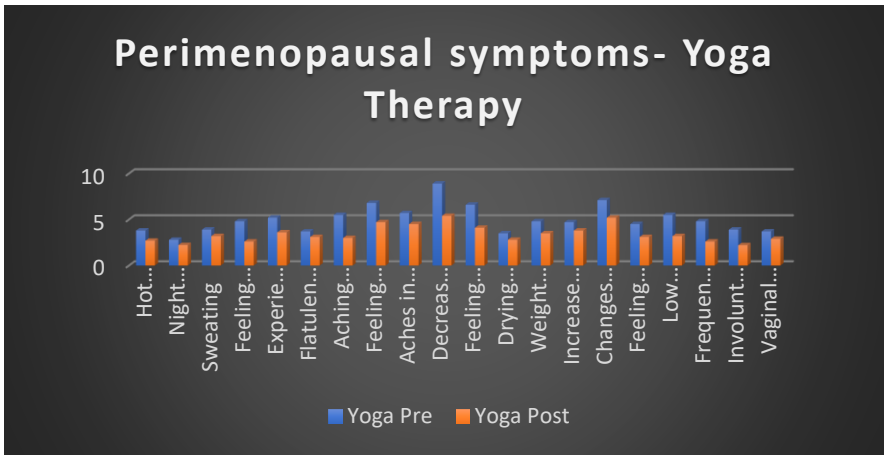

Figure 4: Yoga therapy and effect on Perimenopausal symptoms

The results of effect of yoga therapy (test group) and exercise (control group) on the symptoms of all the two domains are presented in Table 2. In the psychosocial domain, yoga therapy resulted in the significant difference in all the symptoms while exercise therapy resulted in the improvement of four symptoms but failed to provide relief for the remaining symptoms. All the symptoms in the physical domain were significantly improved in yoga group. In control group, highly significant ($P < 0.05$) decrease was observed only in one symptom and moderate in other six symptoms. The symptom of aching in muscles and joints was relieved somewhat after physical exercise and no significant change was observed in the remaining symptoms.

Outcome Measures	"t" Value	"p" Value
MENQOL	-3.48	P<0.05

Table 3: Independent "t" test values

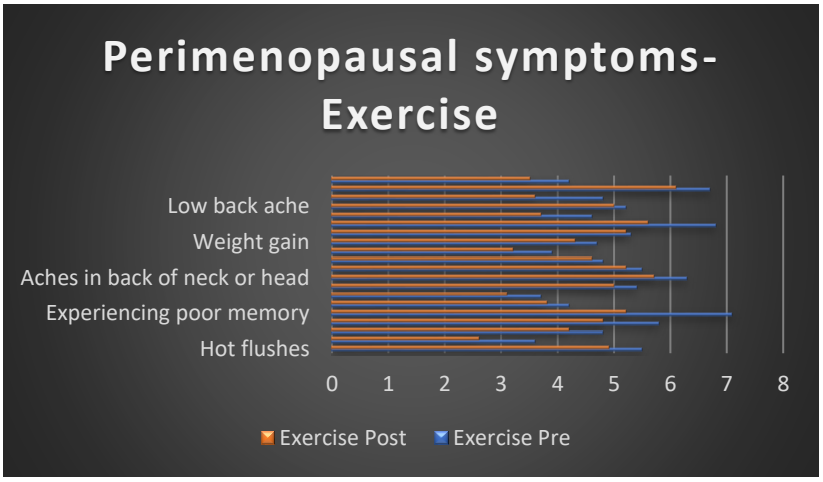

Figure 5: Exercise and effect on Perimenopausal symptoms

The effect size' was greater in yoga therapy group in all domains compared to the control group. 'Between the group effect', there was significant difference between the groups in all domain ($P = 0.53$) [Table 3]. The overall quality of life is measured by the mean of overall scores of each domain and yoga therapy group showed a very significant improvement ($P < 0.05$) compared to control group.

DISCUSSION

The present study thus clearly documents the significant presence of various perimenopausal symptoms in the local population severely affecting the quality of life. Many of these women expressed their distress and helplessness regarding these symptoms, which were seriously interfering in their day-to-day living. Thus, there is a need to search and develop a cost-effective, simple, community-based therapeutic tool to provide symptom relief and to improve health status, and in this perspective yoga has emerged as the appropriate system to deal effectively with issues related to perimenopause.

The present study clearly demonstrates the clinical utility of yoga in significantly reducing the perimenopausal symptom in all domains and thereby improves the overall quality of life. Asanas, pranayama and dhyana, the components of yoga therapy, seem to improve the symptom profile in the all domains through several physiological and biochemical mechanisms. The improvement in physical strength and fitness caused by yoga seems to be related to several factors like muscular strength and endurance, flexibility, cardiorespiratory fitness, body composition and pulmonary function.[19] The intense stretching and muscle conditioning associated with attaining and holding yoga postures increases the skeletal muscle oxidative capacity and decrease glycogen utilization, possibly caused by increased vascularization, increased intramuscular oxygen and glycogen stores or by increased numbers of mitochondria.[20] Yoga practice also may increase the absorption of the calcium from the intestine, stimulate bone remodeling and maintain the load bearing capacity of the bone; reduces the pain in the back of the head, neck, lower back and headache by influencing limbic system modulation of endogenous pain control system.[21]

This impact of yoga seems to be due to its effect on the functioning of nervous system leading to increase in alpha rhythm, intra hemispheric coherence and homogeneity in the brain [22,23] and increase in P 300 phase amplitude [19] all of which seems to enhance the cognitive processes. Menopausal anxiety can be a very difficult symptom to manage, but yoga therapy showed significant improvement compared to physical exercise. Several mechanisms like altered neurotransmitters, changed brain blood flow and brain metabolism and sympathetic activation seems to be responsible for this improvement brought by yoga practice. [24]

Compared to physical exercise group, yoga showed most significant effect in managing the symptoms of vasomotor domain. All the three symptoms in this domain, that is, hot flushes, night sweats and sweating were significantly reduced in the yoga group while no improvement was observed in any of the symptoms in control group. Especially, the improvement in hot flushes through yoga was very rewarding, since this is most difficult symptom to manage and affects the overall quality of life. The vasomotor symptom improvement brought about by yoga intervention seems to be due to its effect in modulating autonomous nervous system with special attention to decreased sympathetic nervous system activation [25] which in turn seems to affect the thermoregulation resulting in vasodilatation and sweating.[26]

The yoga postures used in this study are known to improve the tone of the muscles of pelvic region and enhance the blood circulation to the urogenital area.[27] Thus, yoga improved most of the symptom profile thus contributing significantly in the improvement of overall quality of life. Yoga is relatively simple to learn and is economical, non-invasive with multiple collateral lifestyle benefits. Group and individual practice may also help to improve lifestyle choices and health-related attitudes in part, by enhancing psychological well-being and thereby contributing significantly to chronic disease protection and health promotion.

Though most of the clinical effects of yoga are probably brought about by vagal stimulation and parasympathetic activation, the complete mechanisms underlying the reported benefits remain poorly understood. Clearly, additional high-quality research is warranted to confirm and further explore the putative beneficial effects of yoga in perimenopausal women.

CONCLUSION

This study clearly demonstrates the effectiveness of yoga therapy in managing the distressing perimenopausal symptoms. It is easy, safe, non-expensive alternative therapy helping the well-being of perimenopausal women and must be encouraged in the regular management of perimenopausal symptoms.

ABSTRACT

BACKGROUND: Obesity is a complex disease involving an excessive amount of body fat. Obesity isn't just a cosmetic concern. An obese patient is at risk of developing diseases such as: Coronary heart disease , High blood pressure, Heart failure, Diabetes mellitus, Stroke, Body fat abnormalities, Metabolic syndrome, Menstrual issues, leading to infertility, osteoarthritis, and hypoxemia. Zumba is a fitness program that involves cardio and Latin-inspired dance. Zumba choreography is composed using all or some of sixteen core steps. There are four basic rhythms: salsa, reggaeton, merengue, and cumbia each basic rhythm has four core steps. Aerobic exercise is any type of cardiovascular conditioning. It can include activities like brisk walking, swimming, running, or cycling. Your breathing and heart rate will increase during aerobic activities.

METHODOLOGY: It is a comparative study with pre-test and post-test design. 30 subjects in between the age of 25 to 40 years with obesity were allocated into two different groups. The body mass index (BMI) was

evaluated before and after the test. All the participants performed low-impact aerobic exercise and zumba dance for 4 weeks.

RESULT: At the end of the study, the BMI mean and SD of group1 is 19.512 and 1.839 respectively, whereas the mean BMI and SD of group 2 is 21.158 and 1.727 respectively, and their difference mean BMI and SD is 2.006 and 0.112 respectively.

CONCLUSIONS: At the end of the study, it has been concluded that low-impact aerobic exercise is more effective than Zumba dance on body fat percentage in patients with obesity.

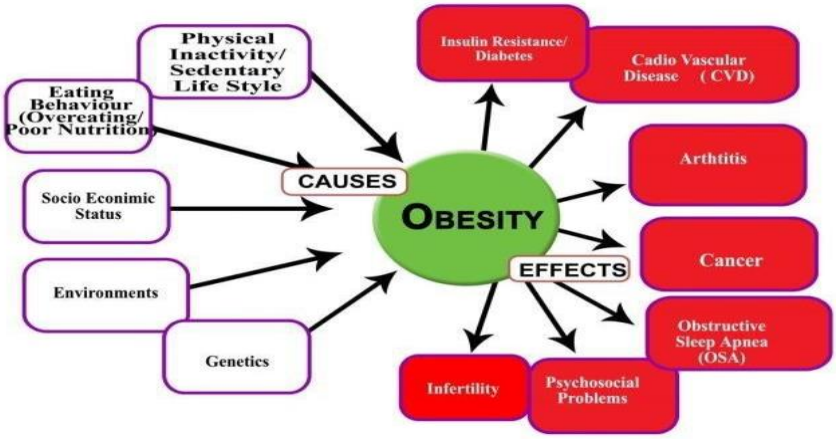
INTRODUCTION

INTRODUCTION

Obesity is a problem affecting many countries of the world irrespective of their levels of development. And it is the major public health condition with comorbidities leading to reduction in life expectancy. Therefore, obesity should not only be seen as a condition that develops through an unhealthy lifestyle but one which creates significant risk to health [1].

Approximately 1.2 billion people in the world are over-weight and at least 300 million people of them are obese. This is a major threat to public health because it increases the risk of chronic diseases. Thus, it is one of the problems that need serious attention .Unhealthy food intake such as those with low nutrient density, sweet drinks and the likes, leading to the condition while changes in the eating and snacking at home, improved sedentary lifestyles and the likes are some of the things that can get rid of it within the population [1].

Besides physical discomfort, an obese individual is at risk of developing diseases such as: Coronary heart



disease, High blood pressure, Heart failure, Diabetes mellitus, Stroke, Body fat abnormalities, Metabolic syndrome, Menstrual issues, leading to infertility, osteoarthritis, and hypoxemia [2].

Fig 1: Effects and causes of obesity

Obesity has, in the recent years become a global phenomenon. This has serious implications, particularly in countries like India, where one-fourth of the population is diabetic. Factors such as age, sex, ethnicity, and muscle mass can influence the relationship between BMI and body fat. Also, BMI doesn't distinguish between excess fat, muscle, or bone mass, nor does it provide any indication of the distribution of fat among individuals [2].

Common specific causes of obesity include: genetics, which can affect how your body processes food into energy and how fat is stored, growing older, which can lead to less muscle mass and a slower metabolic rate, making it easier to gain weight, not sleeping enough, which can lead to hormonal changes that make you feel hungrier and crave certain high-calorie foods, pregnancy, as weight gained during pregnancy may be difficult to lose and might eventually lead to obesity [3].

Certain health conditions can also lead to weight gain, which may lead to obesity. These include:

polycystic ovary syndrome (PCOS), a condition that causes an imbalance of female reproductive hormones, Prader-Willi syndrome, a rare condition present at birth that causes excessive hunger, Cushing syndrome, a condition caused by having high cortisol levels (the stress hormone) in your system, hypothyroidism (underactive thyroid), a condition in which the thyroid gland doesn't produce enough of certain important hormones, osteoarthritis (OA) and other conditions that cause pain that may lead to reduced activity [4].

Depression can sometimes lead to weight gain, as some people may turn to food for emotional comfort. Certain antidepressants can also increase the risk of weight gain. Quitting smoking is always a good thing, but quitting may lead to weight gain too. In some people, it may lead to excessive trusted source weight gain. For that reason, it's important to focus on diet and exercise while you're quitting, at least after the initial withdrawal period. Medications, such as steroids or birth control pills, can also raise your risk for weight gain [5].

Obesity prevention requires a complex approach, including interventions at community, family, and

individual levels.

Obesity can lead to more than simple weight gain. Having a high ratio of body fat to muscle puts strain on your bones as well as your internal organs. It also increases inflammation in the body, which is thought to be a risk factor for cancer. Obesity is also a major risk factor for type 2 diabetes [5].

Obesity has been linked to a number of health complications, some of which can be life threatening if not treated: type 2 diabetes, heart disease, high blood pressure, certain cancers (breast, colon, and endometrial), stroke, gallbladder disease, fatty liver disease, high cholesterol, sleep apnea and other breathing problems, arthritis, infertility.

A sedentary lifestyle plays a significant role in obesity. Worldwide there has been a large shift towards less physically demanding work, and currently at least 30% of the world's population gets insufficient exercise. This is primarily due to increasing use of mechanized transportation and a greater prevalence of labor-saving technology in the home. In children, there appear to be declines in levels of physical activity), likely due to safety concerns, changes in social, and inadequate urban design. World trends in active leisure time physical activity are less clear [5].

The main treatment for obesity consists of weight loss via lifestyle interventions, including prescribed diets and physical exercise. Although it is unclear what diets might support long-term weight loss, and although the effectiveness of low-calorie diets is debated, lifestyle changes that reduce calorie consumption or increase physical exercise over the long term also tend to produce some sustained weight loss, despite slow weight regain over time[6] .

Although 87% of participants in the National Weight Control Registry were able to maintain 10% body weight loss for 10 years, the most appropriate dietary approach for long term weight loss maintenance is still unknown. In the USA, intensive behavioral interventions combining both dietary changes and exercise are recommended. Intermittent fasting has no additional benefit of weight loss compared to continuous energy restriction. Adherence is a more important factor in weight loss success than whatever kind of diet an individual undertakes.

Several hypo-caloric diets are effective. In the short-term low carbohydrate diets appear better than low fat diets for weight loss. In the long term, however, all types of low-carbohydrate and low-fat diets appear

equally beneficial [6].

Exercise is also like a medicine in that it has an appropriate dosage, indications, contraindications, and adverse effects associated with its use. The importance of proper technique in strength training and flexibility exercise, the appropriate guidance in aerobic activity progression, the role of kinetic chain and movement pattern analysis are all essential to an accurate and safe exercise prescription for obese people[7].

Looking at the state of sport development today, it is an advanced state, especially the aerobic dance that is common among young generation. Other benefits this gives the body include increasing the work rate of the heart increasing muscle strength, burning fat, etc. aerobic dance is one of the most common exercise practices in the world. This is because there have been many gymnastic club have been established and now almost every agency or office also organizes aerobic dance exercises.

The fact that low-impact aerobic dance exercise has been well adapted to keep and improve health in a wide range of the population. And that regular aerobic dance exercise can prevent obesity and build muscles [8].

Zumba is a dance-based activity based on a variety of Latin dance styles :salsa, reggaeton, cumbia, etc, and including steps in multiple directions. Also, it is an alternative activity that helps the body in burning excessive fats and a systematic review has shown that zumba has beneficial effects on reducing body weight. Therefore, both exercises help in reducing the body fat percentage [9].

The WHO recommended the body mass index (BMI) as a simpler marker to reflect total body fat and is used as a measure of over-weight and obesity [10]. This can also be used to determine the ideal body weight.

The relationship between BMI, BF%, and body fat distribution were different between populations.Hence, the subjects in this study were grouped based on those that have mild or severe obesity by calculating the BMI of each participant [11]..

REVIEW OF LITERATURE

REVIEW OF LITERATURE:

1.Comparison of the effects of Yoga, Zumba, Aerobic exercises in controlling blood pressure in Indian population. Jerusha Santa Packyanathan and S.Preetha Et Al(2009)[12].

This study is designed to analyze the effects of Yoga, Zumba, and Aerobic exercises in controlling blood pressure and to determine which of these three is better to treat hypertension without using hypertensive drugs. It is concluded that comparing the three activities, it is found that the drop in the blood pressure was greatest among participants who practiced yoga, followed by participants who performed Zumba dance and finally among participants of aerobics.

2. The effectiveness of an 8 weeks Zumba program for weight reduction in a group of over-weight and obese patients. Charles Miscallef Et Al(2014)[13].

The study investigated the before–after effects of a Zumba program on the weight and body mass index (BMI) of 36 females, mean age 34.25 ± 8.50 years and mean BMI 32.98 ± 5.32 kg/m2. Methods: The intervention involved 16 hourly Zumba sessions held twice weekly over 8 weeks. The exercises comprised a mixture of merengue, salsa, reggaeton and bachata with warm-up and cool-down activities. They were of low-impact style, but were maintained at vigorous intensity that was still bearable for the obese subjects.

3 .An 8 weeks exercise intervention based on Zumba improves Aerobic fitness. Anne A Delextrat, Sarah Warner Et Al(2014)[14]. The objective of this study was to investigate the effects of Zumba on physiological and psychological outcomes in healthy women. Zumba provided significant positive changes in maximal aerobic fitness (+3.6%), self-perception of physical strength (+16.3%) and muscular development (+18.6%), greater autonomy (+8.0%), and purpose in life (+4.4%). No significant changes were observed in the control group. These results highlight that Zumba is beneficial to improve fitness and well-being in healthy women, but does not change body composition.

4. Effects of Pilates and Aerobic exercises on blood pressure, heart rates, and serum lipids in sedentary females . SemraSetin, CumaEce, Murat Sen Et Al(2019)[15].

The aim of this study was to determinate the effects of 12 weeks pilates and aerobic exercise on blood pressure, heart rates, and blood serum lipids in sedentary females. 18 sedentary women with an average age of 45.52 years, height of 161.14 cm and weight of 72.5 kg have been selected and put through a plates and aerobic exercise programmer one hour a day for three days a week. In this study, together Pilates and aerobic exercise was effective in sedentary women with initially high total cholesterol, triglyceride, and Low density lipoprotein levels. At end of the cycles of 12 weeks Pilates and aerobic exercises, has a positive effect of waist to hip ratio, blood pressure, and heart beats in sedentary females. Risk of heart and vascular disease is reduced. Pilates and aerobic exercises are recommended for decrease risk.

5. Effects of Zumba fitness program on body composition of women. Adriana Ljubojevic Et Al (2014)[16].

The aim of this research was to determine the effects of zumba fitness program on changes of women body composition. 12 women aged 25-35 participated in the conducted research. The zumba fitness program was estimated after eight weeks of exercise, total of 24 training sessions. Body weight, fat percentage, fat mass, fat free mass and total body water were measured at the beginning and at the end of the research.

6. Zumba dancing and Aerobic exercise can improve working memory, motor function, and depressive symptoms in female patients with Fibromyalgia. Ebrahim Norouzi Et Al(2019)[17].

This study compares the impact of two different interventions, aerobic exercise training and Zumba dancing, on working memory, motor function and depressive symptoms among female patients with FM. The design also included a control condition. Method: A total of sixty middle-aged female patients with

FM (mean age: 35.76 years) and undergoing standard care took part in the study. Participants were randomly assigned to one of the following three conditions: aerobic exercise training, Zumba dancing, or control.

7. Effects of the Aerobic Exercise Program with music on the body composition and subcutaneous fat of young women: A Systematic Review. Milijan Hadzovic Et Al (2020)[18].

The aim of this research was to determine the effects of aerobic exercise to music on body composition and

subcutaneous fat among young women. The research results confirm the positive influence of aerobic exercise to music on the parameters of body composition and subcutaneous fat among young women, irrespective of the overall duration of the exercise programs, with the conclusion that programs lasting up to 12 weeks are more effective when it comes to the decrease and maintenance of body weight, fat reduction, increase in muscle tissue, and lead to an improvement in aerobic abilities.

8. Benefits of Zumba Fitness among sedentary adults with components of the metabolic syndrome: A pilot study. Araneta MR, Tanori D Et Al (2014)[19].

The aim of this study was to assess the feasibility of a 12 week Zumba Fitness® pilot study and temporal changes in components of the metabolic syndrome (MetS) among sedentary, obese women with at least two MetS components. This twelve week Zumba Fitness® intervention showed good feasibility and adherence, with significant reductions in blood pressure and triglyceride levels, despite minimal weight loss.

NEED OF THE STUDY

NEED OF THE STUDY

NEED OF THE STUDY

This study is required to determine the significant effects of Zumba dance and low-impact Aerobic exercises on body fat percentage in patients with obesity. With the increasing demand of Zumba dance, it is important to have knowledge about its effects on body fat percentage in obese patients in comparison to aerobic exercise.

AIM AND OBJECTIVES OF THE STUDY

AIM AND OBJECTIVES OF THE STUDY

AIM OF THE STUDY:

To determine the effect of low-impact aerobic exercise and Zumba dance on body fat percentage in

patients with obesity.

OBJECTIVE OF THE STUDY:

- To determine the effect of low-impact aerobic exercise on body fat percentage in patients with obesity.
- To determine the effect of Zumba dance on body fat percentage in patients with obesity.
- To compare the effect of both of the exercises on body fat percentage in patients with obesity and to determine which of these two is better for obese patients.

HYPOTHESIS

NULL HYPOTHESIS:

There will be no significant difference between the effects of low-impact aerobic exercise and zumba dance on body fat percentage in patients with obesity.

ALTERNATE HYPOTHESIS:

There will be significant difference between the effects of low-impact aerobic exercise and zumba dance on body fat percentage in patients with obesity.

METHODOLOGY

METHODOLOGY

STUDY DESIGN: A Comparative Study

SOURCE OF STUDY: Classes conducting Zumba and Aerobics

POPULATION: Subjects with obesity of age group 25 to 40 years

SAMPLING METHOD: Convenient sampling

DURATION OF STUDY: 1 Month

TREATMENT DURATION: 3 sessions per week for 4 weeks

SAMPLE SIZE: 30

A) GROUP 1: 15

B) GROUP 2: 15

METHOD OF SELECTION OF SUBJECTS:

INCLUSION CRITERIA:

- Age group-25 to 40 years
- Subjects with obesity

EXCLUSION CRITERIA:

- Patients suffering from back pain
- Patients having any previous spinal cord injury
- Patients with joint pain
- Patients with any neuromuscular disorder
- Patients with any cardiovascular disorder

MATERIALS AND TOOLS USED:

1. Pen, pencil, paper
2. Consent form
3. Eraser
4. Measuring tape
5. Weighing machine

Fig :2

Fig :3

OUTCOME MEASURES:

BMI (BODY MASS INDEX)

Body mass index (**BMI**) is a value derived from the mass (weight) and height of a person. The BMI is defined as the body mass divided by the square of the body height, and is expressed in units of kg/m^2, resulting from mass in kilograms and height in meters. The BMI is a convenient rule of thumb used to broadly categorize a person as underweight, normal weight, overweight, or obese based on tissue mass (muscle, fat, and bone) and height. Major adult BMI classifications are underweight (under 18.5 kg/m^2), normal weight (18.5 to 24.9), overweight (25 to 29.9), and obese (30 or more).When used to predict an individual's health, rather than as a statistical measurement for groups, the BMI has limitations that can make it less useful than some of the alternatives, especially when applied to individuals with abdominal obesity, short stature, or unusually high muscle mass.

Classification	BMI (kg/m^2)	Risk of associated illness
Underweight	< 18.5	Low (but greater risk of other clinical problems)
Normal range	18.5–24.9	
Overweight	> 25.0	Average
Pre-obese	25.0–29.9	Increased
Obese class I	30.0–34.9	Moderate
Obese class II	35.0–39.9	Severe
Obese class III	> 40.0	Very severe

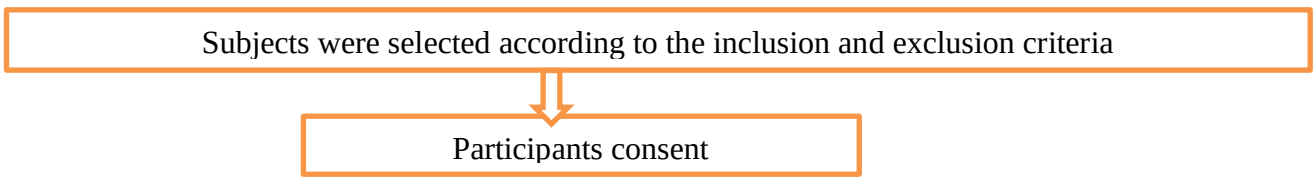
Table no.1: Classification of obesity

The clinical limitations of BMI should be considered. BMI is a surrogate measure of body fatness because it is a measure of excess weight rather than excess body fat. Factors such as age, sex, ethnicity, and muscle mass can influence the relationship between BMI and body fat. Also, BMI does not distinguish between excess fat, muscle, or bone mass, nor does it provide any indication of the distribution of fat among individuals. The following are some examples of how certain variables can influence the interpretation of BMI:

- On average, older adults tend to have more body fat than younger adults for an equivalent BMI.
- On average, women have greater amounts of total body fat than men with an equivalent BMI.
- Muscular individuals, or highly-trained athletes, may have a high BMI because of increased muscle mass

PROCEDURE:

All the subjects for the study were selected according to the inclusion criteria. Research objectives, procedure, and benefits are fully explained to the patients. Before the experiment, subject's measurements such as height, and weight were carried out. Mechanical scales and measuring tape were used in order to measure weight and height respectively. After that, the subjects were parted into two groups.



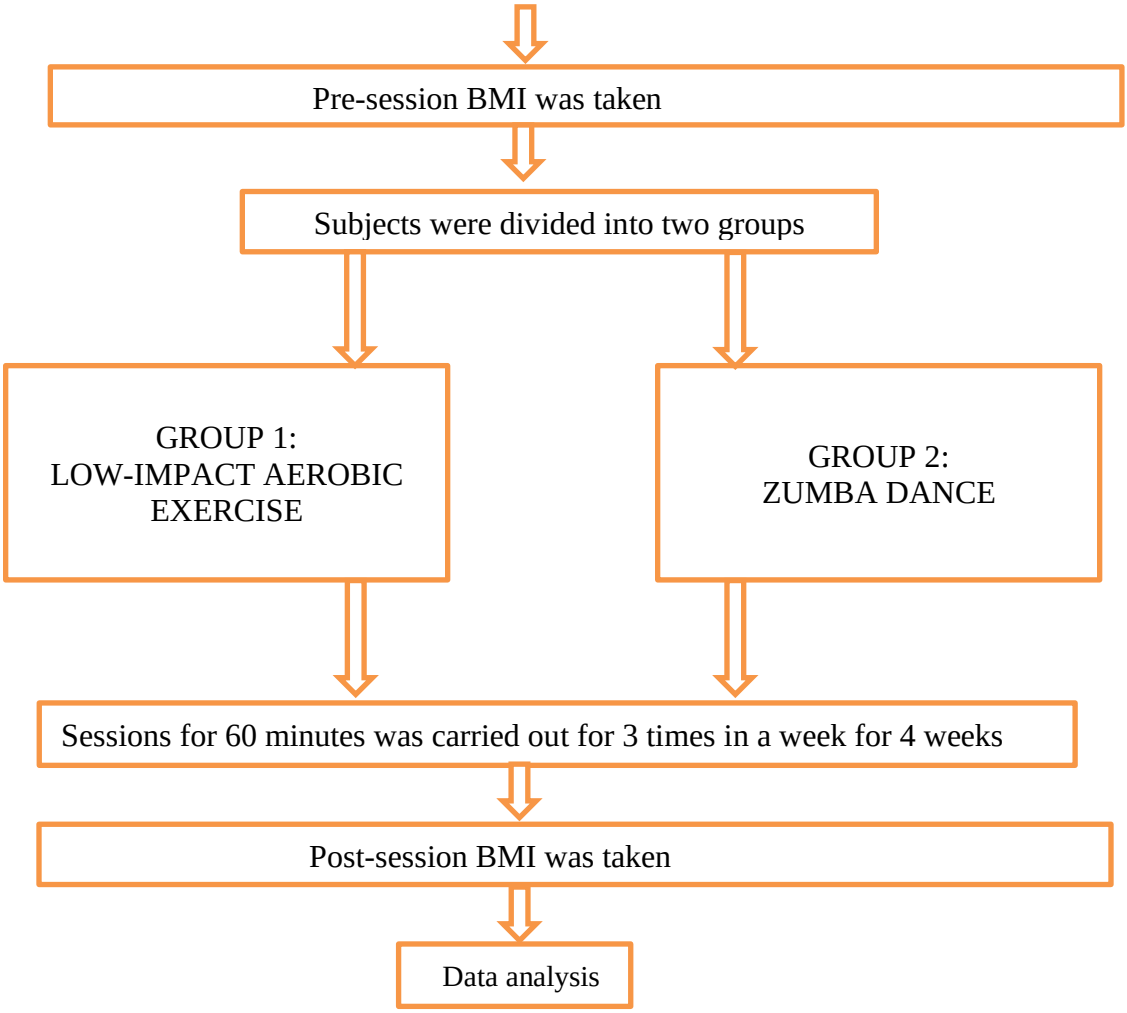


Fig no. 4: flowchart of study procedure

GROUP 1: Low-impact aerobic exercise:

The exercise was choreographed by an experienced Aerobic instructor. The participants were explained the procedures for implementing this treatment after which consent form was filled. The treatment period was made up of 3 sessions in a week for 4 weeks and each session lasted for 1 hour including 10 – 15 minutes warm-up phase, 30 – 35 minutes low-impact aerobic exercise and ended up with a 5 – 10 minutes cooling phase.

The aerobic exercises includes :

>Walking

>Jogging

>Cycling

>Stair climbing

>Skipping

GROUP 2: Zumba dance:

The exercise program was led by a Zumba instructor and just like what was done in the low-impact aerobic dance exercise, the participants were given the explanation regarding the procedures for implementing the treatment, its duration and location. The treatment period was made up of 3 sessions in a week for 4 weeks and each session includes three dance steps along with 15 minutes of rest period during the session.

The zumba dance includes the main three dance steps:

>Salsa steps: Dance with an 8 beat pattern:

Beat 1: step forward with your left foot
Beat 2: shift your weight to your right foot
Beat 3: step back to your starting position with your foot
Beat 4: pause
Beat 5: step back with right foot
Beat 6: shift your weight to your left foot
Beat 7: step your right foot back to your starting position
Beat 8: pause.
This dance step was performed for 15 minutes continuously followed by 5 minutes rest.

>Merengue steps: Dance with stepping on each beat:

Beat 1: shift your hips to the right and stomp with your left foot
Beat 2: shift your hips to the left and stomp with your right foot
This dance step was performed for 15 minutes continuously followed by 5 minutes rest.

>**Reggaeton steps:** Dance with stepping on each beat:

Beat 1: take a wide step with your left foot

Beat 2: tap your right foot next to your left foot while leaning to the right

Beat 3: take a wide step with your right foot

Beat 4: tap your left foot next to your right foot

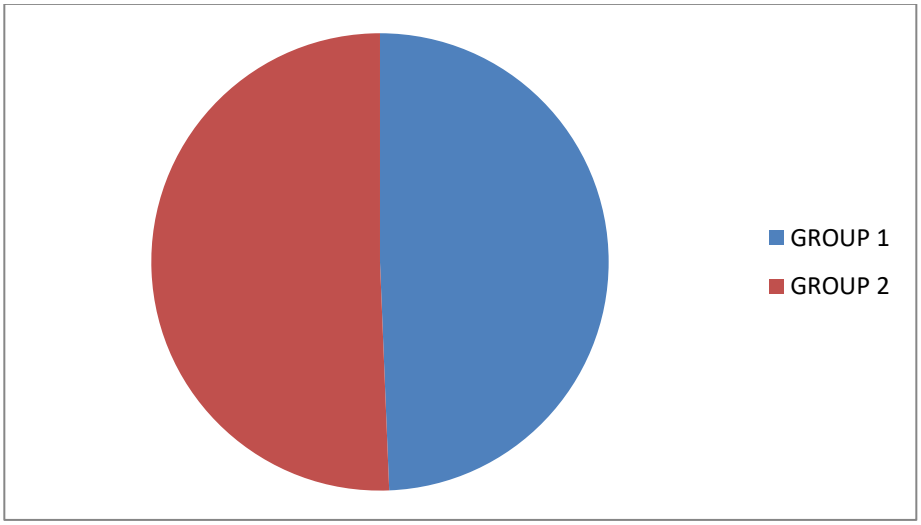
This dance step was performed for 15 minutes continuously followed by 5 minutes rest.

RESULTS

RESULTS

Table 2: Age distribution of both groups

	NO OF PATIENTS	MEAN AGE	SD
GROUP 1	15	50.033	3.058
GROUP 2	15	51.333	3.498

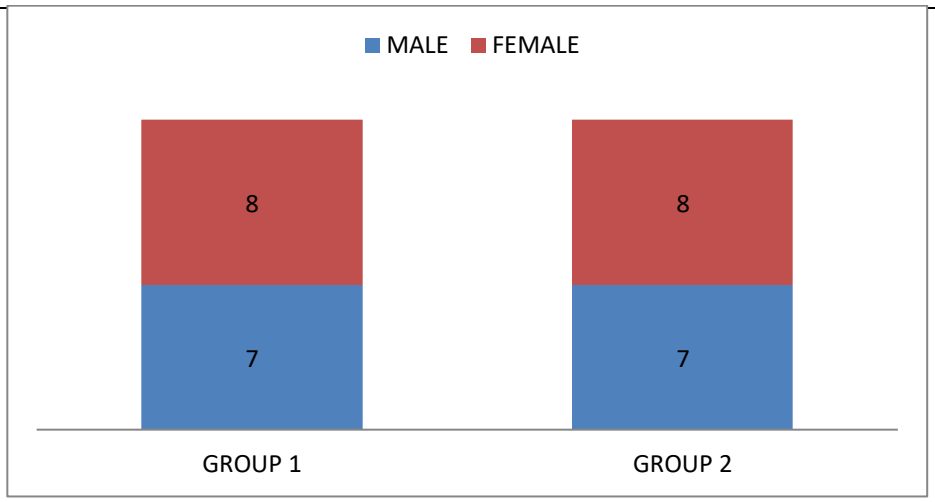


(Graph1: Age distribution in both groups)

The above pie chart represents the mean age of group 1 and group 2. It depicts that the mean age of group 1 and group 2 are 50.033 and 51.333 respectively.

Table 3: Gender distribution in both groups

	MALE	FEMALE	TOTAL
GROUP 1	7	8	15
GROUP 2	7	8	15

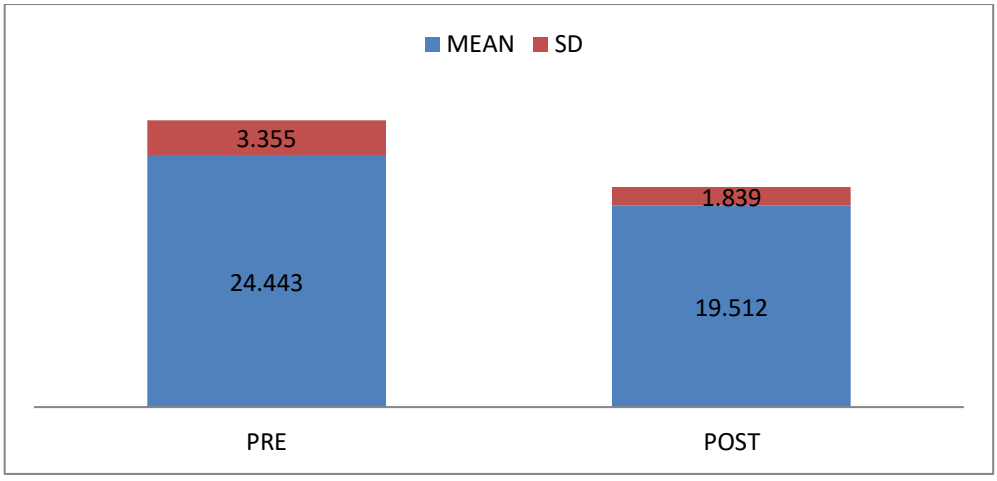


(Graph 2: Gender distribution in both groups)

The above bar graph represents the gender distribution in group1 and group 2. It shows that the number of male and female in group 1 and group 2 are 7 and 8 respectively.

Table 4: Comparison of pre and post BMI mean in group 1

GROUP 1 BMI				
	MEAN	**SD**	**DF**	**T-value**
PRE	**24.443**	**3.355**	**14**	**4.985**
POST	**19.512**	**1.839**		

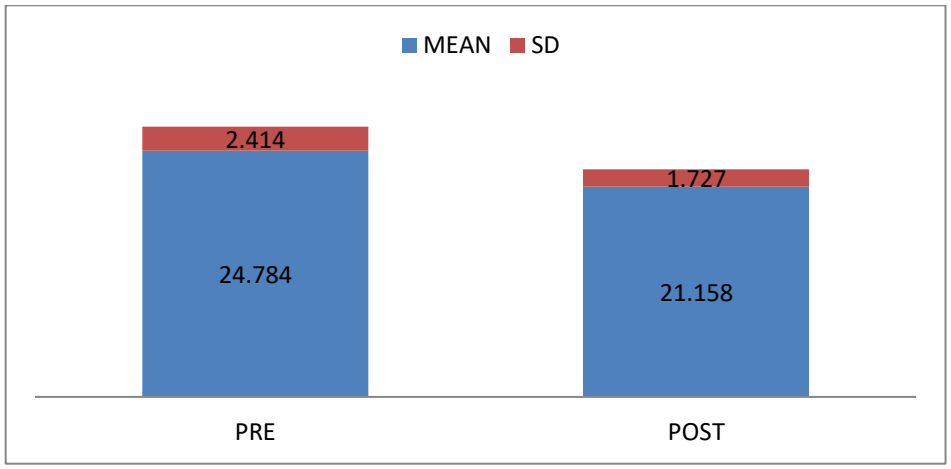


(Graph 3: comparison of pre and post-test BMI mean in group1)

The graph 3 represents the comparison of pre-test and post-test BMI mean in group 1. It shows that the pre-test BMI mean and standard deviation are 24.443 and 3.355 respectively .Whereas, the post-test BMI mean and standard deviation are 19.512 and 1.839 respectively.

Table 5: Comparison of pre and post BMI mean of group 2

GROUP 2 BMI				
	MEAN	**SD**	**DF**	**T-value**
PRE	**24.784**	**2.414**	**14**	**4.749**
POST	**21.158**	**1.727**		

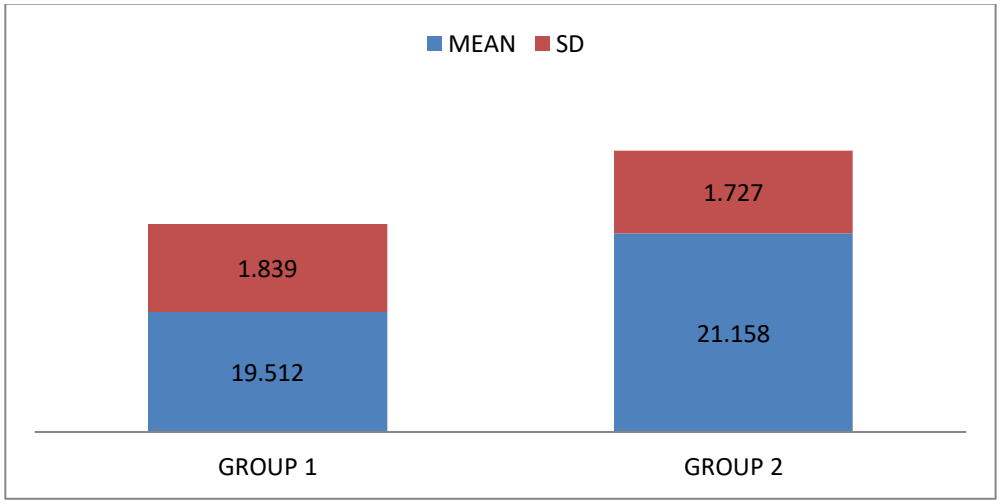


(Graph 4: Comparison of pre and post-test BMI mean in group 2)

The above graph represents the comparison of pre-test and post-test BMI mean in group 2. It shows that the pre-test BMI mean and standard deviation are 24.784 and 2.414 respectively .Whereas, the post-test BMI mean and standard deviation are 21.158 and 1.727 respectively.

Table 6: Comparison of post-test BMI mean in group 1 and group 2

POST BMI OF BOTH GROUPS					
	MEAN	**SD**	**DF**	**T-value**	**SIG**
GROUP 1	**19.512**	**1.839**	**28**	**2.540**	**0.01**
GROUP 2	**21.158**	**1.727**			



(Graph 5: Comparison of post-test BMI mean in group 1 and group 2)

The above bar graph depicts the comparison of post-test BMI mean in group 1 and group 2. It shows that the BMI mean and standard deviation in group 1 are 19.512 and 1.839. And in group 2, the mean and standard deviation are 21.158 and 1.727 respectively. It clearly represents that the subjects in group 1 showed a significant reduction in BMI in comparison to the subjects in group 2.

DISCUSSION

DISCUSSION

The result of the study conclude that the use of low-impact aerobic exercise and zumba dance are both effective for reducing the BMI of patients with obesity. The study rejects the null hypothesis:- There is no significant difference between the effect low-impact aerobic exercise and zumba dance on BMI of patients with obesity, and accepts the experimental hypothesis:- There is significant difference between the effect of low-impact aerobic exercise and zumba dance on BMI of patients with obesity [20].

According to the study done by Jerusha Packyanathan and S.Pretha in 2020, it was concluded that, hypertension can be controlled without drug intervention. Exercises like Aerobics, Zumba dance and yoga are other interventions that can bring about a fall in hypertension. They help reduce the morbidity and mortality from cardiovascular diseases which are now on top of the lists. Comparing the three activities, it is found that the drop in the blood pressure was greatest among participants who practiced yoga, followed by participants who performed Zumba dance and finally among participants of aerobics. However, it should be noted that all the three activities produce no side effects which is evident while using drug interventions for prolonged periods. Obesity and HBP are almost risk associated with coronary artery disease and the same result is shown in thus study [21].

According to the study done by Charles Miscallef in 2014, it was investigated the before–after effects of a Zumba program on the weight and body mass index (BMI) of 36 females, mean age 34.25 ± 8.50 years and mean BMI 32.98 ± 5.32 kg/m2. Methods: The intervention involved 16 hourly Zumba sessions held twice weekly over 8 weeks. The subjects had statistically significant decreases and large effects for weight and BMI: 2.13 kg, t(35) = 13.77, P\0.0005, d = 2.30, and 0.83 kg/m2, t(35) = 13.02,

P\0.0005, d = 2.17, respectively [22].

According to a study done by Anne A Delextrat and Sarah Warner in 2014, it was concluded that Zumba provided significant positive changes in maximal aerobic fitness (+3.6%), self-perception of physical strength (+16.3%) and muscular development (+18.6%), greater autonomy (+8.0%), and purpose in life (+4.4%). No significant changes were observed in the control group. In addition, some psychological changes were significantly correlated to body fat at baseline, and changes in fitness. These results highlight that Zumba is beneficial to improve fitness and well-being in healthy women, but does not change body composition [23].

CONCLUSION AND SUMMARY

CONCLUSION:

The result of the study conclude that the use of low-impact aerobic exercise and zumba dance are both effective for reducing the BMI of patients with obesity. But the result says that the low-impact aerobic exercise is much more effective as compared to zumba dance.

SUMMARY:

During the course of the study, it has been concluded that low-impact aerobic exercise and zumba dance are both helpful in reducing BMI of obese patients. But it is seen that the group performing low-impact aerobic shown a significant reduction in BMI of patients with obesity than the group performing zumba dance.

LIMITATIONS

Limitations:

- Limited sample size
- Specified age group of 25 to 40 years
- No follow ups

Future recommendation:

- Study can be done on large population
- Study can give long term effects
- Study can be done on older people

[1]Swarrnim Startup & Innovation University, Gandhinagar

ABSTRACT

BACKGROUND: Chronic low back pain is defined as pain, muscle tension or stiffness localized below the costal margin and above the inferior gluteal folds, persists for 12 weeks or more. For treating Chronic Low back pain various techniques are available. Basic aim is to compare the effect of Pilates exercise and MFR technique in patients with chronic low back pain.

METHODOLOGY: After taking informed, written consent patients were divided into 2 groups by simple random sampling method. Group A received Pilates exercise plus conventional treatment and Group B received MFR technique plus conventional treatment. Both groups received treatment 4 sessions per week for 4 weeks. Pre and post intervention NPRS were measured. Data were analyzed with both groups.

RESULT: As the data followed normal distribution, parametric tests were used. Paired t test was applied to analyze pre and post outcome measures between both groups. Both the groups showed significant improvement in NPRS scores in within group analysis ($p<0.05$) but there was no statistically significant difference found in NPRS at the end of 4 weeks in between groups analysis ($p>0.05$).

CONCLUSIONS: The present study concludes that Pilates exercise along with conventional treatment and MFR technique along with conventional treatment, both are equally effective in reducing pain in patients with Chronic Low Back Pain.

KEY WORDS: Pilates exercise, MFR technique, Chronic low back pain.

INTRODUCTION

Chronic low back pain is defined as a pain, muscle tension or stiffness localized below the costal margin and above the inferior gluteal folds, which persists for 12 weeks or more[1] Exercise training has collectively been shown to be effective in reducing pain when compared with non-exercise training-based treatments in adults. [2] Risk factor of chronic low back are female sex, middle age, sedentary lifestyle as well as strenuous physical activity, occupational overload, smoking and obesity. [3]

Pilates exercise used for the core strengthening, posture and breathing pattern also. These exercises aim to improve static and dynamic stability, posture and ADLs. [4] The use of specialized Pilates exercise requirements are spring resistance, such as reformer has also recommended for Chronic Low Back Pain (CLBP) patients. [5] It has recommended in management of people with CLBP, this type of exercise helpful to strengthen deep and stabilizing muscle which support to the lumbar spine (transverse abdominis muscle). The muscles are inhibited in people with CLBP. [6]

Myofascial release (MFR) used for manual medicine which include the application of low-load, long duration of stretch to the myofascial complex with intent to restore optimal length of fascia-tissue, reduce pain and improve functional ability. Applied combined intervention of MFR with other therapeutic appear like muscular energy, soft tissue, high velocity-low amplitude thrust and cranial sacral techniques. [7]

Advance stage of research includes the progression towards more functional task giving to the patient to activate of deep muscle and global trunk muscles. [8] In recent years, increased interest in the issues fascia, which until recently was neglected in the etiology of LBP. At the same time as term is defined as fascial system- a network that has ability to transfer forces, where separate elements manually interact and form complex involved in traversing.

Those patients which suffering from long time CLBP gives rise to, restrictions within the fascial tissues. The combination of different structures of the complex lumbar-pelvic- hip joint may cause the source of pain is a considerable distance from the origin of pain. [9] Long standing limitation of motion occurring in people with risk factors for development of LBP, it's cause restrictions within the fascial tissue. Restrictions can cause abdominal tension which lead to an increase in excitability of receptors located in the fascia, bone structures involve in wrong direction, thus leading to excessive compression in the intervertebral joints. As a result, dysfunction and pain.[10]

NEED OF THE STUDY:

According to research done in past the Myofascial release and Pilates both methods individually when given shown beneficial effects but no studies were compared these methods. Both methods are individually effective in low back pain according to the previous research article but which one is more beneficial to reduce pain is not shown till now. Our need of the study is to compare both treatments so it is helpful in clinical practice for better treatment outcome.

AIM AND OBJECTIVES:

AIM: - To compare effects of Pilates exercise and MFR in people with CLBP.

OBJECTIVES: -

1. To find out the effects of Pilates exercise in CLBP on pain

2. To find out the effects of MFR in CLBP on pain

3. To compare effects of Pilates exercise and MFR on pain

HYPOTHESIS:

1. NULL HYPOTHESIS:

- There is no significant difference between effect of MFR and Pilates in chronic low back pain patients.

2. **ALTERNATIVE/ RESEARCH HYPOTHESIS:**

- There is significant difference between effect of MFR and Pilates in chronic low back pain patients.

METHODOLOGY:

STUDY DESIGN**:** A Comparative study

SOURCE OF DATA: OPD of Venus Institute of Physiotherapy

POPULATION: Chronic low back pain patient (Age between 30 to 50 years)

SAMPLING METHOD: Simple random sampling

DURATION OF STUDY: 4 weeks

TREATMENT DURATION**:** 4 sessions per week for 4 weeks

SAMPLE SIZE**:** 30 (Calculated via following formula) [11]

$N = 4\,\Sigma^2\,(Z_\alpha + Z_\beta)^2 / D^2$

N = Sample size

Σ = Standard Deviation

Z_α = Level of desired significance (1.96)

Z_β = Desired Power (0.84 for 80% power)

D = Effect size (Mean difference)

A) Group A: 15

B) Group B: 15

METHOD OF SELECTION OF SUBJECTS: -

INCLUSION CRITERIA:

- Patient's willingness to participate
- Both males and females
- Age group between 30-50 years
- Patient having chronic low back pain with more than 3 months
- Without identifiable specific anatomical/neurological factors

EXCLUSION CRITERIA:

- Any orthopedic or neurological condition of lumbar spine

- Patient with previous spinal injury
- Spondylolisthesis
- Past history of vertebral fractures
- Cancer of spine
- Tuberculosis of spine

MATERIALS AND TOOLS REQUIRED: -

1. Consent form
2. Pen, pencil, paper
3. Plinth and Pillow
4. Pilate mat
5. Transcutaneous electrical nerve stimulation (TENS) unit with gel, cotton and
6. Micro-pore

OUTCOME MEASURES: -

NUMERICAL PAIN RATING SCALE (NPRS): [12]

- The NPRS for pain is a Uni-dimensional measure of pain intensity in adults. Similar to visual analogue scale (VAS), the NPRS is anchored by describing pain severity extremes. The NPRS can be administered verbally on graphically for self-completion.
- A 11-point numeric scale with 0 representing one pain extreme (e.g., no pain), and 10 representing the other pain extreme (e.g., "pain as bad you can imagine" and "worse pain imaginable"). The patient is asked to indicate the numeric value on the segmented scale that best describes their pain intensity. Scores range from 0-10. Higher scores indicate greater pain intensity.
- Reliability: High test-retest reliability has been observed in both literate and illiterate patients with rheumatoid arthritis (r=0.96 and 0.95, respectively) before and after medical consultation.
- Validity: For construct validity, the NPRS was shown to be highly correlated to the VAS in patients with rheumatic and other chronic pain conditions (pain>6 months) range from 0.86 to 0.95.

CLINICAL INTERVENTIONS: -

All the participants/ patients of the study were advised to continue their normal routine activities but they should not take any pharmacological agents or other form of treatment Other than the designed protocol, during the period of study. After taking informed consent patients were divided into 2 groups by simple random sampling method and treatment was given 4 sessions per week for 4 weeks.

Group A: Patients of these group received Pilates exercise plus conventional treatment.

Group B: Patients of these group received MFR technique plus conventional treatment.

Conventional therapy for both groups:

Patients received conventional therapy in the form of Transcutaneous Electrical Nerve Stimulation [Pulse width - 50-300 µs, Frequency - 150 Hz, Pulse shape - rectangular shape, Intensity - 0 to 60 mA (Milliamps) (It can be varying from patient to patient), Duration - 10 minutes], hamstrings and calf stretching, cat and camel exercise, extension of trunk (cobra pose), static glutes and static back exercise for 4 days a week for 4 weeks.

FLOW CHART OF THE STUDY PROCEDURE

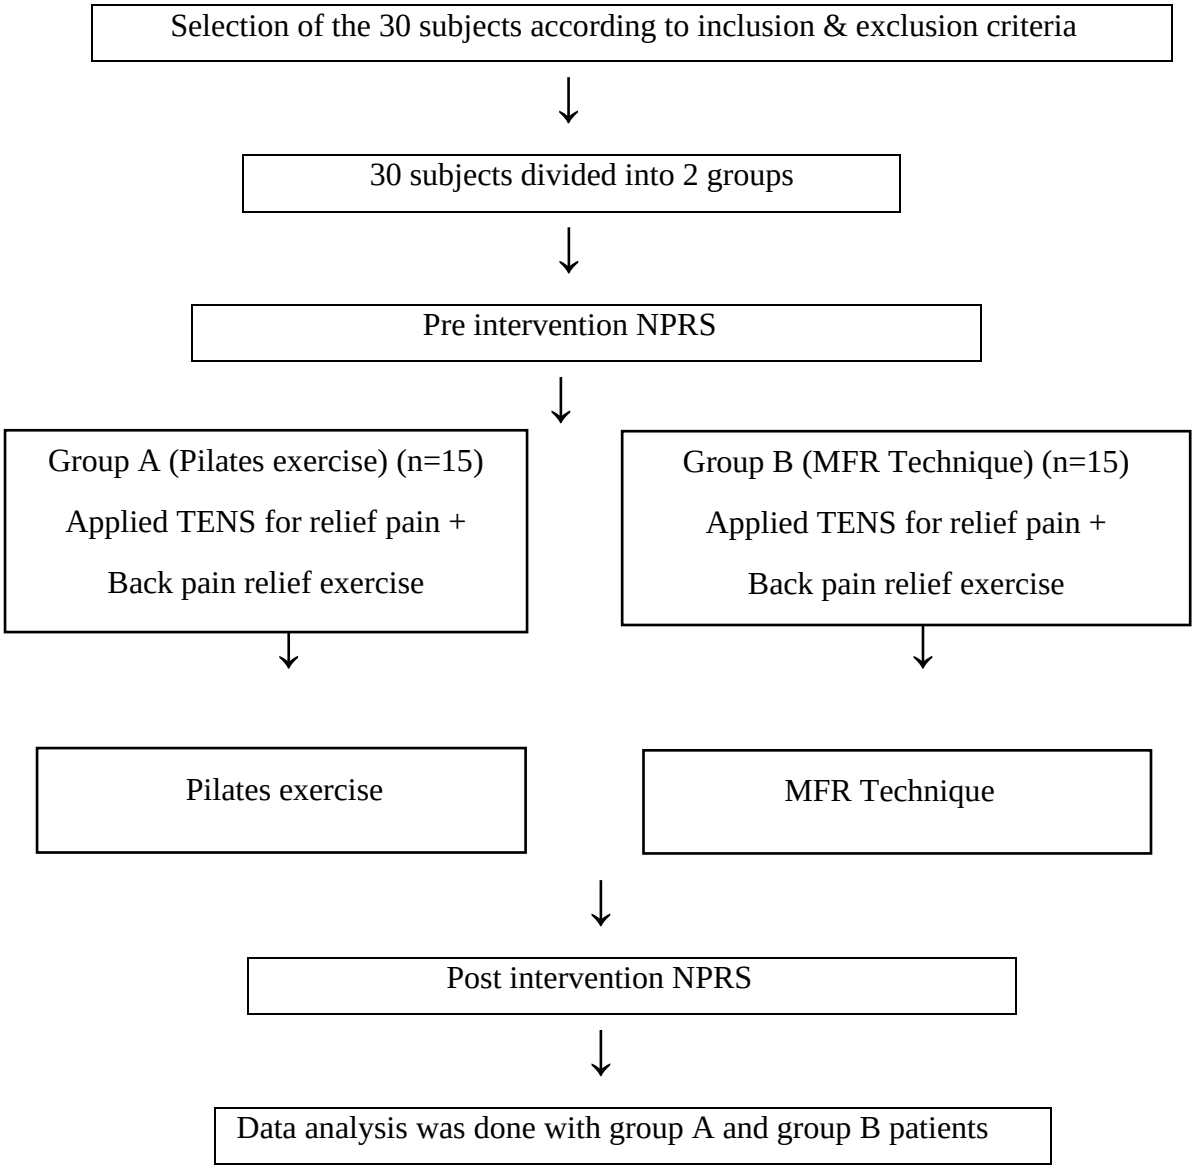

Figure 1: Flow chart of study Procedure

■ **<u>Group A [Pilates exercise plus conventional treatment]</u>:**

Pilates exercise: -

(1) <u>CURL-UPS</u>:

- Patient position: supine with knee semi-flexed
- First instruct the patient to perform the contraction of abdominal muscles and then lift the head. Progress by lifting the shoulders until the scapula and thorax clear the mat, keeping the arms horizontal.
- Hold this position as much as patient can (maximum 10 seconds) and then relax. 10 repetitions with 3 second interval.

(2) <u>BRIDGING</u>:

- Patient position: hook-lying position
- Have the patient press upper back and feet into the met, elevate the pelvis and extend the hips.
- Hold this position for 10 seconds and then relax. 10 repetitions with 3 second interval.

(3) KNEE TO CHEST:

- Patient position: supine
- Gently pull one knee up to chest until feel a stretch in lower back. Bring the knee as close to your chest as comfortably possible. Keep the opposite leg relaxed in a comfortable position, either with knee bent or with leg extended. Hold for about 5 seconds and then relax. 10 repetitions with 3 second intervals.

(4) BILATERAL STRAIGHT LEG RISING:

- Patient position: supine
- Bend the knee of one leg at 90-degree angle, planting the foot flatly on the floor. Stabilize the muscles on straight leg by contracting the quadriceps.
- Inhaling slowly, lift the straight leg at least 6 inches off the ground. Hold for 3 seconds then relax. 10 repetitions with 3 seconds interval.

(5) BIRD DOG EXERCISE:

- Patient position: Quadruped
- Place patient's knees under their hips and their hands under the shoulders. Maintain a neutral spine by using an abdominal muscles. Raise right arm and left leg, keeping shoulders and hips parallel to the floor. Hold this position for the few seconds, then lower back down to the starting position. Raise opposite arm and leg (left arm and right leg), holding this position for a few seconds. Return to the starting position. This is 1 round. Repeat this 10 times with 2 sets and each round 3 second interval time.

■ **Group B [MFR technique plus conventional treatment]:**

❖ **MFR technique: -**

- Myofascial release is a hands-on soft tissue technique that facilitates a stretch into the restricted fascia. A sustained pressure is applied into the tissue barrier, after 60 to 90 seconds. The tissue will undergo histological length changes allowing the first release to be felt. The therapist Follows the release into a new tissue barrier and holds. After a few releases the tissue will become softer and more pliable.
- Patient position: prone
- Therapist stands contra lateral to the side to be treated, at the level of patient's iliac crest. The therapist's superior hand is positioned thinner sided adjacent to the lumbar spine with extensive contact at the TFL at the level of L1 to L4 and acts as a palpation hand.
- The superior hand work as a palpation hand and initiates a direct stretch of the fascia laterally to a noticeable tissue resistance. The therapist follows the creep of myofascial tissue to initiate further stretching of the TFL and piriformis muscle. The applied force on the tissue is only moderate in the direction of the abdominal muscles.
- The duration of entire technique is 60 to 90 seconds at the same place of the lower back. [NOTE: The therapist contact (which could involve thumb, finger, knuckle or elbow) moves longitudinally along muscle fibers, distal to the proximal.]

RESULT:

Data analysis: Statistical analysis was performed on the data obtained from 30 patients. Data was analysed using SPSS (Version 16). Descriptive statistics for all outcome measures were expressed as mean, standard deviations and test of significance such as paired 't' test used for comparing data within each group and independent 't' test for comparing between the groups. Data was considered statistically significant with P<0.05. Pre and post mean difference of pain (NPRS) shows 1.46 ± 2.12 in group A and 1.73 ± 1.22 in group B. Independent "t" test values chronic LBP shows not significant difference between both groups.

Table 1: Paired "t" test values for Chronic LBP (NPRS)

Groups	Within group analysis	Mean	Mean Difference	Standard Deviation	"t" Value	"p" Value
Group A	Pre-Test Post Test	5.46 4	-1.46	2.12	-3.8977	P<0.05
Group B	Pre-Test Post Test	6.33 4.6	-1.73	1.22	-5.49	P<0.05

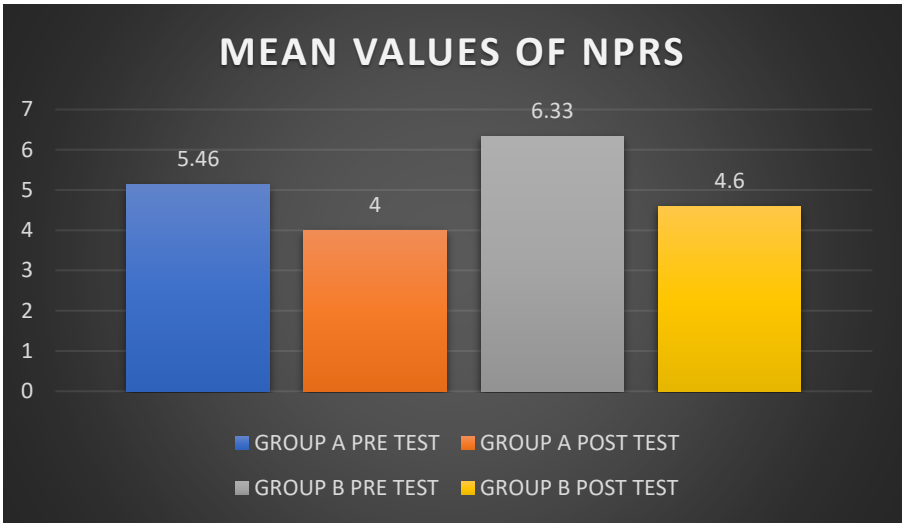

Figure 2. Mean Values of NPRS

Table 2: Independent "t" test values chronic LBP

Outcome Measures	"t" Value	"p" Value
NPRS	-1.16	0.1267

DISCUSSION:

The present study was designed to study effects of Pilates exercise and MFR technique in patients with chronic low back pain. Total 30 patients with low back pain more than 3 months were included in the study with the age group of 30 to 50 years and according to the inclusion and exclusion criteria.

After taking informed, written consent subjects were divided into two groups by simple random Sampling method. Group A received Pilates exercises plus conventional treatment and group B received MFR technique plus conventional treatment. Both groups were assessed before and after treatment duration to determine the extent of reduction of pain using Numerical pain rating scale taken as outcome measures.

At the end of 4 weeks, patients in both groups showed reduction in pain and improvement in NPRS scores on statistical analysis. The result showed that there was no statistically significant difference of effectiveness of pain between Both groups (group A and group B).

So here, both groups were improved after intervention. By comparing NPRS measure group A showed statistically significant improvement in pain equal to the group B. The mean difference of NPRS is almost equal to the both groups. So, Pilates exercise along with conventional treatment and MFR technique along with conventional treatment both are equally effective in reducing pain in patients with Chronic Low Back Pain.

CONCLUSION:

The present study concludes that Pilates exercise along with conventional treatment and Myo Fascial Release technique along with conventional treatment both are equally effective in reducing pain in patients with Chronic Low Back Pain.

LIMITATIONS

- In this study age limit is 30-50 years.
- MFR technique only assessed in chronic low back pain patients.
- Long term follow up is not taken.

FURTHER RECCOMENDATION

- Study can be done with chronic low back pain patients with other age groups.
- MFR technique effectiveness can also be determined for acute low back pain patients.
- Long term follows up of the patients can be taken to compare sustainability of treatment.

ABBREVIATIONS

- **CLBP** = Chronic low back pain
- **MFR** = Myofascial release
- **LBP** = low back pain
- **ADLs** = Activities of daily living
- **TENS** = Transcutaneous electrical nerve stimulation
- **TFL** = Tensor fascia late
- **SLR** = Straight leg raise
- **NPRS** =Numerical pain rating scale
- **VAS** = Visual Analogue Scale

INTRODUCTION

Chronic pain is a major public health problem all over the world.[1] The chronic low back pain is define as the chronic lower back pain is established by the persistence of pain beyond 3 month of symptoms.[1] CLBP can have a debilitating effect on patient's lives, resulting in disability and reducing their ability to carry out activities of daily living.[1] Acute low back pain is pain remains for less than 6 months.[2] Sub-acute back pain is back pain for between 6weeks and 3moths.[2]

Low back pain can affect all age and genders.[2] back pain is then further categorized into specific or non-specific back pain. Non-specific back pain refers to a pain is diagnosed when the cause of back pain is unknown. And specific back pain refers to a specific cause

for the pain, for example an infection or a fracture.[3] back pain is a major health issue in western countries and 60%-80% of adults are likely to experience low back pain[4]. Chronic pain is a significant health problem that leads to major consequences for the individuals afflicted, their families, and society.[4] Chronic pain can lead to various disabilities. Currently, there are in general no curative options for chronic pain, so treatments focus on reducing pain and disability.[4]

Physical activity and physical exercise are commonly prescribed as treatment for chronic pain. Physical activity is defined as any bodily movement produced by skeletal muscles that results in energy expenditure[5]. Physical exercise is described as a subset of physical activity characterized by planned, structured, and repetitive physical activities with an objective to maintain or improve physical fitness.[5] Because the terms physical activity and physical exercise are often used 3 interchangeably in the literature, the term physical activity and exercise (PA&E) is used in this study[6]. PA&E interventions for chronic pain patients can include aerobic exercises, strength exercises, and motor control exercises[6]. PA&E as treatment has shown significant improvements (up to medium effect sizes) for pain intensity, physical disability, and psychological distress in chronic neck pain, chronic low back pain.[6]

WHO defines physical activity as any bodily movement produced by skeletal muscles that requires energy expenditure – including activities undertaken while working, playing, carrying out household chores, travelling and engaging in recreational pursuits.[7] An increase in physical activity is one of the measures that is said to have the greatest positive effect on public health.[7] Physical activity plays an important role in the prevention and treatment of chronic musculoskeletal pain, but chronic pain may implicate a poor rehabilitation outcome.[7] PA increases the blood flow to the back which is important for the healing process of the soft tissues in the back.[7] Physical activity can reduce the risk of chronic disease including cancer, depression, cardiovascular diseases.[8] physical activity is reduced in the people who is suffered from chronic pain.[8]

Activity has been identified as the most important health-related behavior to change, the patients ask health care staff for support in making lifestyle changes.[8] Physical activity increases the blood flow to the back which is important for the healing process of the soft tissues in the back.[8]

The term "physical activity" should not be confused with "exercise", which is a subcategory of physical activity that planned, structured, repetitive, and aims to improve or maintain one or more components of physical fitness.[8] Physical activity to increase aerobic capacity and muscular strength, especially of the lumbar extensor muscles, is important for patients with CLBP in assisting them to complete activities to daily living.[8]

Pain is a subjective and personal experience, and its presence in the chronic form brings not only biological changes but emotional, cognitive and also behavioral changes.[8] The Back Pain Attitudes Questionnaire (Back-PAQ) was developed following these Interviews with people experiencing acute and chronic LBP. It aims to assess beliefs which underlie common attitudes about back pain[9]. Evidence showed that patients with chronic pain that had depression, anxiety and anguish have reported higher intensity of pain and disability.[10] A considerable body of research, based on cognitive-behavioral theory, has established the importance of individuals' pain-related cognitions and coping responses in their adaptation to chronic pain.[11] Beliefs and attitudes influence the acceptance, the results and the satisfaction

with treatment, also impacting the capacity of individuals to build an active and satisfactory life, despite the pain.[12]

For the beliefs facing pain, the Brief Pain Inventory (BPI-brief) was used, validated for the Portuguese language in 2006.[12] The purpose of this instrument is to evaluate the attitudes and beliefs facing pain in patients with non-oncologic chronic pain[12]. It has 30 items corresponding to seven domains: solicitude, emotion, medical cure, control, disability, physical damage, and medication.[12]

The "solicitude" domain relates to how much the patient believes that his/her family and other people should be more solicitous during the pain episodes. "Emotion" relates to the belief of the emotional effects, good or bad, in the painful experience."Medical Cure" relates to how much the patient believes in medicine to cure his/her pain. "Control" relates to how much the patient believes that he/she has control over his/her pain. "Disability" relates to how much the patient believes that the pain has disabled him/her. "Physical Damage" relates to how much, in the patient's point of view, the pain hurts him/herself, and because of it, exercises should be avoided."Medication" relates to how much the patient believes that drugs are the best treatment for chronic pain.[12]

Beliefs are culturally learned certainties; they are each individual's notion concerning its own reality, of the others and of the space, which interferes with the behavior[12]. Beliefs have been described as 'a cognitive process resulting in a concrete cognition of how we think things are'.[13] Attitudes are organized in affective arrangements, relatively stable, that reflect the trend to respond positively or negatively to something or some event. Both are formed from personal experiences[14]. Attitudes are 'a more complex cognitive state involving beliefs and feelings as well as values and predispositions to act in a certain way'.[15] Beliefs and attitudes influence the acceptance, the results and the satisfaction with treatment, also impacting the capacity of individuals to build an active and satisfactory life, despite the pain.[16]

Beliefs about a stressor such as pain, and in particular, appraisals of threat, influence an individual's coping responses (Lazarus, 1993). Coping has been defined as `constantly changing cognitive and behavioral efforts to manage specific external 6 and/or internal demands that are appraised as taxing or exceeding the resources of the person'[17]

Review question

- **What is the attitude and belief towards physical activity in chronic low back pain?**

- **What is the most appropriate treatment to cure the chronic low back pain?**

NEED OF STUDY

NEED OF STUDY

- To understand determinants of belief and attitude towards physical activity and exercise in patients with chronic low back pain.

OBJECTIVE OF REVIEW

OBJECTIVE OF REVIEW

- To identify attitude and belief towards physical activity and exercise in chronic pain.
- To identify attitudes and beliefs about LBP in the general population to analyse their association with individual characteristics and the belief that exercise is an effective treatment for LBP.

HYPOTHESIS

- ***Null Hypothesis(H0):***

There will be no effect or zero pain relief in patient with chronic low back pain.

- ***Alternative Hypothesis(H1):***

There will be significant effect or progress in pain relief in patient with chronic low back pain.

METHODOLOGY

- **KEYWORDS USED FOR SEARCH :**
  - Chronic low back pain, Attitude and belief towards physical activity and exercise

- **SEARCH STRATEGY :**
  - For the literature review, we used standard search strategies involving the querying of online databases MEDLINE (pub med) , Google scholar using key words followed by relevant articles. We included articles in overview.
  - Eligible criteria for the articles were :

Eligible criteria for the articles were:

- Duration of publication : 2013 Onwards
- Article should be in English language
- Age criteria : 45 – 65 years
- Article that assess the physical attitude and the need of exercise
- Exclusion criteria for the articles were :
- Unpublished articles
- Article which published in another language

➢ **DATA SEARCHED** :

- To identified potentially relevant articles in the medical
- Literature, we searched MEDLINE (PUBMED), Google scholar, Sci-hub data bases

➢ **DATA SYNTHESIS :**

- Narrative synthesis of data will be done.

YEAR	2018
STUDY DESIGN	Qualitative interview study
AIM& OBJECTIVE	The purpose of this study was to describe how patients with chronic pain experience physical activity and exercise (PA&E).
OUTCOME	International Physical Activity Question naire (IPAQ) Hospital, Anxiety and Depressio n Scale (HADS), Pain Self- Efficacy Questionnarie (PSEQ), Fear Avoidance Beliefs Questionnarie(FABQ), Psychological.
REMARKS	Physical activity was highly valued in daily life although experiences of PA&E were characterized by difficulties and failure. A will to engage in desired PA&E was apparent, but it was seldom successful even though the participants tried a variety of strategies. This intention– behavior gap identified might be related to the pain condition as well as to motivational aspects, self- efficacy, and action-control, a conclusion that requires careful analysis and support when PA&E is applied as treatment for chronic pain.

AUTHORS	Gur Prasad Dureja, Paraman and N. Jain ,Naresh Shetty, Shyama Prasad Mandal, Ram Prabhoo, Murlidhar Joshi, Subrata Goswami, Karthic Babu, Natarajan, Rajgopalan Iyer, D. Tanna ; Pahari Ghosh Ashok Saxena, Ganesh Kadhe, Abhay A Phansalkar
YEAR	2013
STUDY DESIGN	Epidemiological telephonic survey
AIM& OBJECTIVE	The present epidemiological study identified point prevalence of chronic pain in India, impact on individual's QoL, unveiling current pain treatment practices, and levels of satisfaction with treatment.
REMARKS	A significant population of India suffers from chronic pain, and their QoL is affected leading to disability. A proportion of respondents receiving pain treatment were taking nonprescription medications with a majority of respondents on NSAIDs. A very few were consulting pain management specialists.

YEAR	2015
STUDY DESIGN	Systematic review
AIM& OBJECTIVE	To identify and synthesize qualitative empirical studies that explored what peoplewith non-specific chronic low back pain believe about exercise therapy and physical activity or training for the management of their condition and make recommendations for clinical practice and research.
REMARKS	People are likely to prefer and participate in exercise or training programs and activities that are designed with consideration of their preferences, circumstances, fitness levels and exercise experiences. In the area ofexercise and low back pain research there is a paucity of qualitative data.

STUDY DESIGN	SYSTEMATIC REVIEW
AIM& OBJECTIVE	What influence do physiotherapist' s beliefs and attitudes about chronic low back pain have on their clinical management of people with chronic low back pain
OUTCOME	PABS-PT SCORE FEAR AVOIDANCE
REMARKS	Both quantitative and qualitative studies showed a relationship between treatment orientation and clinical practice. The inclusion of qualitative studies captured the influence of patient factors in clinical practice in chronic low back pain. There is a need to recognize that both beliefs and attitudes regarding treatment orientation of physiotherapists, and therapist-patient factors need to be considered when introducing new clinical practice models, so that the adoption of new clinical practice is maximised

STUDY DESIGN	Systematic review
AIM& OBJECTIVE	To identify psychosocia l predictors of failureto return to work in non-chronic (lasting less than3 months) non-specific low back pain (NSLBP)
REMARKS	To predict work outcome in non-chronic NSLBP, psychosocial assessment should focus on recovery expectation and fear avoidance.The importance of fear avoidance beliefs in chronic pain has been established and it appears these beliefs and behaviours also play an important role in the non-chronic phase of NSLBP and can assist in predicting work outcome.

RESULT

RESULT

275 records were identified using databases searching. Duplicates screening was performed and 6 articles were removed in duplicates screening and than 3 reviews independently scanned the abstract and title or both and determined which studies were to be assessed further and if there were any discrepancies it were then further remove by the supervisor. Prisma flowchart was adapted for the study selection. Following it 275 studies were screened after the duplicates were removed out of which 6 studies were screened after the duplicates were removed. Furthermore excluded as full texts of 67 articles were screened out of which studies were excluded due to many reasons as mentioned in prisma flowchart of study selection. At last we included 13 studies in our data synthesis. The detail of study used in the data synthesis were be mentioned I the data extraction table which include the following detailed: author and year of publication, study design, aim and objective, outcome measure and remarks.

In this study we have observed that chronic low back pain often present dysfunction belief and attitude in relation to pain and that such belief showed in many cases, an association with intensity of pain anxiety and depression. A large proportion of respondents believed that they needed to protect their back to prevent injury; we theorise that this belief may result in reduced confidence to use the back and contribute to fear avoidance. People experiencing back pain may benefit from more targeted information about the positive prognosis. The provision of clear guidance about levels of activity may enable confident participation in an active recovery. According to cognitive behavior therapy altering pain beliefs and improving coping skills may modified the pain. experiecnces and thereby improve the health related quality of life

A very high proportion of respondents believed they should stay active when they have back pain. Among from all the people who are suffering from chronic low back pain, women are having a increasing complain of low back pain in compare of men. If we look most specifically than we found that age group of 41-50 years are those who are suffering from chronic low back pain. In addition to that smoking in men had no significant relationship with low back pain, because those who were found positive chronic low back pain where non smoker. The assosiation of low back pain with reproductive history is found significantly. According to that those women who has history of caesarean section more prone to have a low back pain later a time. Even those who have history of sterilization.

Some study also shows that both men and women who where household and in lower socio economical status reported more back pain than those who were in higher socio economic status. We have found that low back pain in ruler housewifes is around 83%, out of those more than 50% of housewife have severe disability with low back pain. They have also significant impact of social burden on their daily life.

Chronic fatigue syndrome is characterized by severe, disabling chronic fatigue lasting for at least six months. Other symptoms can include musculoskeletal pain, sleep disturbances, impaired concentration and headaches. Patients with chronic fatigue syndrome appear to be less physically active compared with asymptomatic controls.

There is no difference in variation of physical activity levels between patients with chronic fatigue syndrome and healthy control subjects, but the validity and reliability of some methods of measuring physical activity is questionable or unknown.

DISCUSSION

DISCUSSION

The present review was intended to understand determinants of belief and attitude towards physical activity and exercise in patients with chronic low back pain. Main aim of the review was to identify what are the multiple dimension bother the patient to perform physical activity and exercise in chronic low back pain[1]. As well as the review suggests belief may result in reduced confidence to use the back and contribute to fear avoidance[2].

We have found that the prevalence of chronic low back pain more common in aged population (41-50years). In general the prevalence of LBP was higher in women (52.9%) compared to men (28.4%). The alterations in sleep due to the chronic low back pain are very common results and show the impact of this painful syndrome on the quality of life and disability of the individual[4]. Study has also showed that a reduce the level of basic activity in patient with chronic low back pain, whereas increased their sportive and leisure time activities.

There are several studies that conform to the pattern that height is not correlated with the occurrence of low back pain in women, though in men many studies reported a positive correlation[15,17,18]. This study has also examined the association between low back pain and weight. The results conform to the pattern wherein weight does not correlate with the occurrence of low back pain and is consistent with previous studies.[24] These findings provide no evidence that a greater body mass index and waist-hip ratio is associated with an increased risk of low back pain.

The current review found that treatment orientation and fear avoidance beliefs of the physiotherapist had an influence on clinical practice and advice given to patients. A therapist with higher biomedical orientation and fear avoidance beliefs towards chronic low back pain was associated with advice to restrict return to work duties and restrict return to activity, a higher perception of risk associated with work or activity, and increased certification of sick leave. Healthcare professionals' beliefs about chronic low back pain have been shown to have an influence on patient beliefs.

The findings of the present study suggest that 83% of the non working rural housewives have low back pain and activity restriction due to their pain. They have significant impact of social burden on their low back pain. High prevalence (83%) of low back pain among rural housewives is an alarming sign for our society. Better health-care measures to enhance rural housewives education about good posture, ergonomic measures, health schemes, health awareness, and activity pacing could help rural housewives.

In this study, women who have undergone caesarean section or sterilization reported more low back pain than who have not undergone these procedures. This may be due to the sedentary life style after the caesarean section. Nevertheless, it was also observed that women who have occupation described as “Physically demanding” also have higher risk of low back pain suggesting that extremes of activity are probably not ideal.

CONCLUSION

CONCLUSION

Majority of available literature review suggest that patient with chronic low back pain often present dysfunctional beliefs and attitude in relation to pain. A large population subjects believed that they need to protect their back to prevent injury: Which shows that this belief may result in reduce confidence to use the back and contribute to fear avoidance.

Key findings of this literature review are:

- The reason for chronic low back pain are multi factorial which include reduce physical activity, food habit, occupation, under lying disease.
- Patient with low back pain often present that dysfunctional belief and attitude in relation to pain.
- Chronic pain often may lead to disability.

LIMITATIONS

Limitations

- Our review includes limited number of articles so some of the causes of attitude and belief might be missed
- Number of article were very less

ANNEXURE

	AUTHORS	YEAR	STUDY DESIGN	AIM & OBJECTIVE	OUTCOME	REMARKS
1	1. Anil Chankaramangalam Mathew, Rowther Shamna Safal, Thazhuthekudiyil Sathyam Anthadan, Moosa Saira Banu, Singanallur Lakshmanan, Ravi Shankar, Bellyur Krishna Dinakar Rai, Thomas Vengall Chacko	2013	A cross sectional study	The aim of this study was to estimate the prevalence of low back pain and its association with height, fat distribution, reproductive history and socioeconomic infl uence.	HEIGHT WEIGHT BMI WEIST CIRCUMFARANCE, WEST HIP RATIO	The Back Pain Attitudes Questionnaire (Back-PAQ) was developed following these interviews with people experiencing acute and chronic LBP.23 It aims to assess beliefs which underlie common attitudes about back pain.
2	2. GARIMA GUPTA and NUPUR NANDINI	2014	A cross sectional study	The perpose of the study was to evaluate the prevalence of low back pain in non-working rural housewivwsw. also an attempt has been made to determine thew impact of social burden on loe back pain.	Nordic Musculoskeletal Questionnaire – NMQ, Oswestry Disability Index – ODI, and Zarit Burden Interview – ZBI	The findings of the present study suggest that 83% of the non working rural housewives have low back pain and activity restriction due to their pain
3	6. Rebecca gordon and Saul Bloxham	2016	Systematic Review	This paper explores the impact of back pain on society and the role of physical activity for treatment of non-specific low back pain.		Exercise intervention programmes involving either muscularstrength,flexibility, aoraeroic, fitness is beneficial for NSCLBP but not acute low back pain. Non-specific acute low back pain patients recover in 4–6 weeks with or without a treatment , and exercising should be avoided to reduce the swelling of the affected area.
4	4. Linn Karlsson Björn Gerdle Ewa-Pekka Takala Gerhard Andersson Britt Larsson	2018	qualitative interview study	The purpose of this study was to describe how patients with chronic pain experience physical activity and exercise (PASE).	International Physical Activity Questionnaire (IPAQ) Hospital Anxiety and Depression Scale (HADS), Pain Self-Efficacy Questionnaire (PSEQ), Fear Avoidance Beliefs Questionnaire (FABQ), Psychological Inflexibility in Pain Scale (PIPS)	Physical activity was highly valued in daily life although experiences of PASE were characterized by difficulties and failure. A will to engage in desired PASE was apparent, but it was seldom successful even though the participants tried a variety of strategies. This intention–behavior gap identified might be related to the pain condition as well as to motivational aspects, self-efficacy, and action-control, a conclusion that requires careful analysis and support when PASE is applied as treatment for chronic pain.
5	5.Gerthi Persson,Annika Brörsson , Eva Ekvall Hansson,Margareta Troein and Eva Lena Brandberg	2013	qualitative study	The aim of the study was to explore and understand the meaning of prescribing physical activity from the general practitioner's perspective		There is uncertainty about using PAP as a treatment since physicians lack education in non-pharmaceutical methods, the GPs do not regard the written referral as a prioritized task and rather refer to other professionals in the health care system to prescribe PAP
7	6.Monica Joessona , Susanne Bernhardssona and Maria E. H. Larsson.	2017	qualitative study	The objective of this study was to describe the experiences of and thoughts about receiving a prescription for physical activity of people with chronic musculoskeletal pain		There is uncertainty about using PAP as a treatment since physicians lack education in non-pharmaceutical methods, the GPs do not regard the written referral as a prioritized task and rather refer to other professionals in the health care system to prescribe PAP
8	7.Fernanda Martins Barbosa, Erica Brandão de Moraes Vieira , João Batista Santos Garcia	2018	cross-sectional , quantitative study	The objective of this study was to evaluate the behavior of beliefs and attitudes in chronic low back pain and to correlate them with the intensity of pain, disicability, anxiety, and depression	NPRS, BPI, CDI, HADS	This study suggests that patients with chronic musculoskeletal pain have a greater need for information and extra support to overcome existing barriers, before or when physical activity is prescribed.
9	8.D.W. Griffin a, D.C. Harmon b, N.M. Kennede	2012	systematic review	The aim of this systematic review was to determine, based on the current body of evidence, if patients with chronic low back pain have a lower level and/or altered pattern of physical activity compared with asymptomatic, healthy individuals.	Newcastle Ottawa Scale (NOS)	there is no conclusive evidence that patients eith CLBP are less active than health individuals, based on limited number of studies , there is some evidence that the distribution of activites over the course of a day is different between patients with CLBP and controls.
10	9.Janet K. FreburgerGeorge M. Holmes, Robert P. Agans, Anne M. Jackman, Jane D. Darter, Andres S. Wallace, Liana D. Castel, William D. Kaiser and Timothy S. Carey,	February, 2009	cross-sectional, telephone survey	The objective of this study was to determine whether the prevalence of chronic LBP, and the demographic, health-related, and care-seeking characteristics of individuals with the condition have changed over the past 14 years.		The prevalence of chronic, impairing LBP has risen significantly in NC, with continuing high levels of disability and care utilization. A substantial portion of the rise in LBP care costs over the past two decades may be related to this rising prevalence
11	10.Elin Dysvik, Torill Christine Lindstrøm, Ole-Johan Eikeland, and Gerd Karin Natvig	2004	survey design	The present study focused on HRQL as measured by the Medical Outcomes Survey-Short Form (SF-36) and addressed possible relationships between pain beliefs as measured by the Pain Beliefs and Perceptions Inventory (PBAPI).	,VAS, SF-36, PBAPI, HRQL	according to CBT altering pain beliefs and improving coping skills may modified the pain exeperiences and there by improve the health related quality of life.
12	12.Ivan P.J. Huijnen a,*, Jeanine A. Verbunt a,b,c, Madelon L. Peters d, Philippe Delespaul e,Hanne P.J. Kindermans d , Jeffrey Roelofs d, Marielle Goossens d,Henk A.M. Seelen	2010	cohort study	This study evaluates whether patients with Chronic Low Back Pain (CLBP) who are more depressed and/or report more pain indeed have a lower objectively assessed daily life activity level or whether they only perceive their activity level as lower	Roland Disability Questionnaire (RDQ) Baecke Physical Activity Questionnaire (BPAQ) VAS Beck Depression Inventory II (BDI-II)	the patients with CLBP, who had a higher level of depression, underestimated their daily activity level, although their actual activity level did not differ.
13	13.Judith A. Turnera, Mark P. Jensenb, Joan M. Romanoa	October 1999			NPRS	This result of the study confirm that beliefs, coping, and catastrophizing would each be associated significantly with physical disability and depression in patients beginning a multidisciplinary pain treatment program.
14	14.Gur Prasad Dureja, Paramanand N. Jain,Naresh Bhatty,Bhyana Prasad Mandal, Ram Prabhoo Murallidhar Joshi, Subrata Goswami, Karthic Babu Natarajan, Rajagopalan Iyer, D. Tahina, Pahari Ghosh Ashok Saxena, Ganesh Kadhe, Abhay A. Phansalkar	2013	epidemiological telephonic survey	The present epidemiologic study identified point prevalence of chronic pain in India, impact on individual's QoL, unveiling current pain treatment practices, and levels of satisfaction with treatment.		A signiTcant population of India suffers from chronic pain, and their QoL is affected leading to disability. A proportion of respondents receiving pain treatment were taking nonprescription medications with a majority of respondents on NSAIDs. A very few were consulting pain management specialists.
15	15.S. Slade, S. Patel, M. Underwood J. Keating	May, 2015	systmetic review	To identify and synthesize qualitative empirical studies that explored what people with non-specific chronic low back pain believe about exercise therapy and physical activity or training for the management of their condition and make recommendations for clinical practice and research.		People are likely to prefer and participate in exercise or training programs and activities that are designed with consideration of their preferences, circumstances, fitness levels and exercise experiences. In the area of exercise and low back pain research there is a paucity of qualitative data
16	16.Geneen LJ, Moore RA, Clarke C, Martin D, Colvin LA, Smith BH	2020	cochrain review	To provide an overview of Cochrane Reviews of adults with chronic pain to determine the effectiveness of different physical activity and exercise interventions in reducing pain severity and its impact on function, quality of life, and healthcare use & the evidence for any adverse effects or harm associated with physical activity and exercise interventions.	NPRS, SF-36	There is limited evidence of improvement in pain severity as a result of exercise. There is some evidence of improved physical function and a variable effect on both psychological function and quality of life. physical activity and exercise is an intervention with few adverse events that may improve pain severity and physical function, and consequent quality of life. physical activity and exercise is an intervention with few adverse events that may improve pain severity and physical function, and consequent quality of life.
17	17.Melda Boysal,Bilge Kara, M. Nuri Arda2	2012		To investigate physical activity level in patients with chronic low back and neck pain.	Oswestry Disability Index (ODI), Physical Activity Questionnaire (IPAQ), (SF-36), Sleep Quality Index (PSQI) , Beck Depression Inventory	Physical activity modification was found in patients with chronic low back and neck pain. Physical activity level, disability, sleep, depression and quality of life scores of preoperative patients with low back pain more affected than neck patients.
18	18.Tania Gardner, Kathryn Refshauge , Lorraine Smith , James McAuley c,Markus Hübscher c, Stephen Goodall	2017	systmetic review	What influence do physiotherapists' beliefs and attitudes about chronic low back pain have on their clinical management of people with chronic low back pain	FABB-PT SCORE FEAR AVOIDANCE	Both quantitative and qualitative studies showed a relationship between treatment orientation and clinical practice. The inclusion of qualitative studies captured the influence of patient factors in clinical practice in chronic low back pain. There is a need to recognise that both beliefs and attitudes regarding treatment orientation of physiotherapists, and therapist-patient factors need to be considered when introducing new clinical practice models, so that the adoption of new clinical practice is maximised.
19	19.Tomoko Fujii, Hiroyuki Oka, Kenichiro Takano2, Fuminori Asada3, Takuo Nomura4, Kayo Kawamata1, Hiroshi Okazaki5, Sakae Tanaka6 and Ko Matsudaira	June 2015	cross-sectional study	High prevalence of low back pain (LBP) in nurses has been reported globally. Ergonomic factors and work-related psychosocial factors have been focused on as risk factors.	Fear-Avoidance Beliefs Questionnaire (FABQ), Kessler Psychological Distress Scale (K-6)	A small number of nurses had chronic disabling LBP that interfered with their work. In the nurses who had any type of LBP, high FABs were significantly associated with experiencing chronic disabling LBP. FABs about physical activity might be a potential target for LBP management in nurses.

Abstract

Background:
Exercise is an important component of healthy lifestyle to reduce a person's risk of developing the disease and subsequent disability. Stress, anxiety, and depression are overwhelmingly prevalent across the globe during this COVID-19 pandemic, and multiple factors can influence the rate of mental health conditions. Our factorial analysis showed notable associations and manifestations of stress, anxiety, and depressive symptoms. In Corona pandemic one can easily understand that new world order has established and many things changed drastically but importance of physical activity is still at utmost importance so one shouldn't neglect importance of same.

Objectives:
To find out the association of physical activity and mental health in college going student's and to know their mental health status.

Methodology:
This study involved 150 participants between the ages of 18 to 25 years college going students. This survey based study was conducted via mail incitation.

Results:
Self-reported PA was lower post-COVID among participants reporting being previously active (mean change: - 32.3% [95% CI: - 36.3% to - 28.1%]) but largely unchanged among previously inactive participants (+2.3% [- 3.5% to +8.1%]). Decreased PA and increased screen time were associated with worsening in depression, anxiety and stress.

Conclusion:
The current findings strongly support the mental health benefits of implementing measures that promote physical activity.

Key-words:
COVID-19, physical impact, psychological impact, university students.

INTRODUCTION

COVID-19 outbreak: As per World Health Organization (WHO) - Coronavirus disease (COVID-19) is an infectious disease caused by a newly discovered coronavirus. Most people who fall sick with COVID-19 will experience mild to moderate symptoms and recover without special treatment. It was caused by a novel coronavirus, which originated from a wet market in Wuhan, China, and has spread worldwide, earning the pandemic status by WHO on March 11, 2020.[1] As of the 3rd week of July, India has emerged as the third hardest-hit country with 10, 40,980 confirmed cases of COVID-19 and 25,602 deaths and the numbers are still increasing. According to WHO, the most common symptoms: are fever, dry cough, and tiredness. Less common symptoms: aches and pains, sore throat, diarrhoea, conjunctivitis, headache, loss of taste or smell, a rash on skin, or discoloration of fingers or toes. Serious symptoms: difficulty breathing or shortness of breath, chest pain or pressure, loss of speech or movement, Seek immediate medical attention if you have serious symptoms.[2]

Owing to COVID 19, prolonged home stay may lead to increased sedentary behaviours such as spending excessive amounts of time sitting, reclining, or lying down for screening activities (playing games, watching television, using mobile devices); reducing regular physical activity (hence lower energy expenditure); or engaging in avoidance activities that consequently, lead to inactivity and contribute to anxiety and depression and stress, which in turn can lead to a sedentary lifestyle known to result in a range of chronic health conditions. Maintaining regular physical activity and routinely exercising in a safe home environment is an important strategy for healthy living during the coronavirus crisis as an improvement in mental health status of college going students. Mental health is a state of well-being in which an individual realizes their abilities and to cope up with daily stresses of life and able to do productive work and to contribute to society.[3]

Mental health has core symptoms such as anxiety, depression and stress lead to disturbance in mental health. For accurate analysis of depression, anxiety, stress standard scale is DASS-21 (Depression, Anxiety, and Stress Scales – 21) this scale was developed by Lovibond. The three-dimensional self-reporting scales assess the presence and intensity of affective states of depression, anxiety, and stress. And to measure physical Activity standard scale is IPAQ (International physical activity questionnaire) it comprises a set of 4 questionnaires, long (5 activity domains asked independently) and short (4 generic items) versions for use by either telephone or self-administered methods are available.[4]

METHODOLOGY

Research Design: Cross-sectional Survey

Study setting: Online mode

Sampling Method: Convenient Sampling

Sample size: 150

Inclusion criteria:

- Indian college-going students between 18-25
- Able to read, write and understand English language
- Has Internet facility with e-mail

Exclusion criteria:

- Mini-mental scale less than 24
- Any systemic illness (musculoskeletal, cardiovascular, degenerative, and neurological)

Data collection tool:

- Physical activity assessed by: International Physical Activity Questionnaire (IPAQ)
- Mental health assess by DASS-21 (Depression, anxiety, stress scale)

Procedure:

The study was conducted among the college-going students of the Indian population between the ages of 18 to 25 years. Participants entered into the study from different fields of education. A random selection of the participants was used. Firstly, the Google form was created and circulated on an online platform via mail. The online consent form was taken from all the participants before they answered the questions. Secondly, with respective permission, they entered into the online survey of the DASS-21 and IPAQ along with consent and demographic details. Google form consisted of three pages and a total of 28 questions. The first page was about consent and the demographic detail of the participants. The second page was about the depression anxiety, stress scale which consisted of 21 questions and the rating scale was from 0 to 3. Whereas, 0 means did not apply at all and 3 means apply to very much and most of the time. After fillip in the second page, they entered the third page of the survey form. The third page was about the international physical activity questionnaire which consisted of 7 subparts the physical activity in different circumstances. They filled the form with tangible self-experience. The distribution of the survey form was extended to the whole country, however mostly in Gujarat where the majority of students belong. Then we waited for two days for survey collection. Initially, we received 100 responses from the first circulation. After that, we did follow up with the college-going students again via calls and messages. Moreover, we sent a new invitation to other students of the colleges. Then again we waited for the 2 days for more responses. Eventually, at the end of the survey collection, we received more than 160 responses. After the collection of the sample size, we started statistical analysis of the online survey.

DATA ANALYSIS

- Descriptive analysis was done for demographic details.

- Pearson correlation coefficient was to find out the association between physical activity and mental health of college-going students.

RESULT:

160 responses were received, out of which 10 responses were incomplete and hence excluded. The final sample size was 150. The participants were of age group 18 to 25 years with an average age of 21.6 ± 2.15 years.

Table 1: Number the participants according to Gender and Educational Status

Variables	Subgroups	No of Participants	%
Gender	**Male**	79	51.97
	Female	73	48.03
Educational Status	**Bachelor's Degree**	140	92.10
	Master's Degree	11	7.23
	PhD	1	0.65

Table 2: DASS-21 Score for number the participants

	Depression	Anxiety	Stress
Normal	89	72	108
Mild	17	13	14
Moderate	27	23	15
Severe	6	21	8
Extremely Severe	13	23	7

Table 3: IPAQ Analysis for the participants

Type of Activity	Average Days/Weeks	Average Minute/Weeks
Vigorous Physical Activity	3.85	62.5
Moderate Physical Activity	4.33	53.29
Walking	3.85	63.71
Travelling	2.88	67.38
Bicycling	4.17	43.17
Leisure Time	4.68	27.15

DISCUSSION

This research presents a timely investigation of changes in physical activity, sitting time, and screen time as a result of COVID-19 public health restrictions, and their associations with mental health in students. The current findings indicate: (1) large reductions in physical activity and increases in sedentary time across the population and particularly among previously physically active and self-isolated/quarantined individuals; (2) consistent associations between reductions in physical activity and increases in screen time with higher negative mental health and lower positive mental health; and, (3) more severe anxiety and depressive symptoms for those in self-isolation compared to less restrictive situations, which were not moderated by changes in physical activity or sedentary behaviour. We found that females were 1.7 times more likely to be present with depressive symptoms, 2.6 times as likely to show symptoms of anxiety, and twice as likely to show stress symptoms when compared to males but when adjusted for other confounding factors, females were quadruple times as likely as males to have depression and 3.5 times as likely as males to have anxiety. Our results are similar to previous studies conducted during the SARS and COVID-19 pandemic in Italy and China, where the prevalence of psychological disorders was steadily associated with the female gender[4, 5, and 6]. This trend was noted in India before the outbreak too where the prevalence of depression and anxiety disorders was more in females than males. There was no significant association between gender and the likelihood of stress which is in accordance with studies conducted during earlier epidemic/pandemic situations[7]. Gender-specific help and counselling should be offered to mitigate the psychological strain on the population. An interesting finding in our study was the variation in the association between age and depression, anxiety, and stress. Educational status influences the occupation and income of the individual, which are in turn associated with psychosocial wellbeing. The economic crisis due to lockdown might put the individuals without formal education at a higher risk of developing anxiety. Counselling, guidance, or any form of mental health help should include verbal or pictorial representations to aid this group population.

CONCLUSION

The current findings strongly support the mental health benefits of implementing measures that promote physical activity during periods of societal modification due to a pandemic. Potentially effective methods to do so may be through enhanced telehealth or public broadcasting time devoted to the promotion/implementation of home-based physical activity.

LIMITATIONS

- This cross-sectional design precludes inference of causality and the sample is predominantly well-educated.
- In particular, as this study sample is not representative of the entire Indian population, generalizations should be limited based on the sample characteristics.
- All behaviours and currently followed public health guidelines were self-reported and included a recall of pre-COVID-19 activity, which is potentially subject to misreporting. The self-selection and convenience sampling of participants to complete the survey may also affect the results, although a >70% completion rate for those who began the survey is high.

FUTURE RECOMMENDATIONS

Future research should replicate these findings in other large samples, investigate potential cross-national differences, longitudinally assess dynamic relationships between these factors, and integrate device-based measures.

Abstract

Background
Physical inactivity is a commonly observed cause of increasing incidence of lifestyle diseases like obesity which has increased the incidence of low back pain. As dancing is a physical activity that can be tailored to fit a target population's age and culture therefore, Zumba is becoming a global dance fitness activity to reduce lifestyle disease epidemic. It has a mixture of popular entertaining music, different dance styles and aerobic exercises which improves the health of all age groups. Thus, physiological effects of Zumba can be used as adjuncts to conventional medicine for prevention of various lifestyle diseases e.g., diabetes and obesity. Zumba incorporates movement of large muscle groups for aerobic endurance, strength training and flexibility thereby contributing in reducing obesity and thus decreasing back pain in all ages, especially in the geriatric population. Various researchers have also recorded the positive effect of Zumba on weight, BMI, body fat mass. To summarize, these findings reflect that Zumba intervention can be explored further as a therapeutic tool in complementary and alternative medicine for improving low back pain in obese people.

Methodology
An experimental study with a pre-test/post-test design. 30 obese participants between the ages of 18 to 45 years with low back pain were included. We evaluated changes over time (pre-test to post- test) in all outcome measures. Paired t-tests were used to analyze pain and BMI.

Result
Statistically significant improvements were seen in the Pain ($p = 0.0000005$) and BMI ($p = 0.0000002$).

Conclusion
Conclusion the current finding strongly support that Zumba has health benefits and it reduces lower back pain in obese people.

Keywords
ZUMBA, Low back pain, Obesity, Life style disease.

INTRODUCTION

Low back pain is a symptom not a disease, and can result from several different known or unknown abnormalities or diseases. It is defined by the location of pain, typically between the lower rib margins and the buttock creases. It is commonly accompanied by pain in one or both legs and some people with low back pain have associated neurological symptoms in the lower limbs. For nearly all people presenting with low back pain, the specific nociceptive source cannot be identified and those affected are then classified as having so-called non-specific low back pain. People with low back pain often have concurrent pain in other body sites, and more general physical and mental health problems, when compared with people not reporting low

back pain. The combined effect on individuals of low back pain and co-morbidity is often more than the effect of the low back pain or the co-morbidity alone and results in more care, yet typically a poorer response to arrange of treatments.[1]

Obesity is one of the co morbidity which has been associated with low back pain. Obesity is defined by waist circumference was associated with increased incidence of radiating low back pain after adjustment for age, gender, educational status, occupational status, and smoking status.[2] Scientifically, obesity is caused by consuming more calories than needed by the body, they are not burnt through physical activity / exercise. One of the diseases of inactivity is obesity or overweight. Lack of physical work such as sitting for long periods will give a negative effect on health and can lead to obesity, therefore Physical exercise is vital for a healthy life and has several positive influences on the body.[3] Despite this evidence, many clinicians consider obesity to be a self-inflicted condition of little medical significance. It is thus important to focus on obesity which can decrease the incidence of low back pain immensely.[4]

In an effort to reduce rates of obesity Zumba Exercise has deliberately chosen, for reasons that it can be made in the form of weight-bearing exercise program that is homogeneous in an attempt to lose weight by exercise in the right dose. Lately, Zumba dance workout has been highly in demand by the women and young mothers, as it is evident from the increasing amount of participation in gym. In such case, it appears that high moving motivation overtake fatigue and directly influence the reduction of body fat.[3]

Zumba can be used as a physical activity which provides a large calorie burn through aerobic activities done with interval training. The average person will burn around 600 to 1,000calories in a single Zumba class. It Burn an excessive amount of calorie in compared to cardio workout and improves coordination as it is needed when you grow old. It is a full body workout besides this it help you reach your target heart rate, 145 beats per minute which can help in increasing the cardiovascular endurance.[5]

This study is necessary because the prevalence of low back pain is very high in obese people and this study will help to find the effectiveness of Zumba exercise in low back pain in obese people.

METHODOLOGY

Study Design: Experimental Study

Study setting: Community

Sampling Method: Convenient Sampling

Sample size: 30

Inclusion criteria:

- Age- 18 to 45years
- BMI- 30 or higher
- Low Back Pain

Exclusion criteria:

- Age- Below 18 years and above 45 years.
- People with active lifestyle.
- People suffering from cardiovascular, neurological and musculoskeletal conditions.

Outcome Measure:

- Numeric Pain Rating Scale (NPRS).
- Modified Oswestry low back pain disability questionnaire (MODQ)
- Body Mass Index (BMI)

Procedure:

Identification of subjects were done according to the inclusion criteria. Each of them was explained about the study and its benefits and written consent was obtained from each individual. Subjects who fulfilled inclusion and exclusion criteria along with BMI scoring were recruited and assigned into group: **Zumba Exercise group**. Each individual's weight, pain and disability level i.e. BMI, NPRS and MODQ score were taken Pre and Post Intervention.

Exercise group:

30 subjects were taken into the group for 4 weeks, each session was of 45minutes.

The Zumba Exercise schedule consists of:

a) Warm-up session- 5-10minutes

• Upper limb stretching

• Lower limb stretching

• Trunk stretching

b) Zumba exercise - 30minutes

c) Cool-down - 10minutes

• Slowly decrease the intensity of exercise

• Stretching

DATA ANALYSIS

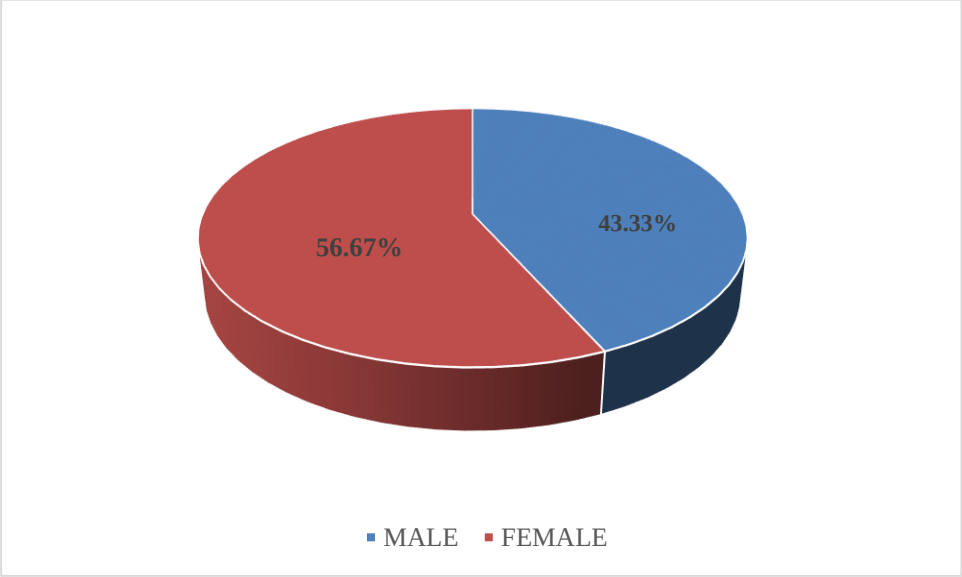
Data were analysed using SPSS statistical software using an intention-to-treat approach. Prior to all hypothesis testing, independent sample t-tests were conducted to examine whether significant mean differences existed in demographic, MODQ, BMI, NPRS scale variables among the group at baseline. We examined whether outcomes changed differentially from baseline to post intervention.

RESULT:

Demographic Profile:

1. GENDER DISTRIBUTION:

There were total 30 participants among which 17 were females and 13 were males.

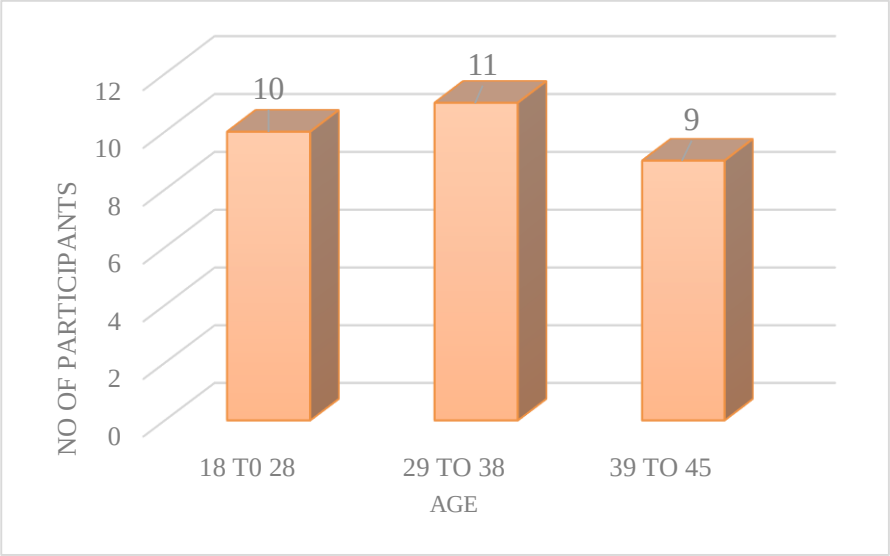


GRAPH 1: GENDER DISTRIBUTION

2. AGE DISTRIBUTION:

MEASURES	MEAN
GROUP	32

TABLE No. 1: Mean of Age Distribution within group



GRAPH 2: AGE DISTRIBUTION

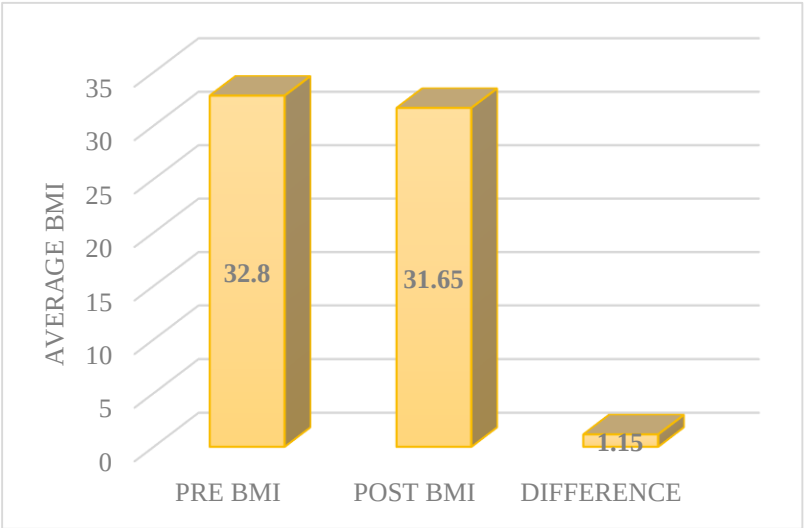
The above given age chart depicts the information about the number of participants taken in different age groups. It is apparent that the highest participant are in the age group of 29 to 38 which is 11, whereas in the age group of 18 to 28 there are 10 participants. In the age group of 39 to 45 there are 9 participants which is the lowest among all.

Clinical Parameters:

3. BMI:

MEASURES	BMI		DIFFERENCE	T-VALUE	P-VALUE
	PRE	POST			
GROUP (comparison within group)	32.70±2.86	31.65±2.39	1.05	0.00000000421308	< 0.01

TABLE No. 2: Comparison of within Groups for BMI



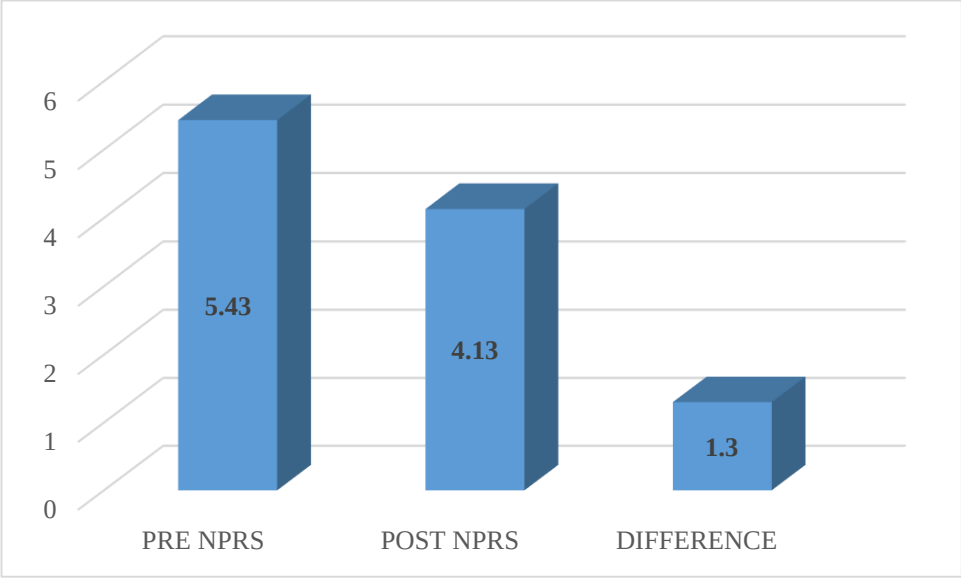
GRAPH 3: Comparison of within Groups for BMI

The above given graph shows the comparison of BMI within the groups. The average BMI were taken before the treatment and it seemed to be 32.8, whereas when the post BMI were taken it had decreased up to 31.65, hence the difference between both turns out to be 1.05.

4. NPRS (NUMERIC PAIN RATING SCALE)

MEASURES	NPRS (NUMARIC PAIN RATING SCALE)		DIFFERENCE	T-VALUE	P-VALUE
GROUP (comparison within group)	PRE	POST	1.3	0.00000000421308	< 0.01
	5.43	4.13			

TABLE No. 3: Comparison of within Groups for NPRS (NUMERIC PAIN RATING SCALE)



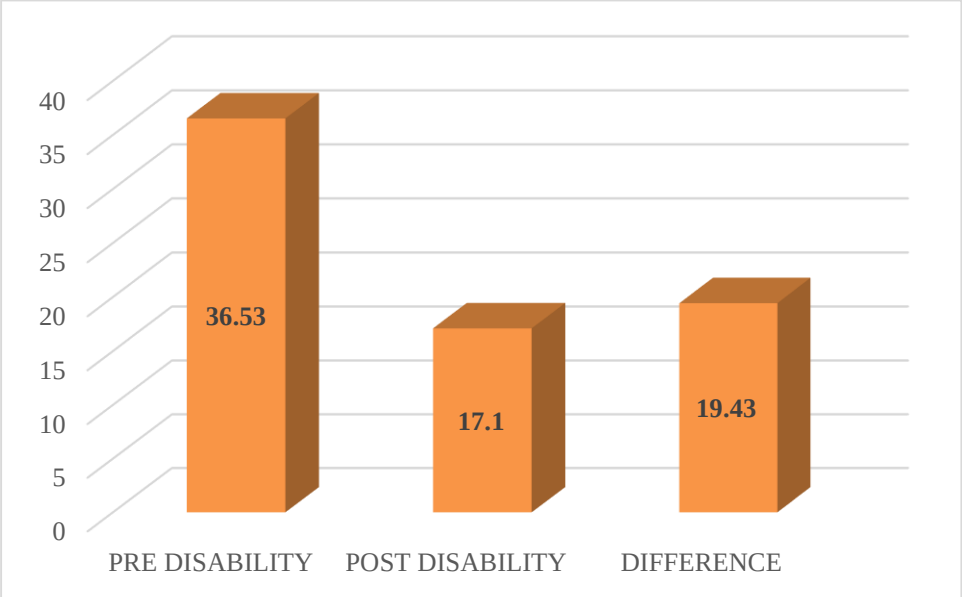
GRAPH 4: Comparison of within Groups for NPRS (NUMERIC PAIN RATING SCALE)

The above given chart shows the comparison of NPRS between the pre and post group. The pre NPRS was noted to be 5.43, however the post NPRS which was taken after the treatment was up to 4.13, hence the difference was noted to be 1.3.

5. MODIFIED OSWESTRY LOW BACK PAIN DISABILITY QUESTIONNAIRE (MODQ).

MEASURES	MODQ		DIFFERENCE	T-VALUE	P-VALUE
GROUP	PRE	POST	19.43	0.00000000000000589	< 0.01
	36.53	17.1			

TABLE No. 4: Comparison of within Groups for MODQ



GRAPH 5: Comparison of within Groups for MODQ.

The above given disability chart illustrates comparison of MODQ within the groups. The number of disability points seem to be high in pre-treatment part which is 36.53, nevertheless after the treatment a drastic change was noted and it dropped at 17.1 in the post phase of treatment, hence the difference seems to be 19.43.

DISCUSSION

The results of the study support the use of effectiveness of Zumba among obese people in low back pain. The findings obtained suggest that 4 weeks of Zumba exercise (five, forty five minute sessions a week) shows significant differences in Disability, Pain, and BMI on Obese individual.

Excessive body weight is directly related to several conditions of the spine, including the number of lumbar discs with degeneration, progression of disc disease, increased likelihood of radicular pain and neurologic symptoms and a higher prevalence of lumbar facet osteoarthritis. There are known postural changes with obesity that are likely contributing factors to an increase in mechanical load to the spine that include:

- A more flexed trunk posture leading to a decrease in flexion motion of the thoracic and thoracolumbar segments.
- An increased lordosis and decreased lateral bending of the lumbar spine.
- An increased hip joint movement.
- An increased anterior pelvic tilt.
- An increased hip-to-bench ratio for table-top work activities (a person has to stand further back from the table due to the size of the abdomen and reach farther forward). This limited spinal mobility has a negative impact on disc nutrition by limiting fluid movement and rehydration. The discs and facet joints are also affected directly by increased inflammatory responses generated by the adipose cells in the form of cytokines and acute-phase reactants.[6]

Despite these proposed and known theories of the effects of obesity on the spine, the role of obesity in directly causing LBP is still being confirmed. A review by Leboeuf-Yde of 56 research studies between 1965 and 1997 led to a conclusion that increased body weight may be a possible weak risk factor for LBP, but there were insufficient data to link it as a clear causative factor.[7]

Snow et al. randomized 54 obese patients (mean BMI 42.6 kg/m2) with musculoskeletal pain as measured by VAS (0–10 points) >5 to a physical therapy treatment program versus control group prior to a weight-loss program. The group receiving physical therapy experienced a significant reduction in VAS to 2.3 with the weight-loss program.[8]

The most recent study of nonsurgical weight loss in 46 adults with LBP and a mean BMI of 44.7 kg/m2 used a 52-week multidisciplinary program. This program included liquid meal replacements for 12 weeks (phase 1) followed by supervised caloric restriction from weeks 13–52 (phase 2). Study participants went to weekly educational meetings and group therapy sessions for the first 26 weeks, and monthly group meetings for the Second 26 weeks. During the second 26 weeks, they also participated in 60–90 min of physical activity. Over the year-long study, mean BMI was reduced to 39.6 kg/m2 (mean decrease of 5.1 kg/m2 [11.4%]) and ODI improved significantly from 31.9 to 27.1, and Numerical Pain Score (NPS) showed improvement (3.3 at baseline; 2.6 at 1 year). Weight, BMI, NPS and ODI all showed the most improvement during the initial 13 weeks of liquid meal replacements, and as the mean weight and BMI decreased, the NPS and ODI scores also decreased.[9]

Many health-associated problems are caused by the increased body fat mass and overweight. Given the global prevalence of overweight, using an accurate method is necessary to decrease overweight. Although Zumba is currently used to lose weight, this type of sport is rarely addressed in practical research as a weight loss method. Thus through this study it can be said that Zumba can be used as a conservative management to reduce weight which significantly decreases low back pain and Disability.

CONCLUSION

The current findings strongly support that Zumba exercise benefits the people having low back pain and who are suffering from obesity.

LIMITATIONS

- Small sample size.
- Limited age group of 18-45 years.
- The self-selection and convenience sampling of participants to complete the study may also influence on the result.

FUTURE RECOMMENDATIONS

- Future research should replicate these findings in other large samples, take larger age groups
- Investigate relationship between Pain and Obesity.

Abstract

Background:
Job and career satisfaction is an integral part of an individual's professional life. It affects job performance, consequently influencing growth of the profession. This study aims to assess the level of job and career satisfaction among physiotherapists of Gujarat State.
Methodology:
A cross-sectional survey was done with a self-administered e-questionnaire. 467 surveys collected were subjected to descriptive statistical analysis.
Result:
Overall job satisfaction is 39.83% (3.14±1.20) and career satisfaction is 42.84% (3.18±1.23).
Conclusions:
The majorities of physiotherapists were not satisfied with their jobs and moderately satisfied with their careers. It is essential to incorporate favourable factors in the workplace that promote professional satisfaction and there is a need to enhance opportunities for continued medical education.
Keywords:
Job satisfaction, Career satisfaction, Physiotherapists, Gujarat

INTRODUCTION

Work plays a prominent role in our lives. It occupies more time than any other single activity and provides the economical basis for our life style. Therefore, job satisfaction is a key research area for numerous specialists and is one of the most frequently studied work attitudes.[1]

Health services are affected by many factors such as human resources, delivery system and health infra structures. Among these human resources is a vital component in delivering health services. Job satisfaction of the health workers is highly important in building up employee motivation and efficiency as higher job satisfaction determine better employee performance and higher level of patients' satisfaction. Job satisfaction in health care workers has a great impact on quality, effectiveness and work efficiency and at the same time on health-care costs. Besides its importance for patients and health care system as a whole, professional satisfaction in health care workers is directly connected with absence from work, human relations and organization of work.[2, 3, 4]

Job satisfaction is how an individual feels about his or her job.[5] Job satisfaction, or dissatisfaction, not only depends on the nature of the job, but also on the individual's expectations from the job, and relies on the degree of motivation an employee has. The most common predictors for job satisfaction are leadership, interpersonal relationships, salary and promotion.[6]

Job satisfaction is under the influence of a series of factors such as: The nature of work, Salary, Advancement opportunities, Management, Work groups and Work conditions. [7] Job satisfaction is an important factor in increasing the level of work performance

and career aspirations. It is noted in the literature that there is high correlation between job satisfaction, commitment and better performance.[8, 9.]

One common research finding is that job satisfaction is correlated with life satisfaction. This correlation is reciprocal, meaning people who are satisfied with life tend to be satisfied with their job and people who are satisfied with their job tend to be satisfied with life. However, some research has found that job satisfaction is not significantly related to life satisfaction when other variables such as non-work satisfaction and core self-evaluations are taken into account.[10, 11]

There are important reasons why the researcher should be concerned with job satisfaction the first is that the people deserve to be treated fairly and with respect. Job satisfaction to some extent is a reflection of good treatment. It can also be considered as an indicator of emotional wellbeing or physiological health. The second reason is that job satisfaction can lead to behaviour of employees that affects organizational functioning .Furthermore job satisfaction can be a reflection of organizational functioning. Differences among organizational units in job satisfaction can be diagnostic of potential trouble spots.[12] Dissatisfied workers are more likely to provide inferior services, the physical and mental status and the social functioning of these workers can be affected substantially by the level of their job satisfaction.[13]

In recent years the scope of physiotherapy is also expanding to outside of medical institutions. So, that physiotherapist is increasingly expected to practice according to the social needs.[14] this necessitates practitioners to improve their quality of treatment. In order to deliver high quality of physiotherapy service it is necessary for the physiotherapist to have a firm commitment to their work, awareness of themselves as a professional & motivation & ambition to apply present and past learning and work experience to their future work.[15] One of the premises for quality treatment is job satisfaction, and this, in turn, influences employee retention in the work field, decreases absenteeism, improves work productivity and enhances performance.[16]

Knowledge about Physiotherapists job satisfaction will indirectly influence career choice and professional preferences in students for choosing Physiotherapy as a profession. One of the premises for quality treatment is job satisfaction, and this, in turn, influences employee retention in the work field, decreases absenteeism, improves work productivity and enhances performance.[17] Knowledge about Physiotherapists job satisfaction will indirectly influence career choice and professional preferences in students for choosing Physiotherapy as a profession.[18]

METHODOLOGY

Study design: A cross sectional survey study

Source of data: Physiotherapy colleges of Gujarat, Hospitals and Private Clinics of Gujarat, Social Media (Google, Facebook, Instagram, LinkedIn, and Whatsapp)

Population: Physiotherapists with more than 6 months of experience

Method of collection of data: Online survey form

Sample size: Convenient

Duration of study: 1 year

Inclusion criteria:

- Physiotherapists working in Physiotherapy Colleges of Gujarat.
- Physiotherapists having private practice or working at hospitals of Gujarat
- Physiotherapists having postal and/or email address.
- Physiotherapists having more than 6 months of work/teaching experience.

Exclusion criteria:

- Physiotherapists not willing to participate in the study.
- Physiotherapists not replying to the questionnaire in the fixed time period.
- Physiotherapists having less than 6 months of work/teaching experience.

Procedure:

The questionnaire was constructed with closed questions pertaining to job and career satisfaction. Job satisfaction included a set of questions on knowledge, work ethics, qualification, remuneration, rewards, communication among co-workers, and opportunities provided at the workplace. Career satisfaction included a set of questions on professional status, opportunities, immigration, career path, contribution, and research activity. It also covered basic demographics such as age, gender, years of experience and qualification (i.e. master‘s/bachelor‘s degree). Only the responses of individuals with more than 6 months of experience were included. The questionnaire was developed on Google Forms and consisted 15 closed questions, equally distributed on job and career satisfaction, eight of which focused on job satisfaction, and seven on career satisfaction.

STEP: 1

Identifying eligible candidates according to the inclusion criteria

STEP: 2

Selecting suitable candidates

STEP: 3

Sending consent form

STEP: 4

Sending survey form after receiving consent form

STEP: 5

Collection of data

STEP: 6

Assessment of collected data

STEP: 7

Statistical data analysis

STEP: 8

Result

DATA ANALYSIS

Statistical analysis was carried out with SPSS (v.26). Convenience sampling was used and descriptive statistics was performed. Mean, standard deviation and percentage were used and the level of satisfaction for each question was expressed in percentage. Finally, overall combined job and career satisfaction was calculated in percentage.

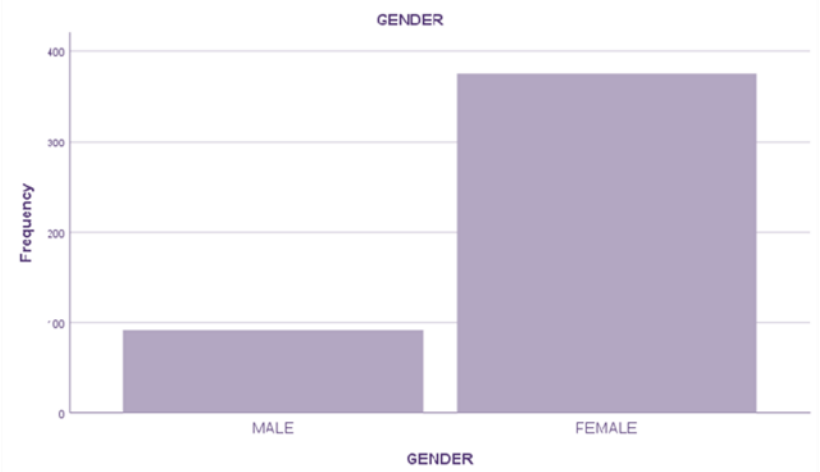
RESULT:

The demographic detail of the respondents is shown in the tables below. There were a total of 467 responses.

GENDER					
		Frequency	**Percent**	**Valid Percent**	**Cumulative Percent**
Valid	**Male**	92	19.7	19.7	19.7
	Female	375	80.3	80.3	100.0
	Total	467	100.0	100.0	

TABLE.1

As shown in the table 1, out of total number of respondents, 92 were male and 375 were female.



GRAPH.1

AGE RECORDED					
		Frequency	**Percent**	**Valid Percent**	**Cumulative Percent**
Valid	**18-24**	322	69.0	69.0	69.0
	25-35	116	24.8	24.8	93.8
	36+	29	6.2	6.2	100.0
	Total	467	100.0	100.0	

TABLE.2

As shown in the table 2, 322 respondents were of age group ranging from 18-24 years, 116 respondents were of age group ranging from 25-35 years and 29 respondents were of age group ranging from 36-45 years.

Q15	**Indian PTs are immigrating for better prospects**	4.0321	.30908	96.8%
20–40% disagree; 41–60% moderately disagree; 61–80% agree; >80% highly agree				

Table 24 and Table 25 represent career satisfaction level among physiotherapists

The results were as follows for satisfaction with:

- Satisfaction with professional status: 49.5% (3.224±1.390)
- Opportunities for continued medical education: 20.8% (2.68±0.987).
- Satisfied with the career path chosen: 49.2% (3.76±1.363)
- Contribution to the profession: 57% (3.546 ±1.247).
- Opportunities at work: 37.7% (3.10±1.165)
- Qualification level influences the income: 43.1% (2.74±1.439),
- Physiotherapists emigrating for better prospects: 96.8% (4.032±0.309).
- Overall career satisfaction among physiotherapists: 42.84% (3.18±1.137).

DISCUSSION:

In this state level survey, it was found that most physiotherapists surveyed were moderately dissatisfied with their job and career. The authors were unable to find literature on career satisfaction among Physiotherapists of Gujarat State.

Job satisfaction

Workplace opportunities, communication, ethics, and qualification-matching designation:

Physiotherapy is a skill-based profession where most of the techniques require a hands-on approach. Therefore, it is important for individual physiotherapists to have periodic training to update their skills and knowledge within their workplaces based upon international standards. Developing countries like India lack such opportunities. However, this study reveals that the majority of the

individual surveys were happy about the current opportunities provided to them. Interpersonal relationships, which affect communication among co-workers, is another sensitive area that has an impact on professional development[19]. The survey within this study showed that 53.1% of the physiotherapists were satisfied with their communication with co-workers and supervisors. One of the important aspects of job satisfaction is having an appropriate designation based on an individual's qualification. This is the indirect way of keeping workers effective at work. Depending on their designation, their remuneration and work responsibilities can change. In this study, 57.4% of physiotherapists were happy with their designation based on their qualification. Work ethics is also one of the important factors, which determines employee satisfaction on. This study shows that the majority of the employees reported being satisfied with their organization's work ethics.[20]

Career satisfaction

Professional status, qualification influence on income, and immigration:

In the current study, 49.5% of the physiotherapists were satisfied with their professional status in the community. The majority of the participants agree that physiotherapists are immigrating to other places for better prospects. This indirectly states that the majority of them are dissatisfied working in Gujarat, and it is presumed to be the same in other developing countries. Since this survey has been able to reach only a few of the PTs in Gujarat, however, this statement cannot be generalized. There is a need for extensive research regarding this aspect.

Remuneration, salary increments, organizational criteria and rewards:

Remuneration is another important element of job satisfaction. This survey reveals that only 35.4% of physiotherapists were happy with the remuneration they receive for the work they do. This provides some insight into the situation in India where it appears physiotherapists feel they are underpaid. Motivating the employee to improve their performance in the workplace is necessary, as is rewarding them periodically for their performance.[21]

In the current survey, 25.5% of the respondents was satisfied with the rewards they received for their work performance.

Career choice, contribution to the profession and opportunities for research activity:

The most encouraging aspect of this survey is that the majority of the participants were happy about the career they have chosen. It is essential to keep ourselves updated with recent information in order to provide safe, effective and quality care for our patients. Of the population in the current study, 79.2% expressed dissatisfaction towards the opportunities provided for continued professional education.

CONCLUSION

The majority of physiotherapists in the current study were not satisfied with their job and moderately satisfied with their career in the state of Gujarat. This study represents the scenario in state of Gujarat in India, providing insight into the situation in developing countries and also provides a global outlook when compared with developed countries.

LIMITATIONS

- Convenient sample size. Responses were collected from the physiotherapists whose contacts were possible either through email or social media.
- The main limitation of the study was the participation in the survey. As the survey was sent electronically, the response rate was solely dependent on participants 'motivation.
- The major drawback of the study was that it could only reach the major cities in Gujarat, and those who used networks. This should be a consideration for future study.
- This was a preliminary survey which does not represent the entire population; hence, a detailed study should be carried out with large sample size in order to be able to generalize the results.

FUTURE RECOMMENDATIONS:

- Other factors affecting job satisfaction can be considered.
- Individual factor for job satisfaction can be studied.
- Inclusion of all the physiotherapists in Gujarat.
- Job satisfaction of Physiotherapists can be compared with other health care professionals.
- Job satisfaction among Physiotherapists working in different health care settings can be studied.

ABSTRACT

BACKGROUND AND OBJECTIVES :

This study was conducted to find the prevalence of osteoarthritis of knee in young people age between 21 to 30 years having sitting or standing work profession. The purpose of the study was to find prevalence ratio of OA in young people. Osteoarthritis (OA) is defined as a heterogeneous group of conditions that lead to joint symptoms and signs associated with a defective articular cartilage and related changes in bone morphology. It is considered the most common type of arthritis, as well as one of the most significant health problems that pervades our modern world. In 2019, it was estimated that 43 million adults suffered from arthritis. Of those, 26.9 million adults aged 25 years or older had OA. One in four people is expected to develop symptomatic OA in his or her lifetime.

INTRODUCTION :

Arthritis is a common joint problem usually associated with older adults. And there are very less study/,research Conducted on osteoarthritis in young age. According to the National Library of Medicine (NLM)Trusted Source, most people show symptoms of osteoarthritis by the time they are 70 years old, but there are also potential chances of osteoathritis in young age. So, this research helps to determine the Prevalence rate in various conditions. So this study may help to determine the prevalence ratio of OA in young people.

METHODOLOGY:

Research will be done on around 100 subjects age between 21 to 30 years with having sitting or standing profession to find Prevalence ratio for OA in young people.

Prevalence rate will be calculated by below formula.
* Prevalence percentage = OA will be found for given
Criteria / OA Will be not found for given criteria (Number of sub.) * 100 %

An observational study was conducted by using the convenient sample method. One hundred working professionals of ahmedabad and nearby area participated in this study by performa validated assessment form and clinical measures.

RESULT:

The prevalence of OA varies according to the definition of OA, the specific joint(s) under study, and the characteristics of the study population. The age standardized prevalence of radiographic knee OA in given subjects age between 21-30 years was only 5% among the all participants. Out of 100 subjects only 5 subjects primarily suspected of having OA of knee. Out of 100 subjects there was 56 female and 44 male subject in this survey. And OA was found in 3 female and 2 male subject after assessing clinical measures.

So, the prevalence percentage of OA of knee in young people age between 21 to 30 years having prolonged sitting or standing work profession would be as below:

$$\text{Prevalence percentage} = \frac{\text{OA will be found for given Criteria}}{\text{OA Will be not found for given criteria}} \times 100$$

PREVALENCE PERCENTAGE = 5/95 * 100% = **5.2631%**

A sum of 100 working professionals responded answering the questionnaire. An analysis was done by excel & calculation was done by chi square test calculator. The chi- square statistics found as **0.1695.** The p value is **0.918761**. The result is not significant at **p < .01**.

Keywords : Osteoarthritis , Prevalence , Young working professionals

Introduction

●Osteoarthritis (OA) is a common chronic condition resulting in pain, fatigue, functional limitations, increased healthcare utilization and high economic costs to society. The burden of OA is projected to increase, due in part to obesity and population aging.
●While the prevalence of OA increases with age, there is a growing recognition that OA affects people at younger ages.
●Recent US data demonstrated that half of people with symptomatic knee OA are diagnosed by age 55.

• Osteoarthritis (OA) is one of the most devastating chronic conditions that affect people around the world.
• Although the usual population associated with the condition is the elderly, who are mostly inactive, athletes and younger individuals are also susceptible.
• Depending on the population, the etiology may differ; injuries, occupational activities, and obesity appear to be the most common
causes of OA in young and athletic populations. [1]

Fig 1.1 X-RAY FINDING OF KNEE OA

Left) In this x-ray of a normal knee, the space between the bones indicates healthy cartilage (arrows). (Right) This x-ray of an arthritic knee shows severe loss of joint space.

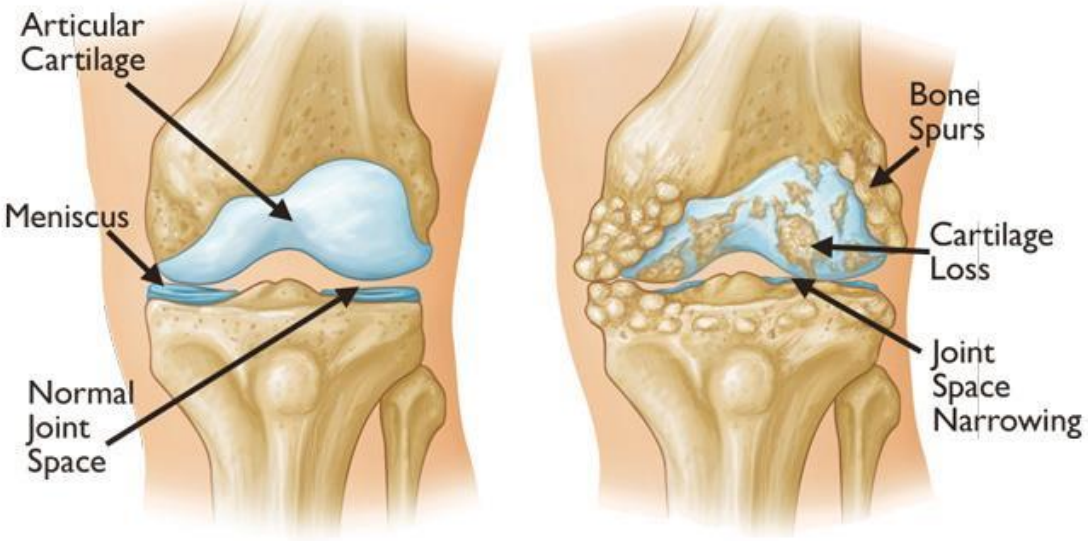

Fig 1.2 NORMAL KNEE VS OA KNEE

Osteoarthritis often results in bone rubbing on bone. Bone spurs are a common feature of this form of arthritis.

Stage 0 represents a normal joint.

- Stage 1 represents very minor wear and tear on a joint, but pain is unlikely.
- Stage 2 represents mild osteoarthritis, which is when most will typically begin experiencing pain and discomfort.
- Stage 3 is designated moderate, where there is obvious cartilage erosion. This may come with joint stiffness, more severe pain, and the experience of popping or snapping sounds.
- Stage 4 osteoarthritis is severe, where the joint space between the bones is considerably reduced. This creates greater friction, which generates more pain and discomfort.

What Are the Symptoms of Osteoarthritis?

• Symptoms of osteoarthritis most often develop gradually and include:
• Joint aching and soreness, especially with movement
• Pain after overuse or after long periods of inactivity
• Stiffness after periods of rest
• Bony enlargements in the middle and end joints of the fingers

(which may or may not be painful)

• Joint swelling
Some Of Potential Causes That Can Develop OA In Young People.
• There are several factors that increase a person's chances of developing osteoarthritis. These include:

• **Heredity**. Some people have an inherited defect in one of the genes responsible for making cartilage. This causes defective cartilage, which leads to more rapid deterioration of joints.
•People born with joint abnormalities are more likely to develop osteoarthritis, and those born with an abnormality of the spine (such as scoliosis or curvature of the spine) are more likely to develop osteoarthritis of the spine.[3]

• **Obesity** . Obesity increases the risk for osteoarthritis of the knee, hip, and spine. Maintaining ideal weight or losing excess weight may help prevent osteoarthritis of these areas or decrease the rate of progression once osteoarthritis is established.

• **Injury**. Injuries contribute to the development of osteoarthritis. For example, athletes who have knee-related injuries may be at higher risk of developing osteoarthritis of the knee. In addition, people who have had a severe back injury may
be predisposed to develop osteoarthritis of the spine. People who have had a broken bone near a joint are prone to develop osteoarthritis in that joint.[3]

• **Joint overuse**. Overuse of certain joints increases the risk of developing osteoarthritis. For example, people in jobs requiring repeated bending of the knee are at increased risk for developing osteoarthritis of the knee.
• Other diseases. People with rheumatoid arthritis, the second most common type of arthritis, are more likely to develop osteoarthritis. In addition, certain rare conditions, such as iron overload or excess growth hormone, increase the chance of developing OA.[3]

•OA isn’t restricted to older adults. Younger adults can also experience symptoms that may signify OA, including:

• morning joint stiffness
• aching pain
• tender joints
• limited range of motion
• Most often pathology develops in women but found in men.
Usually it is detected when it has already happened to
fracture, especially of the femur, which is considered the
most serious and life-threatening.[4]

• After pain, stiffness was identified as a significant
symptom that…
• impacted daily life. Other impactful symptoms included:

• - functional, walking and standing limitations
• - loss of flexibility
• - sleep disturbance
• - fatigue
• - grating (bone on bone) sensation
• - joint swelling
• - disfigurement
• - other numbness and instability (OA VOP 2017)[4]

• Diagnosing OA in athletes and young individuals is sometimes challenging because of their increased pain tolerance. However, the treatment of OA in these populations does not differ from its management in the general population.
• Several considerations need to be taken into account when choosing a treatment modality. The purpose of this review is to address OA in athletes and younger individuals and to discuss its presentation, diagnosis, and treatment.[4]

Clinical Findings for OA

X-Rays – Cartilage loss, a tell-tale sign of osteoarthritis, appears as a narrowing of the space between bones in the joint. While an X-ray image will not show the cartilage itself, your doctor can use this bone proximity to provide a diagnosis. An X-ray can also show bone spurs around a joint, which may cause pain and tenderness.

MRI – A magnetic resonance imaging test, or MRI, can produce detailed images of bone and soft tissues. This includes cartilage. This test is not typically needed for an initial diagnosis, but it can provide more information about the disease's progression.

Blood tests – Certain blood tests can help rule out other causes of joint pain, like rheumatoid arthritis, narrowing your doctor's field of potential diagnoses.

Joint fluid analysis – In this test, your doctor will use a syringe to draw fluid from the affected joint. They then test the fluid to determine whether the inflammation is caused by an infection or gout, homing in on a definitive diagnosis.

Epidemiology

●Osteoarthritis (OA) of the knee is the most common form of joint disease and prevalence of both radio graphically evident and symptomatic. The females having higher prevalence than males (11.4% vs 6.8%).

●The gender difference in prevalence has recently been emphasized in a meta-analyses, which provides evidence for a greater risk in females for prevalent and
incident knee OA.

●The meta-analysis also reported that females tend to have more severe knee OA radio graphically assessed than males and that the gender differences increase with
age > 55 years. The prevalence of OA will increase as the population of the kingdom ages, especially if the incidence of obesity remains at over 50% in the 45+ age.

• OA in adults is frequently accompanied by comorbidities that
• contribute to decreased quality of life:
• - obesity or being overweight (90 percent)
• - hypertension (40 percent)
• - depression (30 percent)
• Osteoporosis at a young age is very rare, so at the first manifestations should be sure to look for the causes of the disease.[2]
• Activity Limitation: • Arthritis limits the activities of 23.7 million US adults. Around 44% of adults with doctor-diagnosed arthritis had arthritis attributable activity limitations in 2013–2015.
• Leading Cause of Work Disability
• Arthritis and other rheumatic conditions are a leading cause of work disability among US adults.3
• In all US states, 1 in 25 working-age adults aged 18 to 64 years face work limitations they attribute to arthritis; among those with arthritis, at least 1 in 4 have work limitations. The prevalence of work limitations due to arthritis varies by state.
•Risks of revision surgery are especially pronounced in the younger patient, who may be more physically active and, consequently, subject to multiple revision surgeries over a lifetime. (DR.S.Bhandari 2012)[5]

NEED OF STUDY

• Arthritis is a common joint problem usually associated with older adults. And there are very less study/research Conducted on osteoarthritis in young age. According to the National Library of Medicine (NLM)Trusted Source, most people show symptoms of osteoarthritis by the time they are 70 years old, but there are also potential chances of osteoathritis in young age. So, this research helps to determine the Prevalence rate and percentage of OA in young working professionals who have prolonged sitting ans standing work profession. So this study may help to determine the prevalence ratio of OA in young people.

OBJECTIVE OF THE STUDY

• To find prevalence of OA in young people(Age between 21 to 30 years) having prolonged sitting or standing work profession in ahmedabad and gandhinagar area.

• *REVIEW OF LITERATURE*

1. Prevalence of osteoarthritis of knee joint among adult population in a rural area of Kanchipuram District, TN [Venkatachalam.J, Natesan.M, Bharath Z] Year -2018.[9]

•A total of 1986 adult respondents were interviewed out of which 27.1% had OA of knee. Age more than 50 years, female gender, tobacco usage, illiteracy, lower socioeconomic class, positive family history of OA, diabetes, and hypertension were found to be associated with OA knee ($P < 0.05$).

• Conclusion: The burden of osteoarthritis knee was high in this region. Hence, effective preventive strategy has to be taken to minimize this burden.

2. Osteoarthritis Affects Younger People, Too by ILANA N. ACKERMAN, PT, PhD (Article published in 2019)[10]

●Conclusion of this study

• In this article researcher found that In younger people presenting with persistent joint pain and transitory stiffness (particularly those who have sustained a previous traumatic joint injury), the early signs of OA should be suspected. Routine imaging is not indicated for the diagnosis of uncomplicated knee or hip OA.
•While X-rays are inexpensive, radiographic findings are not well correlated with symptoms and are unlikely to alter the management plan or predict future disease progression. Magnetic resonance imaging can detect early OA changes that may be useful in a research context,but the clinical significance of these changes is questionable. Overuse of MRI is costly for health systems and may lead to unwarranted surgical interventions.

• These include activity-related joint pain and either no joint-related morning stiffness or morning stiffness lasting no longer than 30 minutes.Atypical features (eg, a hot swollen joint, prolonged morning stiffness, or rapid worsening) warrant investigation, as they may indicate other diagnoses, including inflammatory or septic arthritis, or malignancy.

3. Hip and knee osteoarthritis In young age (ADAM G. CULVENOR, PT, PhD), RANA S. HINMAN, PT, PhD(Vol 2. Feb. 2017)[11]

• Hip and knee OA is not restricted to older age groups and can profoundly affect quality of life and work participation among younger people. Knee joint injury is a strong risk factor for subsequent knee OA, and early signs and symptoms may present in the decade following injury or reconstructive surgery.

•Thorough physical examination can identify key impairments, and PROMs are valuable tools for tracking changes in pain, function, and well-being. Nonsurgical management approaches relevant to younger patients include education and self-management support, physical therapist–prescribed exercise programs, and weight management.

4. Epidemiology of osteoarthritis: state of the evidence. Kelli D. Allen, Yvonne M. Golightly [2019].[12]

• This study concludes the Risk factors with strong evidence for osteoarthritis onset and/or progression include age, sex, socioeconomic status, obesity, family history, joint injury, joint alignment, and occupational joint loading.Traditional epidemiologic studies and mining of large health administrative databases show a large and increasing impact of osteoarthritis.

5. Risk Factors for Osteoarthritis and Contributing Factors to Current Arthritic Pain in South Korean Older Adults.Kyoung Min Lee, Chin Youb Chung, Ki Hyuk Sung, Seung Yeol Lee, Sung Hun Won, Tae Published online 2014 Dec 10.[13]

• The Fourth Korean National Health and Nutrition Examination Surveys was conducted in 2009. Therein, 720 males and 1008 females aged between 25 years to 45 years older were included. Comprehensive data on habitual, socioeconomic, medical, nutritional, and psychological factors were collected along with the presence of osteoarthritis and arthritic pain. After univariate analysis, binary logistic regression analysis was performed to identify risk factors for osteoarthritis and contributing
factors to current arthritic pain. And the study conclude that higher BMI, lack of weekly moderate intensity activity, and unfavorable subjective health status were significant factors contributing to current arthritic pain. More attention needs to be paid to psychiatric effects on osteoarthritis and joint related pain.

6. What Are the common risk factors that cause OA in younger athletes (Whittaker.J 2015)[14]

This study concludes some major and most common risk factors that cause OA in younger athletes that mentioned as below.

• Five common athletic injuries have been identified as placing patients at greater risk of developing post-traumatic OA:

• - anterior cruciate ligament (ACL) ruptures
• - meniscus tears (the second most common structure damaged in athletes)
• - shoulder dislocation
• - patellar dislocation
• - ankle instability (the most commonly injured joint in the body)

7.Osteoarthritis in Young, Active, and Athletic Individuals. *Adae O Amoako(2018)*[10]

This study concludes several risk factors associated with OA. In the athlete or young individual, injury, occupational activities, and obesity are the main factors that contribute to OA. Diagnosis of OA in the athlete is often delayed and difficult

because of high tolerance to pain, as well as the athlete's preference for expedited return to play. History, physical examination, laboratory tests, and radiographic findings may be used to make a definite diagnosis of OA. Exercise remains the recommended initial treatment for OA in all populations. NSAIDs, braces, and surgery are other treatment modalities for OA. The treatment of OA in the athlete or young individual should be patient specific, with consideration for the patient's expectations and the period of absence from sports activities.

8. Workplace policies and prevalence of knee osteoarthritis: the Johnston County Osteoarthritis Project. J-C Chen, L Linnan, L F Callahan, E H Yelin, and J B Renner, J M Jordan [2007 Jun 13]

The negative associations between KOA and workplace policies raise concerns about possible employment discrimination or beneficial effects of workplace policies.

Longitudinal studies are needed to clarify the dynamic complexities of KOA risks and outcomes in relation to workplace policies.

Studies on the interrelations of work and osteoarthritis (OA) remain an active area of research because of their profound implications for clinical practice and public policy. As indicated in recent reviews of epidemiological literature on the relationship between occupational factors and risks of knee OA (KOA),[1,2] both case–control and prospective cohort studies have shown the positive associations between KOA and physical exposures in the workplace, and the strength of scientific evidence is moderate.

Specifically, previous studies have shown that certain occupational activities (e.g., kneeling, squatting or climbing) increase the risk of KOA,[3,4,5,6] presumably due to increased biomechanical loads on knee joints.

However, most of the previous studies were primarily focused on individual-level attributes; very little data are available to examine the potential link between KOA and organisation-level workplace characteristics (e.g., workplace policies, employers' commitment), many of which play an important role in occupational health and safety.

HYPOTHESIS

NULL HYPOTHESIS :

There's no correlation find between knee OA and young people (Age between 21 to 30 years) having prolonged sitting or standing work profession. That's why prevalence rate is difficult to find and result is not significant.

RESEARCH HYPOTHESIS :

There's some correlation find between knee OA and young people (Age between 21 to 30 years) having prolonged sitting or standing work profession. Hens prevalence

rate can be find and significance can be find through this research.

METHODOLOGY

MATERIALS AND METHODOLOGY :-

STUDY DESIGN : Cross-sectional study

SOURCE OF DATA : Hospitals and Offices

POPULATION : Young Working professionals having age between 21 to 30 years who have prolonged sitting or standing work profession.

SAMPLING METHOD : Convenient Sampling Method

DURATION OF STUDY : 1 month

SAMPLE SIZE : 100

•Method of selection of data:

Research will be conducted on young people age between 21 to 30 years having prolonged standing or sitting work profession. An observational study was conducted by using the convenient sample method. One hundred working professionals of ahmedabad and nearby area participated in this study by perform validated assessment form and clinical measures.

• *INCLUSION CRITERIA*

• Subject having age between 21 to 30 Years.

• Both male and female subject.

• Subject who having prolonged sitting or standing work profession (Ex: Nurse, Teacher/Professor, Petrol filler man).

• *EXCLUSION CRITERIA*

• Subject having diabetes, hyperthyroidism, hypertension, osteoporosis, rickets and various type of muscular disorders.

• Subject having autoimmune disease.

• Subject with previous history OA surgery.

• Subject with history of any other neurological and cardio-thoracic conditions.

• Subject having OA of hip, wrist or hand and feet.

• OUTCOME MEASURES

• Clinical assessment forms

• Patient's X-ray, and other radiological reports

• Clinical Measures

• Excel sheet

• The Visual Analogue WOMAC 3.0 scale & VAS scale

• Goniometer

RESULT :

PROCEDURE OF RESEARCH:

Survey of the working professionals

Data collection by using the questionnaire

Data analysis

Data Interpretation

Result

Conclusion

A sum of 100 working professionals responded answering the questionnaire. An analysis was done by excel & calculation was done by chi square test calculator. The chi- square statistics found as 0.1695. The p value is 0.918761. The result is not significant at $p < .01$.

RESULTS			
	NONE	MILD	MODERATE
MALE	42 (41.80) [0.00]	1 (1.32) [0.08]	1 (0.88) [0.02]
FEMALE	53 (53.20) [0.00]	2 (1.68) [0.06]	1 (1.12) [0.01]

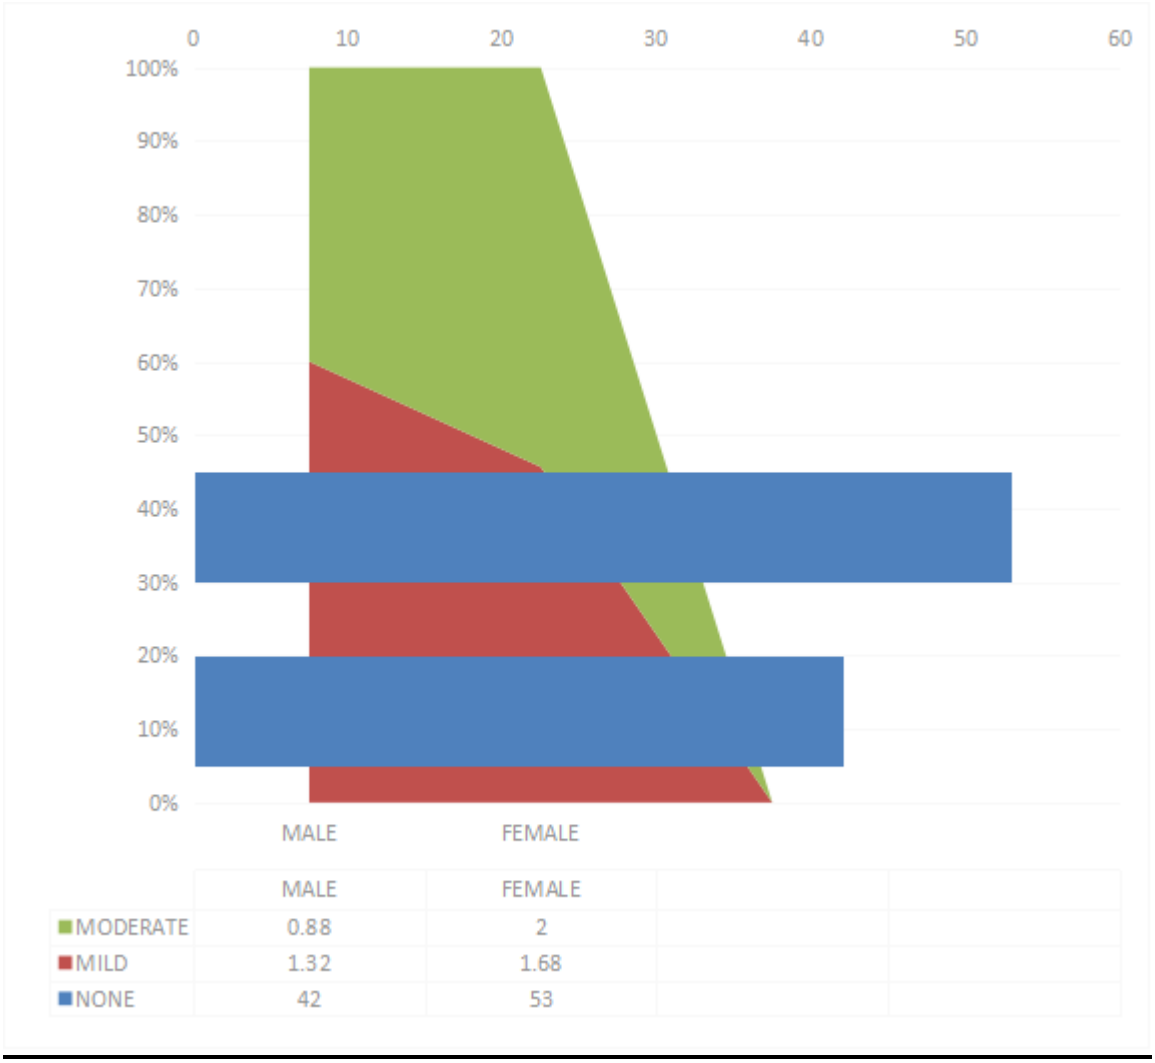
1.1 RESULT TABLE WITH P VALUE AND CHI SQUARE DATA

The prevalence of OA varies according to the definition of OA, the specific joint(s) under study, and the characteristics of the study population. The age standardized prevalence of radiographic knee OA in given subjects age between 21-30 years was only 5% among the all participants. Out of 100 subjects only 5 subjects primarily suspected of having OA of knee. Out of 100 subjects there was 56 female and 44 male subject in this survey. And OA was found in 3 female and 2 male subject after assessing clinical measures.

So, the prevalence percentage of OA of knee in young people age between 21 to 30 years having prolonged sitting or standing work profession would be as below:

Prevalence percentage = OA will be found for given Criteria **DEVIDED BY** OA Will be not found for given criteria **INTO 100%**

TOTAL PREVALENCE PERCENTAGE = **5.2631%**
PREVALANCE PERCENTAGE IN MALES = **2.10%**
PREVALANCE PERCENTAGE IN FEMALES = **3.15%**



GRAPH 1.1 CHI SQUARE

➡ ***CHI SQUARE STATISTICS WITH PREVALANCE DATA***

A chi-squared test (also chi-square or χ^2 test) is a statistical hypothesis test that is valid to perform when the test statistic is chi-squared distributed under the null hypothesis, specifically Pearson's chi-squared test and variants thereof. Pearson's chi-squared test is used to determine whether there is a statistically significant difference between the expected frequencies and the observed frequencies in one or more categories of a contingency table.

Symptoms - These questions should be answered thinking of your knee symptoms during the **last week**

DISCUSSION :

The present study was carried out to find prevalence of osteoarthritis in young people (Age between 21 to 30 years) having prolonged sitting and standing profession. This study was performed in the ahmedabad and nearby areas. any damage to the joints cannot be reversed, the symptoms of osteoarthritis can be managed, allowing sufferers to live as normal a life as possible.

Treatments for osteoarthritis include lifestyle advice, medications, orthobiologics and surgery.

Lifestyle changes include taking steps to lose weight if necessary and doing low impact exercise, such as yoga, to help strengthen muscles around the joint to stabilise it. Your doctor may refer you to a physiotherapist if your job or choice of physical activity is causing your symptoms. They may also recommend topical treatments or the use of hot or cold compresses.

Osteoarthritis typically affects people over the age of 50, but young people can be affected as well.[2] The CDC estimates that about 7% of the U.S. population aged 18–44 had been diagnosed with OA from 2013–2015.

Younger people who are active in sports or other physically demanding activities, or who have sustained an injury such as a torn meniscus—a tear in the cartilage of the knee—may be more prone to developing the condition earlier in life.

Over 32 million people across the U.S. live with osteoarthritis.[3] While this condition can affect any joint, it typically affects the knees, hips, back, hands, and neck. Symptoms such as pain or swelling may not occur right away and can worsen over time.

This study was conducted to find the prevalence of osteoarthritis of knee in young people age between 21 to 30 years having sitting or standing work profession. The purpose of the study was to find prevalence ratio of OA in young people. Osteoarthritis (OA) is defined as a heterogeneous group of conditions that lead to joint symptoms and signs associated with a defective articular cartilage and related changes in bone morphology. It is considered the most common type of arthritis, as well as one of the most significant health problems that pervades our modern world. In 2019, it was estimated that 43 million adults suffered from arthritis. Of those, 26.9 million adults aged 25 years or older had OA. One in four people is expected to develop symptomatic OA in his or her lifetime.

SUMMARY & CONCLUSION

The prevalence of OA varies according to the definition of OA, the specific joint(s) under study, and the characteristics of the study population. The age standardized prevalence of radiographic knee OA in given subjects age between 21-30 years was only 5% among the all participants. Out of 100 subjects only 5 subjects primarily suspected of having OA of knee. Out of 100 subjects there was 56 female and 44 male subject in this survey. And OA was found in 3 female and 2 male subject after assessing clinical measures.

A sum of 100 working professionals responded answering the questionnaire. An analysis was done by excel & calculation was done by chi square test calculator. The chi- square statistics found as 0.1695. The p value is 0.918761. The result is not significant at $p < .01$.

This study concludes that prevalence of osteoarthritis is very less in young working professionals that's why we can conclude that young people is not very prone for OA.
But there are some potential chances for having OA is present like lifestyle, genetic factors and other factors that can cause OA in young age.

LIMITATION & FUTURE RECOMMENDATION

1. Small sample size.
2. Limited research area.
3. The self selection and convenient sampling of participates to complete the study may also influence the result.
4. Very limited access to clinical measures.
5. Very small subject group.

FUTURE RECOMMENDATION

- Future research should replicate these findings in other large samples , take larger age groups to find most accurate prevalence of OA in young working professionals.

ANNEXURE A

Clinician's name (or ref) **Patient's d.o.b :**

INSTRUCTIONS: This survey asks for your view about your knee. This information will help us keep track of how you feel about your knee and how well you are able to do your usual activities.

Answer every question by ticking the appropriate box. If you are unsure about how to answer a question, please give the best answer you can.

Symptoms - These questions should be answered thinking of your knee symptoms during the **last week.**

S1. Do you have swelling in your knee?

○ Never ○ Rarely ○ Sometimes ○ Often ○ Always

S2. Do you feel grinding, hear clicking or any other type of noise when your knee moves?

○ Never ○ Rarely ○ Sometimes ○ Often ○ Always

S3. Does your knee catch or hang up when moving?

○ Never ○ Rarely ○ Sometimes ○ Often ○ Always

S4. Can you straighten your knee fully?

○ Never ○ Rarely ○ Sometimes ○ Often ○ Always

S5. Can you bend your knee fully?

○ Never ○ Rarely ○ Sometimes ○ Often ○ Always

Stiffness - The following questions concern the amount of joint stiffness you have experienced during the **last week** in your knee. Stiffness is a sensation of restriction or slowness in the ease with which you move your knee joint.

S6. How severe is your knee joint stiffness after first wakening in the morning?

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

S7. How severe is your knee stiffness after sitting, lying or resting **later in the day?**

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

Pain[1]

P1. How often do you experience knee pain?

○ Never ○ Monthly ○ Weekly ○ Daily ○ Always

What amount of knee pain have you experienced the **last week** during the following activities?

P2. Twisting/pivoting on your knee

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

P3. Straightening knee fully

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

P4. Bending knee fully

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

P5. Walking on flat surface

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

P6. Going up or down stairs

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

P7. At night while in bed

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

P8. Sitting or lying

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

P9. Standing upright

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

Function, daily living - The following questions concern your physical function. By this we mean your ability to move around and to look after yourself. For each of the following activities please indicate the degree of difficulty you have experienced in the **last week** due to your knee.

Al. Descending stairs				
○ None	○ Mild	○ Moderate	○ Severe	○ Extreme

A2. Ascending stairs				
○ None	○ Mild	○ Moderate	○ Severe	○ Extreme

For each of the following activities please indicate the degree of difficulty you have experienced in the **last week** due to your knee.

A3. Rising from sitting				
○ None	○ Mild	○ Moderate	○ Severe	○ Extreme

A4. Standing				
○ None	○ Mild	○ Moderate	○ Severe	○ Extreme

A5. Bending to floor/pick up an object				
None	Mild	Moderate	Severe	Extreme

A6. Walking on flat surface				
○ None	○ Mild	○ Moderate	○ Severe	○ Extreme

A7. Getting in/out of car				
○ None	○ Mild	○ Moderate	○ Severe	○ Extreme

A8. Going shopping				
○ None	○ Mild	○ Moderate	○ Severe	○ Extreme

A9. Putting on socks/stockings				
○ None	○ Mild	○ Moderate	○ Severe	○ Extreme

A10. Rising from bed				
○ None	○ Mild	○ Moderate	○ Severe	○ Extreme

A11. Taking off socks/stockings

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

A12. Lying in bed (turning over, maintaining knee position)

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

A13. Getting in/out of bath

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

A14. Sitting

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

A15. Getting on/off toilet

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

For each of the following activities please indicate the degree of difficulty you have experienced in the **last week** due to your knee

A16. Heavy domestic duties (moving heavy boxes, scrubbing floors, etc)

○ Never ○ Rarely ○ Sometimes ○ Often ○ Always

A17. Light domestic duties (cooking, dusting, etc)

○ Never ○ Rarely ○ Sometimes ○ Often ○ Always

Thank you very much for completing all the questions in this questionnaire.

ABSTRACT

BACKGROUND:

Frozen Shoulder Is An Idiopathic Diseases Characterized By Fibrosis, Decrease Volume Of The Glenoid Capsule, And Progressive Pain With Loss Of ROM.

SCAPULAR PNF TECHNQUES :

PNF Is A Treatment Concept With Four Theoretical Mechanisms, Referred To As Autogenic Inhibition, Reciprocal Inhibition, Stress Relaxation, And The Gate Control Theory, That Enhance ROM And Muscle Activation. PNF Has An Positive Effect On Pain, Muscle Strength.

CLASSIC SHOULDER EXERCIES :

- **Strengthening exercises :**

- Codman Pendulum exercises.
- Wand (stick) exercises.
- Pulley exercises.

- Finger walk.
- Resisted Exercise With Theraband

- **OBJECTIVES:**

- To Determine The Acute Effect Of Scapular PNF Techniques With Tens In Patients With Adhesive Capsulitis.
- To Determine The Acute Effect Of Classic Shoulder Exercises With Tens In Patients With Frozen Shoulder.
- To Compare The Acute Effect Between The Scapular PNF Techniques With Tens And Classic Shoulder Exercises With Tens In Patients With Adhesive Capsulitis.

METHODOLOGY:

30 Patients are Allocate To 2 Groups Scapular PNF Exercise And Tens, Classic Exercise And Tens. The Intervention Were Apply In A Single Session. The Visual Analog Scale(Vas), Lateral Scapular Slide Test, Range Of Motion And Simple Shoulder Test Were Evaluate Before And After The Intervention. All The Participants Of The Study Were Be Given Treatment According To The Group For 4 Weeks.

Subjects – 30 Subjects

Groups – 2 Groups

Sampling Method – Randomized Sampling Method

	Group 1	Group 2
Treatment Method	Scapular PNF With TENS	Classic Shoulder Exercise With TENS
Subjects	15	15
Duration: 4x/W/4 Weeks	4x/W/4 Weeks	

Inclusion Criteria:

- Having A Painfull Stiff Shoulder For At Least 3 Months, And Diagnosed As Frozen Shoulder.

- Having Limited Rom Of Shoulder Joint(Rom Losses Of 25% Or Greater Compared With The Non Involved Shoulder In At Least 2 Of The Following Shoulder Motion; Glenohumeral Flexion, Abduction.

Exclusion Criteria:

- Diabetes Mellitus
- A History Of Surgery On The Particular Shoulder
- A Pain Full Stiff Shoulder After A Severe Trauma
- Fracture Of The Shoulder Complex
- Rheumatoid Arthritis
- Rotator Cuff Rupture
- Tendon Calcification

Analysis:

- Between group analysis of obtained data were be done by using Unpaired T- test.
- Within the same group analysis (pre and post) of obtain data were be done by using paired T-test.

RESULT & CONCLUSIONS:

During The Course Of The Study It Has Been Concluded That Scapular PNF Techniques And Classic Shoulder Exercises Both Are Improved Pain, Scapular Dyskinesis And Functional Impairment The Patients With Adhesive Capsulitis. There Is Significant Increase In Both Scapular PNF Techniques And Classic Shoulder Exercises After 4-Week Treatment Duration In Both Groups. But Group Receiving Scapular PNF Techniques Showed More Power Full Improvement In Pain, Scapular Dyskinesis And Functional Improvement.

INTRODUCTION

INTRODUCTION

Adhesive capsulitis, Describes The common Shoulder condition Characterized By Painful And Limited Active And Passive Range of Motion(Rom). Individuals With Primary Adhesive capsulitis Are Commonly

Between 40 and 65 Years And The Incidence Appears Higher In Females Than Males.(1)

- The Term Adhesive capsulitis Were BE Used, Because It Encompasses Both Primary Adhesive Capsulitis And Secondary Adhesive Capsulitis Related to Systemic Diseases And Extrinsic or Intrinsic Factors, Excluding Cerebral Vascular Accident, Proximal humeral #, And Causative Rotator Cuff or Labral Pathology.(1)

(FIG 1: ADHESIVE CAPSULITIS)

Adhesive capsulitis IS Estimated To Affected 2% Of The General Population, With A Cumulative Incidence Between Of 2.4 Per 1000 Person-Years. It Is Rare Before The Age Of 40,With A Peak Incidence Between 40 and 60 And Is Unsual In Patient Over 70 Years (Except Secondary Traumatic Adhesive Capsulitis) And In Manual Workers. It Affects Women Slighly More Often Than Men. The Economic Impact Of The Condition Is Underscored By Its Predilection For Adults Of Working Age(8.2% For Men And 10.1% For Women).(2)

Diabetes Mellitus Is The Common Condition Most Commonly Associated With Adhesive Capsulitis. The Combined Prevalence Of A Diabetic Predisposition And Adhesive Capsulitis Is Estimated To Be As High As 71.5% Diabetics Have A 10% to 20% Lifetime Risk Of Developing A Adhesive Capsulitis, With A 4% Point Prevalence, And A Two To Four Times Greater Risk Than The General Population.(2)

The Glenohumeral joint Is An Incongruous, Ball & Socket Triaxial Joint With A Lax Joint Capsule. Its Supported By The Tendons Of The Rotator Cuff And The Glenohumeral (Suprior, Middle, Inferior) And Coracohumeral Ligaments.(3)

ANATOMY OF SHOULDER JOINT

PRESENTOR :DR.B.VAMSHIKIRAN

(FIG 2: NORMAL SHOULDER ANATOMY)

The Coracohumeral Ligament Originated From The Base And Lateral Border Of The Coracoid Process And Runs Transversely To The Grater Tuberosity. Its Anterior Border Is Distrincts Medially And Merges Laterally. Whereas Its Posterior Border Is Indistinct. it's a Primary Restraint To The Long Head Of Biceps Tendon.(4)

Causes:

The Causes are mainly idiopathic and are due to fibrosis following chronic inflammation. This could be due to:

1}Primary shoulder

2}Secondary Non-shoulder

1 Primary shoulder cause problems directly related to shoulder joint which can give rise to adhesive capsulitis :

tendinitis of rotator cuff

bicipitaltenditis

and dislocation around the shoulder

2 Secondary Non shoulder causes problems not related to shoulder joint like

Diabetes

Hyperthyroidism

Reflex sympathetic dystrophy

Frozen hand syndrome

Complication of Collis's fracture can all leads to adhesive capsulitis.

The reason could be prolonged immobilization of the shoulder joint due to reffered pain, Etc.(5)

Classification:

The Classification System By Including Disease Such As Diabetes Mellitus, Myocardial Infraction Or Various Neurological Disorder Under Secondary Frozen Shoulder Classification Scheme Where, **Primary Adhesivecapsulitis**And Idiopathic Adhesive capsulitis Are Considered Identical And Non AssociatedWith A Systemic Condition Or History Of Injury.

1. Secondary Adhesive capsulitis Was Defined By 3 Subcategories Extrinsic Secondary Adhesive capsulitis Includes Patients Whose Pathology Is Not Directly Related To The Shoulder, And Intrinsic Secondary Adhesive capsulitis Describes Patients With A Known Pathology Of The Glenohumeral Joint Soft Tissues Or Structures. Specific Causes Of Secondary Adhesive capsulitis May Influence Prognosis. For Instance, Individuals With Secondary Adhesive capsulitis Related To Insulin-Dependent Diabetes Are More Likely To Have A More Protracted And Difficult Clinical Course.(6)

Stage Of Adhesive Capsulitis

Stage 1

- Duration Of Symptoms: 0 To 3 Months.
- Pain With Active And Passive Rom.
- Pathologic Changes: Hypertrophic, HypervascularSynovitis, Rare Inflammatory Cell
- Infiltrates, Normal Underlying Capsule.

Stage 2: Freezing stage

- Duration Of Symptoms: 3 To 9 Months
- Chronic Pain With Active And Passive Rom
- Significant Limitation Of Forward Flexion, Abduction, Internal Rotation, External Rotation
- Pathologic changes: hypertrophic, hypervascularsynovitis with perivascular and subsynovialscar ,fibroplasias and scar formation in the underlying capsule.

Stage 3: Frozen Stage

- Duration Of Symptoms: 9 To 15 Months.
- Minimal Pain Except At End Rom.
- Significant Limitation Of Rom With Rigid End Feel.
- Pathologic Changes: “Burned-Out” SynovitisWithout Significant Hypertrophy Or Hypervascularity. Underlying Capsule Shows Dense Scar Formation.

Stage 4: Thawing Phase

- Duration Of Symptoms: 15 To 24 Months.
- Minimal Pain.
- Progressive Improvement In Rom.(1)

Common Structural and Functional Impairments

- Night Pain And Disturbed Sleep During Acute Flares.
- Pain On Motion And Often At Rest During Acute Flares.
- Mobility: Decreased Joint Play And ROM, Usually Limiting External Rotation And Abduction With Some Limitation Of Internal Rotation And Elevation In Flexion.
- Posture: Possible Faulty Postural Compensations With Protracted And Anteriorly Tilted Scapula, Rounded Shoulders, And Elevated And Protected Shoulder.
- Decreased Arm Swing During Gait.

- Muscle Performance: General Muscle Weakness And Poor Endurance In the Glenohumeral Muscles With Overuse Of The Scapular Muscles Leading To Pain In The Trapezius, LevatorScapulae, And Posterior Cervical Muscles.
- Substitution For Limited Glenohumeral Motion With Increased Scapular Motion, Especially Elevation.(3)

Common Activity Limitation And Participation Restriction

- Instability To Reach Overhead, Behind Head, Out To The Side, And Behind Back; Thus, Having Difficulty Dressing (Putting On A Jacket Or Coat Or In The Case Of Women, Fastening Undergarments Behind Their Back), Reaching Hand Into Back Pocket Of Pants (To Retrieve Wallet), Reaching Out A Car Window (To Use An ATM Machine), Self-Grooming (Combing hair, Brushing Teeth, Washing Face), And Bringing Eating Utensils To The Mouth.
- Difficulty Lifting Weighted Objects, Such As Dishes Into A Cupboard.
- Limited Ability To Sustain Repetitive Activities.

Scapular Dyskinesis:

- The Scapula Is The Large Triangular-Shaped Bone At The Back Of Your Shoulder Frequency Known As The Shoulder Blade. Its Only Attachment To The Rest Of The Skeleton Is Throught The Collarbone At The Acromioclavicular Joint. Therefore, The Bone Is Primarily Held In Place By The Attached And Surrouding Muscles. Many Muscle Use The Large Area Of The Scapula For Attachment and They Enable The Vast Range Of Shoulder Motion.(7)
- At The Order Edge Of The Scapula A Shallow Socket Form And Is Where The Humeral Heads Sits Forming The Shoulder Joint. Proper Positioning And Movement Of The Scapula Is Critical For Full And Normal Shoulder Range Of Motion.(7)
- We Use The Acronym **SICK(Scapular Malposition, Inferior Medial Border Prominence, Coracoid Pain And Malposition, And Dyskinesis Of Scapular Movement)** To Refer to An Injury Resulting From Overuse And Fatigue Of The Muscle That Stabilize And Provide Motion For The Scapula.(7)

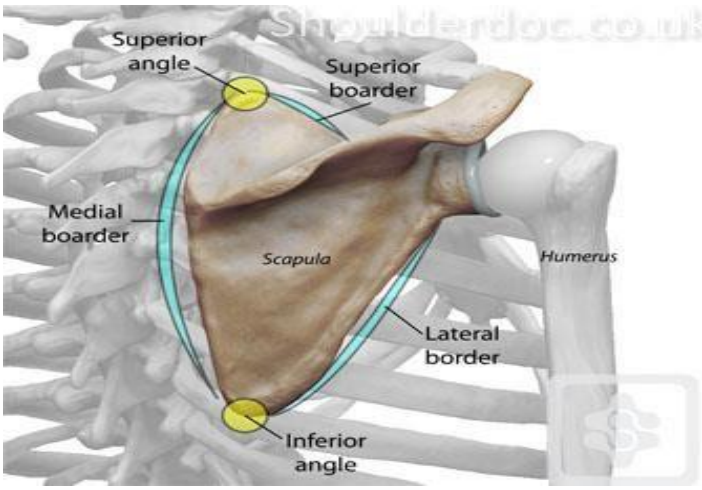

FIG 3: SICK SCAPULA

Risk Factors

- Intense, Repetitive Overhead Activity (Throwing, Tennis, Volleyball)
- Overuse Fatigue.
- Injury To Other Structure Of The Shoulder.
- Direct Trauma
- Muscle Strain
- Tense Pectoralis Major Possibly Resulting From Unbalanced Weight Training(7)

Signs And Symptoms

- Affected Shoulder Appears Dropped Or Lower Than Unaffected Shoulder
- Medial Scapular Protrusion
- Noticeable Hitches And Jumps In Scapular Motion During Arm Movements.
- Scapular Pain
- Pain At The Front, Back, Or Top Of The Shoulder.
- Pain On The Outside Of Your Upper Arm.(7)

Scapular Dyskinesis Classification System(8,9)

- **Type 1: Inferior Border**
- At Rest, The Inferior Medial Scapular Border May Be Prominent Dorsally. During Arm Motion. The Inferior Angle Tilts Dorsally And The Acromion Tilts Ventrally over The Top Of The Thorax.
- The axis Other Rotation Is In The Horizontal Plane.

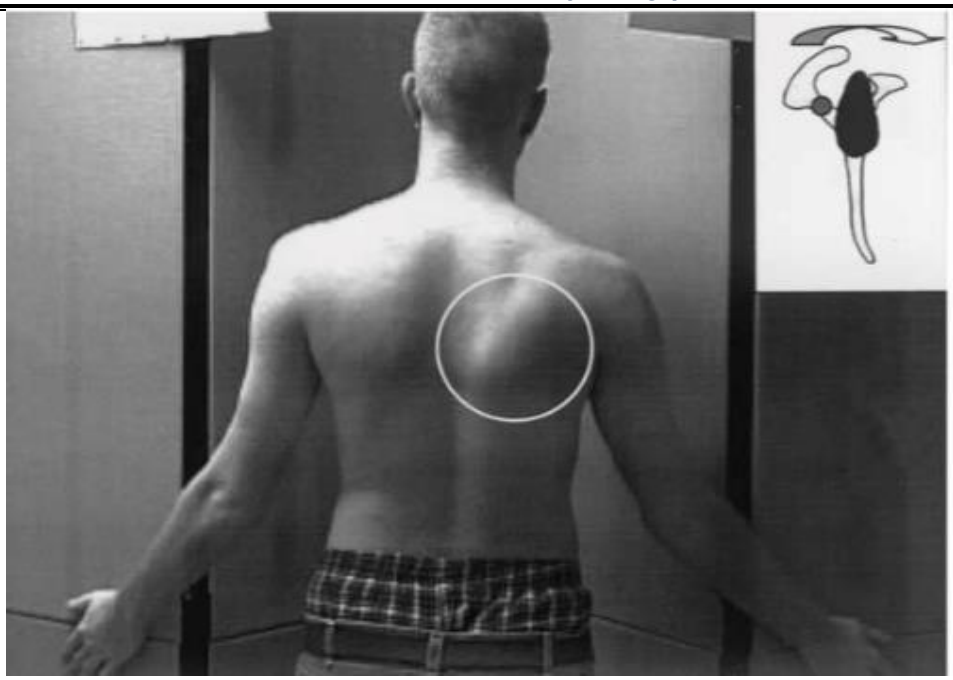

FIG 4: INFERIOR BORDER SCAPULA DYSKINESIS

TYPE 2: MEDIAL BORDER

- At Rest, The Entire Medial Border May Be Prominent Dorsally. During Arm Motion, The Medial Scapular Border Tilts Dorsally Off The Thorax. The Axis Of The Rotation Is Vertical In The Frontal Plane.

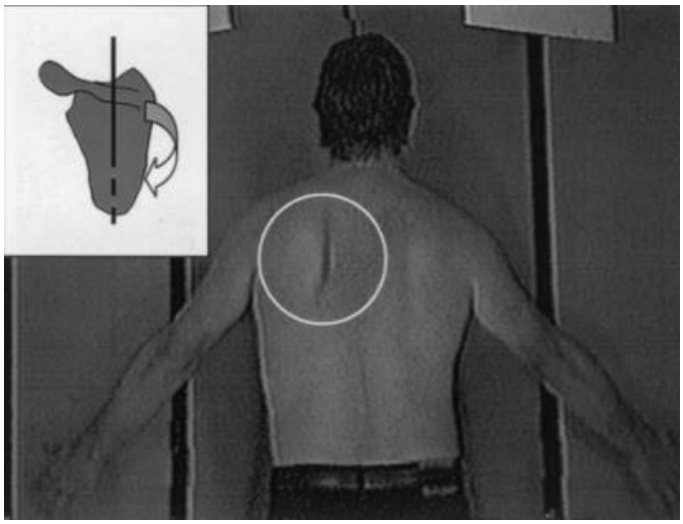

FIG 5: MEDIAL BORDER OF SCAPULAR DYSKINESIS

TYPE 3 : Superior Border

- At Rest, The Superior Border Of The Scapula May Be Elevated And The Scapula Can Also Be Anteriorly Displaced. During Arm Motion, A Shoulder Shrug Initiates Movement Without Significant Winging OF The Scapula Occurring. The Axis Of This Motion Occurs In The Sagittal Plane.

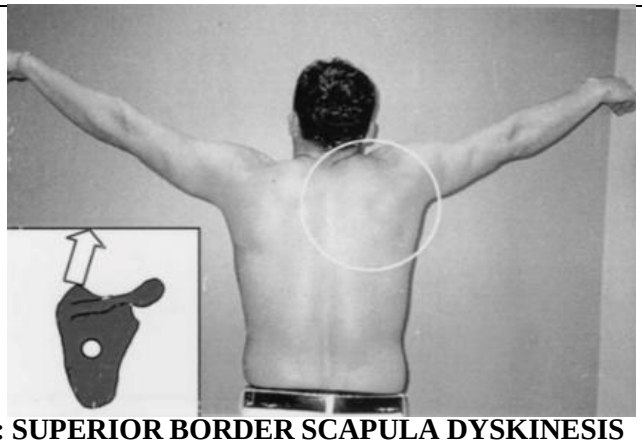

FIG 6: SUPERIOR BORDER SCAPULA DYSKINESIS

Type 4 : Symmetric Scapulohumaral

- At Rest, The Position Of Both Scapula Are Relatively Symmetrical, Taking Into Account That The Dominant Arm May Be Slightly Lower. During Arm Motion, The Scapulae Rotate Symmetrically Upward Such That The InferiorAngles Translate Laterally Away From The Midline.

FIG 7: SYMMETRIC SCAPULOHUMERAL

The Studies Cited Have Shown That Various Forms Of Exercise Are Effective In Reducing The Motion Restriction And Pain Of Patients With Adhesive Capsulitis. Physical Therapists, As Specialists Dealing With Exercise And Movement Dysfunction, Play A Major Role In Restoring Function To These Persons. After Performing The Necessary Tests To Confirm The Diagnosis Of Adhesive Capsulitis Ascertain The Current Status Of The Condition, And Identify Causative Factors, A Physical Therapist Is Prepared To Design A Treatment Program. Each Individual Case Were Dictate Whether Physical Therapy Is To Be Used Alone Or In Conjunction With Other Medical Or Surgical Treatment.

A Combination Of Exercise And Physical Modalities Helps Accomplish This Objective. Activate And Active-Assistive Exercises Such As Pedulum, Wand , And Physiologic ROM Should Be Performed For At Least One Half-Hour Three Times A Day. Passive Exercise Has Multiple Benefits. Gentle Passive Movement, Short Of Pain And The Pathological limit Of Motion, Reduces Pain. Often, Reflex Muscle Spasm Prevents A Patient From Performing Active Exercise, Whereas A TherapistCan Passively Guide The Lime Further Into The Range Without Eliciting Spasm Or A Stretch Reflex. Also , Because Many Patients Are Reluctant Psychologically To Perform Regular, Appropriate Active Exercise, Passive Exercise Becomes The Treatment Of Choice(10).

Evaluation Of The Position Of The Scapula Is Very Important In The Pathologies Of The Shoulder Because These Pathologies Are Responsible For The Second And Third most Common Causes Of Musculoskeletal Pain. Abnormal Changes In The Position Of The Scapula At Different Angles Of The Shoulder Indicate A Disturbance Of The ScapulohumeralRhythm(11,12).

Even Though Scapular Alterations Have Been Assessed In Patients With Frozen Shoulder, Treatment Programs Were Focused On Pain Relief And Improvement In ROM. Scapular Exercises Were Not Included In The Programs

Even Though The Scapula Plays Several Roles In Facilitating Optimal Shoulder Funcation(13).

SCAPULAR PNF TECHNQUES :

PNF Is A Treatment Concept With Four Theoretical Mechanisms, Referred To As Autogenic Inhibition, Reciprocal Inhibition, Stress Relaxation, And The Gate Control Theory, That Enhance ROM And Muscle Activation.(14,15)

PNF Has Been Reported To Be Effective In Relieving Pain And Improving Functional Abilities. PNF Methods, Particularly Those Involving Reciprocal Activation Of The Agonist And Antagonist To The Desired Motion, Provide The Greatest potential For Muscle Functioning.(16,17)

Among Therapeutic Approaches, Joint Mobilization Using PNA Has A Positive Effect On Pain, Muscle Strength, And ROM. Proper Function Of The Upper Extremities Requires Both Motion And Stability Of The Scapula.(19,20)

The Scapula Patterns Defined In PNF Are Activated Within The Upper Extremity Patterns And Scapular Motion Together(21). The Effects Of The Shoulder Have Been Investigated In Some Studies(22-29). However, No Previous Study Has Investigated The Effects Of Scapular PNF Exercises In AC Rehabilitation.

CLASSIC SHOULDER EXERCIES :

- **Strengthening exercises :**
- Codman Pendulum exercises.
- Wand (stick) exercises.
- Pulley exercises.
- Finger walk.
- Resisted Exercises With Theraband(30).
- Therefore, The **Aim Of This Study** Was To Compare The Acute Effects Of Scapular PNF Techniques And Classic Shoulder Exercises With TENS On Pain, Scapular Dyskinesis, Shoulder ROM, And Functionality In Patients With AC.
- In This Study, Pain, Scapular Dyskinesis And Shoulder Function Were Be Measured Using Visual Analogue Scale(VAS), Lateral Scapular Slide Test (LSST) And Simple Shoulder Test.

REVIEWOF LITERATURE

1. **Positional stretching of the coracohumeral ligament on a patient with adhesive capsulitisJose Orlando Ruiz Et Al(2009)** Performed A Study On Positional Streching Of Coracohumeral Ligament On A Patient With Adhesive Capsulitis And Concluded That the Coracohumeral Ligament Streching Is An Effective Therapeutic Strategy To Help Reduce Loss Of Joint Mobility And Function.(31)

2. **Adhesive shoulder capsulitis : Does the timing of manipulation influence outcome ?Olivia Flannery Et Al (2007)** Conducted A Study On The Adhesive Shoulder Capsulitis. In Their Study They Mentioned That Duplay Was The First To Describe A Painful, Stiffening Condition Of The Shoulder, Which He Termed **Peri** – Arthritis Scapula Humerale And Codman In 1934 Named The Condition **Adheshive Capsulitis** Conclued That It Was Characterized By Slow Onset, Pain near The Insertion Of The Deltoid, Instability To Sleep On The Affected Side, Painful And Restricted Elevation And Term **Adheshive Capsulitis** Was Introducted By Neviaser In 1945, Based Upon His Finding Of Synovial Changes In The Gleno - Humeral joint.(32)

3. **The Pathology Of Frozen ShoulderG.C.R. Hand Et Al (2007)** Studies The Pathology Of Adhesive capsulitis. Twenty Two Subjects, Diagnosed As Primary Adhesive capsulitis Was inclued In Their Study Biopsies Were Taken From This Site And Histological And Immunocyto -chemical Analysis Was Performed To Identify The Type Of Cell Present. The Tissue Was Characterized By The Presence Of Fibroblast, Profiferating, Fibroblast And Chronic Inflamatory Response With Fibroblastic Proliferation Which May be Immune Modulated(33).

4. **J.Mobilization Techniques In Subjects With Frozen Shoulder Syndrome: Randomized Multiple-Treatment Trial. PhysTher 2007 Oct;87(10):1307-15. Epub 2007 Aug 7.Jing – Ian Yang (2007)** Did A Randomized Multiple Treatment Trial Of Mobilization Technique In Subject With Adhesive capsulitis Syndrome And The Results Concluded End Range Mobilization And Movement With Mobilization Are More Effective, Than Mid Range Mobilization In Increasing Mobility And Functional Ability In Patients With Adhesive capsulitis.(34)

5. **Adhesive Capsulitis : Does The Timing Of Manipulation Infulence Outcome. AetaOrthop. Belg, 2007,73,21-25.Oliva Flannery, HanamMullett Et Al(2007)** Performed A Study On Adhesive Shoulder capsulitis. In Their Study Used VAS For The Assessment Of Pain In The Shoulder In Subjects Suffering from Adhesive capsulitis And They Concluded That VAS Was Significant To Assess Pain In The Affected Shoulder(35).

6. **Non Operative Management Of Idiopathic Adhesive Capsulitis Journal Of Shoulder And Elbow Surgery 2006.569-573.Wereiam N> Levine Et Al (2006)** Performed A Study On Non Operative Management Of Idiopathic Adhesive capsulitis. In Their study They Said That This Condition Was First Describe By Duplay In 1872 And Named As **FROZEN SHOULDER** In 1934 And Is Characterized By Pain And Restriction Of Both Active and Passive ROM. They Concluded That the Pathology Is Anatomy Was First Describe For Frozen shoulder.(36)

7. **Frozen Shoulder Richard Dias Et Al (2005)** Performed A Study On The Clinical Review Of Frozen Shoulder. They Studied The Incidence, Clinical Presentation, Diagnosis And Treatment Modalities In Adhesive capsulitis. Regarding The Incidence They Concluded That The Onset Of This Condition Before The Age Of 40 Is Very Uncommon. The Peak Age Is 56 Yrs And The Condition Occurs Slightly More Often In Women Than Men. In 6-17% Of Patients, The Other Shoulder Becomes Affected. The Non Dominant Shoulder Is Slightly More Likely To Be Affected.(37)

8. **Acromiohumeral distance in a seated position in persons with impingement syndrome Hebert LJ Et Al(2003)** Had Done A Prospective Cohort Study To Identify The Bestindicators Of The Current Disability Of Patients With Shoulder Impingement Syndrome(Sis)And The Strongest Predictors Of 3 Months SIS-Related Disability. The SPADI Score ALBaseline And The Presence Of Sis On The Dominant Side,Among Other Variables Predicted86% The Variance Of The SPADI At 3 Months And Concluded That Variables That BestExplain The Current Disability Level And Predictors Of Short-Term Leval Of DisabityShould Be Considered In SIS Treatment Planning As Well As For Establishing Prognosis.(38)

9. **Influence of Comorbidity on Self-Assessment Instrument Scores of Patients with Idiopathic Adhesive Capsulitis Jennifer Moriatis Wolf And Andrew Green(2002)** Did A Study To Determine The"Influence Of Co- Morbidity On Self - Assessment Instruments Scots Of Patients With Adhesive Capsulitis. Phase 2 Adhesive Capsulitis Were Prospectively Evaluated With The Use Of VAS And They Found That The Score On VAS Can Be Applied To The Evaluation Of The Patient And May Help To Identify Patients Who Potentially Require A Longer Treatment Course Or Those Outcome WereBe Less Satisfactory.(39)

10. **End-range mobilization techniques in adhesive capsulitis of the shoulder joint: A multiple-subject case report VermeulenHM Et Al (2000)** Did A Study On Effectiveness Of End Range Mobilization Technique In Adhesive

    Capsulitis Of Shoulder Joint In 45 Subjects And The Results Concluded End Range Mobilization Technique To Be Beneficial In Improving Joint Mobility.(40)

11. **Idiopathic adhesive capsulitis. A prospective functional outcome study of nonoperative treatment Griggs Et Al (2000)**Reported That Following A Physical Therapy Program Consisting Of Passive Stretching Exercises (Forward Elevation, External Rotation, Horizontal Adduction And Internal Rotation) At A Mean Follow - Up Of 22 Months, Patients Demonstated A Reduction In Pain Score From 1-57 To 1 -16 In Range From One To Five Points Improvements in Active Range Of Motion, And 64 Patients (20%) Reported A Satisfactory Outcome.(42)

12. **Reliability of goniometric measurements Boone DC, Azen SP Et Al(1987)** Conducted A Study To Determine The Intra - Tester And Inter-Tester Variability And Reliability Of Goniometric Measurement Taken By Four Physical Therapists On Upper And Lower Extremity Motions. Their Findings Indicated The Necessity For Using The Same Lester When Effects Of Treatment Are Evaluated.(43)

NEEDOF STUDY

NEEDOFSTUDY

NEEDOFSTUDY

- There Are Lots Of Study Available Which Suggest The Treatment Of Adhesive Capsulitis Which Includes Scapular PNF Techniques , Classic Shoulder Exercises, Strengthning Exercises , Mobilization Techniques Etc. But There Are Lack Of Evidence Which Compare The Acute Effect Of Scapular PNF Techniques And Classic Shoulder Exercises With TENS In The Effectiveness Between These Treatment Groups For Adhesive Capsulitis Patients.

OBJECTIVESOFTHESTUDY

OBJECTIVES OFTHESTUDY

OBJECTIVEOFTHESTUDY

To Determine The Acute Effect Of Scapular PNF Techniques With Tens In Patients With Adhesive Capsulitis.

To Determine The Acute Effect Of Classic Shoulder Exercises With Tens In Patients With Frozen Shoulder.

To Compare The Acute Effect Between The Scapular PNF Techniques With Tens And Classic Shoulder Exercises With Tens IN Patients With Adhesive Capsulitis.

HYPOTHESIS

HYPOTHESES

HYPOTHESIS

- **Null Hypothesis :**

  There Is No Significant Difference In Effect Of Scapular PNF Techniques And Classic Shoulder Exercises With Tens In The Patients With Adhesive Capsulitis.

- **Alternate hypothesis :**

  There Is Significant Difference In Effect Of Scapular PNF Techniques And Classic Shoulder Exercises With Tens In The Patients With Adhesive Capsulitis.

METHODOLOGY

Participants Were Allocate To Treatment Groups Using Sealed, Opaque Envelopes. The Envelopes Contained Stickers Denoting 1 Or 2. Subjects Who Picked 1 Were Included In The Groups 1 (scapular PNF techniques) And The Subjects Who Picked 2 Were Included In Group 2 (classic shoulder Exercises). Following This, Demographic Information were Conducting. Duration Of Symptoms And Side Affected Noted And Initial Evaluation Of Pain Profile Was Done Using Visual Analogue Scale (VAS).
Functional Performance Were Assessing Using The simple shoulder test scale (SST), And Lateral Scapular Slide Test (LSST).

Group 1 : Subjects Received scapular PNF techniques.
Group 2 : Subjects Received classic shoulder Exercises.

PROCEDURE:

The Purpose And The Procedure Of The Study were Explain In Details To The Patients Who Satisfied The Inclusion Criteria Both The Treatment Groups Completed With Written Informed Consent Form. Patients were Allocate To Treatment Groups Using Sealed, Opaque Envelopes. The Envelopes Contained Stickers Denoting 1 Or 2. Then Both Treatment Groups Of Each Patients Completed 2 times (Pre & Post) VAS, SST, LSST.

The Patients were Collect Along With The Routine Evaluation With Emphasis On; Pain Scores Using VAS Where A Horizontal Line (10cm Long) Was Drawn On A Paper And Patients Were Ask To Mark A Ponton The Line That Beat Defined The Present PAIN Level, Where – 0 Indicated No Pain And – 10 Indicated Severe Pain, Functional Performance were Assessed Using SST Scale. Outcome Measure Were Taken On Day 1 And After Completion Of Treatment Protocol I.E. After 4 Weeks.

SUBJECTS AND METHODS

This Study wereDesign As Randomized Control Trial. Thirty Subjects (Females, Males) Shoulder Exercises Groups And TENS (N=15),Simple Randomization And A Random-Number Table Were Used As The Method Of Sequence Generation For Patients.Same Therapist Evaluated All The Patients, While Another Therapist Applied The Intervention Methods The Therapist Who Applied The Interventions Was Experienced In Ac Treatment And Also Had A PNF Certificate.
All Patients Received An Explanation About The Purpose And Test Procedures Involved In The Study Before Enrollment. Each Patient Was Informed About The Study And Gave Written Informed Consent To Patient

GROUP 1 :

- **SCAPULAR PNF TECHNIQUES :**

In the PNF groups, scapular PNF was applied by a therapist in two diagonals, anterior elevation and posterior depression and posterior elevation and anterior depression with 20 repetitions. Patients lay on the unaffected side while the therapists stood in the line of desired motion. Firstly, the therapist gave preparatory instructions. In the beginning of the
Pattern, the therapist pulled the scapula to the elongated position and then gave instructions for the desired movement. Rhythmic initiation and repeated contractions facilitation techniques were applied in all patterns. These techniques are the best matchedmatched scapular facililation techniques of the PNF agonistic techniques.

GROUP 2 :

In the **classic Shoulder exercise group,** TENS were applied using the same procedure as describe above. After the TENS, strengthening exercises with Theraband and dumbbells were assigned to the patients. One set of want , finger walk , pulley and Codman pendulum exercises scapular elevation adduction (posture), and scapular stabilization exercises were also performed with 20 repetitions for each exercise.
wereRecruite For This Study Form The Near by Clinics In Kalol.
Subjects Werebe Randomly Allocated To Two Groups :SCAPULAR PNF TECH. And TENS (N=15), Classic

DISCUSSION

DISCUSSION

DISCUSSION

Adhesive Capsulitis Is Characterized By Painful Stiffness Of Shoulder That May Persist For Several Years. It Is A Common Disorder; With An Estimated Annual Incidence Of 3% To 5% In The General Population (Bridgman 1972, Pal Et Al 1986). Advocated Treatments Include Rest And Analgesics, Corticosteroid Injections, Acupuncture, Physical Therapy, Manipulation Under Anesthesia, And Arthroscopic Or Open Surgery. There Is No General Acceptance Of One Standard Treatment.

Adhesive Capsulitis Is A Contracture Of The Capsule And Depending On How Severe The Contracture Is (For It Varies In Intensity From Patient To Patient) The Treatment Is Decided. The First Objective In The Treatment Of Patients With Adhesive Capsulitis Is Pain Relief. This Is Essential, For It Permits Patients To More Readily Participate In An Exercise Program Aimed At Restoring Motion And Recovering Function.

The Primary Mode Of Treatment For Adhesive Capsulitis Is Prevention. Avoiding Prolonged Immobilization Of The Shoulder After Trauma Or When Shoulder Pain Develops Is Key. The Overall Goal Of Treatment Is To Relieve Pain, Restore Motion, And To Restore Function. Although Adhesive Capsulitis Is Generally Considered To Be A Self- Limiting Condition That Can Be Treated With Physical Therapy, The Best Treatment Has Been The Subject Of Extensive Investigation. A Variety Of Different Treatments Have Been Recommended.

CONCLUSIONANDSUMMARY

CONCLUSION &SUMMARY

CONCLUSION

The Study Rejects The Null Hypothesis – There Is No Significant Effect Of Scapular PNF Techniques And For Improving Pain, Scapular Dyskinesis And Functional Impairments The Patients With Adhesive Capsulitis And Accept The Experimental Hypothesis – There Is **Highly Significant Effect Of Scapular PNF Technique** And For Improving Pain, Scapular Dyskinesis And Functional Impairments The Patients With Adhesive Capsulitis .

During The Course Of The Study It Has Been Concluded That Scapular PNF Techniques And Classic Shoulder Exercises Both Are Improved Pain, Scapular Dyskinesis And Functional Impairments The Patients With Adhesive Capsulitis. There Is Significant Increase In Both Scapular PNF Techniques And Classic Shoulder Exercises After 4-Week Treatment Duration In Both Groups. But Group 1 Receiving **Scapular PNF Techniques Showed More Power Full Improvement In Pain, Scapular Dyskinesis And Functional Improvement.**

LIMITATIONS

LIMITATIONS

Limitations

- Sample Size Was Limited.
- There Is No Control Group.
- No Follow Up

Futurerecommendation

- The Same Study Can Be Done With Large Group.
- The Same Study Can Be Done With A Longer Follow- Up.
- The Same Study Can Be Done With Control Group.

Simple Shoulder Test

Answer each question by circling "Yes" or "No"

If you do not normally do the activity, try to imagine if you could. Would your shoulder restrict you. If the activity causes no pain, or rarely produces pain, then answer "Yes". If your shoulder hurts sometimes, often or always when you do the netivity, answer "No"

1.Is your shoulder comfortable with your arm at rest by your side?	Yes	No
2.Does your shoulder allow you to sleep comfortably?	Yes	No
3.Can you reach the small of your back to tuck in your shirt?	Yes	No
4.Can you place your hand behind your head with the elbow straight out to the side?	Yes	No
5.Can you place a coin on a shelf at the level of your Shoulder Without bonding your albow?	Yes	No
6.Can you lift one pound (full pint container) to the level at your shoulder without bending your elbow?	Yes	No
7.Can you lift eight pound (full gallon container) to the level of your shoulder without bending your elbow?	Yes	No
8.Can you carry twenty pounds at your side with the affected extremity?	Yes	No
9.Do you think yon can toss a softball under- hand twenty yards with the affected extremity?	Yes	No
10.Do you think you can toss a softball over hand twenty yards with the affected extremity?	Yes	No

11.Can you wash the back of your opposite shoulder with the affected extremity? Yes No

12.Would your shoulder allow you to work full-time at your regular job? Yes No

Immediate changes in Pain after TENS in patients with Abdominal Surgeries: A Case Series

[1]Dr. Arvind Kumar, PhD; [2]Gor Rajeshri, BPT

[1]Principal and Professor (PhD Physiotherapy): [2]Bachelor of Physiotherapy;

[1]Venus Institute of Physiotherapy – Swarrnim Startup & Innovation University,Gandhinagar, Gujarat
[2]Venus Institute of Physiotherapy – Swarrnim Startup & Innovation University, Gandhinagar, Gujarat

Abstract

Background:
Abdominal surgical procedures cause tissue damage by direct visceral manipulation, through the incision on anterior abdominal wall and by the use of surgical retractors that help to expose the surgical field. Pain is an important negative influence in the postoperative evolution of abdominal surgeries so the study was conducted to see the changes in pain after TENS in patients' abdominal surgeries through VAS.

Methodology:
A case series was done in six patients in Dhiraj General Hospital, Vadodara. Physiotherapy treatment was given in form of TENS was given to the patients with abdominal surgeries twice a day. Prior to treatment patients were assessed for pain through VAS. Routine physiotherapy management was continued according to patient's conditions.

Result:
SIX patients were included in case series. There was reduction in visual analogue scale in patient with abdominal surgeries.

Conclusions:
There was reduction in pain in all the patients with abdominal surgeries who received physiotherapy treatment in form of TENS for 3 consecutive days.

Keywords:
Abdominal surgeries, physiotherapy

INTRODUCTION

Abdominal surgical procedures cause tissue damage by direct visceral manipulation, through the incision on anterior abdominal wall and by the use of surgical retractors that help to expose the surgical field. Pain after surgery causes discomfort to the patient, preventing the patient from relaxing, leading shallow breathing and hindering the patient's movements in bed. Thus decrease diaphragmatic breathing and cough efficacy that might lead to atelectasis, especially in the lower lung fields. Pain is an important negative influence in the postoperative evolution of abdominal surgeries.The concept of Pain Gait control theory is based on the fact that peripheral stimulation produces impulses that are transmitted to three spinal cord systems: substantial gelatinoids fibers in dorsal horn, dorsal column fibers projecting towards the brain and first central transmission (T cells) in the dorsal horns. What the theory proposes is that substantial gelatinoids is a gait system which modulate efferent impulses before T cells are activated. TENS can be used as conventional analgesia for postoperative pain. Besides being a non- invasive and non-pharmacologic technique; it is comfortable for the patient in 95% of the cases. It can be effective in controlling pain after abdominal surgeries without any side effects.[1] Transcutaneous electrical nerve stimulation (TENS) is a physical therapy tool widely used to relieve pain. The effects of TENS follow the "Pain Gait Theory" (Melzek and Wall, 1965)[2].Laparoscopic surgery has become the standard approach for a large number of gynecologic procedures. The frequency of laparoscopy varies widely across the globe. Laparoscopic operations are performed annually for the following indications: sterilization, diagnosis, cyst enucleating, and salpingooophorectomy.Pain is often a problem after gynecologic laparoscopic surgery, even if the postoperative pain is less significant when compared to that after a similar major laparotomy surgery[3].

Appendectomy was performed through a skin crease incision and muscle splitting approach. An absorbable suture was used to legate and buries the appendix stump. Closer was in layer with an absorbable suture and skin closure was with 3.0 nylon. Patients were excluded if the wound had to be extended by cutting muscle or if there was generalized peritonitis[4]. Electro therapy can treat diverse symptoms produced by diseases that affect the human body. Electro therapy using transcutaneous electrical nerve stimulation is a low cost, non-invasive and easily accessible technique to treat pain. In this context, numerous description emerge on the effectiveness of transcutaneous electrical nerve stimulation (TENS) for treating diverse types of pain, knee osteoarthritis and dysmenorrhea[5]. Transcutaneous electrical nerve stimulation (TENS) is a technique in which a special device transmits low voltage electrical impulses through electrodes on the skin to the area of the body that is in pain. Clinic studies on the role of transcutaneous electrical nerve stimulation (TENS) on postoperative pain were systematically searched and reviewed with the aim to determine its role in post-operative analgesic efficacy[6].

Technical Aspects of Transcutaneous electrical nerve stimulation:-

A TENS unit consists of electrical signal generator, battery and a set of electrodes. The TENS unit is small and programmable and the generator can deliver stimuli with variable current strengths, pulse rates and pulse width. The waveform in TENS machine can be monophonic or biphasic.

The usual settings for the stimulus parameters used clinically are the following:

- Amplitude-TENS unit's intensity ranges from 1 to 100 mA6 Pulse width-40-250 μs.6
- Pulse rate-1 or 2 Hz to 200-250 Hz.
- There are a number of TENS devices available in the market, the main types being conventional TENS acupuncture TENS and intense TENS[6].

Mechanism of action of transcutaneous electrical nerve stimulation:-

The mechanism of pain relief by TENS has been explained by various theories. According to the gate control theory by Melzack and Wall. When an electrical current is applied to a painful area, transmission of the perception of pain through small diameter fibers to the brain is inhibited by the activity of the large diameter, fast-conducting highly militated, proprioceptive sensory nerve fibers, closing the gate to the pain perception to the brain. Another mechanism proposed is activation of descending inhibitory pathway, through release of endogenous opioids. The areas involved in descending inhibition include nucleus raphe Magnus in rostral ventral medulla (RVM) and the periaqueductal gray (PAG). The PAG sends projections to the RVM, which in turn send projections to the spinal dorsal horn. The stimulation of PAG or the RVM produces inhibition of dorsal horn nucleus including spin thalamic tract cells. Specific and different opioids receptors are activated through release of endogenous opioids by different frequencies of TENS. Application of low frequency TENS causes activation of δ-opioids receptors and high frequency TENS activates μ-opioids receptors. These opioids receptors in turn activate the PAG-RVM pathway.8 Uncontrolled postoperative pain may produce a range of detrimental acute and chronic effects. Attenuation of postoperative pathophysiology that occurs during surgery through reduction of nociceptive input into the central nervous system (CNS) and optimization of preoperative analgesic may decrease complications and facilitate the patient's recovery during the immediate postoperative period and after discharge from the hospital[7]. Evidence based practice is essential in clinical practice to hasten the recovery of a patient. In electro therapy the applied energy is the trigger that stimulates or activates physiological events, which achieve therapeutic benefits that bring about pain relief[8].

METHODOLOGY

Research design: Case series

Study Population: Patients with abdominal surgeries

Source of data: Patients coming to Dhiraj General Hospital, Vadodara.

Sample size: 6 patients

Outcome measures: VAS (visual analogue scale)

Inclusion criteria:

- Subjects referred for post-operative physiotherapy following abdominal Surgery:- Gynaecologic Laparoscopy
- Appendectomy

Exclusion criteria:

- History of pain other than incision site.
- Patients with cognitive deficiencies.
- Patients with Cardiovascular instability

Outcome Measures:

- Visual analogue scale

Materials used:

- TENS-Transcutaneous electrical nerve stimulator.
- Electrode gel.
- Carbon rubber electrode.
- Microspore tape

After getting approval from Institutional Ethical Committee of Venus Institute of Physiotherapy, a referred post-operative surgery patients coming to Dhiraj General Hospital, Vadodara were screened according to assessment format. The patient fulfilled the inclusion criteria he/she was included in the study. Each subject was explained about the study and informed consent was taken.The purpose of the study was explained to the participants. Then pre VAS was taken. Accordingly, patient was treated with TENS at the incision site.In gynaecological laparoscopy the electrodes were placed over the area of pain, usually at dermatome Th11- L1for approximately 60 s. High-intensity stimulation was achieved through increasing the stimulation step by step to reach a stimulation intensity of 40 to 60 mA. The pain intensity was reassessed immediately after the end of treatment, i.e., after 60 s of stimulation. Then post VAS was taken. This procedure repeat for twice a day.The purpose of the study was explained to the participants. Then pre VAS was taken. Then Appendectomy was performed through a skin crease incision and muscle splitting approach. Electrodes applied to either side of the wound for 30 minutes. The pain intensity was re-assessed immediately after the end of treatment, i.e., after 60 s of stimulation. Then post VAS was taken. This procedure repeat for twice a day.

- Frequency - 100 Hz
- Plus duration - Short
- Time duration - 30 minutes

Visual analogue scale is used to measure intensity of pain for example the amount of pain that patient feels ranges across a continuum from none to an extreme amount of pain.A VAS is usually a horizontal line 100mm in length, anchored by word descriptors at each end as illustrated in figure. The patient marks on the line the point that they feel represents their perception of their current state. The VAS score is determined by measuring in millimetres from the left hand end of the line to the point that the patient mark.Other than TENS regular medical management was continued.

DATA ANALYSIS

Descriptive statistical analysis was carried out in the present study. Scale Vas scale (VAS). Significance was assessed at 5% level of significance $p<0.005$ (2-tailed hypothesis test considered).

Statistical tests:

- Paired “T” test as a parametric was used for analysis of Vas scale (VAS) variables within the Case series calculation of percentage of change.

Statistical software:

- **T**he Statistical software namely SPSS2.1.0.1 will be used for the analysis of the data and Microsoft word and Excel was used to generate graphs, tables etc.

RESULT:

In present study 6 peoples with the age group of 24 to 66 were taken. 6 subjects follow the session, 6 subjects were analysed. All the 6 participants were evaluated with the transcutaneous electrical nerve stimulation by the same rather before and after Vas scale (VAS scale). The data obtained in the gender are as follows. Statistical package for social science (SPSS) version 20 was used for the data analysis

Sr No.	Age/Gender	Day 1				Day 2				Day 3				Result
		Morning		Afternoon		Morning		Afternoon		Morning		Afternoon		
		Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post	
1	24/F	5	4	5	4	5	3	4	3	4	3	3	2	<3
2	50/F	6	5	6	5	5	4	5	4	4	3	4	2	<5
3	24/M	5	4	5	4	5	4	4	3	3	2	2	1	<4
4	66/M	6	5	6	5	6	5	5	4	5	4	5	4	<4
5	35/F	7	7	7	6	6	5	6	6	6	5	6	5	<5
6	56/M	6	5	5	4	5	4	5	4	4	3	4	3	<4

Table no 1:Represent the ratioof male and female

GENDER	SCALE	PRE	POST	T-	P-
		MEAN/SD	MEAN/SD	VALUE	VALUE
	VAS	181.0000 ±12.56777	192.7500±14.13987	-9.945	.000

Table no 2: Pre-Post Mean Value of VAS SCALE

Intra analysis: The above table shows the Visual Analogue Scale (VAS) for functional assessment the done through paired t test. The p value of pre and post treatment Scale of VAS is 0.000. The p value is < 0.05 which shows that is significant in improving Visual Analogue Scale (VAS). So, Null hypothesis is H0 is rejected and alternate hypothesis H1 is accepted.

	GENDER	MEAN/SD	T-VALUE	P-VALUE
VAS	MALE	-12.000± 6.07644	-426	0.671
	FEMALE	-11.5000 ±4.26675		

Table no 3: INTER MALE / FEMALE FOR VAS SCALE

The above table shows inter -group comparison of post treatment 6MWT scores for functional assessment of group A and B. the analysis was carried out by. At base line, the p value is <0.05. It shows that there is significant difference between the post-treatments scores of both groups. The value comparing the post treatment score for Group A and Group B is 0.671 which is suggestive of significant improvement both groups.However, statistically significant result were noticed in both the groups, clinically it was observed and also observed that PMR technique had greater effects than conventional therapy.

DISCUSSION

Abdominal surgical procedures cause tissue damage by direct visceral manipulation, through the incision on anterior abdominal wall and by the use of surgical retractors that help to expose the surgical field. Pain after surgery causes discomfort to the patient, preventing the patient from relaxing, leading shallow breathing and hindering the patient's movements in bed. Thus decrease diaphragmatic breathing and cough efficacy that might lead to atelectasis, especially in the lower lung fields. Pain is an important negative influence in the postoperative evolution of abdominal surgeries. Transcutaneous electrical nerve stimulation (TENS) is a physical therapy tool widely used to relieve pain.[1]

Laparoscopic surgery has become the standard approach for a large number of gynaecologic procedures. The frequency of laparoscopy varies widely across the globe. Laparoscopic operations are performed annually for the following indications: sterilization, diagnosis, cyst enucleating, and salpingo-oophorectomy.Pain is often a problem after gynaecologic laparoscopic surgery, even if the postoperative pain is less significant when compared to that after a similar major laparotomy surgery.[3] Appendectomy was performed through a skin crease incision and muscle splitting approach. An absorbable suture was used to legate and buries the appendix stump. Closer was in layer with an absorbable suture and skin closure was with 3.0 nylon. Patients were excluded if the wound had to be extended by cutting muscle or if there was generalized peritonitis.[4] Transcutaneous electrical stimulation (TENS) is not major benefit compared with the usual opioids and non-opioids analgesics when pain intensity is high but it can be used as an adjunct to other medications when the pain is moderate and can be the only pain therapy when the pain is mild[6].Uncontrolled postoperative pain may produce range of determinate acute and chronic effects. Electrotherapy can treat diverse symptoms produced by disease that affect the human body[7].In electro therapy the applied energy is the trigger that stimulates or activates physiological events which achieve therapeutic benefits that bring about pain relief. Hence, this study is designed to see the immediate change in pain after TENS application in patient with abdominal surgeries[8].Electro therapy can treat diverse symptoms produced by diseases that affect the human body. Electro therapy using transcutaneous electrical nerve stimulation is a low cost, non-invasive and easily accessible technique to treat pain. In this context, numerous description emerge on the effectiveness of Transcuteous electrical nerve stimulation (TENS) for treating diverse types of pain, knee osteoarthritis and dysmenorrheal[5].Transcutaneous electrical nerve stimulation (TENS) is a technique in which a special device transmits low voltage electrical impulses through electrodes on the skin to the area of the body that is in pain. Clinic studies on the role of transcutaneous electrical nerve stimulation (TENS) on postoperative pain were systematically searched and reviewed with the aim to determine its role in post-operative analgesic efficacy[6].In a case series a total of 6 patients of abdominal surgeries referred for physiotherapy were included in study according to inclusion criteria. Patients were assessed and treated for 3 consecutive days. •TENS was given for 3 consecutive days two times in a day to see the changes in incision pain.In this study high TENS was given for 30 minutes twice a day with frequency 100 Hz.Result showed the changes in visual analogue scale (VAS) after applying transcutaneous electrical nerve stimulation (TENS) in abdominal surgeries. The visual analogue scale for pain is a straight line with one end meaning no pain and the other end meaning the worst pain imaginable. A patient marks a point on the line that matches the amount of pain he or she feels. It may be used to help choose the right dose of

pain medicine. Also called VAS.There was reduction in pain in all the patients with abdominal surgeries who received physiotherapy treatment in form of TENS for 3 consecutive days.

CONCLUSION

In this case series we found that there was decrease in pain in all the patients of abdominal surgeries who received physiotherapy treatment in form of TENS for 3 consecutive days.Exploration of the effect of PMR on stress, fatigue, and quality of life during postpartum

SUMMARY

Background. LBP is one of the major problems in a primary care communal illness with a lifetime prevalence estimating to be as high as 84%. The unspecified structural problems can ascend from day to day mechanical and postural stress on the spine and its related ligaments and muscles. It is associated worldwide with vast amounts of expenditure in terms of direct health care and losses in relation to disability. Currently, there has been a huge focus on physical exercises intended to enhance segmental motion control and lumbar spine stabilization.

Methods. The study sample comprises a total of 239 patients with non-specific LBP. From the sample population, a total of 100 patients were evaluated to GPR based intervention therapy and the 100 patients evaluated with MCE based intervention therapy after dropout. After the end of the intervention procedure the following were evaluated: pain level by numeric pain rating scale, disability by Modified Oswestry Low back pain Disability Index and functional status by fingertip to floor test. The frequency of the session performed in both groups were three times in a week over the study period of five weeks

Results. While comparing the evaluated report pain intensity was effectively reduced in both study groups ($p < 0.001$). The GPR group effectively reduced pain intensity at the end of the intervention compared to the MCE group ($p < 0.001$). The Modified Oswestry Low back pain Disability Index reduced in both groups; however, the GPR Group more significantly reduced the score compared to MCE Group ($p < 0.001$). Fingertip to Floor test showed that the GPR Group had a significantly higher flexibi - ity than the MCE Group ($p < 0.001$).

Conclusions. Patients allocated to the GPR group showed significant improvement in functional status, disability and pain intensity as compared to the MCE group ($p < 0.001$) in patients with nonspecific low back pain

KEY WORDS

Global postural reeducation; disability; motor control exercises; numerical pain rating scale; non-specific low back pain; lumbar stabilization

BACKGROUND

Low back pain (LBP) is one of the most common illnesses with a lifetime prevalence estimating to be as high as 84% (1). The definition of LBP defined as stiffness in the lower back under the costal margin or muscle tension and above the inferior gluteal folds, without or with leg pain (2). Low back pain is found to be one of the foremost causes of health problems worldwide. The prevalence of low back pain differs from 5-65%. It has been reported that the 90% of LBP related to unspecified causes (2)

The lumbar region of back pain which lasts for 4 weeks and more has not been diagnosed as a specific disease or spinal

abnormality is termed as NSLBP (3). It has been reported that the weakened abdominal, back muscles, poorly stretched muscles, incorrect posture, obesity, strained muscles from incorrect body mechanics which often results in the NSLBP pain (4). Lower levels of physical fitness and shorter duration of sitting activities at home may be associated with reduced extensor muscle endurance instead of long duration sitting posture in nonspecific chronic LBP (5)

It has been observed that there are many physiotherapy therapeutic approaches including therapeutic electric stimulation currents, and exercises of CNLBP have been evolved as one most effective therapeutic approach, focus on maintaining spine stability (6, 7). Core stability exercises with neuromuscular electric stimulation was shown to reduce pain and improve the function and stability of the lumbopelvic complex (8).

Motor control exercise was advanced based on a perception that persons with LBP showed some variations in control and coordination of spine muscles. Lumbar muscles must have enough strength and endurance to meet the demands needed for control of spine, but the accuracy and efficacy of the muscular system is controlled by the CNS (9). The CNS must interpret continuously the status of stability and movement, then plan mechanisms and rapidly initiate appropriate activity in response to overcome unexpected challenges. Many studies have shown that low back pain patients may exhibit a delayed onset of activity of the deep spine muscles (10, 11). In summary, the evidence seems to suggest that, with LBP, there is an alteration in control of the deep intrinsic spinal muscles that consistently manifests as hypoactivity. Although others argue that paraspinal muscles react to pain and injury with hyperactivity (12-14).

MCE emphasis on stimulation of deep spine muscles (*i.e.*, transverse abdominals and multifidus), pointing reinstatement of control and synchronization of this muscle (15).

GPR is based on an assimilated awareness of muscular schema as shaped by muscle chains, which can facade lessening resultant from legitimate, behavioral, and psychological features. The intention of GPR is to expand the shortened muscles by means of creep property of viscoelastic tissue and to enhance contraction of the antagonist muscles, thus avoiding postural asymmetry (16).

Two randomized controlled trials showed that GPR was more effective than analytic stretching and mobilizing exercises in improving clinical and functional measures (18). Available studies do not provide sufficient evidence for exact conclusions. This study compared the effectiveness of Lumbopelvic Stabilization Exercises and McKenzie Method in Low Back Pain and found that both techniques were efficient in reducing pain and improving function in patients with low back pain due to disc protrusion. However, the groups that used stabilization exercises showed better results in activating lumbopelvic stabilizing muscles (19). The present study compared the effectiveness of GPR and MCE on nonspecific low back pain patients

MATERIALS AND METHODS

Design of the study

The study design incorporated in the following research is "Experimental Study". The study was conducted at the USB college of Physiotherapy of the Rajasthan University of Health Sciences, Rajasthan, India from January 2013 to December 2019. The study was approved by the USB Institutional Ethics Committee of the USB Group of colleges under Ref. no. USB/Ethical/21, dated: 06/01/2013. The study meets the ethical standards of the Helsinki protocol.

Sampling and randomization

Three hundred two patients were initially selected and included in the study for baseline evaluation. During evaluation sixty-three were excluded because forty-four did not meet inclusion criteria and nineteen chosen not to participate in the study. Therefore, remaining two hundred thirty-nine were concluded the study.

Two hundred thirty-nine patients were randomly allocated to the MCE group (n = 123) and GPR group (n = 116) by an independent researcher by means of sealed envelopes containing the group name. Twenty-three patients dropout from MCE group and sixteen patient dropout from GPR group. Finally, hundred patients were completed study and analyzed at the end of intervention in both group (**figure 1**).

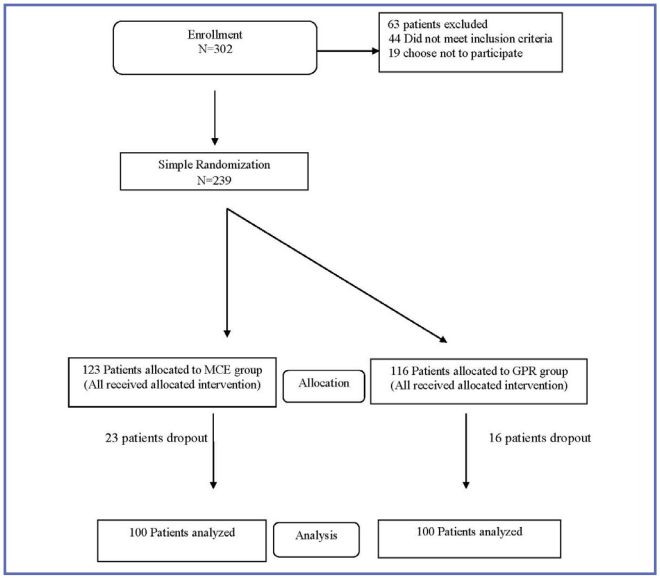

Figure 1. Study Flow Chart.

Eligibility criteria

Inclusion criteria were aged 18 years or above for both genders suffering from non-specific LBP for more than 4 weeks and willing to participate in the study.

Exclusion criteria were the LBP less than 4 weeks (acute LBP), specific LBP caused due to previous/existing medical conditions such as disc herniation, lumbar stenosis, spinal deformity, fracture, spondylolisthesis, neurologic signs (both central/peripheral), systemic illness such as rheumatologic diseases and tumor, psychiatric/mental deficits, patients who had a previous surgical history (within 6 months) were also excluded prior to the baseline assessment.

Evaluation protocol

The baseline evaluation was performed initially prior to randomization and at the end of the intervention in both the group. Evaluator had more than 10 years of experience with the evaluation tools used in the study. Selected modules of physical fitness, anthropometric measurements (height, weight and finall , the BMI), and physiological variables were taken from each subject

The PAR-Q self-screening tool used before starting any intervention either MCE or GPR group for safety or possible risk of exercising for an individual based on their health history, and current symptoms and risk factors.

Outcome measures of the study were subjected to objectively determining the patient's baseline function at the beginning of intervention period, for evaluating the intervention's/treatment's end outcome. The outcome measures employed in the following study were: Modified Oswestry Low Back Pain Disability Index (MOLBPDI), Numeric Pain Rating Scale (NPRS) and Fingertip to Floor Test (FFT). Pain analysis was done using the Numeric Pain Rating Scale (NPRS).Moreover, functional status and disability were evaluated through the Modified Oswestry Low Back Pain Disability Index (MOLBPDI) and Fingertip to Floor Test (FFT).

Intervention protocol

Each session of the intervention lasts up to one hour with one-to-one supervision to avoid unnecessary complication while undergoing intervention procedure by the sample patients. The frequency of the sessions performed three times in a week, with each session being distributed on an even scale, over the study period of five weeks, totaling 15 intervention sessions in both the group.

Group A: the Motor Control Exercise (MCE) Intervention Group

The sample populations belonging to Group-A received the MCE program. The intervention procedure incorporated numerous preparatory exercises prior to intervention procedure. The interventions started immediately after the baseline evaluation. Each individual belonging to the group was suggested to rehearse the proposed exercises that were taught by the researcher in their previous physical therapy session. The patient must perform the proposed exercise at home every day for 15 minutes. The holding time and the number of repetitions performed were increased progressively (increased up to 10 contraction repetitions × 10-second duration for each exercise).

The patients were taught and instructed how to contract trunk muscles. The patient was instructed to perform a slow and normal breathing while performing the intervention and while activating/holding muscular contraction in each step of the intervention exercise. The intervention program was initiated with low-load activation of local motor control composing of local motor control exercises which were intended to activate the muscle regions isometrically with minimal loading positions. The motor control exercise intervention was based on the treatment method described in previous publications (15). The treatment approach has been designed into 3 progressive stages (**figure 2**). The motor control exercise treatment program has been given through three phases.

Figure 2. Activation of multifidus in prone lying position.

Table I. Intervention protocol with motor control exercises.

Phases	Exercises (Repetitions/Time Max up to 10 × 10 sec)
Phase 1 Low-load activation of local motor control (Mainly TrA, Deep Multifidus, Diaphragm and Pelvic floor	Crook lying abdominal hollowing exercise for transverse abdominis activation
	Activation of multifidus in pron
	Abdominal hollowing in sitting
	Abdominal hollowing in four points kneeling
	Activation of multifidus from sitting to lumbar neutral positio
Phase 2 Closed chain with low load and low velocity	Bridge in supine position
	Bridge in prone position
	Lateral bridge
Phase 3 Open chain with high load and velocity	Lower limb abduction
	Knee and hip extension in Crook lying
	Leg cycling
	Sitting knee raises on gym ball
	Abdominal slide
	Lying trunk curl with leg lift
	Basic superman

Group B: Global Postural Re-education (GPR) Intervention Group

The sample populations belonging to Group-B received the GPR program. The intervention group was taught with three postures that were found to be quite effective in stretching/lengthening the anterior as well as the posterior chains of the muscle group. For this study purpose to make the treatment uniformity, 2 or 3 postures were used (**table II**). The GPR intervention was based on the treatment method described in previous publications (16). These therapeutic postures held for 15-20 minutes each (**figure 3**). These postures are as follows:

- the lying posture with an extension of the legs and flexion of hip joints;
- the lying posture with flexion of hip joints
- the standing posture with flexion of the trunk

Statistical analysis

Standard Statistical Package for Social Sciences (SPSS) software was used for analyzing the data. This tests the reliability and validity of the scales by administering paired sample t-test. This is followed by testing of hypotheses by applying mean, median, mode, standard deviation, charts, and chi-square. The simple features of the study data are described by using descriptive statistics. They provide simple summaries about the measures and samples. Togeth-

Figure 3. The standing posture with flexion of the trunk.

Table II. Intervention protocol with Global Postural Reeducation.

Posture	Description (Postures held for 15-20 minutes each)
1.The lying posture with an extension of the legs and flexion of hip joints to release anterior muscle chain including diaphragm muscle	The patients were instructed to lie down in the supine position with upper limbs abducted to 30° and placing the forearms in the supine position. The hip region was flexed, abducted and rotated on the lateral aspects. The foot sole must be touching each other while performing the posture. Manual traction was applied along the neck region for aligning the dorsal and cervical portion of the spinal column. Sacral traction was also performed to straighten the lumbar part of the spinal column.
2.The lying posture with flexion of hip joints to release posterior muscle chain	The patients were instructed to lie down in supine position with adduction of the upper limbs followed by flexion of hip joint to stretch the posterior part of the muscle chain. Progression consisted of increasing hip flexion, knee ex ension and ankle dorsiflexion
3. The standing posture with flexion of the trunk to release posterior muscle chain	The sample patients were instructed to maintain a posture in an upright position followed by the patient to progressively bending towards the forward direction, as well as maintaining the occiput, sacral and thoracic spine portion to be aligned properly.

er with simple graphics analysis, they form the basis of virtually every quantitative data analysis. The level of significance was established at P-value < 0.05.

Sample size and calculation

The sample size was calculated using following formula:

$N = 4\ \sigma 2\ (Z_{\alpha} + Z_{\beta})\ 2/D2$

Where:

- N is the total sample size require;
- σ is the standard deviation of the outcome variable same for both the group;
- Z_{α} is the confidence level
- Z_{β} is the power;
- D is the effect size.

Level of significance taken was as per 0.05 value and power was 0.80. Effect size was calculated from mean and standard deviation of previous study. Values of standard deviation, mean was taken from previous study and effect size was calculated on the basis of previous study also (16, 17).

RESULTS

The study participants were subjected to MCE group and GPR group, each group comprising 100 participants in each group were evaluated after dropout of 23 participants from MCE group and 16 participants from GPR group.

The obtained results include the demographic profile of the respondents, descriptive statistics reflecting the characteristics of the sample and response rate of the respondents. The Effectiveness of this study is on a "Global Postural Re-education (GPR)" program and motor control exercises (MCE) for non-specific Low Back Pain

This tests the reliability and validity of the scales by administering paired sample t-test. This is followed by testing of hypotheses by applying mean, median, mode, standard deviation, charts, and chi-square. Standard Statistical Package for Social Sciences (SPSS) software was used for analyzing the data.

Both groups significantly reduced pain after intervention compared to the baseline evaluation. Baseline evaluation in MCE presented a pain level of 4.98 ± 1.26 points. At the end of intervention, the pain reduced to 4.25 ± 1.23 ($p < 0.001$) (**table III**). On the other hand, GPR showed baseline pain level of 4.98 ± 1.26 points and after intervention reducing to 1.72 ± 0.92 ($p < 0.001$) (**table III**). Finally, GPR demonstrated significantly lower pain level (1.72 ± 0.92) than MCE (5.00 ± 1.29) after the intervention protocol ($p < 0.001$) (**table III**).

The MOLBPDI (Modified Oswestry low Back Pain Disability Index) decreased markedly to 37.46 ± 7.41 to 32.66 ± 7.15 in MCE group after the intervention ($p < 0.001$) (**table III**) and GPR group maintained noticeably lower scores of 38.3 ± 8.75 to 20.3 ± 4.81 as compared to pre scores. Both groups improved their scores at the post intervention evaluation ($p < 0.001$) (**table III**), but GPR group scores decreases significantl . There was a statistically significant difference in post mean values of GPR-MOLBPDI and MCE-MOLBPDI, 20.30 ± 4.81 and 32.66 ± 7.15 respectively (**table III**).

Functional status were evaluated by using Fingertip to Floor test ($p < 0.001$) and improved flexibility in both groups but GPR showed a significant increase in functional status of 18.12 ± 4.67 to 9.22 ± 2.88 when compared pre and post mean values (**table III**) and MCE group showed less significant result from 18.93 ± 4.23 to 16.26 ± 3.99 (**table III**).

Table III. Comparison between the GPR and MCE group at pre and post intervention scores.

Outcome measures	Group	Baseline or Pre intervention Scores	Post intervention Scores	Post mean Values	P-value
NPRS for Pain	**MCE**	4.98 ± 1.26	4.25 ± 1.23	5.00 ± 1.29	< 0.001
	GPR	4.98 ± 1.26	1.72 ± 0.92	1.72 ± 0.92	< 0.001
MOLBPDI for Disability	**MCE**	37.46 ± 7.41	32.66 ± 7.15	32.66 ± 7.15	< 0.001
	GPR	38.3 ± 8.75	20.3 ± 4.81	20.30 ± 4.81	< 0.001
FFT for Functional status	**MCE**	18.93 ± 4.23	16.26 ± 3.99	16.26 ± 3.99	< 0.001
	GPR	18.12 ± 4.67	9.22 ± 2.88	9.22 ± 2.88	< 0.001

The GPR group showed a significant reduction in all outcome measures as compared to MCE group when compared pre scores to post scores.

DISCUSSION

The study result demonstrates that the conducts of care provider and the contents of exercise programs based on the home were both important and the contributor follows the programs. Health providers' home-based exercise and style program conditions emerged as powerful themes in our data. Our discovery supports the hypothesis that the GPR involvement is fruitful in non-specific low back pain with less disability levels when compared to MCE. Patients allocated to the GPR group showed significant improvement in functional disability and pain intensity as compared to the MCE group. The results are similar to those get in both male and female but the majority of respondents are male (19), who display the good results of the GPR as a compared program of analytical exercises in patients with ankylosing spondylitis, and those get in other researchers on LBP cited in the review (18). Therefore, it appears that Global Postural re-education is better in reducing pain and disability in subjects with non-specific LBP than segmental techniques. However, these results are varied from those by Cunha *et al.* (20), who did not find various outcomes comparing conventional static stretching and muscle chain stretching in chronic neck pain (20). The causes for these various outcomes may be related to both the areas affected by spinal pain and the fact that GPR might be more effective when compared to analytical stabilization or mobilization techniques, although it is not higher level to other stretching techniques (16).

When bearing in mind the clinical importance of our research, we can state that the GPR program produced a clinically meaningful improvement in comparison with MCE group. Both the groups were treated three times in week for five weeks and one hour per session. The mean fruitful of the MCE program were low relevant than those reported in some previous trials (21) but are in line with those obtained in some other recent studies (22).

Even than these results are slightly varied from Choopani *et al.*, who compared segmental stabilization exercises and general exercises and found that stabilization exercises were more effective in patients with spondylolisthesis ($p < 0.001$) (20). My study also shows effectiveness of stabilization exercise, but GPR technique was more fruitful.

However, the identification of subgroups is a tough process, since it cannot be identified yet be guided by a coherent theory of causation of back pain (24). Moreover, the disability levels of the patients cover in our research are less compared to previously published disability scores in "non-specific LBP" populations. Moreover, both therapies consisted of a one-to-one supervised exercise program actively requiring the patient: according to the literature, these kinds of management are fruitful to decrease disability and improve function in chronic LBP (25).

Apart from the strong clustering, the diagnosis could be adjusted only for patient factors (*e.g.*, because of the variance in socioeconomic factors between patient arms they adjusted for socio-occupational status). The outcome variance can be calculated, and some other factors also describe the part of outcome variance calculation. It is usually assumed that the more experienced physical therapists give the better outcomes in clinical (26). However, some current researchers assess the relationship between year of patient outcomes and the year of experienced physiotherapists, if the outcomes reported were not associated with improved patient outcomes in outpatient rehabilitation (27).

Moreover, the major strength of this study was presence of the simple randomization. This practical choice could have not led to some possible sources of bias: the two groups were having the same baseline, but slightly varied for socio-economical characteristics; this issue was considered in the multivariate analysis, taking this into account the possible different aggregation of patients within the different centres.

Another major restriction was the elevated number of dropouts in both the groups MCE as well as GPR. Furthermore, dropped-out patients varied on critical baseline behaviors from those who completed the study; on the other hand,

they were equally represented in the two groups (MCE and GPR). The high number of dropouts was mainly due to the resolution of patients to give up therapy in the absence of expected results and from GPR group was due to the inability to hold the posture for particular time. Dropouts from both groups had higher levels of disability and pain. This aspect was managed with the intent to treat approach, which confirmed the improvement obtained in the GPR group with respect to the MCE group at the per protocol analysis (28).

According to my views, GPR alone cannot be effective for non-specific LBP treatment, and it can be considered an important approach in the management of non-specific LBP patients at low disability levels. As per results of my study we cannot apply GPR intervention to subjects with high disability level of non-specific LBP. The GPR method is based on the global stretching of antigravity muscles and the stretching of muscles that are organized on muscles kinetic chain (29). When the length of the muscle fibre is chronically altered, the numbers of sarcomeres adjust to compensate the change, which affects the functional capability of muscle. One study shows that the generation of the tension in the skeletal muscle, measured by evaluation the length-tension relationship, is directly correlated with the degree of superimposed of actin and myosin filaments. During rest, less superimposition of actin and myosin fil - ments translating to greater capacity of the muscle of greater tension (30). This principle explains the result of my study as I applied global stretching techniques designed to improve length-tension relationship along with contraction of antagonist muscle, thereby improving postural symmetry and muscle capability because postural asymmetry may results in lower endurance of affected muscles and the increased risk of injury in the future when compared to people without postural asymmetry predicates effectiveness of postural correction (31).

Many physiotherapy methods are effective in management of non-specific LBP according to literature. Now a day's GPR method is not considering as treatment of choice for non-specific low back pain. This may be because of little evidence of effectiveness of GPR method. So, my study will be benefitted to professionals who are working for non-specific LBP and also for community suffering from this ailment.

It also needs higher level of studies. Some suggestions are the measurements of effectiveness of the clinical effects of the GPR on non-specific LBP subgroups, related to the phases of pain as acute, sub-acute and chronic pain and others are age of patients, *etc.*

Furthermore, the GPR effectiveness with other techniques such as manipulation, specific exercises or traction, *etc.*, can be compared.

Moreover, patients follow the home exercise program which could not be monitored. Indeed, follow the therapeutic program represents in a crucial aspect of chronic low back pain therapy (28) and appear to be related to professional characteristic and explanations and to the total number of exercises prescribed, as well as to individual and psychological characteristics (32).

Since the potential effect of physical and sports actions or cognitive-characteristic aspects was not review, the presence of a complex condition as a result of physical and psychosocial factors can be included (33). As an outcome, definitely explain the GPR alone does not helpful for the patient with low back pain, but the GPR can be considered as a significance approach for the management of a patient with low disability level and persistent LBP. Because dropouts from both GPR and MCE groups had increased level of disability and pain than the subjects who completed the trial, they cannot apply our outcomes to the subject with more disabling low back pain.

Many of the physical therapy methods could be helpful in low back pain; most of the therapist studied by serious clinical trials. The current research trend on this title allows to identify clinical prediction restrictions and some of the proposed classifications that can be applied to low back pain subgroups.

Low back pain patients sub grouping is related to techniques as particular exercises or traction, manipulation and stabilization. But the GPR therapy is not considered within that sub grouping. This is mainly due to a usual lack of knowledge and to the compact proof of fruitfulness of this method. Exercise programs based on home is known to interfere with daily routine and normal lifestyles (34). The statement of this study consistent with proof that present contributors have chronic neck or back pain reduction more to follow the prescribed home exercises when the home program requires a longer time for execution or includes exercises which are difficult to perform. To minimize the daily routine interruption caused by exercises it gives a solution for a continuation of home-based exercise (35). One solution would be restricting the number of exercises advice in each program. Similarly, there is evidence suggesting that more than eight exercises in a program play a negative influence on contributor follow the advised exercises (36).

The results proposed that a proper supervision during the exercise execution for the duration of a session may be a further chance to reduce patient's lack of confidence and panic of exercising at home. Health provider's style is fin - ings on the subject of how health provider's style is important for contributor following adherence to home-based exercise program confirm and expand previous findings (37). The contributor to this study recognized that a super-

vised instruction which includes proper feedback which is most important for their adherence. It is proof that exercises based only on written instructions are not often performed properly, and therefore lead to poorer outcomes than when compared with outcomes from exercises learned under the supervision of a care provider (34). Nevertheless, there is also proof that an attractive exercise mode mixed with written command improves adherence to exercises of patients presenting back pain (32).

Put in writing command during particular daily activities were normally used as reminders for our contributor. The contributor to our research often felt that these nudges were important. In the same way, the use of nudge has also been suggested by related studies, due to the fact that patients tend to forget exercising or have serious complexities in fitting the exercises into their daily routine (38)

Our study may represent the first step in this direction, but it should be followed by further, higher level studies. Accordingly, some suggestions for future research are the calculation of the clinical effects of the GPR on specific LBP subgroups, with respect to the age of patients, the phase of disorder (*e.g.*, acute, sub-acute or chronic pain), and the clinical characteristics. The GPR can be investigated with or without the novel lumbar support device on pain modulation and core muscle function among people with CNLBP (39). Moreover, the fruitfulness of GPR should be compared with other techniques, as manipulative treatment, cognitive characteristic treatment, *etc.*

Study limitations

However, there are some weaknesses in our study. The major restriction was the elevated number of dropouts in both the groups MCE as well as GPR.

The study satisfied the sample size, even than the study included short-term intervention such as three times a week for five-week treatment period onl .

Another limitation is lack of short- and mid-term follow-up, which would reveal a significant result (from baseline) in all outcome measures with respect to both the group.

The study should have included a control group, so future study should include control group for obtaining best results. Another limiting factor of my study is lack of sub grouping. Some suggestions are the measurements of effectiveness of the clinical effects of the GPR on non-specific LBP subgroups, related to the phases of pain as acute, sub-acute and chronic pain and others are age of patients, *etc.*

Furthermore, the GPR effectiveness with other techniques such as manipulation, specific exercises or traction, *etc.*, can be compared.

CONCLUSIONS

The evaluated test report of MCG and GPR were compared, all the post effect showed an improvement when compared to pre-results. Both the method Global Postural Re-Educational Program and Motor Control Exercise during the assessment showed less or more similar effectiveness. While comparing the evaluated report and effects from Motor Controlled Exercise and Global Postural Re-education program, effectiveness was found in GPR program than MCE, this is compared and evaluated during the difference obtained from pre-study to post-study results from MOLB-PDI, NPRS and FFT process.

ABSTRACT

Background: Primary Dysmenorrhoea is a difficult menstrual flow in the absence of any pelvic pathology where pain is spasmodic in character and felt mainly in the lower abdomen. Women that participated in sports experienced fewer occurrences of symptoms of dysmenorrhea.

Aim: To assess the effect of one term of stretching exercise on primary dysmenorrhea in adolescent girls.

Materials and Methods: 30 girls aged between 18-28 years with mild to severe primary dysmenorrhea were selected; the girls were non-athletes and volunteered for the study. The participants were randomly divided into 2 groups: an exercise group (n=15) and a control group (n=15). In the intervention group, the subjects were requested to complete an active stretching for 12 weeks (4 days per week, 1 time per day, 10 minutes, and post test was examined 12 weeks later.

Results: After the intervention, however, a significant difference was found between the two groups regarding the mean intensity of dysmenorrhea in the first and second menstrual cycles. Also, a significant difference was observed between the stretching group and the control group. However, no such difference was observed in control group.

Conclusions: Stretching exercises are effective in reducing pain intensity, pain duration, and the amount of absenteeism in schools and colleges due to having pain during menstruation.

Key Words: Dysmenorrhoea, Adolescent girls, Stretching, Exercise, Physiotherapy

INTRODUCTION

Dysmenorrhea literally means painful menstruation but more realistic and practical definition includes cases of painful menstruation of sufficient magnitude so as to incapacitate day to day activities. [1]

It is commonly classified into primary dysmenorrhea when there is no co- existent pathology and secondary dysmenorrhea where there is an identifiable pathological condition. About 40-70% of women of reproductive age suffer with dysmenorrhoea. [2]

Primary dysmenorrhea begins when young girls first experience the ovulatory cycles and its prevalence increases during adolescence (15-17) years and decreases progressively then after. In dysmenorrhea pain begins few hours before or after the onset of menstruation and lasts for 24-48 hours. The pain is more in the first day and rarely continues to next day. [3]

Primary dysmenorrhea is commonly seen only in ovulatory cycles, usually developing within 6 to 12 months of menarche and is characterized by lower abdominal sharp pain that may radiate to the back and upper thighs. The pain of primary dysmenorrhea starts with the onset of menstrual flow or a few hours after the onset and may last for a few hours up to 2 days. The pain of secondary dysmenorrhea usually begins few days before the start of menstrual flow and may be present during much of the menstrual cycle. Pain that occurs with the first menses or after the age of 25 or is associated with an ovulatory cycles is more likely to be secondary dysmenorrhea. [4]

It is characterized by lower abdominal pain that potentially could radiate to the back and thigh regions. The pain may be associated with headache, fatigue, nervousness, nausea, vomiting, mood swings.

Primary dysmenorrhea most likely caused by increased prostaglandin production within the uterus and associated uterine hyper- contractility. [5]

In primary dysmenorrhea pain is spasmodic in character and felt mainly in the lower abdomen, but it may radiate to the back and along the thighs. There may be associated systemic symptoms like nausea, vomiting, diarrhea, and headache. [6]

Despite the widespread use of stretch in physical rehabilitation, considerable uncertainty remains surrounding its lasting effects. There is little doubt that stretch induces immediate increases in muscle extensibility due to the viscoelastic nature of soft tissues. [8] However, these effects are transient and quickly dissipate. The lasting effects of stretch are more controversial but arguably of more importance, particularly for individuals with chronic pain.

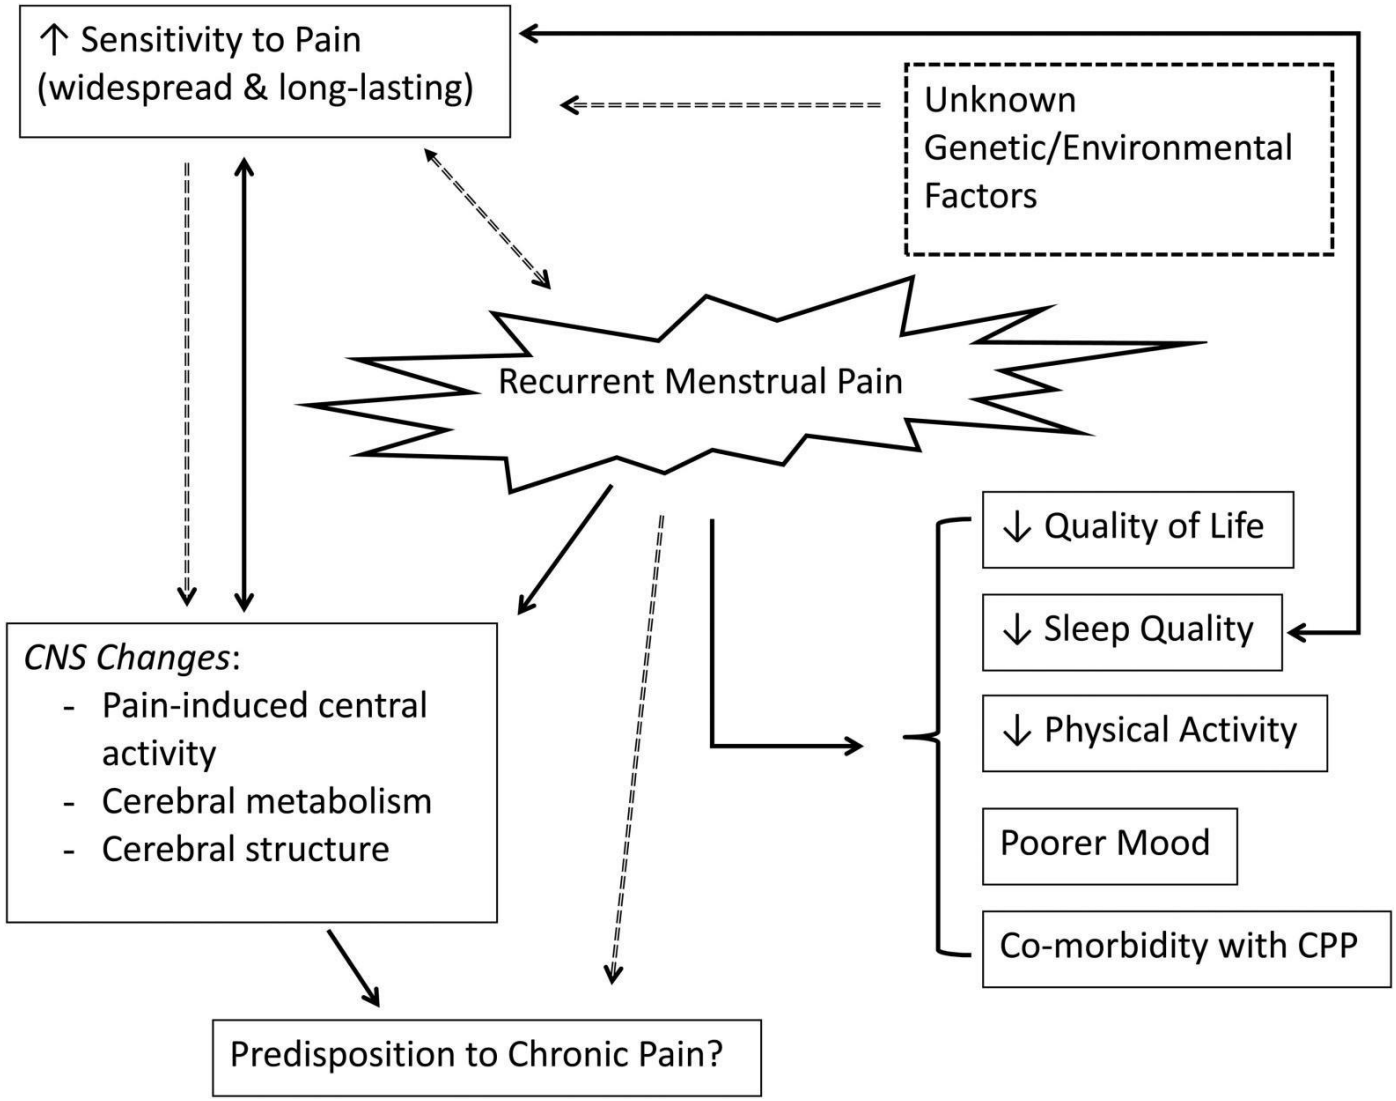

Figure.1 A schematic representation of the proposed (dotted lines) and known (solid lines) effects of recurrent dysmenorrheal pain [7]

The controversy arises from the discrepancy between strong anecdotal evidence and evidence from studies of animals [9] supporting the effectiveness of stretch and high-quality randomized controlled trials indicating otherwise. Studies of animals showed that soft tissues are adaptable and undergo structural remodelling in response to stretch. On the other hand, results of studies of humans are less consistent. In this article, improvements in extensibility refer to an increase in joint ROM when repeat measurements are taken with the same testing torque (torque is the product of applied force and moment arm or the tendency of a force to cause rotation).

Some investigators contend that what appear to be lasting changes in extensibility are in fact changes in people's willingness to tolerate the discomfort associated with stretch over time. For example, following a hamstring muscle stretch program, an individual may touch his or her toes more easily. This patient outcome may not be due to any underlying change in muscle extensibility, but may instead be due to the direct relationship between applied stretch torque and resultant joint ROM. That is, the harder an individual

leans forward (ie, the stretch torque), the further he or she can reach down toward the toes (ie, the joint ROM). The ability to reach further is due to altered perceptions and increased willingness to tolerate the discomfort associated with stretch [10]

The causes of primary dysmenorrhea are still unclear, but one of the most accepted explanations is increased synthesis of prostaglandins, of which types E2 and F2α play a significant role in the development of ischemia and hypoxia, resulting in dysrhythmia uterine contractions and decreased blood flow. [11]

Drug therapies and complementary medicine are often used to treat dysmenorrhea. [12] According to the literature, NSAIDs and OCPs rank among the most frequently used medications. These drugs reduce pain by inhibiting the production and release of prostaglandins. However, long-term use of NSAIDs has been associated with side effects such as headache, dizziness, drowsiness, loss of appetite, nausea, vomiting, gastrointestinal bleeding, increased acute asthma, dysuria, and acne. [13]

OCPs inhibit ovulation, reduce endometrial proliferation, and create an endocrine environment that mimics the early stages of the proliferative phase of the menstrual cycle, in which prostaglandin levels are at theirlowest. Lower prostaglandin levels lead to fewer uterine cramps. In the realm of complementary medicine, methods resorting to herbs, yoga, relaxation, psychotherapy, massage, hypnosis, vitamins (E, B, C), and supplements (calcium and magnesium) as well as acupressure and acupuncture have been used. The herbs used more commonly to treat dysmenorrhea are chamomile, ginger, fennel, cinnamon, and aloe Vera. [14] Common treatments for dysmenorrhea are extensive and in some cases subject to restrictions. For example, NSAIDs are contraindicated for patients with digestive problems, while medicinal plants are not always readily available. This research aimed to investigate the effects of a set of stretching exercises on reducing the pain of dysmenorrhea.

REVIEW OF LITERATURE

1. **An epidemiological study of young women with dysmenorrhoea[15] : B Andersch et al. (1982)**

   The study was conducted in 1982**,** The prevalence of dysmenorrhoea was studied in a random sample of 19 year old women from an Urban-Swedish population, dysmenorrhoea was reported by 72% of the women 15% suffered from dysmenorrhoea which limited daily activity and was unimproved by analgesics.

2. **Prevalence of dysmenorrhea and its effects on quality of life among a group of female university students.[16] : A Unsal et al. (2009)**

   This cross-sectional study was conducted between 15 march and 15 April 2009. The study group included 623 female students. The severity of dysmenorrhea was determined with 10-point visual analog scale. The average age of the study groups was 17-30 years. They concluded that prevalence of dysmenorrhea was found to be 72.7% and it was significantly higher in coffee consumers, females with

menstrual bleeding duration 7 days, and those who had a positive history of dysmenorrhea when compared to the others.

3. **Association of psychologic and nonpsychologic factor with primary dysmenorrhea.[17] : M Faramarzi et al. (2014)**

   This study was conducted in Aug 2014, in this study 180 females with dysmenorrhea and 180 females without dysmenorrhea were enrolled. Psychological risk factors were evaluated in four domains including affects, social support, personality, and alexithymia. The data was collected by using questionnaires and they concluded and high caffeine diet are important risk factors risk factors for women with primary dysmenorrhea.

4. **Comparing the effects of aerobic and stretching exercises on the intensity of primary dysmenorrhea in the students of universities of busher[18]: F Vaziri et al. (2015)**

   The study was conducted in March, 2015. This randomized clinical trial was conducted on 105 females who were suffering from primary dysmenorrhea. The participants were divided into aerobic, stretching and control groups. The 2 groups performed exercise three times a week for 8 weeks. Then after the intensity of dysmenorrhea was determined using several modified questionnaires that assessed several symptoms of dysmenorrhea. After all, the data was compared between and within groups through analysis of variance. They concluded the aerobic and stretching exercises are effective in reducing Severity of dysmenorrhea.

5. **Primary dysmenorrhea and its effects on quality of life in young girls.[19]: T Joshi et al. (2015)**

   The study was conducted in March 2015, A cross sectional study and data were collected among 310 young girls on presence and absence of dysmenorrhea, premenstrual symptoms, dietary habits using questionnaire and they concluded that concluded that dysmenorrhea is a leading causes of a absenteeism in colleges and has an adverse effects on the quality of young girls.

6. **Effects of different exercise techniques on primary dysmenorrhea among higher secondary school girls. [20]: D Khare et al. (2016)**

   The study was conducted in 2016, to study the effectiveness of isometric exercises and variousstretching techniques used as a treatment protocol for primary dysmenorrhea. The students were divided into control and experimental groups, both groups performed set protocol from fourth day of menstrual cycle. They concluded that isometric and stretching both exercise has a positive effects on treatments of primary dysmenorrhea in school girls.

7. **Effects of exercises on primary dysmenorrhea in young females.[21]S Shah et al. (2016)**

This study was conducted in year 2016, A convenient sample was taken of 40 participants, randomly and equally divided into 2 groups. Groups A received stretching exercises and group B was control groups. Participants in group A completed an active stretching exercise program for 6 active stretching exercises in the abdominal, pelvic and groin regions for 8 weeks, group B was control group. All the participants were examined for pain intensity with VAS and VMSS. After the research they concluded that stretching exercises are effective in reducing pain in young females with primary dysmenorrhea.

8. **Effects of selected muscle stretching exercise on primary dysmenorrhea among studentnurses.[22]: B Gomathi et al. (2017)**

This study was conducted in July 2017, To assess the effectiveness of selected muscle stretching exercise on primary dysmenorrhea. 67 student nurses with primary dysmenorrhea were selected from college by using non probability purposive sampling technique and they were randomly assigned into experimental group and control group. Muscle stretching exercise taught to the experimental group and practiced for 8 weeks. Pain intensity was assisted by using numerical pain rating scale and they concluded that selective muscle stretching exercise are effective in reducing pain in dysmenorrhea.

9. **What we know about primary dysmenorrhea today: a critical review[23]S Lacovides et al. (2015)**

Comprehensive literature searches on primary dysmenorrhea were performed using the electronic databases PubMed, Google Scholar and the Cochrane Library. Full-text manuscripts published between the years 1944 and 2015 were reviewed for relevancy and reference lists were cross-checked for additional relevant studies. In combination with the word „dysmenorrhea" one or more of the following search terms were used to obtain articles published in peer-reviewed journals only: pain, risk factors, etiology, experimental pain, clinical pain, adenomyosis, chronic pain, women, menstrual cycle, hyperalgesia, pain threshold, pain tolerance, pain sensitivity, pain reactivity, pain perception, central sensitization, quality of life, sleep, treatment, non-steroidal anti-inflammatory drugs.

NEED OF STUDY

Dysmenorrhea pain is associated with restriction of activities and it is considered as the leading cause of absenteeism from work place and colleges in young girls. Dysmenorrhea is the most commonly relieved by medication ranging for commercially available formulas to contraceptive. The side effects from such medication are well known (nausea, breast tenderness, and drowsiness, hearing and visual disturbances).
Despite the widespread belief that exercise can reduce dysmenorrhea, evidence based studies are limited. Several observational studies reported that physical exercise was associated with reduce prevalence of dysmenorrhea, although numerous other studies found no significant association between outcomesevidence

from controlled trials suggests that exercises can reduce dysmenorrhea and associated symptoms. Hence this study is designed to determine the value of stretching exercise weather it is helpful in reducingthe symptoms of primary dysmenorrhea or not.

OBJECTIVE OF THE STUDY

1) **Aims:** To check the effects of stretching exercises on reducing the symptoms of primary dysmenorrhea in adolescent girls.
2) **Objectives of the studies:** To find out effects of stretching exercise on primary dysmenorrhea in adolescent girls.

HYPOTHESIS

1) **NULL HYPOTHESIS**

   There will be no significant effects of stretching exercise on reducing the symptoms of primary dysmenorrhea in adolescent girls.

2) **EXPERIMENTAL HYPOTHESIS**

   There will be significant effects of stretching exercise on reducing the symptoms of primary dysmenorrhea in adolescent girls

METHODOLOGY

Materials and Methods:

- **Study design:** Randomized control trial
- **Source of data:** Nearby colleges and working girls through online question forms
- **Population:** All subjects are adolescent girls that are having symptoms of primary dysmenorrhea
- **Sampling method:** Purposive sampling
- **Sample size:** 30 subjects
- **Duration of study:** 3 months

All the data were collected by general assessment form, questionnaires regarding menstrual characteristics and dysmenorrhea, Numerical rating scale and verbal rating were used for assessment of intensity of pain. The general assessment form and questionnaires were distributed to all the girls who agreed to participatein

the study.

Then participants were explained the procedure and purpose of the study and consent was taken in an understandable language.

Then after participants was randomly divided into 2 groups, Group A: Stretching exercise group, Group B: Control group. Severity of the pain was measured by using Numerical rating scale and Verbal pain rating scale for pretreatment and post treatment.

Group A participants was asked to perform 5 self- stretching exercises in the back, thigh and pelvic regions for 8 weeks (4 days per week). Also they were asked to avoid performing stretching exercise during the menstrual cycle and group B participants were asked not to perform any kind of exercise on daily basis.

The exercises are as follows:

1. **Double Knee Chest**

First you have to lie down on a mat then bring one knee towards the chest then the other one, clasp the hands around the thighs and pull them to the chest, elevating the lower back part off the mat, you should not grasp over the knee part but end area of the thigh. Do it for 20 seconds and 5 times.[This exercise will stretch the lumbar spine muscle and tissues posterior to the spine]

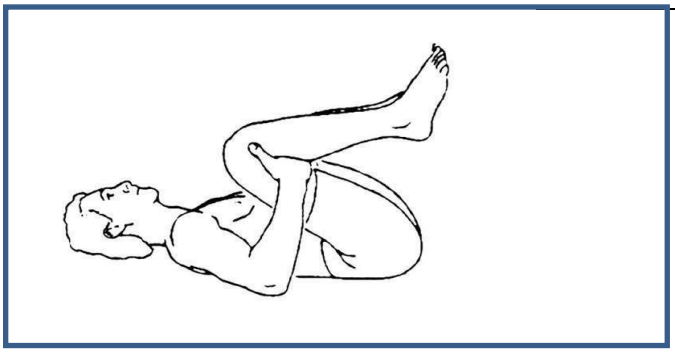

Figure.2 Double knee chest

2. **Gluteal Muscle Stretch**

Knee to chest: Pull your left knee towards your chest while lying on the ground , focus on placing your lower back flat on the ground while breathing long and deep, hold the stretch for 20 seconds and 5 times. Then perform this same on the right side of knee for 20 seconds 5 times.[This exercise will stretch the gluteal muscles , hamstrings and lower back muscles]

Figure.3 Gluteal muscle stretch

3. Child's Pose

Go on all 4 limbs and with both arms reach as far as possible with your elbows locked and your arms straight. Then lean back with your shoulders relaxed.

The stretch should be felt in the lower back and shoulders. Focus on breathing deeply with your long breaths (20 seconds 5 times) [This exercise will stretch the lumbar spine muscle , gluteal Maximus , quadriceps femoris and shoulderextensor muscle].

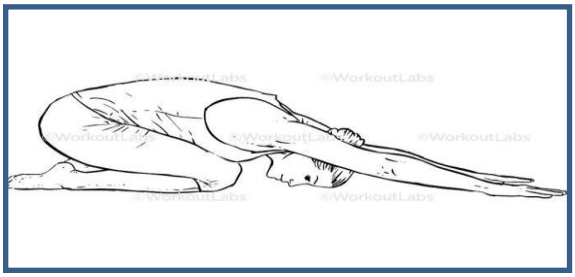

Figure.4 Childs pose

4. Cobra Pose

Lay down on your stomach then place your hands by your sides at chest level and push up while leaving your waist on the floor. Try to relax your back and waist and allow the stretch in your stomach and lower back. Focus on breathing deeply and increase movement in the spine.(20 seconds 5 times) [This exercise will stretch the soft tissues anterior to the lumbar spine and hip joints].

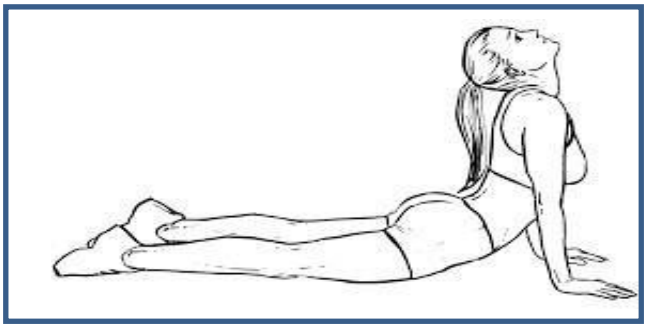

Figure.5 Cobra pose

5. Quadratus Lumborum Stretch

Lay down the ground and pull the left leg over the right side, try to leave the same side of shoulder on thefloor while you are holding the stretch. To increase the intensity of stretch extend your leg and pull the leg closer to your chest, keep inmind that do not stretch beyond your limits. (20 seconds 5times) [This exercise will stretch the quadratus lumborum muscle]

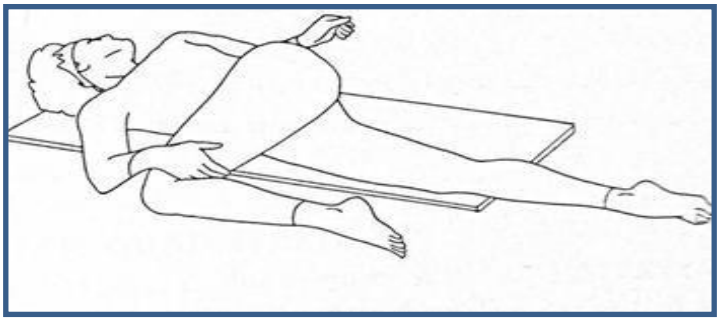

Figure.6 QL stretch

- Then same perform to the right side (20 seconds 5 times)
- Group B will be Control Group and will be asked not to perform any type of exercise during this time of study. Again data will be collected, that includes their menstrual pain before study and menstrual pain after 8 weeks, from both the group. Data will be compared and conclusion will be made on results

- Scales that were used for pain assessment of girls are as follow

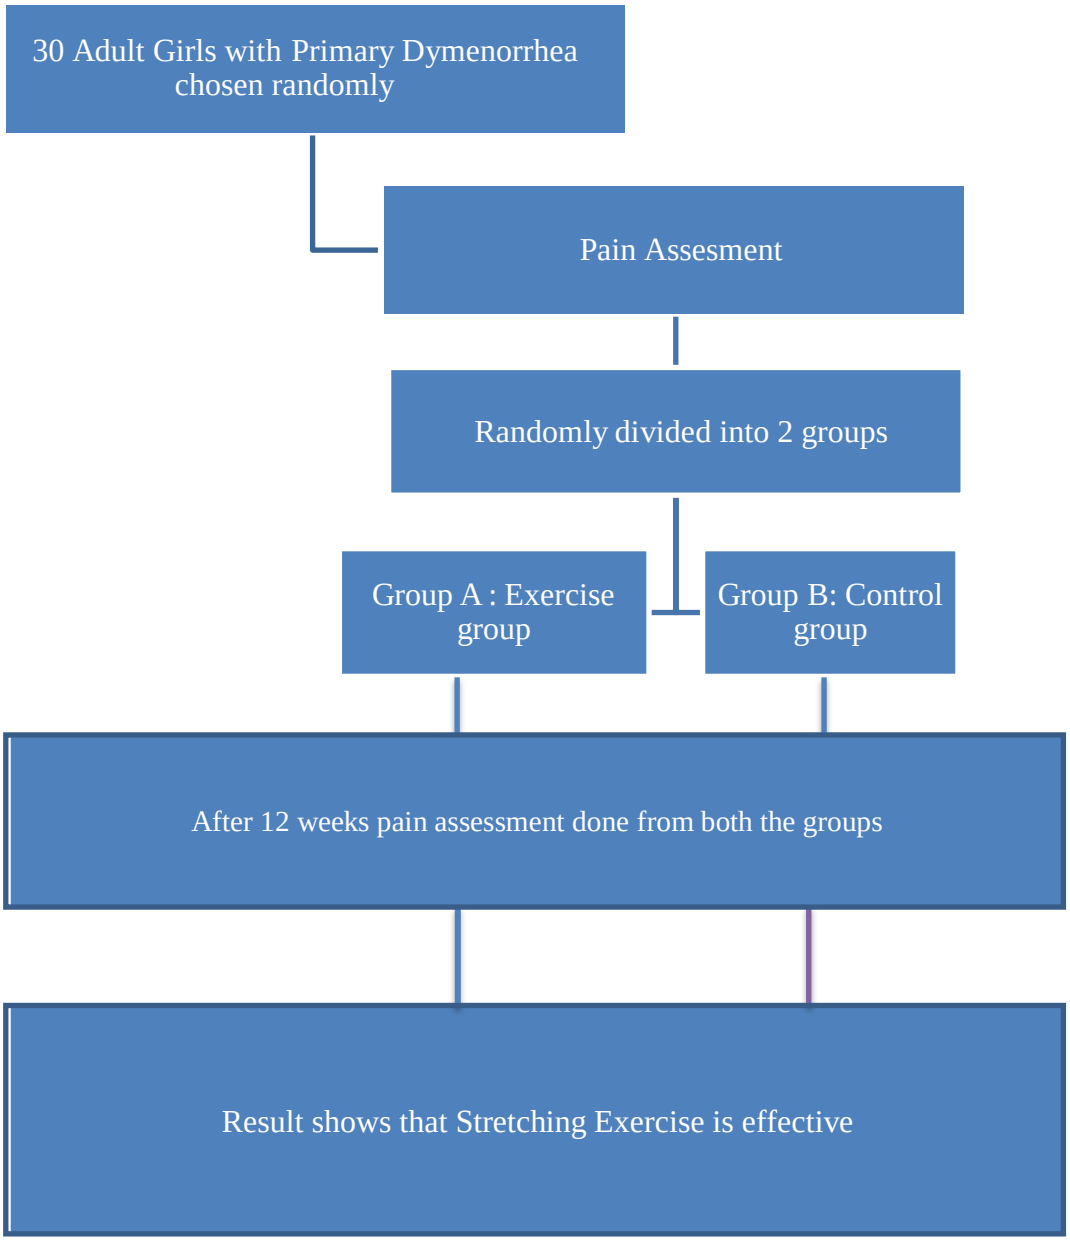
1) Numerical pain rating scale
2) Verbal pain rating scale

. Numerical pain rating scale

0 1 2 3 4 5 6 7 8 9 10

. Verbal pain rating scale

- None
- Mild
- Moderate
- Severe



RESULT

In present study 30 subjects with the age of 18-28 years were selected and divided into two groups:

- Group A – Exercise group
- Group B - Control group

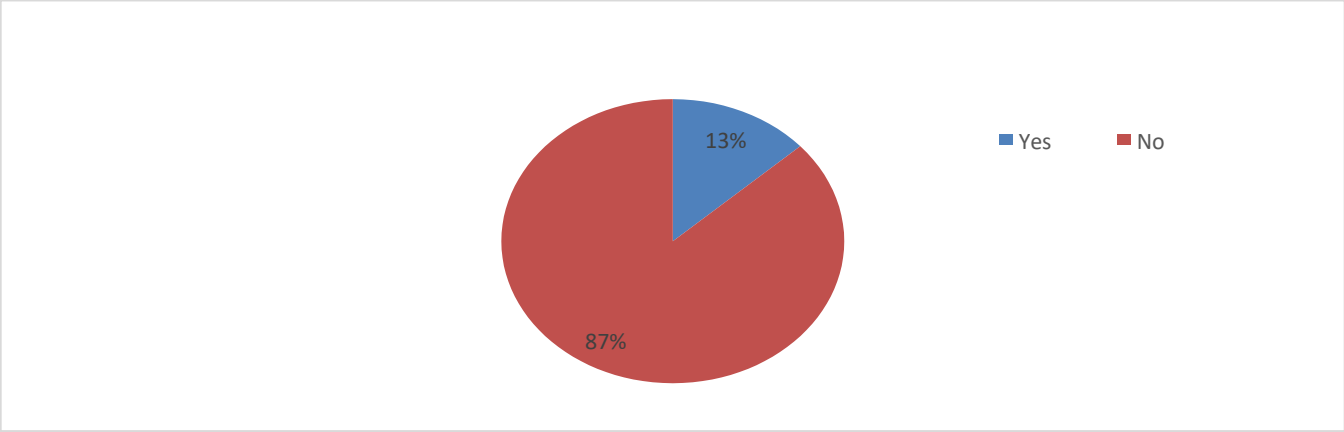
30 individuals completed the study program without any complications. The data obtained in both the groups are as follows.

Table 1 Medication taken by patients

Medicines (pain relief)	NO. of Patients
YES	4
NO	26
Total	30

Interpretation: The above table shows the no. of patients that took medication for pain relief in both the groups

Graph.1



Interpretation: Above graph shows no. of patients who respond yes and no to the medication

Table 2: Pain and any other symptoms

Pain and symptoms	No. of patients
Yes	20
Sometimes	10
Total	30

DISCUSSION

The present study was conducted to see the effect of stretching exercises on the pain intensity of primary dysmenorrhea. In present study, pain has reduced in primary dysmenorrhea more in stretching exercise group than in control group.

This improvement may be due to the increase in the blood flow and metabolism of the uterus during exercise which may be effective in the reduction of dysmenorrheal symptoms. A study done by Izzo and Labriola (1991) [26] has shown that improved metabolism is a factor in the reduction of symptoms. It is also suggested that increased menstrual pain by uterine muscle contraction is derived from a nervous system that is innervated by the sympathetic nerve hence; stress through hyperactivity of sympathetic nerve system via the increase contractibility of uterine muscles may lead to menstruation symptoms. A study done by Dawood MY (2006) [27] has shown that therapeutic exercise can increase the secretion of endorphins from the brain, and these materials in turn raise the pain threshold of the body. Daley AJ (2009) [28] believed that contracted ligamentous bands in the abdominal region were the causative factor for physical compression of nerve pathways and their irritation, so the proposed series of stretching exercise was considered very effective.

Pain in general has disabling nature and makes dysmenorrhea stressful and it can become important irritating factor in the life of lots of women, particularly who are self-financing. Some women are completely prostrated and cramped to bed, whereas others are able to remain in the works with the support of analgesics. So, many studies were done to replace medication by physical exercises in management of primary. The present study was conducted to see effect of stretching exercises in relieving pain of primary dysmenorrhea. In this study, treated females reported a significant reduction in menstrual pain within an average of 8 weeks of exercises (Group A).

Since time ago, Israel et al. [29] found that after 12 weeks of aerobic training, the intensity of symptoms decreased and Golub et al. [30]expressed that dysmenorrhea in high school girls who were involved in sports and physical activities were less than non-exercise group. In present study, pain of primary dysmenorrhea has reduced in exercise group than in control group as regard intensity and duration. These findings are similar to those of lots of authors who studied the effects of exercises on primary dysmenorrhea. Abbaspour et al. [31] and Shahr-jerdy et al. [32] proved that stretching exercises are effective in reducing pain intensity, pain duration, and the amount of painkillers used by girls with primary dysmenorrhea. Onur et al. [33] studied the impact of home-based exercise on quality of life of women with primary dysmenorrhea and concluded that there is evidence that exercise has a positive effect in the treatment of dysmenorrhea.This improvement may be due to the increase in the blood flow and metabolism of the uterus during exercise which may be effective in the reduction of dysmenorrheal symptoms. Stress tends to enhance sympathetic activity and may increase menstrual pain by exacerbating uterine contraction. Exercise may decrease this sympathetic activity and relief the stress through release of endorphins, substances produced by the brain that raise the pain threshold, so reducing symptoms. [34] Dawood [35] has shown that therapeutic exercise can increase the secretion of endorphins from the

brain, and these materials in turn raise the pain threshold of the body. Daley [36] believed that contracted ligamentous bands in the abdominal region were the causative factor for physical compression of nerve pathways and their irritation, so the proposed series of stretching exercise was considered very effective. Golomb et al. [37] concluded that exercise is widely accepted as a mean of moderating stress and biochemical changes in the immune system. A mechanism by which exercise may improve the symptoms of dysmenorrhea (reducing stress) has been articulated so, findings of different studies have shown that therapeutic exercise and physical activity was related with reduced incidence of dysmenorrhea**.**

CONCLUSION:

Stretching exercises are effective in reducing pain intensity and improve the quality of life and also it helps in reducing the amount of pain killers taken by young girls which might have bad long term effects on their health and it is also shown that the productivity has also increased for those days as having less pain among the girls with primary dysmenorrhea.

SUMMARY:

The study was conducted to find out the effects of stretching exercise in reducing pain symptoms among the adult girls that were having primary dysmenorrhea. 30 girls are voluntarily participated in the study, after that pain assessment and data was collected through assessment form and girls were randomly divided into two groups (A: exercise group, B: control group). After that exercise groups was given a set of exercises to practice for 12 weeks (4 days per week) meanwhile control group was asked not to perform any exercise on daily basis. After the study duration pain assessment was taken from both the groups and compared to find out the effects. Results are seen that stretching exercises are effective in reducing pain in the girls of group A while girls of group B did not felt any change in their pain after 12 weeks.

LIMITATIONS:

There are some drawbacks of this study, such as

This study was conducted through online modes so there are some chances of faulty postures of candidates while doing the exercises which can affect the final results of the exercises.

FUTURE RECOMMENDATIONS;

- Study can be done among various other types of exercise forms which could be effective in reducingthe pain intensity of primary dysmenorrhea.

Abstract : Sujok is a simple, easy and effective way to heal oneself. In Sujok therapy, the palms and feet represent all of the organs and meridians in the body. Sujok can be done in addition to other therapies and it has no side effects. By stimulating points on the hands and feet, this therapy can help cure various ailments throughout the body. Physiotherapists help people with injuries, illnesses or disabilities by providing movement and exercise, manual therapy, education and advice. They provide health care for people of all ages, helping patients manage pain and prevent disease. Physiotherapy is a science-based profession that takes a holistic approach to health and wellbeing, including considering a patient's overall lifestyle. An experimental study was conducted using convenient sampling from the physiotherapy clinics situated in the area of Gandhinagar and Ahmedabad of Gujarat state among 90 adult patients of knee OA aged between 18 to 60 years. Data was collected in the period of April and May 2022. There is a significant difference before and after physiotherapy, Sujok and Sujok + Physiotherapy sessions on all 7 consecutive days. There was a significant decrease in the pains of the patients after 3rd day, irrespective of treatment taken by patient. Significant difference was found between physiotherapy and Sujok treatments after day 5. Physiotherapy and Sujok treatments do differ significantly. But there is no benefit

I. INTRODUCTION

Pain disrupts people's lives, and the ability to recognize and understand pain is an early sign of disease states (1), illness, bodily injury (2), and serious or minor health problems (3). One definition of pain is: An unpleasant sensory and emotional experience associated with, or resembling that associated with, actual or potential tissue damage (4). Several literature reviews indicate that there are two types of pain management strategies: multimodal or multidisciplinary (5) and non-multidisciplinary. Multimodal strategies are commonly referred to as "programs". The non-multidisciplinary program is his second strategy for pain relief. This method includes medical treatment and alternative therapy, usually applied in one treatment. Several studies have shown that Su Jok can be used to treat fatigue and weakness (6), elbow eczema (7), migraines (8), asthma (9), and stroke rehabilitation (10). Su Jok for pain relief can also be used for heel spur pain (11). Su Jok Therapy is a complementary and alternative therapy developed in 1987 by his Professor Park Jae Woo in South Korea. Su Jok can provide fast and meaningful results (12). The term Su Jok is of Korean origin. Su means hand, Jok means foot, and Su Jok functions as a therapeutic group for managing health (12). The Su Jok method of treatment is done by stimulating the hands and feet (13). Because they have many similarities with the human body (12). Stimulate the limbs by massaging, applying paint to the skin, moxibustion, placing seeds, magnets, needles, etc. in specific locations. Su-Jok therapy is considered an easier and cheaper treatment than most alternative therapies, and results are generally quicker.

Su Jok Therapy's view of the healing process is based on the concept that the human body is a living organism subject to various factors and has causal relationships with all the energies of the universe. All changes in the human body must obey universal laws of interaction, so that a person's health is determined not only by individual characteristics, but also by environmental forces (14). The aim of this current study was to assess the effects of Sujok therapy, physiotherapy and Sujok + physiotherapy on patients with knee OA.

II. MATERIALS AND METHODOLOGY

An experimental study was conducted using convenient sampling from the physiotherapy clinics situated in the area of Gandhinagar and Ahmedabad of Gujarat state among 90 adult patients of knee OA aged between 18 to 60years. Data was collected in the period of April and May 2022.

Data was collected for the pain and its intensity. Then the patients were divided in to 3 groups -Group A: Patients will be treated by physiotherapy treatment and Sujok therapy. Group B: Patients will be only treated by Sujok therapy. Group C: Patients will be only treated by physiotherapy. In Sujok therapy patients will be diagnosed by probe and then after finding point on hand. Using Su Jok theory, the first thing to do is to find the corresponding areas of the knee on the hand, and then stimulate those points. The most painful points were found on one or several of the areas on Middle or on ring finger and then massaging those areas. Next stage is to massage areas on the fingers (phalanxes of fingers) corresponding to your knee using a Sujok ring or massage ring. The next step

is heating up these areas with Moxa. After that we will apply seeds to the area corresponding to the knee either on the left or right hand. Patients will be examined by VAS (Visual Analog Scale). The visual analog scale (VAS) is a validated, subjective measure for acute and chronic pain. Scores are recorded by making a handwritten mark on a 10-cm line that represents a continuum between "no pain" and "worst pain." for checking the effect of Sujok therapy. Physiotherapy treatment will include the following: - 1. Quadriceps setting, 2. Quadriceps Strengthening, 3. Hamstring Stretch.

The Study was approved by Institutional Ethical Committee, on 25th February 2021 with the outward number VIP/2021/EC/95.

III. RESULTS AND DISCUSSION

		Frequency	Percentage
Gender	**Female**	44	48.9%
	Male	46	51.1%
Treatment Given	**Physiotherapy**	30	33.3%
	Sujok + Physiotherapy	30	33.3%
	Sujok Therapy	30	33.3%

In this study, a total of 90 respondents in this study comprised of 46 males and 44 females. All the 90 respondents were divided equally among all the three treatments. The type of therapy can be seen from Table I.

Table II: Statistical Significant difference between pains in patients before and after physiotherapy sessions

Paired Samples Test							
		Paired Differences			t statistic	df	P-Value
		Mean	Std. Deviation	Std. Error Mean			
Pair 1	**b_day 1 - a_day 1**	0.567	0.568	0.104	5.461	29	0.000
Pair 2	**b_day 2 - a_day 2**	0.567	0.568	0.104	5.461	29	0.000
Pair 3	**b_day 3 - a_day 3**	0.667	0.547	0.100	6.679	29	0.000
Pair 4	**b_day 4 - a_day 4**	0.833	0.461	0.084	9.898	29	0.000
Pair 5	**b_day 5 - a_day 5**	0.833	0.379	0.069	12.042	29	0.000
Pair 6	**b_day 6 - a_day 6**	0.900	0.403	0.074	12.245	29	0.000
Pair 7	**b_day 7 - a_day 7**	0.833	0.379	0.069	12.042	29	0.000

Significant differences before and after Physiotherapy, Sujok and Sujok + Physiotherapy sessions were calculated using t-test on SPSS 20.0 software at 5% level of significance. From the table II it can be concluded that there is a significant difference before and after physiotherapy treatment on day 1, 2, 3, 4, 5, 6, 7 as p-value was found to be 0.000 < 0.05 at 5 % level of significance.

Table III: Statistical Significant difference between pains in patients before and after Sujok sessions + Physiotherapy

Paired Samples Test							
		Paired Differences			t statistic	df	P-value
		Mean	Std. Deviation	Std. Error Mean			
Pair 1	b_day 1 - a_day 1	0.933	0.691	0.126	7.393	29	0.000
Pair 2	b_day 2 - a_day 2	0.867	0.434	0.079	10.933	29	0.000
Pair 3	b_day 3 - a_day 3	0.833	0.379	0.069	12.042	29	0.000
Pair 4	b_day 4 - a_day 4	0.833	0.648	0.118	7.047	29	0.000
Pair 5	b_day 5 - a_day 5	0.767	0.568	0.104	7.389	29	0.000
Pair 6	b_day 6 - a_day 6	0.900	0.548	0.100	9.000	29	0.000
Pair 7	b_day 7 - a_day 7	0.833	0.531	0.097	8.601	29	0.000

From the table III it can be concluded that there is a significant difference before and after Sujok + physiotherapy treatment on day 1, 2, 3, 4, 5, 6, 7 as p-value was found to be 0.000 < 0.05 at 5 % level of significance.

Table IV: Statistical Significant difference between pains in patients before and after Sujok sessions

Paired Samples Test							
		Paired Differences			t statistic	Df	P-Value
		Mean	Std. Deviation	Std. Error Mean			
Pair 1	b_day 1 - a_day 1	1.033	0.183	0.033	31.000	29	0.000
Pair 2	b_day 2 - a_day 2	1.067	0.583	0.106	10.016	29	0.000
Pair 3	b_day 3 - a_day 3	1.100	0.712	0.130	8.462	29	0.000
Pair 4	b_day 4 - a_day 4	1.067	0.691	0.126	8.449	29	0.000
Pair 5	b_day 5 - a_day 5	1.233	0.504	0.092	13.403	29	0.000
Pair 6	b_day 6 - a_day 6	1.067	0.521	0.095	11.217	29	0.000
Pair 7	b_day 7 - a_day 7	0.933	0.450	0.082	11.366	29	0.000

From the table IV it can be concluded that there is a significant difference before and after Sujok treatment on day 1, 2, 3, 4, 5, 6, 7 as p-value was found to be 0.000 < 0.05 at 5 % level of significance in Table IV.

Table V: Significant difference between the pains of patients after physiotherapy session, Sujok session and Sujok + physiotherapy session.

		N	Mean	Std. Deviation	F Statistic	P-Value
Pain after _day 1	Physiotherapy	30	5.43	1.073	0.385	0.682
	Sujok	30	5.27	0.868		
	Sujok + Physiotherapy	30	5.20	1.215		
	Total	90	5.30	1.054		
Pain after _day 2	Physiotherapy	30	5.43	1.073	1.123	0.33
	Sujok	30	5.13	0.860		
	Sujok + Physiotherapy	30	5.07	1.081		
	Total	90	5.21	1.011		
Pain after _day 3	Physiotherapy	30	5.30	1.149	2.239	0.003
	Sujok	30	4.73	0.944		
	Sujok + Physiotherapy	30	4.90	1.094		
	Total	90	4.98	1.081		
Pain after _day 4	Physiotherapy	30	4.97	1.066	2.453	0.092
	Sujok	30	4.43	0.858

	Total	90	4.63	1.033		
Pain after _day 5	Physiotherapy	30	4.70	1.119	4.2	0.018
	Sujok	30	3.90	0.803		
	Sujok + Physiotherapy	30	4.33	1.241		
	Total	90	4.31	1.108		
Pain after _day 6	Physiotherapy	30	4.47	1.042	4.698	0.012
	Sujok	30	3.67	0.758		
	Sujok + Physiotherapy	30	4.03	1.189		
	Total	90	4.06	1.053		
Pain after_day 7	Physiotherapy	30	4.37	1.033	5.676	0.005
	Sujok	30	3.57	0.774		
	Sujok + Physiotherapy	30	3.77	1.040		
	Total	90	3.90	1.006		

To test the significant difference between the pains pertaining to patients after giving physiotherapy session, Sujok session and Sujok + physiotherapy session, ANOVA test was applied at 5% level of significance using SPSS 20.0 software. Following results were concluded from Table V:

After applying all the sessions to respective patients, the significant difference between the after therapy, pain of all the three groups on day 1 and day 2, was not found significant, with P-value > 0.05 at 5% level of significance. In other words, there is no significant difference in therapies after day 1 and day 2.

The significant difference between the after therapy, pain of all the three groups on day 3 was found significant, with P-value 0.003 > 0.05 at 5% level of significance. In other words, there is a significant difference in therapies after day 3. Physiotherapy was found least effective with average VAS for pain (5.30), Sujok + Physiotherapy was found second highest with average VAS for pain (4.90) after Sujok and Sujok was highest effective among all the three with average VAS for pain (4.73).

The significant difference between the after therapy pain of all the three groups on day 4 was not found significant, with P-value 0.092 > 0.05 at 5% level of significance. In other words, there is no significant difference in therapies after day 4, though the effectiveness of the therapies remained same as that on day 3 i.e. Physiotherapy was least effective with average VAS for pain (4.97), Sujok + Physiotherapy less than only Sujok with average VAS for pain (4.50) and Sujok was found highest effective with average VAS for pain (4.43).

The significant difference between the after therapy pain of all the three groups on day 5 was found significant, with P-value 0.018 < 0.05 at 5% level of significance. In other words, there is a significant difference in therapies after day 5. Physiotherapy was found least effective with average VAS for pain (4.70), Sujok + Physiotherapy was found second highest with with average VAS for pain (4.33) after Sujok and Sujok was highest effective among all the three with with average VAS for pain (3.90).

The significant difference between the after therapy pain of all the three groups on day 6 was found significant, with P-value 0.012 < 0.05 at 5% level of significance. In other words, there is a significant difference in therapies after day 6. Physiotherapy was found least effective with average VAS for pain (4.47), Sujok + Physiotherapy was found second highest with average VAS for pain (4.03) after Sujok and Sujok was highest effective among all the three with with average VAS for pain (3.67).

The significant difference between the after therapy pain of all the three groups on day 7 was found significant, with P-value 0.005 < 0.05 at 5% level of significance. In other words, there is a significant difference in therapies after day 7.

In two pooled studies (15), (16), the reduction in the VAS pain score from treatment with physiotherapeutic modalities in combination with stretching exercises was statistically superior to treatment with physiotherapeutic modalities alone. (WMD 0.56; 95% CI 0.20 to 0.92; $I^2 = 0\%$; $P < 0.05$; n = 102 pooled sample size). A similar result was obtained from studies (17), (15), using the KOOS pain scale. (WMD 7.52; 95% CI 4.05 to 10.98; $I^2 = 0\%$; $P < 0.05$; n = 76 pooled sample size).

Fitzgerald et al. (18) evaluated these techniques separately, and found no significant evidence that these exercises improve pain and muscle strength in OA patients. This finding does not corroborate the study by Diracoglu et al., (19) who compared kinesthesia and balance exercises or only strengthening exercises in women with knee OA, obtaining positive outcomes on muscle strength, quality of life, and the physical function scale, according to the WOMAC questionnaire.

In the Chen, HL. Et. al (2022)'s study, functional status was primarily assessed using the WOMAC scale, and significant improvements with the implementation of IFC were observed in short-term assessment but not in long-term follow-up. We also discovered that the results for walk tests (short- and long-term) and stiffness scores (short-term) did not favor IFC use over control treatment. The WOMAC scale evaluates activities of daily living, functional mobility, gait, general health, and quality of life in knee osteoarthritis patients (21). It consists of 24 questions that can be divided into the subscales of pain, physical function, and stiffness. The outlier data of one study were removed in sensitivity testing because we observed high heterogeneity, which could be attributed to the study's inadequate blinding of participants and its small sample size (22). The significance of our meta-analysis findings persisted after sensitivity testing, indicating that the outcomes were reliable.

We found many studies pertaining to knee pain treatments, but no study came to our knowledge in regard to Sujok therapy on knee osteoarthritis patients. In our study overall, Physiotherapy was found least effective with average VAS for pain (4.37), Sujok + Physiotherapy was found second highest with average VAS for pain (3.77) after Sujok and Sujok was highest effective (pain relieving technique) among all the three with average VAS for pain (3.57).

IV. CONCLUSION

There are many ways to manage pain, including traditional and unconventional treatments. The development of pain management research continues, and easier, less expensive therapeutic approaches that produce quicker pain relief are still being sought after. In this retrospective study, Su Jok is one of the complementary therapies for pain, offers a successful method of pain relief and highest effective when compared to that of physiotherapy for patients with Knee osteoarthritis. However, future studies must be conducted using stricter procedures, large sample and with more precise standards for pain management.

V. LIMITATIONS OF THE STUDY

Due to low sample size, Su Jok treatment in combination with Physiotherapy doesn't show more effectiveness compared to solely Physiotherapy treatment. So, further research must be conducted using large sample size.

VI. DECLARATION OF COMPETING INTEREST

There is no conflict of interest in this publication.

ABSTRACT :

BACKGROUND:

To find the effects of holistic yoga on college going girls with anxiety and PCOS. The purpose of the study was to measure the level of depression among females suffering from polycystic ovarian syndrome and to find out the effect of yoga on the level of depression among females suffering from polycystic ovarian syndrome.

METHODOLOGY:

There will be an interactive introductory lecture about the topic and all girls of the college will attend this lecture. 40 girls with PCOS will be selected for the holistic yoga session. The yoga performed will be basically the asanas and meditation and lecturers on holistic yoga lifestyle and stress management. All these asanas will be performed with 6 repetitions with 10 seconds of hold and 15 seconds of resting period. This yoga asanas will be performed daily till 1

hour for 6 weeks.

RESULT:

Changes in the anxiety level after the holistic yoga program were seen and also significant changes in weight, waist and hip circumference have been seen in the college going girls in Gujarat with PCOS.

CONCLUSIONS:

6 Weeks Holistic Yoga Program in college going girls with PCOS was seen as more effective than the other regular exercise to reduce weight, waist and hip circumference with anxiety symptoms respectively.

KEYWORDS:

Yoga; Polycystic ovarian syndrome; Anxiety symptoms

INTRODUCTION

Polycystic ovary syndrome (PCOS) is an abnormal hormonal change in ovaries. It mostly affects the ovaries which produces estrogen and progesterone hormone but sometimes ovaries produce male hormone androgen which results in the excess hair growth, acne, obesity, irregular menstrual cycle, anxiety, depression, stress is also seen in female with PCOS.[1]

The prevalence of PCOS in women is most common in age between 15-30 years. PCOS is the most common endocrine disorder of reproductive women with the prevalence of 5-15%. of women are affected with it.[1]

The common treatment protocol for PCOS are pills for regular menstrual cycle, statins to control the hormonal changes, different exercises like Zumba, aerobics and yoga.[2]

Side-effects of some medications are also seen such as nausea, stomach pain, diarrhea. Lack of vitamin B12 also causes mood swings and memory loss. So proper diet should be taken.[3]

Yoga, a form of holistic mind-body medicine, developed thousands of years ago, is simple and can be performed by all. There is evidence that Yoga reduces anxiety symptoms.[4]

Yoga is a great stress buster. Yoga eases any stress through breathing techniques that bring complete relaxation in the body. Relaxation can work to offset the effects of hormonal imbalance and take care of any negative emotions, irritability and frequent mood swings.[5]

Yoga strengthens the muscles, improves hormonal levels. Yoga along with a healthy diet helps to lose weight.[5]

However, till date, So Many studies and research has been done with yoga and PCOS but with anxiety symptoms only one study was done in south Indian school going girls. The present study will be assessing the effect of yoga on anxiety level in adolescent girls with PCOS.[6]

Depression is a common mood disorder that negatively affects a person's thinking, feeling and behavior. It leads variety of emotional and physical problems.[7]

Depression is more than sadness. People suffering from depression experience lack of interest in daily activities, weight loss or gain, lack of sleep or excessive sleep, lack of energy, excessive guilt and re current thoughts of suicide.[7]

Women experience depression twice as compared to men. Some factors such as biological, life cycle, hormonal and other factors unique in women and it may link to their higher level of depression rate.[7]

Mood is affected by the various PCOS symptoms. According to Farrell and Antoni (2010) women with PCOS experience mood dysfunction and psychiatric problems to a greater degree than women without PCOS.[7]

Many studies show that the level of depression is higher in PCOS than healthy women. PCOS is a common health problem among women. This problem is caused by hormonal imbalance. PCOS Caused by small cysts in the ovary which affect the hormones and dispute the normal menstrual cycle .Around 5-10% women are diagnosed with

PCOS.[7]

Women are suffered from PCOS because of excessive level of stress and strain, perennial tension, following modern faculty lifestyle and some psychological problems like anxiety and depression.[7]

Irregular Periods, Ovarian cyst, pimples, excessive hair fall, abdominal bloating, mood swings, miscarriage, Irritability, hair growth on the face, weight gain, muscles enlargement, imbalance level of sugar in blood, PCOS can also cause type 2 diabetes and heart attack.The aim of the study was to measure the level of depression among females suffering from polycystic ovarian syndrome and to find out the effect of yoga on level of depression among females suffering from polycystic ovarian syndrome.[7]

REVIEW OF LITERATURE

1. **Moran.Effect of suryanamaskar with yoga nidra practices on selected psychological variables among obese women.(2011)[8]** :- They conducted a study on Lifestyle changes in women with polycystic ovary syndrome (PCOS) affects 4% to 18% of reproductive-aged women and is associated with reproductive, metabolic and psychological dysfunction. Obesity worsens the presentation of PCOS, and weight management (weight loss, maintenance or prevention of excess weight gain) is proposed as an initial treatment strategy, best achieved through lifestyle changes incorporating diet, exercise and behavioral interventions.

2. **Panjwani U. Effect of sahaja yogic practice on the psychological changes among the adolescent girls.(1995)[9]** :- They studied the Effect of Sahaja yoga practice on stress management in patients of epilepsy. The study was carried out on 32 patients of epilepsy who were randomly divided into 3 groups: group 1 subjects practiced Sahaja yoga meditation for 6 months, group 2 subjects practiced postural exercises mimicking Sahaja yoga and group 3 served as the epileptic control group.

3. **DiBenedetto M. Effect of varied Yogic practices on selected physiological and psychological variables among adolescents girls.(2000)[10]** :- They examined if a tailored yoga program could improve age-related changes in hip extension, stride length, and associated indices of gait function in healthy elders, changes that have been linked to increased risk for falls, dependency, and mortality in geriatric populations. A 3-dimensional quantitative gait evaluation, including kinetic measurements, was performed pre and post intervention. Home practice on alternate days. Findings of this exploratory study suggest that yoga practice may improve hip extension, increase stride length, and decrease anterior pelvic tilt in healthy elders, and that yoga programs tailored to elderly adults may offer a cost-effective means of preventing or reducing age-related changes in these indices of gait function.

4. **Reshma Mohamed Ansari. Kapalbhati Pranayama: An answer to modern day polycystic ovarian syndrome and coexisting metabolic syndrome.(2016)[11]** :- They examined the role of Kapalbhati pranayama, the modern-day yoga practice to cure the polycystic ovarian syndrome and coexisting metabolic syndrome in women of age group 18-40 years. Yogic exercises are noted to reduce oxidative stress and hence aid in antioxidant defense mechanisms.Pranayama techniques such as Kapalabhati improve autonomic function by balancing the sympathetic and parasympathetic activity which is beneficial in stress-related disorders.Kapalabhati reduces oxidative stress which affects lipid peroxidation.

5. **Valarmathi Selvaraj. Impact of yoga and exercises on polycystic covarian syndrome risk among adolescents school girls.(2016)[12]** :- The Experimental research was conducted among adolescent girls belonging to two Government run schools in Tiruvallur district of Tamil Nadu state, India, from 6 June to 9 December 2016. A standard risk assessment questionnaire was adopted for risk assessment after making few modifications.The experimental group received lifestyle modifications (yoga for two months and walking exercise for two months), with no such intervention provided for the control group. The impact of these interventions was assessed in terms of risk minimization and a P value less than .05 was considered statistically significant.

6. **Vishesha Patel. Regular mindful yoga practice as a method to improve androgen levels in women with polycystic ovary syndrome: A randomized controlled trial.(2020)[13]** :-31 women with PCOS between the ages of 23 and 42 years and living in Erie County, Pennsylvania, were recruited for this randomized, controlled study arm, 22 women completed the 3-month intervention period, 13 in the mindful yoga group and 9 in the control group.The improvements observed suggest that regular mindful yoga practice can be a useful complementary therapeutic option for women with PCOS, particularly for improving serum androgen levels, a hallmark feature of PCOS.

7. **Kamini Balasaheb Bhingardive. Clinical efficacy of vamana karma with ikshvakubeeja yoga followed by shatapusphpadi ghanavati in the management of artavakshaya to polycystic ovarian syndrome.(2017)[14]**:-15 patients of PCOS were clinically diagnosed and treated by Vamana Karma (therapeutic vomiting) procedure with Ikshvaku seed formulation. After completion of Vamana Karma (therapeutic vomiting) and ShatapushpadiGhanavati 2 Vati (each 500 mg) twice in a day with lukewarm water was given for 45 days. Vamana Karma (therapeutic vomiting) followed by ShatapushpadiGhanavati is very effective in the management of obese PCOS patients andincreasing chances of conception.

8. **M. Ezhil Ratnakumari. Study to evaluate the changes in polycystic ovarian morphology after naturopathic and yogic interventions.(2018)[15]** :- 50 PCOS patients of age between 18 and 35 years who satisfied the Rotterdam criteria were recruited for the study.This study revealed Y&N (Yoga and Naturopathy) lifestyle could be the first-line interventions for PCOS. Small changes in lifestyle in accordance with Y & N are known to improve symptoms and psychological well-being of PCOS patients. This study performed to assess morphological changes in the polycystic ovaries in relation to reduction of symptoms has substantiated the approach of Y&N interventions in PCOS.
9. **Anitha. Effect of yoga on level of depression among females suffering from polycystic ovarian syndrome (PCOS).(2017)[16]** :- They determined the prevalence of depression among women with PCOS compared to normal healthy women. They selected 50 cases of PCOS as per the Rotterdam criteria from the Gynecology OPD, Government Chengalpattu Medical College. The depression related information was gathered by Beck's Depression Inventory. The data was compared with that of 50 age matched normal healthy individuals. The finding shows that depression scores were significantly increased in the PCOS group as compared to the

control group. The study showed increased prevalence of mild to moderate depression in PCOS patients compared to the normal subjects.

10. **Arnulfo Ramos-Jiménez. Cardiovascular and metabolic effects of intensive hatha yoga training in middle-aged and older women from Northern Mexico.(2009)[17]** :- An 11-week IHY (Intervention Hatha Yoga) program consisting of 5 sessions/week for 90 min (55 sessions) was found to be capable of improving cardiovascular fitness. Despite the relatively low intensity of the yoga practice, this program increased both VO2max and HDL-C. The data also suggested that HY asanas, practiced as a systematic physical activity and conducted by an expert instructor in untrained and aging individuals, can improve health and serve as the basis for a physically active lifestyle.

11. **Nidhi, R., Padmalatha, V., Nagarathna, R., and Ram, A. Effect of Holistic yoga program on anxiety symptoms in adolescent girls with polycystic ovarian syndrome: A randomized control trial.(2012)[1]**:- They investigated the Effects of a Holistic Yoga Program on Endocrine Parameters in Adolescents with Polycystic Ovarian Syndrome. International Journal of Gynecology and Obstetrics, ninety (90) adolescent (15-18 years) girls from a residential college in Andhra Pradesh who satisfied the Rotterdam criteria were randomized into two groups. The yoga group practiced a holistic yoga module, while the control group practiced a matching set of physical exercises (1 hour/day, for 12 weeks). Anti-müllerian hormone (AMH-primary outcome), luteinizing hormone (LH), follicle- stimulating hormone (FSH), testosterone, prolactin, body-mass index (BMI), hirsutism, and menstrual frequency were measured at inclusion and after 12 weeks.Mann-Whitney test on difference score shows that changes in AMH (Y=-2.51, C=-0.49, p=0.006), LH, and LH/FSH ratio (LH: Y=-4.09, C=3.00, p=0.005; LH/FSH: Y=-1.17, C=0.49, p=0.015) were significantly different between the two intervention groups. Also, changes in testosterone (Y=-6.01, C=2.61, p=0.014) and Modified Ferriman and Gallway (mFG) score (Y=-1.14, C=+0.06, p=0.002) were significantly different between the two groups. On the other hand, changes in FSH and prolactin post intervention were not significantly different between the two groups. Also, body weight and BMI showed non significantly different changes between the two groups, while changes in menstrual frequency were significantly different between the two groups (Y=0.89, C=0.49, p=0.049).A holistic yoga program for 12 weeks is significantly better than physical exercise in reducing AMH, LH, and testosterone, mFG score for hirsutism, and improving menstrual frequency with non-significant changes in body weight, FSH, and prolactin in adolescent PCOS.

NEED OF STUDY

Many studies and research have been done with yoga and PCOS but with anxiety symptoms only one study was done in south Indian school going girls, so we want to do this study in Gujarat, in college going girls how yoga is effective and beneficial for the treatment of PCOS with anxiety symptoms.

OBJECTIVE OF THE STUDY

- To assess the reduction of anxiety symptoms due to PCOS by holistic yoga.
- To assess the effects of holistic yoga on PCOS in college going girls.

HYPOTHESIS

- **NULL HYPOTHESIS** – Holistic Yoga treatment for anxiety and PCOS will be noteffective on adolescent girls.

- **RESEARCH HYPOTHESIS** – Holistic Yoga treatment for anxiety and PCOS will beeffective on adolescent girls.

METHODOLOGY

The study was carried out on college going girls aged 18 to 30 years in Gujarat, India.
Those girls who have satisfied the criteria of PCOS with some features included in it.

INCLUSION CRITERIA

1.) Age group of 18 to 30 years of girl.2.) PCOS for more than 6 months.

3.) Cystic Ovaries

4.) Girls with irregular menstruation

EXCLUSION CRITERIA

1.) Girls taking oral contraceptives

2.) Hormonal treatment

3.) Insulin intake

4.) Thyroid abnormalities

5.) Smoking

6.) Alcohol

7.) Regular exercising girls

All 40 Girls who were selected for the study purpose were gathered through the online zoom yoga sessions of 1hour/every day for 6 weeks and the examination with quasi experimental one way study was performed and checked through pre-intervention to post-intervention in their weight, height, waist and hip circumference and BMI also with decreased anxiety symptoms wereexamined after 6 weeks of program.

There was an interactive introductory lecture about the topic and all girls of the college attended this lecture. 40 girls with PCOS were selected for the holistic yoga session after signing the consent form. The yoga performed was basically the asanas, meditation and lecturers on holistic yoga lifestyle and stress management.

YOGA EXERCISES FOR TREATMENTOF PCOS.[5]

Asanas for PCOS are:

1.) Badhakonasana (Butterfly pose)

2.) SuptaBaddhaKonasana (Reclined bound angle)

3.) Bharadvajasana (Bharadvajasana twist's)

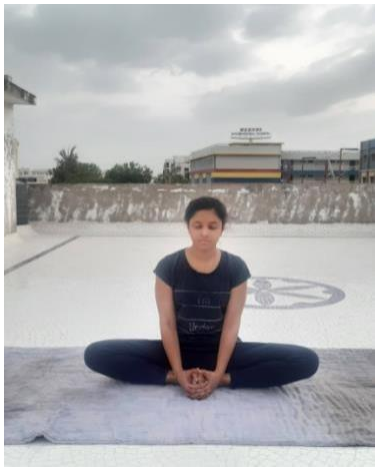
4.) ChakkiChalanasana (Mill churning pose)

5.) Shavasana (Corpse pose)

6.) Padmasana

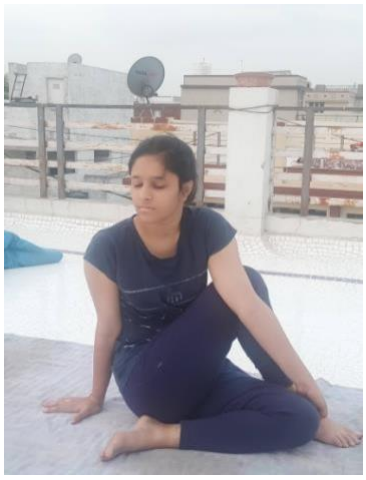
7.) A few rounds of Surya namskar (Sun Salutation)

All these asanas were performed with 6 repetitions with 10 seconds of hold and 15 seconds of resting period. This yoga asanas were performed daily till 1 hour for 6 weeks. Practicing these Asanas would become a reason to boost the health of uterus and ovaries and improve functioning of the endocrine glands. Yoga is safe and effective for treatment of PCOS.



6.1 Badhakonasana.

6.2 SuptaBadhaKonasana



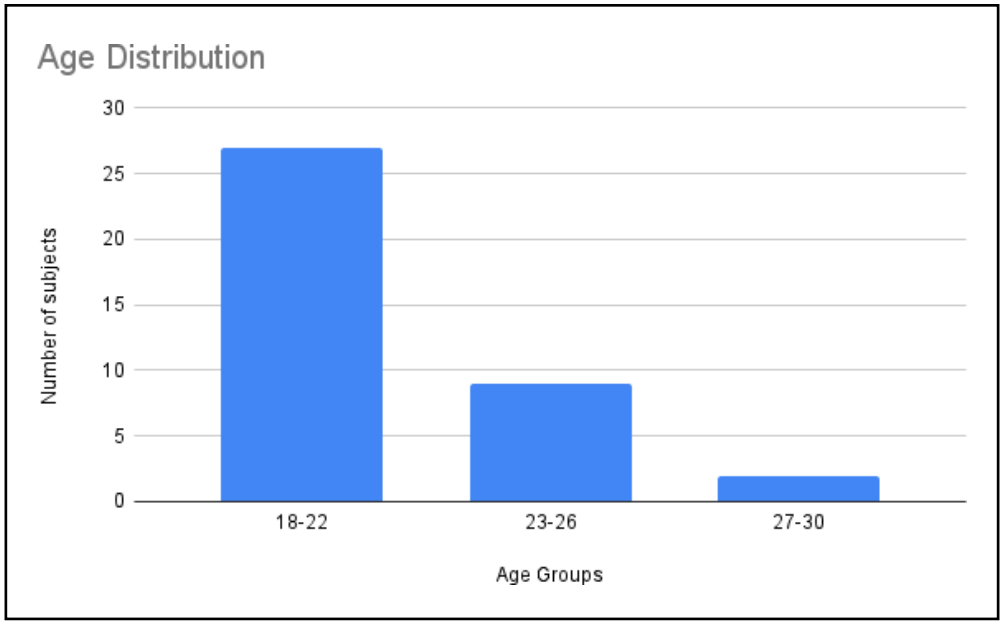
6.3 Bhadravajanasana

6.4 Chakkichalanasana

RESULT

1. Age Distribution

This research was performed on 40 females with PCOS between the age of 18 to 30. There were27 females between the ages of 18 to 22, 9 females between the ages of 23 to 26 and 2 females between the ages of 27 to 30.



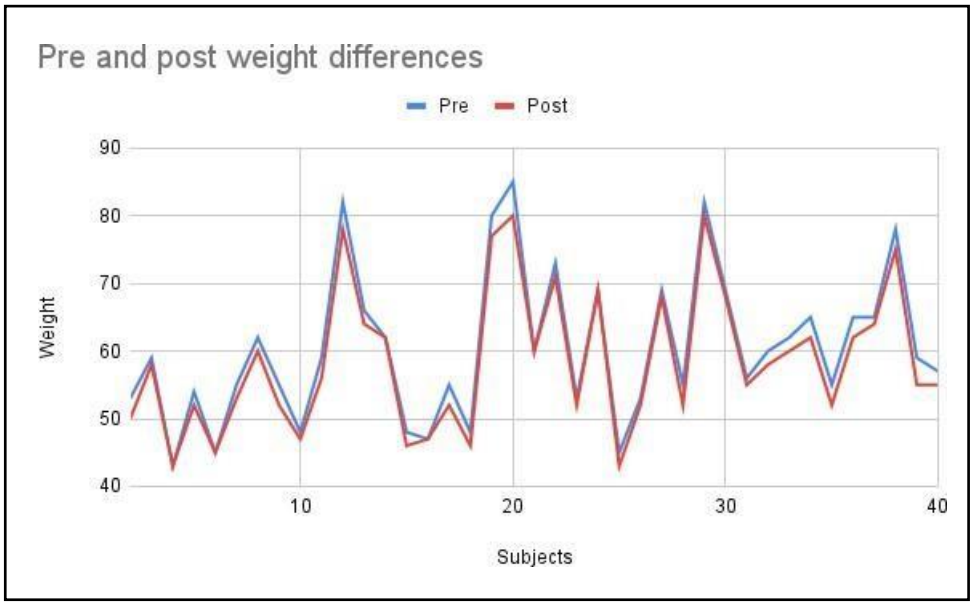
GRAPH: - 7.1.1 AGE DISTRIBUTION CHART

2.Weight Distribution

From the total of 40 subjects, we saw the minor weight change in 34 females while 6 females didnot lose any weight.The pre mean was 60.45 and post mean after yoga and asanas was 58.474 with 1.975 difference among them and P-Value was less than 0.01.

Weight Mean		Difference	P-Value
Pre	Post		
60.45	58.475	1.975	<0.01

Table : 7.1 Mean Weight Distribution



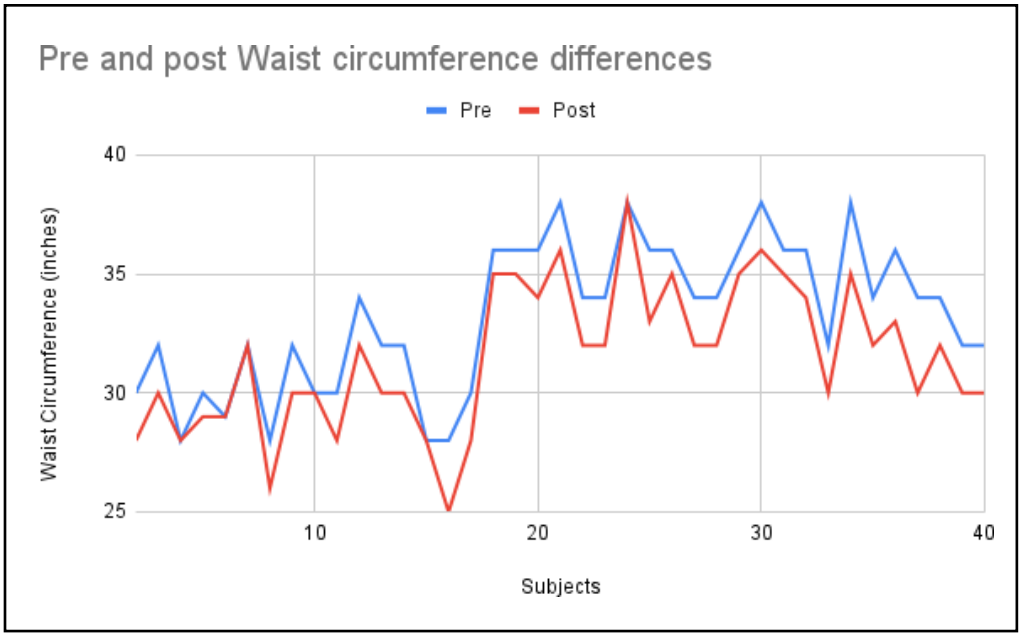
GRAPH: - 7.2.2 WEIGHT DISTRIBUTION CHART

3.Waist Circumference Distribution

From the total of 40 subjects, we saw minor Waist Circumference loss in 34 females while 6 females did not lose any waist. These females were different from the ones who have lost someweight in the previous graph.The pre mean was 33.225 and post mean was 31.525 with 1.7 difference while P-Value was less than 0.01.

Waist Mean		Difference	P-Value
Pre	Post		
33.225	31.525	1.7	<0.01

Table : 7.2 Waist Mean Distribution



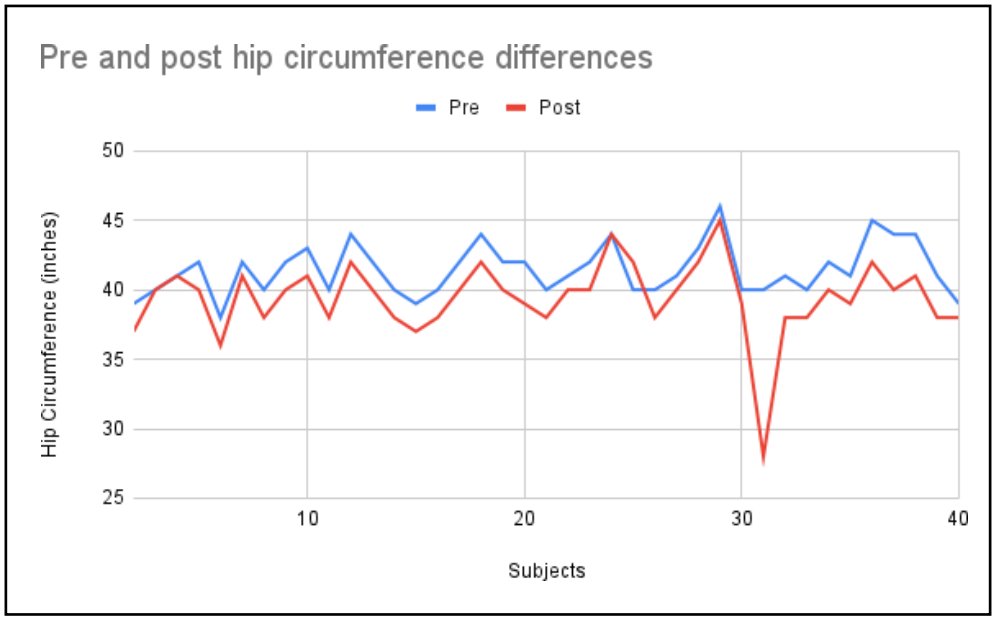
GRAPH: -7.3.3 WAIST CIRCUMFERENCE DISTRIBUTION CHART

4.Hip Circumference Distribution

From the total of 40 subjects, we saw minor hip circumference loss in 36 females while 4 females did not lose any inches as pre mean was 41.425 and post mean was 39.45 as differencewas seen 1.975 among the females after holistic yoga program with P-Value less than 0.01.

Hip Mean		Difference	P-Value
Pre	Post		
41.425	39.45	1.975	<0.01

Table : 7.3 Hip Mean Distribution



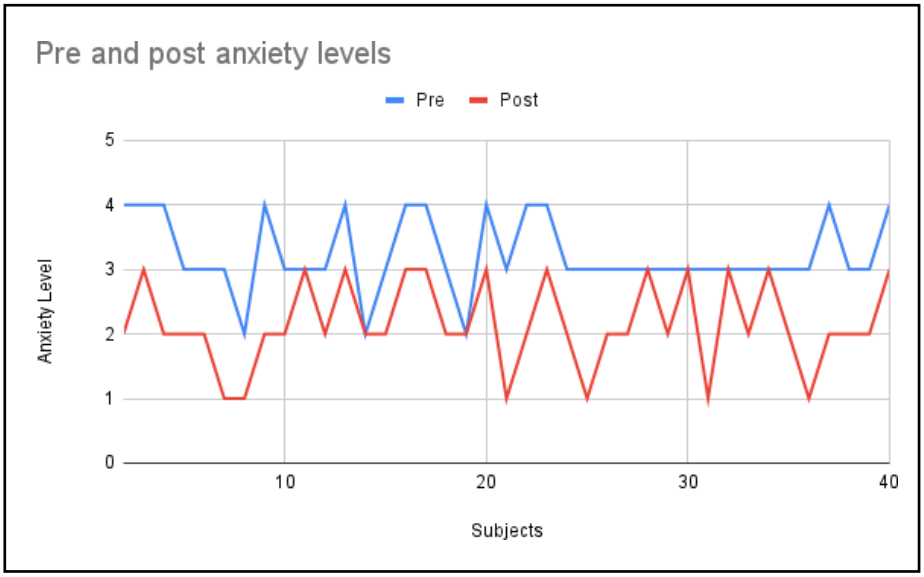
GRAPH: - 7.4.4 HIP CIRCUMFERENCE DISTRIBUTION CHART

5.Anxiety Levels Distribution

From the total of 40 subjects, we noticed a drop in anxiety levels for 33 females while 7 femalesdid not have any decrease as pre anxiety Mean was 3.225 and post was 2.125 with difference of 1.1 and P-Value less than 0.01.

Anxiety Mean		Difference	P-Value
Pre	Post		
3.225	2.125	1.1	<0.01

Table 7.4 Anxiety Mean Distribution



GRAPH: - 7.5.5 ANXIETY LEVEL DISTRIBUTION CHART

DISCUSSION

Many women first experience symptoms of PCOS during anxiety-inducing change, severe stress, or trauma. Patients with PCOS have reported that they feel anxious about their bodies and health. A person's values and culture they live in, also impacts their anxiety level. Because of this behavior, there is a high risk for depression and anxiety in PCOS patients regardless of pregnancy issues, obesity, excess body and facial hair, or lack of control over their health and bodies. In addition, Obesity is a common finding in women with PCOS and between 40-80% women with this condition are reported overweight or obese. In women with PCOS, the metabolic and hormonal issues that are present such as insulin resistance and hyperandrogenism, can lead to weight gain. Obesity in turn can exacerbate the symptoms of PCOS such as further metabolic issues and reproductive abnormalities. In our study the the Anxiety symptoms are also reduced along with the wieght.

When Dr. V. Duraisami from TNPESU, Chennai, did research on the effects of Suryanamaskar with Yoga Nidra practices on selected Psycological variables among obese people, the results showed that these practices helped to reduce anxiety and to increase self-confiedence among the obese people. As compared to this study our research has different holistic yoga program to reduce weight,waist,hip and anxiety symptoms.

L.V.H. Arts, Science & Commerce College, Nashik, did research on the effect of Yoga on Level of depression among Females suffering from PCOS. The sample of the research consisted of 30 females with PCOS where they were provided 1 month Yoga training. The researchers concluded that Providing Yoga training to these females with PCOS has helped in opening the pelvic area leading to relaxation of mind and body.

This Quasi Experimental on-way research presents the effects of Yoga on 40 PCOS adult female patients from age 18 to 30, who are also obese. For six weeks, we provided 1 hour yoga session to these subjects which included BaddhaKonasana, SuptaBaddhaKonasana, Bharadvajasana, ChakkiChalanasana, Shavasana, Padmasana and a few rounds of Surya Namaskar. After the research period, we noticed slight drop in weight, waist and hip circumference and anxiety level. Our research concluded that holistic yoga helps with the anxiety symptoms in females with PCOS.

CONCLUSION

Six Week holistic yoga program in college going girls with PCOS in Gujarat has been significantly proven to reduce the weight, waist and hip circumference with anxiety symptoms. Thus, Yoga and asanas management may help reduce the progression of anxiety symptoms with PCOS.

SUMMARY

The study is to find the effect of holistic yoga on the college going girls with PCOS and anxiety symptoms in Gujarat.40 girls were chosen with the 18-30 age group with weight, waist circumference and hip circumference and body mass index. Hamilton Anxiety rating scale was also taken for the rating of their Anxiety symptoms after holistic yoga asanas. This six-week holistic yoga program was useful in reducing the Anxiety symptoms with weight, waist and hip circumference.

Limitations

- Small sample size.
- Limited age group of 18-30 years.
- The self-selection and convenience sampling of participants to complete the study may alsoinfluence the result.

Future recommendation

- Future research should replicate these findings in other large samples, take larger agegroups and investigatethe relationship between Anxiety and Obesity.

Abstract:

Background: The Tinetti Assessment Tool is a valid and reliable self-reporting Tool evaluating the patient's problems toward the effect of their activities of daily living (ADLs) and works on their balance and gait disorder. Till the date it was translated into various languages but is not available in Gujarati language. This study aimed to translate Tinetti Assessment Tool into Gujarati and to study reliability and validity of Gujarati version**.**

Methodology: Translation and cross culture adaptation were performed according to the guidelines. Content validation was executed by the panel of 6 members who were experts in using Gujarati and English. They were completed the content validity .The psychometric properties were tested by administering the tool to 60 samples (40 to 70 years) was recruited by Purposive sampling. For test-retest reliability, people with Balance Gait disorder were tested after a week by Intra-class correlation coefficient (ICC) and internal consistency was assessed by Cronbach's alpha (α).

Result : The content validity of Gujarati translated Tinetti Assessment Tool by a panel of 6 experts were found to be, I-CVI of individual items of Gujarati version of Tinetti Assessment Tool ≥ 0.93 and the overall S-CVI for idiomatic equivalence (S-CVI =0.89) semantic equivalence (S-CVI=0.91) and content relevance(S-CVI=0.92). The test-retest reliability of Gujarati version Tinetti Assessment Tool was good (ICC (2,1) = 0.986 and 0.977). Internal consistency was found to be good (Cronbach's alpha = 0.993 and0.988).

Conclusion : The Gujarati version of Tinetti Assessment Tool was cross-culturally adapted and validated can be use patient with balance and gait disorder in the Gujarati-speaking populations.

Keywords : Cross cultural adaption, Tinetti Assessment Tool, Reliability, Validity , Balance and Gait disorder

INTRODUCTION

Balance and gait disorders are among the most common causes of falls in older adults.[1] more than one third of persons 65 years of age or older fall each year, and in half of such cases the falls are recurrent. Approximately 1 in 10 falls results in a serious injury, such as hip fracture, other fracture, ,subdural hematoma, other serious soft-tissue injury, or head injury.[2] Chronic diseases and aging can affect the balance ability of older people; therefore, an assessment of balance ability is valuable predicting and preventing falls and a reduction in independent living in older people. [3]

Balance is required for maintaining static posture, stabilizing dynamic movements, performing daily activities and moving around the community.[3] The loss of balance response and increased incidence of falls is of concern to physical therapists. Improvement of the balance may be a desired functional outcome for many patients. Balance function has been reported to decline with age, as evidenced by increased postural sway and decreased stability.[4]

Balance difficulties are reported by 13% of patients at age 65,35%at age 75, and 46% at age 85. Gait impairment has been estimated to occur in 8% to 19% of elderly individual living in the community.[5]

Balance can be affected in various ways which include joint motion limitation, weakness, altered muscular tone, sensory deficits, anomalous postural reactions and cognitive problems.[6] Most of changes in gait that occur in older are related to underlying medical conditions, particularly as condition increase in severity, and should not be viewed as merely an inevitable consequence of aging.[1]

Other causes of balance is the dizziness, vertigo, neurological disorder, vestibular migraine and vestibular neuritis. Balance disorders are recognized risk factors for falls. especially in the elderly with high associated morbidity, mortality, and economic cost.[7] Only few studies describe the distribution of gait disorders. Obviously, the spectrum of underlying illnesses will depend on the population under consideration and the assessment technique. Within a relatively healthy subgroup of 153 community residents aged 88 years and older, about 61% reported distinct diseases as a cause of gait impairment.[0] Non-neurological disorders were the leading causes of gait impairment, in particular joint pain (52 of 87 people), whereas many others had multiple causes for their gait impairment.[8]

Non-neurological disorders were the leading causes of gait impairment, in particular joint pain (52 of 87 people), whereas many others had multiple causes for their gait impairment. Stroke was the most common neurological cause. In another study of 120 elderly outpatients seen in a neurological reference practice, the most common causes for gait disorders were sensory ataxia (18%), myelopathy (17%), multiple strokes (15%), and parkinsonism (12%).2 Largely the same causes dominated in a series of 493 neurological inpatients, 60% of whom had a gait disorder.[8]

Determining that a gait is abnormal can be challenging, because there are no clearly accepted standards to define a normal gait in an older adult.10 Studies comparing healthy persons in their 70s with healthy persons in their 20s demonstrate a 10 to 20 percent reduction in gait velocity and stride length in the older population.18,19 Other characteristics of gait that commonly change with aging include an increased stance width, increased time spent in the double support phase, bent posture, and less vigorous force development at the moment of push off. These changes may represent adaptations to alterations in sensory or motor systems to produce a safer and more stable gait pattern.[1]

They may contribute to gait and balance disorders for a variety of reasons, such as causing pain, dyspnea, imbalance, diminished strength, limited range of motion, poor posture, decreased sensory perception, fatigue, deformity, and decreased awareness of and ability to adapt to and traverse through possibly hazardous surroundings.[1]

In addition, recent surgery or hospitalization and other acute medical illnesses may lead to gait and balance disorders. The use of multiple medications, as well as specific classes of medications, can lead to gait disorders and an increased rate of falls.[00] Although data are limited, surgery may improve gait for patients with cervical spondylotic myelopathy,51 lumbar spinal stenosis,52 normal-pressure hydrocephalus,53 or arthritis of the knee or hip.[1]

In many studies ,risk factor for falls have been determined. These are classified as intrinsic and extrinsic factors. Muscular weakness of the Lower extremities ,decreased grip force, impaired postural balance, Functional and cognitive disorders, and visual problems constitute Intrinsic factors ,while extrinsic factors include environmental factors Such as inadequate illumination, slippery floors and lack of safety equipments in bathrooms. Besides, a decrease in the ability to perform daily living activities and usage of walking aids contribute to the frequency of falls.[9,10]

Tests and functional scales used in proportion to variation in risk factors for falls, and excess number of components of postural control are also numerous.[9] One of these scale tinetti balance was developed by mary tinneti 1986 so as determine as risk falls.[9]

One of the most widely used version of the Tinetti Assessment of Balance and Gait scale. It is composed of two separate categories as balance and gait tests. Balance and gait are evaluated with nine and eight items, respectively. Total score of balance category consists of sitting balance, balance on arising to stand, immediate standing balance (within first 5s), standing balance, maintenance of balance when the subject turns 360 degree around him /herself, and tries to sit down from standing position is 16 points. Total score of the gait category which evaluates initiation of gait, step length and height , step symmetry and continuity deviation from a specified path, sways of patient's trunk and the position of heels while walking is 28 points. As a result, the total score of the amounts to 28 points. The highest score indicates the best performance.[9]

REVIEW OF LITERATURE

1. **Jinse Park. Seong-Beom Koh, Hee Jin Kim, Eungseok Oh, Joong-Seok Kim, Ji Young Yun, Do-Young Kwon, Younsoo Kim, Ji Seon Kim, Kyum-Yil Kwon, Jeong-Ho Park, Jinyoung Youn, and Wooyoung Jang. (2018)[10] :-** ·Validity and Reliability Study of the Korean Tineti Mobility Test for Parkinson's Disease**.:-** Twenty-four patients diagnosed with PD were enrolled in this study. For the interrater reliability test, thirteen clinicians scored the TMT after watching a video clip. We also used the test-retest method to determine intrarater reliability. The interrater reliability and intrarater reliability of the Korean Tinetti balance scale were 0.97 and 0.98, respectively. The interrater reliability and intra-rater reliability of the Korean Tinetti gait scale were 0.94 and 0.96, respectively. The Korean TMT scores were significantly correlated with the other clinical scales and three-dimensional motion capture. The cutoff values for predicting falling were 14 points (balance subscale) and 10 points (gait subscale).
2.
3. **Seung-Heon An, Dong-Geon Lee, PT, Yun-Bok Lee, Gyu-Chang. (2014)[11]**. Inter –rater ? absolute Reliability and Concurrent Validity of Tinetti – gait Scale (Korean version) in stroke patients**. :-** The purpose of this study was to investigate the inter-rater absolute reliability and the concurrent validity of the Tinetti-gait scale that was translated into Korean for chronic stroke patients. Fifty-two with post-stroke participated in this study. Results was The inter-rater reliability of the Tinetti-gait scale was high; ICC(3,1)=.91 ICC(3,1)=.91 (95% CI=.85~.95) (very reliable), the range of Kappa coefficient were .73~.92 (substantial~good). The inter-rater agreement of the each item in Tinetti-gait scale ranged from .74 to .92 (95 % CI=.59~.95) (reliable~very reliable). The SEM and MDC were .56 and 1.55, respectively. In the results of concurrent validity, there were moderate positive correlation between Tinetti-gait scale and DGI (r=.78), 10WT (r=.74), OLST (r=.65~.73), FM-LE (r=67). And there was moderate negative

correlation between Tinetti-gait scale and STS (r=-79) (p<.01). The Tinetti-gait scale(Korean version) was a reliable and valid tool to measure gait ability in stroke patient.

4. **Serap D. Yücel & Füsun Şahin & Beril Doğu & Tülay Şahin, Banu Kuran & Sevda Gürsakal.(2012)[9].** Reliability and Validity of the Turkish version of the Performance- Oriented Mobility Assessment 1. **:-** The aim of this study was translate POMA-l to Turkish and to assess its reliability and validity people with amputated lower extremities. Eighty participants enrolled in the study with a mean age of 76.5 ± 6.75 years.The turkih version of POMA were ICC(0.70)and cronbach's alpha(0.72,0.83,0.88). In the reliability evaluation of the scale in validation study POMA total score had a strong positive correlation with BBS total score ($r = 0.86, p < 0.0001$), and also a negative correlation with TUG ($r = - 0.75, p < 0.0001$). According to the results of this study, the Turkish version of the POMA-l scale has been found to be a reliable and a valid scale for elderly Turkish peopl

5. **Camila Rodriez Guevara. Luz Helena Lugo. (2012)[12] .** Validity and reliability of Tinetti Scale for Colombian people :- A validity study was conducted in 2012 to a validate the Tinetti Scale for its use in Colombian populations. The Spanish version of Tinetti scale was applied by two evaluators to elderly persons with different degress of gait and balance functionally. Results of this study was the The content validity suggests the re-structuring of the items in the domain of equilibrium with a Cronbach's alpha of 0.948 and a variance of 13,894, in the construct validity, 46 of the 48 responses of the scale differences statistically significant in the ability to detect changes in a group without alterations in gait and balance (healthy) and a group with these conditions (sick); the concurrent validity had a high correlation r = -0.82 with Timed up and go. The inter and intra- rater reliability was between 0.4 to 0.6 and 0.6 to 0.8, respectively. The Cronbach's alpha was 0.91 so the scale was valid and reliable.

6. **Huma Parveen. Majumi M. Noohu.(2016)[13].** Evaluation of Psychometric properties of Tinetti Performance-Oriented Mobility Assessment Scale In Subjects with Knee Osteoarthritis :- The objective of this study was to determine the psychometric properties of the (POMA) scale to measure balance and gait impairments in individuals with (OA).A convenient sample of 25 individuals with bilateral OA knee were recruited. The Results Score of BBS was significantly correlated with POMA-B scores, $r_s = 0.63$, $p = 0.001$, whereas TUGT showed a negative correlation with POMA-G, $r_s = -0.481$, $p = 0.020$, showing moderate convergent validity. ICC results of the total POMA scale (POMA-T), POMA-B, and POMA-G were 0.96, 0.93, and 0.96, respectively, indicating high test retest reliability. SEM, for POMA-T, POMA-B, and POMA-G was 0.35, 0.27, and 0.35, respectively; MDC values were 0.97 for POMA-T, 0.75 for POMA-B, and 0.63 for POMA-G. The findings indicate that the POMA is a valid and reliable tool to assess balance and gait impairments in people with OA knee.

7. **Anne D Kloos, Deb A. Kegelmeyer ,Gregory S. Young, Sandra K Kostyk.(2010)[14].**Fall risk assessment using the Tinetti mobility test in individuals with Huntington's disease. :- The Tinetti Mobility Test (TMT) is a clinical balance and gait test that predicts fall risk in the elderly. This study examined the concurrent validity, usefulness of the TMT as a fall risk screening tool, and the potential ability of the TMT to predict falls in individuals with Huntington's disease (HD). Data from a retrospective review of 94 patient records were used. TMT scores were correlated with Unified Huntington Disease Rating Scale motor scores. The ability of the TMT to accurately assess fall risk was determined using validity index measures. Logistic regression was used to assess the ability of the TMT to predict falls. TMT scores correlated with motor scores ($r_s = -0.751$, $P < 0.0001$). Using a cutoff value of 21, the TMT had a sensitivity of 74% and a specificity of 60% to identify fallers. Lower TMT scores and younger age were significant predictors of falls. The TMT is a for assessing balance and gait status and fall risk of individual with HD.

8. **Anne D. Kloos.Nora E. Fritz, Sandra K. Kostyk, Gregory S, Deb A. Kegelmeye Young. (2014)[15].**Clinimetric properties of the Tinetti Mobility Test, Four Square Step Test , Activities-Specific Balance Confidence Scale, and spatiotemporal gait measures in individuals with Huntington's disease:- This study examined the reliability and concurrent validity of spatiotemporal gait measures, the TMT, FSST and ABC scale in individuals with HD. Results of this study was participants Spatiotemporal gait measures, the TMT total and the FSST showed good to excellent test–retest reliability (ICC > 0.75). MDC values were 0.30 m/s and 0.17 m/s for velocity in forward and backward walking respectively, four points for the TMT, and 3 s for the FSST. The TMT and FSST were highly correlated with most spatiotemporal measures. The ABC Scale demonstrated lower reliability and less concurrent validity than other measures. The high test–retest reliability over a six week period and concurrent validity between the TMT, FSST, and spatiotemporal gait measures suggest that the TMT and FSST may be useful outcome measures for future intervention studies in ambulatory individuals with HD.

9. **Lorenzo Panella, Tinelli Carmine, Buizza Angelo, Lombardi Remo, Gandolfi Roberto.(2008)[16].** Towards objective evaluation of balance in the elderly: validityand reliability of measurement instrument applied to the tinetti test **:-** The aim of present study was the validation of an instrument for evaluating balance, applied Tinetti test. Trunk inclination was measured by inclinometers during thr Tinetti test in 163 healthy participants. Reliability was evaluated by cronbach;s alpha and its validity by itemscale correlation, discriminant validity and concurrent validity. Influence of age and gender was assessed by regression model. Repeatable and distribution consistent measurement were obtained (cronbach;s alpha=0.88). parameter distribution was significantly different in control and patients ($p<0.001$). optimal threshold fpr discriminating between normal and abnormal performance (153.9/200) corresponded to sensitivity of 84.7% and area under the receiver operating characteristics curve of 93.

10. **Cipriany-Dacko LM, Dana Innerst, Joann Johannsen, Vicki Rude.(1997)[17].** Interrater reliability of the tinetti balance scores in novice and experienced physical therapy clinicians:- A reliability design was used to assess the interrater agreement and consistency of the BPOMA scores in an elderly population. Twenty-six residents of a skilled nursing home, ranging in age from 66 to 90yrs ($\bar{x}$ = 80.4, SD = 6.8), participated in Phase 1. Twenty-four hospital inpatients and five residents of a skilled nursing home, ranging in age from 60 to 92yrs ($\bar{x}$ = 74.7, SD = 7.9), participated in Phase 2.Phase 1 demonstrated fair to excellent κ coefficients (.40–1.00) in all maneuvers across all raters. The ORs had higher agreement compared with the AR, ranging from good to excellent (.75–1.00). Phase 2 demonstrated fair to good κ coefficients (.40–.75) in 5 of 8 maneuvers across all nine raters. When comparing proportion of observed agreement to evaluate the years of experience on rater agreement, there was no significant difference between clinician groups.Fair to good reliability of BPOMA scores occurred across many raters of varied experience with a small amount of BPOMA scores occurred across many raters of varied experience with a small amount of training..

11. **Bahman Moulodi., Akram Azad, Ghorban Taghizadeh, Mahtab Roohi-Azizi, Parvaneh Mohammadi.(2020)[18].**Reliability and Validity of Persian Version of Performance Oriented Mobility Assessment (POMA) in Community- dwelling Iranian older adults:- This study aimed at investigating the construct validity, factor analysis, internal consistency, test-retest and inter-rater reliability, and ceiling/floor effects of the Persian version of Performance-oriented Mobility Assessment (POMA) in community-dwelling elderly**.** One hundred and forty-five older adults aged 65 years and older were recruited from daily care centers of Tehran by convenience sampling method. Timed Up and Go (TUG) test and Berg Balance Scale (BBS) were used to investigate the construct validity of the POMA. Test-retest (7-14 days with interval) and inter-rater reliability of the gait and balance subscales and the total score of the POMA were moderate to very high correlation ($r= 0.67-0.9$, $P\leq 0.05$) was found between the total score of the POMA and BBS, Fullerton Advanced Balance Scale, step test (right and left), TUG, Dynamic Gait index, and walking speed, whereas the correlation between the total score of the POMA and step length was poor ($r= 0.39$, $P\leq 0.05$). The results of confirmatory factor analysis showed a poor goodness-of-fit of POMA with the two-factor

model (balance and gait) in community-dwelling elderly. Internal consistency (Cronbach's alpha= 0.94), test-retest reliability (ICC = 0.97), as well as inter-rater reliability (ICC = 0.92) of the POMA were excellent. The results revealed no floor effect for the total score of the POMA; however, its ceiling effect was 3.44%.The Persian version of POMA showed excellent psychometric properties for evaluating different aspects of balance in community-dwelling

NEED OF STUDY

Tinetti Assessment Tool is one of the most common Tool that has been used by physiotherapist all over the world. Also it is already translated in many language like Turkish,[9] Korean[10], Spanish[12], persian[18] etc. I want to translate this scale in my mother language i.e. Gujarati because it will be more beneficial for patients to understand the scale in Gujarati and it will be helpful to physiotherapists also who are from Gujarat.

OBJECTIVE OF THE STUDY

- To translate Tinetti Assessment Tool in to Gujarati language.
- To find out test-retest reliability and internal consistency of Gujarati version
- Tinetti Assessment Tool.
- To find out face and contact validity of the Gujarati version Tinetti Assessment Tool.

HYPOTHESIS

- NULL HYPOTHESIS : Tinetti Assessment Tool for balance and gait will be not reliable and valid on Gujarati population.
- RESEARCH HYPOTHESIS : Tinetti Assessment Tool for balance and gait will be reliable and valid on Gujarati population.

METHODOLOGY

The study was carried out on elderly people aged 40 to 70 years in Gujarat, India. Those peoples who have balance and gait disorder.

INCLUSION CRITERIA

1) Patients who can write , reading and understand Gujarati language
2) Age group 40 – 70 years
3) Patient who is having problems with balance and gait

EXCLUSION CRITERIA

1) Subjects who don't know Gujarati
2) Subjects who had fracture within 6 months
3) Patient with neurological and psychological problem

The Tineeti Balance Scale had been cross-culturally adapted into Gujarati version of Tinetti Assessment Tool in following eight steps:

1. Initial translation to Gujarati language/ forward translation: The translation of Tinetti Assessment Tool in Gujarati language was performed by two individuals whose native language is Gujarati.

2. Synthesis: After discussion, the 2 translators produced a consensus version of the Tinetti Assessment Tool

3. Back translation: Back translation of preliminary Tinetti Assessment Tool into English was conducted by two native English speakers who were fluent in both English and Gujarati. The two translators were neither aware nor be informed of the concepts explored, and they had no medical background.

4. Reviewer's committee: An expert committee comprising of panel of 6 members performed cross-cultural adaption and validation. After back translation, the Scale were forwarded to back translators. They reviewed all translation and developed the
Pre-final version of Tinetti Assessment Tool with emphasis on semantic, idiomatic, experimental and conceptual equivalence in relation to original back- translated Tinetti Balance Scale versions. Then the Scale was content validation by the expert committee.

5. Content validation: Content validation was excuted by the panel of 6 pre-identified members who experts in using Gujarati and English. They were provided with five options, "agree", "strongly agree", "neutral", "disagree", and "strongly disagree". For providing their valuable opinion regarding Gujarati version of Tinetti Assessment Tool.. Eighty percent consensus of agreement among the experts were required to validate the translated version of Tinetti Assessment Tool .Eighty percent of agreement between the experts were fixed in recommendation by Lynn to yield the item-level content validation index (I-CVI) of 0.93. According to Lynn's (1986) criteria a minimum I-CVI of 0.78 for 6 to 10 experts is required to validate each item in a scale.[19] Hence, we have used an expert panel with 6 members to validate the Gujarati translated content of Tinetti Assessment Tool .They were provided with options, agree, strongly agree, neutral, disagree and strongly disagree in a five point likert scale with Gujarati translated content of Tinetti Balance Scale Neural, disagree and strongly disagree were considered as negative response while agree and strongly agree was considered as positive. Content validation of Tinetti Assessment Tool was performed until the overall scale-level content validation index (S-CVI) reaches SCVI/Ave $\geq$ 0.90.[19]

6. Pretesting: According to inclusion and exclusion criteria, the pre-final Scale was administered to 10 balance and gait disorder patients. The interviewer reported on each respondents understanding the Scale items and making decision on them. As no further adaptation is indicated, the pre-final and final Tinetti Assessment Tool is identical. The objective was to assess whether the translated Scale was understandable, the vocabulary was appropriate and also the expression was relevant for Gujarati culture

7. Validation study: Face validity and Content validity was obtained by the Experts and the translators.

i. Test-retest reliability: The recruited patients with balance and gait disorder were asked to fill Gujarati version of Tinetti Assessment Tool by themselves twice with minimum gap of one week duration. So that person may not copy the same data as well as he/she will not forgot.[19] The readings were recorded to report test-retest reliability.

ii. Internal consistency: Internal consistency was measured with Cronbach's alpha (α), a statistic which was calculated from the pair wise correlations measured between paired readings of Gujarati version of Tinetti Assessment Tool.

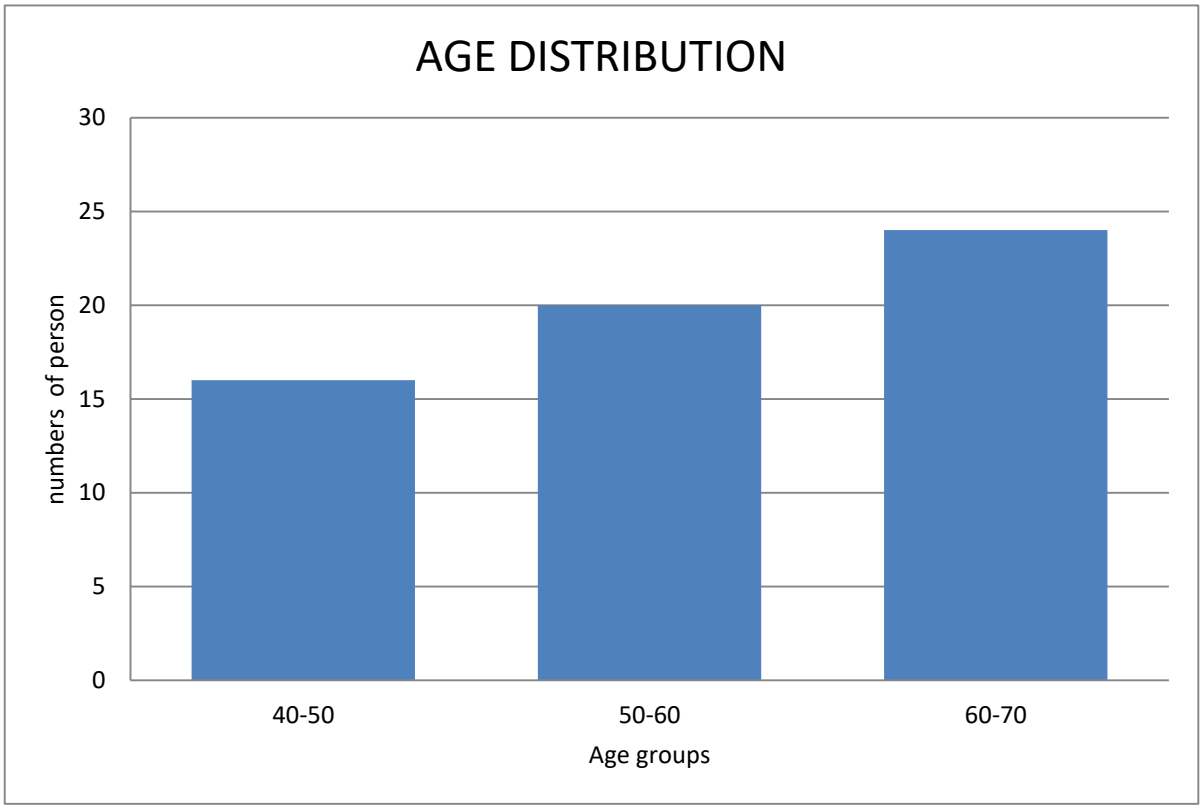
RESULT

1. Age distribution

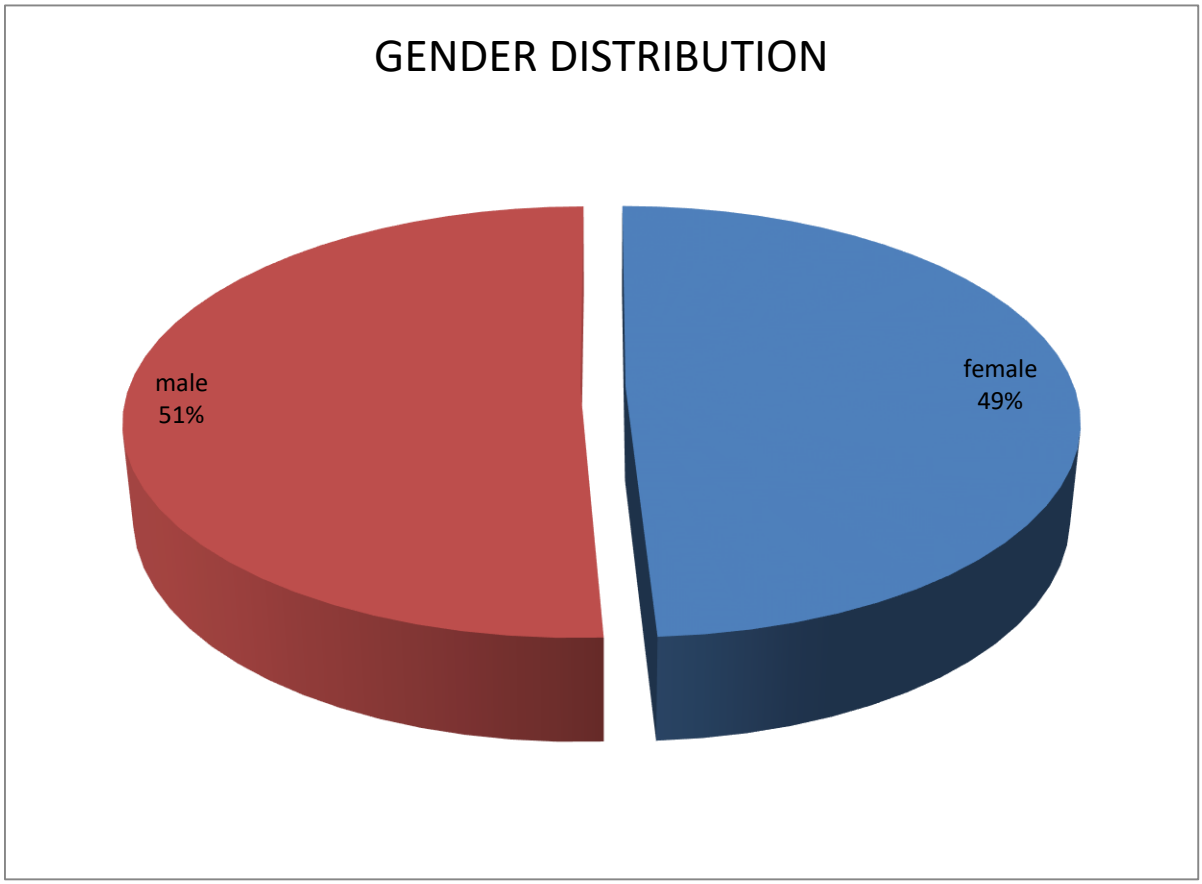
The research was performed on 60 patient with Balance and Gait disorder between the age of 40-70. There were 14 patients between the ages of 40 to 50, 20 patients between the ages 50 to 60, and 24 patients between the ages of 60 to 70. The Mean of age was 20.



GRAPH 7.1 :- AGE DISTRIBUTION CHART

2. Gender distribution

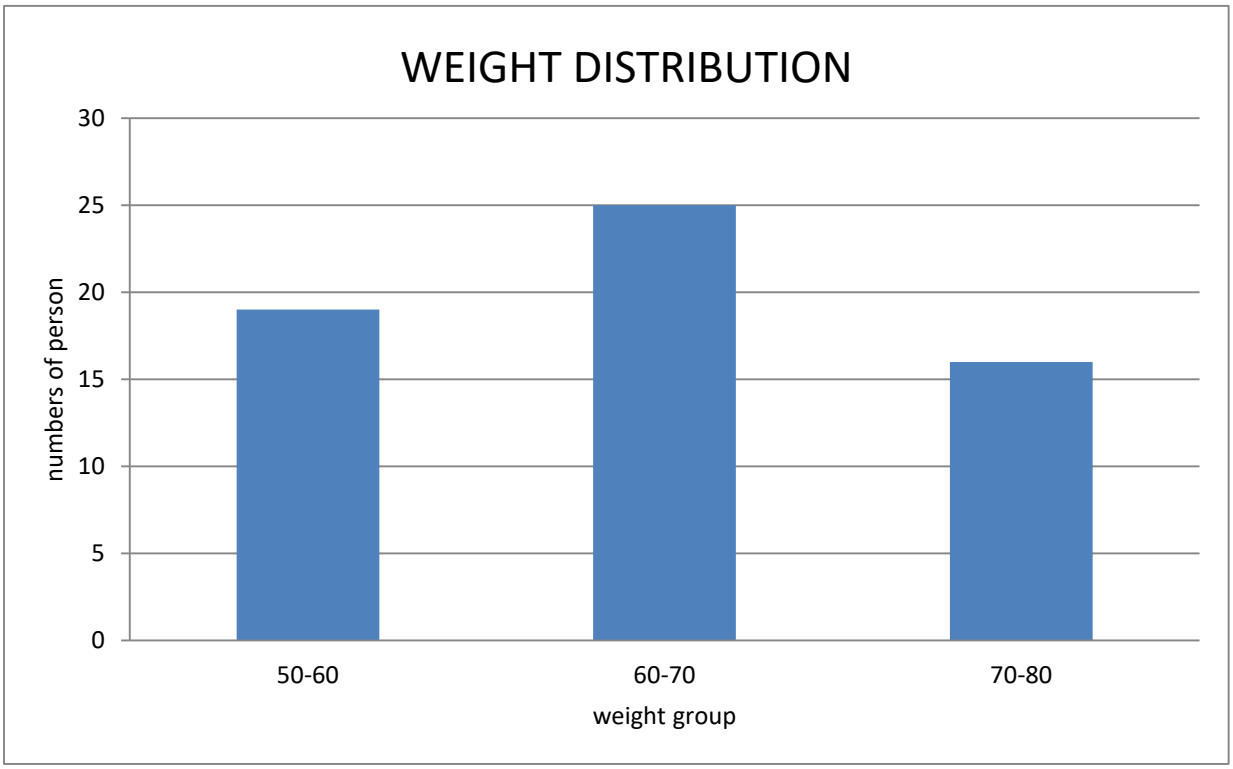
The research was performed on 60 patient with Balance and Gait disorder. In which 30 are Females and 31 are Males. The Mean of gender was 30.5



GRAPH 7.2 :- WEIGHT DISTRIBUTION CHART

3. Weight Distribution

The research was performed on 60 patient with Balance and Gait disorder There were 19 patients between the weight of 50 to 60, 25 patients between the weight of 60 to 70 and 16 patients between the weight 60 to 70 . The Mean of weight was 20.



GRAPH 7.3 :- WEIGHT DISTRIBUTION CHART

The content validity of Gujarati translated Tinetti Assessment Tool by a 6 experts were found to be, I-CVI of individual items Tinetti Assessment Tool of ≥ 0.93 and overall S-CVI for idiomatic equivalence, semantic equivalence and content relevance ≥ 0.90. For content validity equivalence all 6 experts answers were located between mostly agree and strongly agree of Gujarati version of Tinetti Assessment Tool for idiomatic equivalence (average= 0.89) semantic equivalence(average = 0.91) and content relevance (average= 0.92). Test-retest reliability (n=60) was tested by using the intraclass correlation coefficient, ICC (2,1) and Internal consistency (n=60) was reported in terms of cronbach's α measured in two session after 1 week is reported in Table 2.

Tinetti Balance Scale	Session 1	session 2	Cronbach's alpha	ICC	P- value
BALANCE SECTION	10.71±6.34	10.88±6.20	.993	.986	0.980
GAIT SECTION	8.60±3.29	8.41±3.40	.988	.977	0.959

TABLE 7.1 :- TEST-RETEST RELIABILITY OF TINETTI TOO

DISCUSSION

Many elderly people has Balance and Gait disorder caused by neurological disorder, Parkinson, stroke, poor posture, ataxia , myelopathy. They causing pain, dyspnea, imbalance, diminished strength, limited range of motion, poor posture, fatigue. In our study first report of the reliability and validity of the Tinetti Assessment Tool for evaluating patient with Balance and Gait disorder.

In this study 60 patients participated. Gujarati version of Tinetti Assessment Tool was given twice with 1-week interval to measure the test- retest reliability and to validity. The results of the study showed good

correlation Balance scale and Gait scale(ICC= .986,and .977) (P<0.01) and internal consistency (cronbach's alpha = . 993 and .986).

For content validity equivalence all 6 experts answer were located between mostly agree and strongly agree of Gujarati version of Tinetti Assement Tool for idiomatic equivalence (average= 0.89) semantic equivalence (average = 0.91) and content relevance (average= 0.92). Thus, Gujarati version of Tinetti Balance Scale was content validated for idiomatic equivalence, semantic equivalence , content relevance.

In previous studies, interrater reliability and intrarater reliability of the Korean Tinetti balance scale were(ICC =(0.97 and 0.98) respectively. The interrater reliability and intrarater reliability of the Korean Tinetti balance scale were(ICC =0.94 and 0.96). reliability and validity for gait and balance had high sensitivity and specificity for predicting falls among the patient with PD.[10] In Spanish version the concurrent validity had a high correlation (r = 0.74- 0.93). and inter and intra- rater reliability was between 0.4 to 0.6 and 0.6 to 0.8 The tinetti scale is valid and reliable for Colombian population.[12]

Turkish version of the scale was applied on the participants at 2 week intervals. Test-retest shown good reliability (ICC= 0.94) . interrater and intrarater reliability (ICC=0.86 And 0.90).[9] Turkish version of the POMA-1 scale has been found be a reliable and valid.In Persian version of POMA was applied 7-14 days intervals. Internal consistency (cronbach's alpha= 0.94). test-retest reliability (ICC=0.97). inter-rater reliability (ICC=0.92). Persian shown excellent psychometric properties

It was found Gujarati version of Tinetti Assessment Tool items equivalent to those in original version which is intended by translators involve in this study. The results showed that it was translate this scale into other languags without losing psychometric properties of the original English version

CONCLUSION

The Gujarati version of Tinetti Assessment Tool was cross-culturally adapted and validated for use among the Gujarati-speaking populations. The translated version has acceptable reliability and internal consistency.

SUMMARY

The study is find out the reliability and validity of the Tinetti Assessment Tool in Gujarati language on the elderly people with Balance and Gait disorder in Gujarat. 40 people were chosen with the 40-70 age group participated in the study and they were given Tinetti Assessment Tool was given twice with 1 week interval to measure test-retest reliability and to measure validity. The results showed good correlation and internal consistency and content validity

CHRONIC NECK PAIN AMONG COLLEGE STUDENTS A CROSS-SECTIONAL STUDY

[1]Dr. JAYNESH VANDRA, [2]FORAM SOLANKI, [3]Dr. ARVINDKUMAR CHAUHAN

[1]Assistant Professor (MPT in Musculoskeletal and Sports, PhD Scholar), [2]Bachelor of Physiotherapy, [3]Principal and Professor
[1,2,3]Venus Institute of Physiotherapy,
[1,2,3]Swarrnim Startup & Innovation University, Gandhinagar, Gujarat, India.

ABSTRACT :

Chronic neck pain is most common problem in people nowadays. Chronic neck pain can have causes such as working for hours over computer and mobile phones which eventually causes muscle strains.

BACKGROUND:

To find prevelance, determinants and consequences of chronic neck pain among college going students.

METHODOLOGY:

STEP 1: Selection of suitable participants.

STEP 2: Sending the consent form through e-mail.

STEP 3: Sending the link of questionnaire through e-mail.

STEP 4: Collection of data.

STEP 5: Analysis of the survey.

STEP 6: Statistical Analysis

STEP 7: Result

RESULT: Most of the patient did not had any pain or had miled pain during personel care, lifting heavy weights, reading, headaches, Concentration inactivities, work, driving, Sleeping and Recreational activities.

CONCLUSIONS: From the results it can be concluded that more than half of the population had no pain or mild pain and they didn't feel any issues in dealing with personal care lifting heavy weights reading headaches concentration work driving sleeping and Recreation

KEYWORDS: Chronic neck pain, VAS scale, NDI scale, college students

I. INTRODUCTION

Chronic neck pain is most common problem in people nowadays.1,2The chronic neck pain seems to a have large impact on people's health and hinders with an Individual's day to day activity and work.2

Symptoms

- Pain that's often worsened by holding your head in one place for long periods, such as when driving or working at a computer.
- Muscle tightness and spasms.
- Decreased ability to move your head.
- Headache.
- Neck pain is typically classified as chronic when it persists or regularly recurs for at least 3 months.

Causes of neck pain and problems may include:

- Injury (damage to the muscles, tendons, or ligaments) Herniated disk in the neck.
- Arthritis (such as osteoarthritis, rheumatoid arthritis) Cervical (neck) disk degeneration.
- Congenital (present at birth) abnormalities of the vertebrae and bones.
- Tumors.

Your neck is flexible and supports the weight of your head, so it can be vulnerable to injuries and conditions that cause pain and restrict motion. Neck pain causes include:

- Muscle strain : Overuse, such as too many hours hunched over your computer or smartphone, often triggers muscle strains. Even minor things, such as reading in bed or gritting your teeth, can strain neck muscles.
- Worn joints : Just like the other joints in your body, your neck joints tend to wear down with age. Osteoarthritis causes the cushions (cartilage) between your bones (vertebrae) to deteriorate. Your body then forms bone spurs that affect joint motion and cause pain.

- Nerve compression : Herniated disks or bone spurs in the vertebrae of your neck can press on the nerves branching out from the spinal cord.
- Injuries : Rear-end auto collisions often result in whiplash injury, which occurs when the head is jerked backward and then forward, straining the soft tissues of the neck.
- Diseases : Certain diseases, such as rheumatoid arthritis, meningitis or cancer, can cause neck pain.

Neck pain can cause reduced range of motion due to movement restriction muscles of the neck can become strained due to bad posture habits such as spending excessive time on computer and mobile phones where the neck remains continuously in the same position for a prolonged period of time. Pain in the neck most of the time goes away within a few weeks that being said pain that persist for months could be a sign of underlying problem that needs Observation.4 Chronic Neck pain can have causes such as working for hours over computer and mobile phones which eventually causes muscle strains. Whiplash injuries where the head is forced backward and forward and diseases like cancer.4

REVIEW OF LITERATURE

1. Prevalence , determinants and consequences of chronic neck pain in Finland, By Matti Makela, Markku Heliovaara, Kai Sievers, Olli Impivaara, Paul Knekt, Arpo Aromaa , in 1991.

The distribution, determinants, and consequences of chronic neck pain have hitherto been described inadequately. In the Mini-Finland Health Survey, a representative population sample of 8,000 Finns aged ≥30 years was invited to participate in a comprehensive health examination comprising an interview and a clinical examination; 90.2% complied. Predetermined criteria were used to diagnose major cardiovascular, musculoskeletal, respiratory, mental, and other disorders, regardless of other simultaneous disorders. Chronic neck syndrome was diagnosed in 9.5% of the men and 13.5% of the women. When adjusted for age and sex, the prevalence of the neck syndrome was associated with a history of injury to the back, neck, or shoulder and with mental and physical stress at work. Among those aged 30 to 64 years, overweight and parity were also significant determinants. Other musculoskeletal and mental disorders were associated with neck syndrome, and the association persisted after working conditions, injuries, overweight, and parity were adjusted for. There was some independent association between neck syndrome and disabilities, use of physician services, and use of pain killers.

2. Neck pain among undergraduate medical students in a premier institute of central India: A cross-sectional study of prevalence and associated factors,By Prateek Behera, Anindo Majumdar, G Revadi, John Ashutosh Santoshi, Vivek Nagar, Nitu Mishra in 2020 .

This study aimed to evaluate the prevalence of neck pain and the associated factors including gadget use among undergraduate medical students of a premier medical college in central India.

3. Prevalence of neck pain among under graduate student of Lahore, By Ayesha Malik , M.Umer Pasha , Sadia khalid , Ashfaq ahmad , Syed Amir Gilani , 2017 .

The main intent of this study was to find out the prevalence of neck pain in undergraduates Students. A cross sectional study was conducted which was not derived from experiments. A survey was conducted from the undergraduate students of main universities in lahore city named as Punjab university of Lahore and University of Lahore descriptive statistics focused on bar charts histograms and pie charts were Used. Results concluded that out of 402 respondents (56.7%) were suffering with neck pain while (43.3%) respondents were not having neck pain. No association was found between gender and neck pain (p-value 0.351) additionally, there was weaker relation between age and neck pain (p-value 0.785).Neck pain occurring. In students was mainly sudden in onset & intensity was mild to moderate of the neck pain. Mostly students were taking medications & physiotherapy treatment for reducing the neck pain.

4. Improving knowledge of Text Neck and Neck Pain Using Interactive Smartphone Application for Undergraduate Students in Universiti Sains Malaysia, By Jasni Dolah, Joey Loh Jo Yie, Lilian Lee Shiau Gee , In 2020.

The objective of this study is to determine the level of knowledge and awareness of the text neck among undergraduate students of University Sains Malaysia (USM) and to create an interactive mobile application to reduce the prevalence. The app is ARbased neck exercise gamification that alerts incorrect posture using a smartphone front camera and a built-in sensor. The proposed study will enable people who are suffering from, or at risk of, text neck to have more pleasant and engaging neck exercise experience with a better exercise impact, and may promote regular breakaway from the wrong posture.

5. Effects of neck exercise on sitting posture in patients with chronic neck pain , By Deborah Falla, Gwendolen Jull, Trevor Russell, Bill Vicenzino,Paul Hodges , 2007

This study had 2 purposes: (1) to compare change in cervical and thoracic posture during a distracting task between subjects with chronic neck pain and control subjects and (2) to comparethe effects of 2 different neck exercise regimens on the ability of people with neck pain to maintain an upright cervical and thoracic posture during this task. Fifty-eight subjects with chronic, nonsevere neck pain and 10 control subjects participated in the study.

6. Responses to Vignettes about Students with Chronic Pain in K-12 Public Schools Provide by Current Principals and Assistant Principal BY Kimberly S Payne , In 2020.

This dissertation study addresses a gap in the literature in K-12 public education regarding students who experience chronic pain (CP). While awareness and understanding about the plight of children and adolescents with CP are prevalent in the healthcare and medical realms, evidence of how public schools respond to students' pain

complications as they apply to their education, both in the K-12 setting andbeyond, is scant. Despite this, consequences of ignoring or misunderstanding CP instudents by K-12 schools could be significant: Studies from the healthcare realm indicate that students with CP often become caught in a "downward spiral" of chronic pain-invoked absenteeism resulting in falling behind in academics and low school functioning, thus placing them at risk of poorer eventual outcomes in life. Likewise, family members and school personnel become frustrated by lack of information, communication problems, and the inability to attend to students' needs. Additionally, matters are complicated when K-12 school administrators are required to work within fixed legal frameworks that are not necessarily sensitive to CP issues.

7. Active neck muscle training in the treatment of chronic neck pain in women a Randomized Controlled trial, by Jari Ylinen , Esa-Pekka Takala , Matti Nykänen , in 2003

Patients were randomly assigned to either 2 training groups or to a control group, with 60 patients in each group. The endurance training group performed dynamic neck exercises,which included lifting the head up from the supine and prone positions. The strength training group performed high-intensity isometric neck strengthening and stabilization exercises with an elastic band. Both training groups performed dynamic exercises for the shoulders and upper extremities with dumbbells. All groups were advised to do aerobic and stretching exercises regularly 3 times a week

8. A systematic review of the impact of chronic pain on adolescents' school functioning School personnel responses to managing pain in the schools By Fatimah Alsaggaf, Imelda Coyne , In 2020.

To critically synthesize empirical studies on the impact of chronic pain on adolescents' school functioning and school personnel responses to managing pain in schools.

9. Physical exercises and functional rehabilitation for the management of chronic neck Pain , By Jari Ylinen , in 2007

The aim of this review was to reassess the effectiveness of different exercise methods in relieving pain and improving disability in patients with chronic nonspecific neck pain. Ten andomized controlled or comparative high-quality trials were included in a more detailed analysis using patient oriented primary outcome measures (e.g., patient's rated pain and Disability) as well as pressure pain threshold and functional outcomes (neck strength and range of motion). Findings revealed moderate evidence supporting the effectiveness of both long-term dynamic as well as isometric resistance exercises of the neck and shoulder musculature for chronic or frequent neck disorders. Findings revealed no evidence supporting the long-term effectiveness of postural and proprioceptive exercises or other very low intensity exercises. Clinicians are encouraged to consider these findings and incorporate them into their practice when planning the treatment of patients with chronic neck disorders.

NEED OF STUDY

Currently there are many studies done on chronic neck pain but there is limited research on prevalence ,determinants and consequences of chronic neck pain among college going students. Need for study arises to understand the determinants and prevalence of chronic neck pain in college going students as their neck remains in the same position continuously for longer time while studying and using mobile phones as well as laptops.

OBJECTIVE OF THE STUDY

- To find out whether Myofacial Release (MFR) Technique or Active Release Technique is more effective in treating chronic low back pain.
- To find out whether Myofacial Release (MFR) Technique is superior for treating chronic low back pain.
- To find out whether Active Release Technique is superior for treating chronic low back pain.

HYPOTHESIS

H0 : There is no association between pain and personal care, lifting heavy weights, reading, headaches, concentration in activities, work, driving, sleeping, recreational activities.

H1: There is association between pain and personal care, lifting heavy weights, reading, headaches, concentration in activities, work, driving, sleeping, recreational activities.

METHODOLOGY

STEP 1: Selection of suitable participants.

STEP 2: Sending the consent form through e-mail.

STEP 3: Sending the link of questionnaire through e-mail.

Results

Using the graphs the following results were obtained:

1. Most of the patients did not had any pain or had mild pain during personal care (washing, dressing, etc).
2. Most of the patients did not had any pain or had mild pain during Lifting heavy weights.
3. Most of the patients did not had any pain or had mild pain during Reading.
4. Most of the patients did not had any pain or had mild pain during slight headaches, which come infrequently.
5. Most of the patients did not had any pain or had mild pain and so they can concentrate in their day to day activities with no/less difficulty.
6. Most of the patients did not had any pain or had mild pain while doing work.
7. Most of the patients did not had any pain or had mild pain while driving.
8. Most of the patients did not had any pain or had mild pain while sleeping or had no trouble sleeping.
9. Most of the patients did not had any pain or had mild pain and so they were able to engage in all their recreational activities with no/mild neck pain.

DISCUSSION

Neck pain can have causes that aren't due to underlying disease. Examples include prolonged straining (looking up or down), sleeping in an uncomfortable position, stress, chiropractic manipulation or wearing heavy necklaces. Chronic neck pain can range from an achy annoyance to shock-like pain that goes into the arm and becomes debilitating. Neck pain is typically classified as chronic when it persists or regularly recurs for at least 3 months.

Drs Ylinen and Häkkinen,Dr Takala ,Dr Nykänen,Dr Mälkiä,Dr Pohjolainen and Ms Karppi,Dr Airaksinen did research in Active neck muscle training in the treatment of chronic neck pain in women: a randomized controlled trial , the results show that the Both strength and endurance training for 12 months were effective methods for decreasing pain and disability in women with chronic, nonspecific neck pain. Stretching and fitness training are commonly advised for patients with chronic neck pain, but stretching and aerobic exercising alone proved to be a much less effective form of training than strength training. [6]

Author Deborah Falla, Gwendolen Jull, Trevor Russell, Bill Vicenzino, Paul Hodges did research in Effect of neck exercise on sitting posture in patients with chronic neck pain, the results show that the This study showed that people with chronic neck pain demonstrate a reduced ability to maintain an upright posture when distracted. Following intervention with an exercise program targeted at training the craniocervical flexor muscles, subjects with neck pain demonstrated an improved ability to maintain a neutral cervical posture during prolonged sitting. [4]

When Jari Ylinen did research in Physical exercises and functional rehabilitation for the management of chronic neck pain ,the results show that Specific moderate and highintensity neck muscle training can reduce neck pain. A decrease in neck pain is associated with reduced pressure pain sensitivity in neck muscles. Intensive regular training will increase neck muscle strength and range of motion, leading to improved function and less disability in patients with chronic neck pain. Training for a few months is commonly recommended, but it has beenshown to produce only transitory improvements. Long-term progressive resistance training for neck and shoulder muscles is therefore recommended. Moreover, effective training can be performed at home with low-cost training equipment.[8]

In this cross - sectional research chronic neck pain among college going students on 90 students from age 18-24 . In this research NDI scale and VAS scale were used to measure pain and disability of students. My research concluded that the there is no disability among college going students.

I did this research because I observed that college going students have to keep their neck constantly in one position whether it was for attending lectures or working on their desk so I wanted to know if they were experiencing any kind of chronic neck pain in their day to day life.

CONCLUSION

From the results it can be concluded that more than half of the population had no pain or mild pain and they didn't feel any issues in dealing with personal care lifting heavy weights reading headaches concentration work driving sleeping and recreation.

SUMMARY

From the results it can be concluded that more than half of the population had no pain or mild pain and they didn't feel any issues in dealing with personal care lifting heavy weights reading headaches concentration work driving sleeping and recreation.

Limitations

- Smallsamplesize.
- Limitedagegroupof18-24years.
- Neckpainprolongedmorethan12weeks.

ABSTRACT

BACKGROUND : Polycystic means many cysts. Polycystic ovarian Disease is a complex disorder of chronic oligoanovulation or oligomenorrhoea and clinical or biochemical hyperandrogegism. Genetic and environmental factors may contribute to this disorder and may affect 14-44 year age of women . This is one of the main reason for infertility. Women affected with this syndrome often have ovulatory dysfunction hormonal disbalance, hyperandrogenemia, obesity and hyper insulinemia.

METHODOLOGY: They were subjected to Yoga therapy for 30-45 mins /day for 3 months with a break after every 6 days. Treatment duration was 3 months. Pre and post outcome measures were taken.

RESULT: . Data was considered statistically significant with $P<0.05$ and highly significant at $p<0.01$. Pre and post mean difference of BMI shows 33.28 ± 26.64 in pre date collection and 28.36 ± 21.77 in post data collection. As $p<0.05$ there is significant difference between groups. Pre and post mean difference values of VMSS shows 2.33 ± 14.67 and 0.93 ± 23.87. This shows a significant difference between two groups.

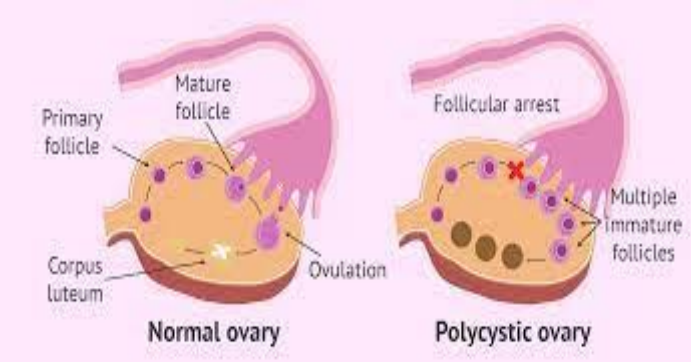
CONCLUSIONS: Daily yoga for 30 minutes with 5 Asanas along with meditation and Shavasana helps in weight reduction and stress management which ultimately stabilize the normal function of hypothalmo-pituitary–ovarian axis and cure PCOD.

KEYWORDS: polycystic ovarian disease, yoga, obesity, Body Mass Index , infertility.

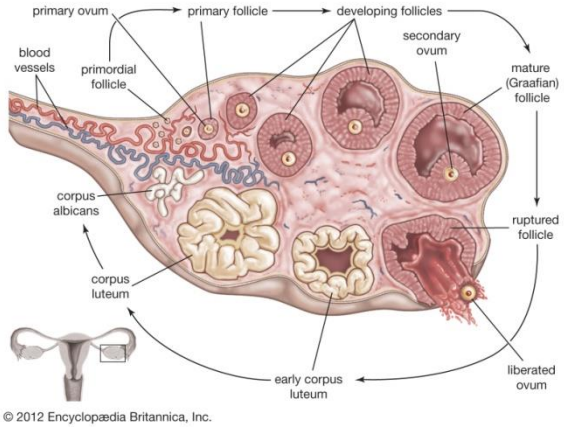
INTRODUCTION

Polycystic means many cysts. Polycystic ovarian Disease is a complex disorder of chronic oligoanovula-tion or oligomenorrhoea and clinical or biochemical hyperandrogegism. Genetic and environ-mental fac-tors may contribute to this disorder and may affect 14-34 age of women .This is one of the main reason for infertility. Women affected with this syndrome often have ovulatory dysfunction hormonal disbalan-ce, hyperandrogenemia, obesity and hyper insulinemia. PCOD has life-long implications with in-creased risk for infertility, metabolic syndrome, type 2 diabetes mellitus, cardiovascular disease and endometrial carcinoma. [1]

Polycystic ovary Disease (PCOD) is a very common endocrine disorder, of uncertain aetiology, that affects an estimated 5–10% of women of reproductive age. PCOD typically presents during adolescence and is a heterogeneous syndrome that classically is characterized by features of an ovulation (amenorrh-ea, oligomenorrhoea) combined with symptoms of androgen excess (Hirsutism, acne, alopecia). [2]



PHOTOGRAPH: 1 NORMAL OVARIES VS PCOD OVARI



PHOTOGRAPH: 2 OVULATION

Polycystic ovary disease (PCOD) is an endocrine disorder associated with metabolic change in women of reproductive age. It is the most common cause of infertility with physical, mental and hormonal imbalances. The prevalence rate of polycystic ovary disease (PCOD) in India is 9.13%.[3]

It is characterized by irregular, short menstruation, depression, obesity, acne, hair fall, cystic ovary, blood sugar imbalance, etc. Various factors responsible for polycystic ovary disease, but also stress and lack of exercise are the most important factor for exaggerating polycystic ovary disease. [3]

Clinical signs of PCOD include elevated luteinizing hormone (LH) and gonadotropin–releasing hormone (GnRH) levels, whereas follicular-stimulating hormone (FSH) levels are muted or unchanged. As a result of the increase in GnRH, stimulation of the ovarian thecal cells, in turn, produces more androgens.[4]

The word yoga is derived from the Sanskrit root yuj, which means to join or yoke. Philosophically, yoga refers to the connection of the individual self with the universal self. Yoga is one of the six branches of classical Indian philosophy and has been practiced for thousands of years.[5]

Yoga is an ancient discipline designed to bring balance and health to the physical, mental, emotional, and spiri- tual dimensions of the individual. Yoga is often depicted metaphorically as a tree and comprises eight aspects, or ‘‘limbs:’’ yama (universal ethics), niyama (individual ethics), asana (physical postures), pranayama (breath control), pratya- hara (control of the senses), dharana (concentration), dyana (meditation), and samadhi (bliss). Long a popular practice in India, yoga has become increasingly more common in Wes- tern society. In a national, population-based telephone survey (n 1⁄4 2055), 3.8% of respondents reported using yoga in the previous year and cited wellness (64%) and specific health conditions (48%) as the motivation for doing yoga.[6]

Yoga is the union of individual self, jeevatma, with the universal self, paramatma. It is the communion of the human soul with the divinity. Simple meaning of Yoga is union. Yoga is the integration and harmony between thoughts, words, and deeds or integration between head, heart and hands. [7]

NEED *OF STUDY*

Many researchers have studied the individual effect of Suryanamaskar and pelvic opening yoga among with diet and life style mordification but there is no research done without a combination of these two and any diet and lifestyle changes. Thus, it is necessary to conduct the study on Effect of Yoga on PCOD.

AIM AND OBJECTIVES OF THE STUDY

AIM OF STUDY:

To evaluate effect of yoga in PCOD.

OBJECTIVES OF STUDY:

1. To assess and compare the changes in BMI in PCOD before & after 3 months of Yoga.
2. To assess and compare the Oligomenorrhea (irregular menstruation) in PCOD. Before and after 3 months of yoga
3. To assess and compare yoga therapy in PCOD before and after 3 months of Yoga therapy.

HYPOTHESIS

1. **Null hypothesis:**
   There will be no significant impact of yoga in management of symptoms of PCOD.

2. **Research hypothesis:**
   There will be significant impact of yoga in management of symptoms of PCOD.

MATERIALS AND METHODS

STUDY DESIGN - A Quasi- experimental one- way study
SOURCE OF DATA - Hospitals (Ahmedabad)
POPULATION - 18-30 adolescent girls
SAMPLING METHOD- convenient sampling
SAMPLE SIZE - 30
DURATION OF THE STUDY - 3 months
TRETMENT DURETION - 6 session per week for 3 months

METHOD OF COLLECTION OF DATA

1.Inclusion criteria:

- Age limitation 18 to 30
- Menstrual irregular symptoms with PCOD
- Dysmenorrhea
- Obesity with symptoms with PCOD

2.Exclusion criteria :

- PCOS
- Infertility
- Patient takes any treatment or therapy

MATERIALS AND TOOLS USED

- Yoga Mats
- Pillow
- Blocks
- Mobile phones

OUTCOME MEASURES

BMI (Body Mass Index)

- It is a measure of body fat based on your weight in relation to your height. It is more of an indicator than a direct measurement of a person's total body fat. As the BMI score increases, so does the
- person's total body fat increases.
- Formula to check BMI is BMI= weight/ [height (m2)
- BMI weight ranges: Less than 18.5 = Underweight , Between 18.5 - 24.9 = Healthy Weight, Between 25 - 29.9 = Overweight, Over 30 = Obese.

VMSS (verbal multimensiona scoring system) [8]

- The Verbal Multidimensional Scoring System (VMDS) measures both pain and related systemic signs and symptoms, while the Visual Analogue Scale measures only pain. Hence, primary dysmenorrhea was measured in different degrees of severity in different studies. Dysmenorrhea or pain during menstruation is commonly seen in young women and largely impacts their quality of life. Pain medications are largely used to tackle this situation; however, they have side effects with regular use.

METHODOLOGY

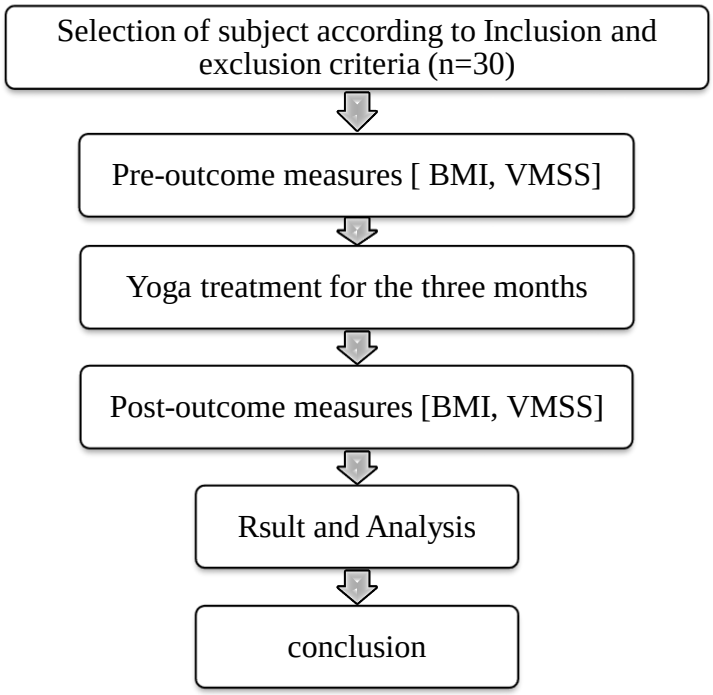


CHART 1: CHART OF STUDY PROCEDURE

The study a quasi -experimental one way study was undertaken by collecting data by convenient sampling of 18-30 age adolescent girls. First of all 30 patients will be selected according to the inclusion and exclusion criteria from the hospitals. Newly diagnosed and a case of PCOD but not under treatment. The patients have already diagnosed dysmenorrhoea severity. All of that patients presenting with complaints of weight gain, irregular periods from several years, lethargy, increased appetite and heaviness in the body.

At the second stage Informed consent was obtained from all the participants. Following which the study was initiated a thorough history was collected using questionnaire in favor of pre outcome measurement.

From all the participants including personal details such as name, age, address and phone number, medical history of any menstrual irregularities (Amenorrhoeal Oligmenorrhoea /menorrhagia) Hyperandrogenism features like (Hirsutism, Acne, Alopecia), history of other exclusion features were collected in detail. As well the Physical examination must be taken in this General examination was done

Height in inch's and weight in kilograms were measured and Body Mass Index (BMI) was calculated as weight/height in meter square; additionally VMSS (verbal multidimensional scoring sysrem) to assessment as concerns to dysmenorrhoea severity. All of that patients presenting with complaints of weight gain, irregular periods from several years , lethargy, increased appetite and heaviness in the body .

After the second stage, all participants will be asked to sign a consent with clear information about the research which will provide a clear understanding of the research project , procedure or treatment and clinical trial. It also includes information of possible risks and benefits, including what the researcher is doing in the field. If a person chooses to take part in the treatment, procedure, trial, or testing, she needs to signs the form to give official consent.

Next stage would be yoga therapy (yoga specific for PCOD along with weight loss) .Therefore for the management of obesity physical exercise, fat reducing medicine and diet is necessary. In this case only Yogasanas were advised without any medicinal treatment and diet management.

Patient prescribes Surya Namaskar, along with pelvic opening asanas. In these yoga package these asanas will include: Suryanamaskar (start with 5 rounds and then slowly increasing the number), Baddhakonasana, Supta baddhakonasana, Ustrasana, Shalabhasana (with 7 repetition) .

These Asanas practiced early in the morning with empty stomach for 45 mins to one hour per day for 3 months. Prior to therapy 6 days of training was given to participant. Participant didn't had any previous experience of yoga practice. Total duration of each asanas during six days training period for three months. While doing these asanas abdomen, thighs and spine are stretched. Stretching helps to reduce extra fat which is accumulated over abdomen, thighs. That's why these Asanas were selected for the study.

PHOTOGRAPH: 3 PATIENTS PERFORMING YOGASANAS

PHOTOGRAPH: 4 PATIENTS PERFORMING YOGASANAS

When patient start practicing yoga, patient was made to perform for 35 mins for seven days of training according to the schedule given in table number 1.

After 7 days yogasana training, duration of asanas was increased. This was followed for 1 hour 15min daily in the morning with empty stomach. Schedule of Yoga therapy practiced for three months by patient as shown in table number 2.

Sr.No.	Yogasanas	Duration	repetition	Rest	Total duration
1	Suryanamaskar	10 min	5	-	10 min
2	Baddhakonasana	30 sec	5	30 sec	3 min
3	Suptabaddhakonasana	30 sec	5	30 sec	3 min
4	Ustrasana	30 sec	5	30 sec	3 min
5	Shalabhasana	30 sec	5	30 sec	3 min

TABLE: 1 YOGA TERAPY FOR SEVEN DAYS

Sr.No.	Yogasanas	Duration	repetition	Rest	Total duration
1	Suryanamaskar	10 min	7	-	10 min
2	Baddhakonasana	30 sec	7	1min	7 min
3	Suptabaddhakonasana	30 sec	7	1min	7 min
4	Ustrasana	30 sec	7	1min	7 min
5	Shalabhasana	30 sec	7	1min	7 min

TABLE: 2 YOGA TERAPY FOR THREE MONTH

In last stage After three months of regular yoga practice history was collected using questionnaire in favor of post outcome measurement from all the participants including personal details such as medical history of any menstrual irregularities (Amenorrhoeal Oligmenorrhoea /menorrhagia). Hyperandrogenism features like (Hirsutism, Acne, Alopecia), history of other exclusion features were collected in detail. In General examination, height and weight were measured in inches and kilograms respectively. In addition physical examination should must be taken and Body Mass Index (BMI) was calculated as weight/height in meter square; additionally VMSS (verbal multidimensional scoring system) to assessment as concerns to dysmenorrheal severity .

RESULT

Study variables were done before starting physiotherapy sessions on group and at the end of the study, study variables include BMI and VMSS.

Data analysis:

Statistical analysis was performed on the data obtained from 30 patients. Data was analyzed using Social Science statistics. It was a website which working with statistics. Descriptive statistics for all outcome measures were expressed as mean, standard deviations and test of significance such as paired‘t’ test used for comparing within group and comparing between the groups. Data was considered statistically significant with $P<0.05$ and highly significant at $p<0.01$. Pre and post mean difference of BMI shows 33.28 ± 26.64 in pre date collection and 28.36 ± 21.77 in post data collection. As $p<0.05$ there is significant difference between group. Pre and post mean difference values of VMSS shows 2.33 ± 14.67 and 0.93 ± 23.87. This shows a significant difference between two groups.

Group	Mean	Mean Difference	Standard Deviation	"t" Value	"p" Value
Pre Test	33.28	4.29	26.64	4.29812	P<0.05
Post Test	28.36	4.29	21.77		P<0.05

TABLE 3: PAIRED "T" TEST VALUES FOR BMI

Group	Mean	Mean Difference	Standard Deviation	"t" Value	"p" Value
Pre Test	2.33	1.4	14.67	-6.65226	P<0.05
Post Test	0.93	1.4	23.87		P<0.05

TABLE 4: PAIRED "T" TEST VALUES FOR VMSS

Outcome Measures	"t" Value	"p" Value
BMI	4.29812	P<0.05
VMSS	-6.65226	P>0.05

TABLE 5: INDEPENDENT "T" TEST VALUES

DISCUSSION

Obesity, hormonal imbalance, mental health problems such as depression, anxiety, stress, etc are among the most common reasons for individuals to seek treatment with Yoga, Asanas and Pranayama. Yoga encourages one to relax, ease the breath and focus on the present,shifting the balance from the sympathetic nervous system and the flight-or-fight response to the parasympathetic system and the relaxation response. It effects are mainly calming and restorative; it lowers breathing and heart rate, decreases blood pressure, lowers cortisol levels, and increases blood flow to the intestines and vital organs.[9]

Yoga calmness of the mind and create a sense of well-being, feelings of relaxation, improved self-confidence, improved efficiency, increased attentiveness, lowered irritability, and an optimistic outlook on life, it also help us treating the symptoms of PCOD such as obesity, stress and hormonal imbalance. It optimizes the body's sympathetic responses to stressful stimuli and restores autonomic regulatory reflex mechanisms associated with stress. The regular practice of Yoga results in lower anxiety, heart rate, respiratory rate, blood pressure, and cardiac output in students practicing yoga and meditation. Consistent yoga practice improves depression and can lead to significant increases in serotonin levels coupled with decreases in the levels of monamine oxidase, an enzyme that breaks down neurotransmitters and cortisol.[9]

Yoga increases blood flow and levels of hemoglobin and red blood cells which allows for more oxygen to reach the body cells, enhancing their function and reducing stress and improving metabolism.Many yoga asanas and postures lowers the resting heart rate, increases endurance, and can improve the maximum uptake and utilization of oxygen during exercise.[9]

The significant positive effects of yoga in reducing stress, anxiety, and depression have been confirmed.

CONCLUSION

Daily yoga for 30 minutes with 5 Asanas along with meditation and Shavasana helps in weight reduction and stress management which ultimately stabilize the normal function of hypothalmo-pituitary–ovarian axis and cure PCOD.

SUMMARY

A study was conducted to evaluate the effect of Yoga therapy on autonomic function and adrenal fatigue in patients with polycystic ovarian disease. 30 PCOD patients were participated in the study & they were given Yoga therapy for 45mins to one hour per day for 3months with 6 days for week. Before and after the therapy, subjects underwent pre and post outcome measurement. The results showed not only a significant reduction in BMI but also regular period cycle per month.

LIMITATION

- Small sample size
- Age group is limited in 18-30 years

FUTURE RECOMMENDATION

Further research can replicate these findings in other variation such as large group or large age group. In addition, comparison between two groups as well as comparison between exercises and yoga. Lastly, yoga therapy with diet plan.

ABBREVIATIONS

ABSTRACT

Background: Perimenopausal period is characterized by a continuous decline in ovarian function due to which women are vulnerable to various physical and psychological symptoms affecting quality of life. Currently these symptoms are managed by hormone replacement therapy. However, hormonal therapy can cause complications including malignancy which has resulted in search for various alternative therapies to improve the quality of life (QOL). Yoga is one such alternative therapy shown to enhance the QOL at all stages of human life associated with the chronic illness. There are very few scientific studies regarding the effect of yoga on perimenopause and in this study, we investigated the effects of yoga therapy on physical and psychological symptoms using the standardized questionnaire.

Objective: To study the effect of yoga therapy on physical and psychological symptoms of perimenopause.

Materials and Methods: It is a prospective non-randomized control study of 56 perimenopausal women with 12 weeks of intervention. The subjects were divided in two groups with either yoga therapy [n = 28] or exercise [n = 28] as the interventional tool. The symptoms control and QOL before and after intervention in both the groups were assessed by using the MENQOL which is standardized questionnaire.

Results: The perimenopausal symptoms in all domains were improved by yoga therapy, thus significantly improving the overall QOL compared to the control group.

Conclusion: This study clearly demonstrates the effectiveness of yoga therapy in managing the distressing perimenopausal symptoms. It is easy, safe, non-expensive alternative therapy helping the well-being of perimenopausal women and must be encouraged in the regular management of perimenopausal symptoms.

Key Words: MENQOL questionnaire, perimenopausal QOL, yoga therapy.

INTRODUCTION

Menopause is an important event in the life of a women when reproductive capacity ceases. During this transitional phase, woman exhibits severe and multiple symptoms. Frequently reported symptoms fall into several categories, including physical disturbances such as hot flushes, psychological complaints such as mood swings, and other changes that may impair personal or social interactions and diminish the overall quality of life.[1] It was seen that in 1990, there were an

estimated 467 million women in this state and this number is expected to increase to 1,200 million by the year 2030. [2]

According to the Indian Menopause Society [3] there will be a large increase in the perimenopausal women in India also. Most women in India over the age of 45 years do not understand the changes taking place in their bodies and spend their valuable years of life battling problems and diseases associated with perimenopause. Hence it becomes very important to develop methods and treatment plans to control perimenopausal symptoms and thereby to improve the quality of life of this large group of women.

DIFFERENCE BETWEEN PERIMENOPAUSE AND MENOPAUSE: Perimenopause is the period of a woman's life shortly before the occurrence of menopause. A women's body will begging the process of menopause meaning the hormone production from the ovaries is beginning to decline.

SYMPTOMS: The common symptoms include

- Irregular menses - As ova production in ovary reduces oestrogen production becomes erratic leading to Irregular menses
- Hot Flashes - Due to blood vessels dilation near the skin as a result of reduced estrogen
- Night sweats - Due to hot flashes
- Weight gain - oestrogen deficiency leads to weight gain
- Mood swings - Perimenopause has increased risk of depression
- Breast tenderness - Due to oestrogen induced water retention
- Alteration of blood cholesterol - Elevated oestrogen favours high density lipoprotein which reduces blood cholesterol
- Low bone density - oestrogen is involved in maintaining equilibrium of calcium in bone

BENEFITS OF YOGA IN PERIMENOPAUSAL WOMEN:

1. It relieves stress: yoga can also help women better manage and support Overall mood
2. A consistent practice may reduce blood pressure: Some research shows blood pressure may increase after menopause due in great part to the hormonal changes that take place in the body. Fortunately, yoga is a traditionally utilized antidote. A consistent practice may help promote better oxygenation and blood circulation throughout the body.
3. Yoga promotes good joint health: Research shows a frequent, and consistent yoga practice may help relieve joint pain Not all menopausal women have arthritis, but the condition does increase with age.
4. Yoga may help lead to fewer hot flashes.

NEED OF STUDY

Yoga, the traditional Indian body-mind science has been used effectively in various health disorders affecting almost all the major organ system including cardiovascular, respiratory, neuroendocrine, gastrointestinal and musculoskeletal system. [12-15] Since perimenopause also affects several organ systems, this study is conducted to evaluate the effects of yoga therapy on menopausal symptoms.

AIM

- To study the effects of Yoga Therapy on Physical and Psychological Quality of Perimenopausal Women

OBJECTIVE

- To study the effects of Yoga Therapy on Physical Quality of Perimenopausal Women
- To study the effects of Yoga Therapy on Psychological Quality of Perimenopausal Women

HYPOTHESIS

1) NULL HYPOTHESIS

There are no significant effects of Yoga Therapy on Physical and Psychological Quality of life Perimenopausal Women.

2) EXPERIMENTAL HYPOTHESIS

There are significant effects of Yoga Therapy on Physical and Psychological Quality of life Perimenopausal Women.

METHODOLOGY

Study Design: An Experimental Study
Source Of Data: Near Ahmedabad
Population: Perimenopausal Women
Sampling Method: Random Sampling
Duration Of Study: 3 Months
Sample Size: 56

Materials and Tools Used:

1. Consent form
2. Pen,
3. Pencil
4. Paper
5. Plinth and
6. Pillow
7. Assessment form

Inclusion Criteria:

1. Aged between 40-50 years,
2. Subjects willing to participate,
3. Subjects able to practice yoga or exercise protocols and,
4. Subjects who are having perimenopausal symptoms.

Exclusion Criteria:

1. Women who were already practicing yoga for a month or more,
2. Women with surgical menopause and receiving any kind of hormone therapy and
3. Active psychological disorders or any other medical disorders.

Outcome Measures:

MENOPAUSE-SPECIFIC QUALITY OF LIFE QUESTIONNAIRE (MENQOL) [13]

The self-administered questionnaire utilized in this study included socio-demographic information with menstrual history and the menopause-specific quality of life questionnaire (MENQOL). MENQOL is a self-administered, 'scaled' 29-item survey questionnaire, designed to measure quality of life in menopausal women and also to measure the extent to which an individual is affected by menopausal symptoms. It comprises the four domains, Vasomotor, Psychosocial, Physical and Sexual, which are graded separately.

Procedure:

This interventional study included 56 perimenopausal women divided into two groups. One group practiced yoga therapy (test group, n = 28) and the other practiced a set of physical exercise (control group, n = 28).

The subjects were from local community and recruited through personal contacts with various women's organizations, clubs and self-help groups. The informed oral consent was obtained from the subjects before starting the intervention.

After taking informed consent patients were divided into 2 groups by simple random sampling method and treatment was given for 3 months.

Group A: Subjects of these group received Yoga therapy.

Group B: Subjects of these group received conventional treatment (Exercise Program).

The intervention program in both groups were started by collecting the baseline data, teaching and practicing the respective protocols for 45 minutes every day, follow-ups and collection of post-interventional data after 12 weeks of practice.

FLOW CHART OF THE STUDY PROCEDURE

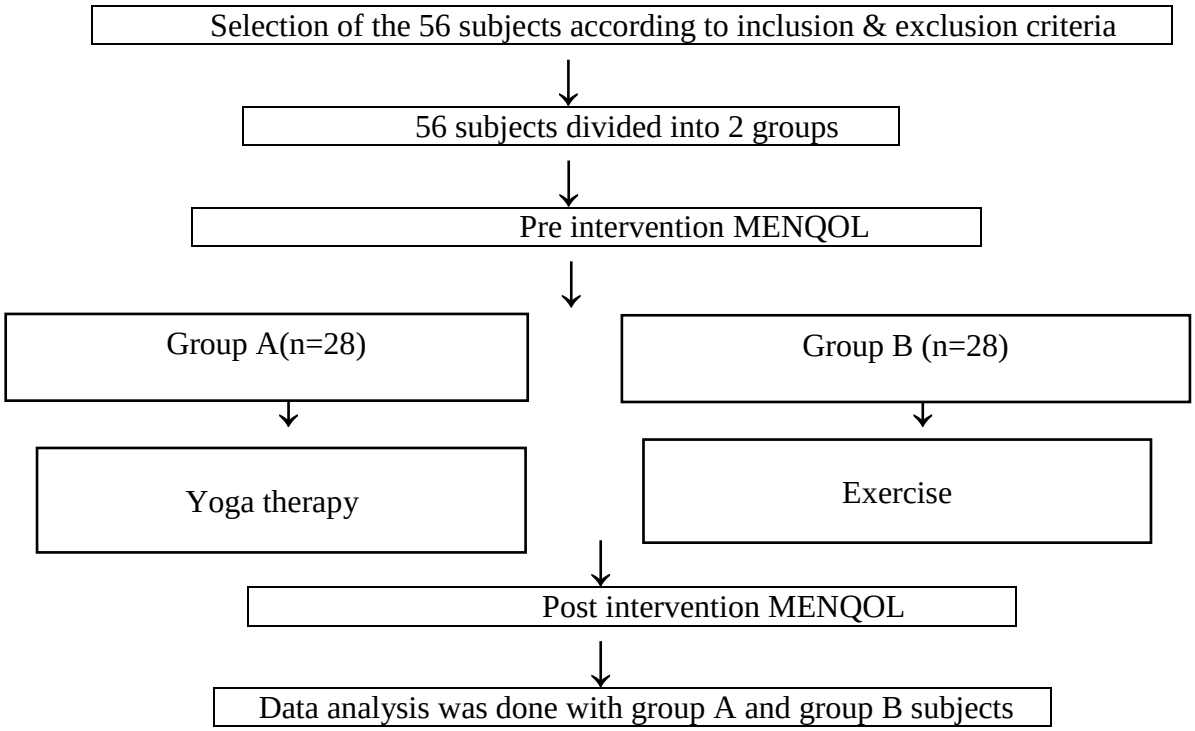

Figure 1: Flow chart of study Procedure

The yoga therapy module used was developed on the basis of Patanjali yoga [16] and Hatha yoga [17] to address the physical, psychological and emotional symptoms with suitable practice of asanas, pranayama and dhyana to result in improvement of overall quality of life. The control group practiced a set of exercise program.[18]

GROUP A: YOGA THERAPY (TEST GROUP)

1. ASANAS (Body postures)

- Sitting: Vajrasana, supta vajrasana Pascimottanasana, Poorvatanasana, Janusirsasana, Upavistakonasana, Baddhakonasana, Vakrasana, Ashvinimudra.
- Standing: Tadasana, Trikonasana, Parshvakonasana.
- Lying on the back (supine): Pavanamuktasana, Padottanasana.
- Lying on the stomach (Prone): Bhujangasana, Shalabhasana, Dhanurasana, Paryankasana.

Figure 2: Asanas

2. PRANAYAMA (Breathing practices)
    - Anuloma-viloma (alternative nostril),
    - Surya bhedana (right nostril),
    - Chandrabhedana (left nostril),
    - Sheetali (through tongue) and
    - Bhramari (honey bee sound during exhalation).

3. Relaxation: Deep relaxation in shavasana (corpse pose).

4. Meditation: 'So Ham' dhyana sitting in meditative postures like swastikasana

GROUP B: EXERCISE INTERVENTION (CONTROL GROUP)

1. Loosening exercises:
    - Sitting: Passive rotation of toes, Toe bending, Ankle bending, Ankle rotation, Knee bending, Knee rotation, Knee cap tightening, Half butterfly, Full butterfly, Neck bending, Neck rotation.
    - Standing: Waist rotation, Wrist rotation, Shoulder rotation.
    - Each one repeated for 10 rounds or 10 rotations.
2. Strengthening exercises (While standing/ Sitting).
    - Wrist — Stretching arms straight in front, make the tight fist, palm facing down, move the fist up and down vigorously from the wrist-10 times.
    - Palms — Holding near the chest bending at the elbow, spread the fingers, and move palms up and down vigorously from the wrist.
    - Fingers — Throwing out the arms in front, give the fingers of both the arms the shape of the hood of cobra, stiffen the entire length of the arms from the shoulder joints to the finger tips till they start trembling-5 times.
    - Elbows — Stretch the arms straight down beside the body, make the tight fist of the palms, and raise the fists forward up to the level of the shoulder with a jerk-10 times.
    - Arms — Make the fists of hands with thumb tucked in, bend the elbow and raise the forearms till they parallel to the ground, push both the arms forward forcefully and vigorously to the level of the shoulder-10 times.

Figure 3: Strengthening Exercise of wrist

- Back — Spreading the legs apart as far as possible, place the hands on the hips bend backward from the waist as far as possible and then forward without bending the knees till head reaches the ground-5 times.
- Thighs — Stretch out the arms facing down straight in front at the shoulder heights, inhaling bend the knees till thighs come parallel to the ground, and then come up exhaling-5 times.
- Calves — Stretch out the arms facing down straight in front at the shoulder heights, inhaling squat and go down as far as possible-5 times. Supine rest 5 to 10 minutes.

RESULT

Statistical analysis

All pre and post data were analyzed by using SPSS Version 16. The individual variables were evaluated to determine the changes in two groups after 12 weeks. The pre and post data of MENQOL questionnaire was analyzed.

The effectiveness was calculated as 'within the group' (yoga and control group), 'between the groups' (yoga vs. control).

Sr. No.	Variables	Yoga	Control
1	Age	47.03 ± 2.56	47.54 ± 2.17
2	BMI	26.08 ± 3.07	26.89 ± 3.45
3	Menstruation regular	6	8
4	Menstruation irregular	13	11
5	No Menstruation	9	9

Table 1: Demographic Data

The largest categories of women were between 46 and 50 years of age. No significant difference was observed between the groups regarding body mass index and menstrual history is shown in Table 1. There was no significant difference between the groups ($P > 0.05$). In the psychosocial domain, large number of women from both the groups (72% to 79%) complained experiencing poor memory as the most prevalent symptom followed by feeling of anxiety, loneliness, depression and impatience. Two of the questions in this domain that is being dissatisfied with personal life and accomplishing less what I used to do were recorded more significantly by control group compared to the yoga group ($P < 0.05$) while other attributes from this domain were all comparable ($P > 0.05$). All the symptoms in the physical domain except for flatulence and muscles and joint pains were comparable in both groups without any significant difference.

Groups	Within group analysis	Mean Difference	Standard Deviation	"t" Value	"p" Value
Group A	Pre-Test Post Test	-1.59	0.64	-8.9	P<0.05
Group B	Pre-Test Post Test	-0.68	0.18	-7.09	P<0.05

Table 2: Paired "t" test values for MENQOL

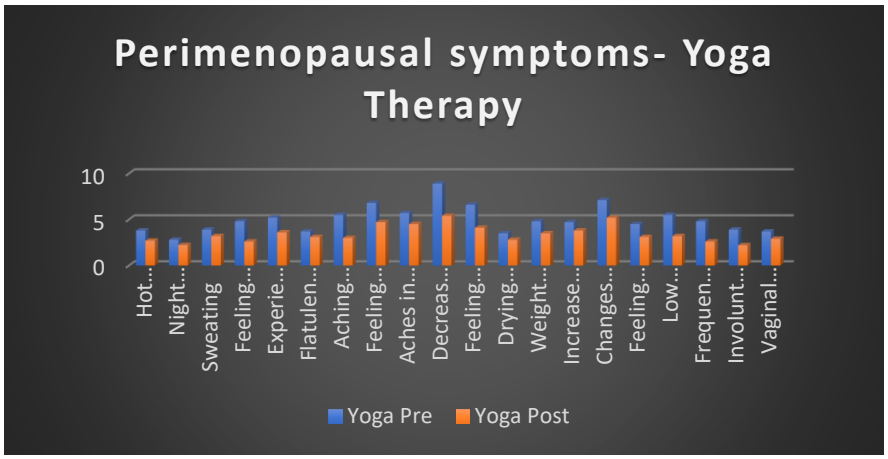

Figure 4: Yoga therapy and effect on Perimenopausal symptoms

The results of effect of yoga therapy (test group) and exercise (control group) on the symptoms of all the two domains are presented in Table 2. In the psychosocial domain, yoga therapy resulted in the significant difference in all the symptoms while exercise therapy resulted in the improvement of four symptoms but failed to provide relief for the remaining symptoms. All the symptoms in the physical domain were significantly improved in yoga group. In control group, highly significant ($P < 0.05$) decrease was observed only in one symptom and moderate in other six symptoms. The symptom of aching in muscles and joints was relieved somewhat after physical exercise and no significant change was observed in the remaining symptoms.

Outcome Measures	"t" Value	"p" Value
MENQOL	-3.48	P<0.05

Table 3: Independent "t" test values

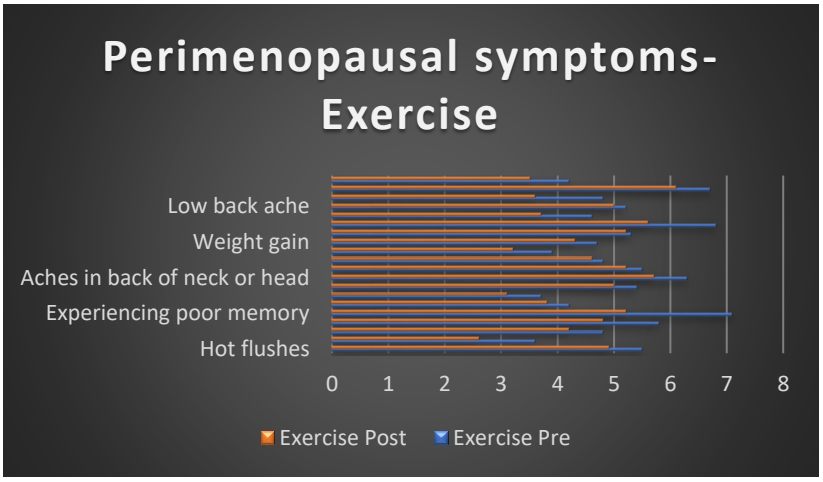

Figure 5: Exercise and effect on Perimenopausal symptoms

The effect size' was greater in yoga therapy group in all domains compared to the control group. 'Between the group effect', there was significant difference between the groups in all domain ($P = 0.53$) [Table 3]. The overall quality of life is measured by the mean of overall scores of each domain and yoga therapy group showed a very significant improvement ($P < 0.05$) compared to control group.

DISCUSSION

The present study thus clearly documents the significant presence of various perimenopausal symptoms in the local population severely affecting the quality of life. Many of these women expressed their distress and helplessness regarding these symptoms, which were seriously interfering in their day-to-day living. Thus, there is a need to search and develop a cost-effective, simple, community-based therapeutic tool to provide symptom relief and to improve health status, and in this perspective yoga has emerged as the appropriate system to deal effectively with issues related to perimenopause.

The present study clearly demonstrates the clinical utility of yoga in significantly reducing the perimenopausal symptom in all domains and thereby improves the overall quality of life. Asanas, pranayama and dhyana, the components of yoga therapy, seem to improve the symptom profile in the all domains through several physiological and biochemical mechanisms. The improvement in physical strength and fitness caused by yoga seems to be related to several factors like muscular strength and endurance, flexibility, cardiorespiratory fitness, body composition and pulmonary function.[19] The intense stretching and muscle conditioning associated with attaining and holding yoga postures increases the skeletal muscle oxidative capacity and decrease glycogen utilization, possibly caused by increased vascularization, increased intramuscular oxygen and glycogen stores or by increased numbers of mitochondria.[20] Yoga practice also may increase the absorption of the calcium from the intestine, stimulate bone remodeling and maintain the load bearing capacity of the bone; reduces the pain in the back of the head, neck, lower back and headache by influencing limbic system modulation of endogenous pain control system.[21]

This impact of yoga seems to be due to its effect on the functioning of nervous system leading to increase in alpha rhythm, intra hemispheric coherence and homogeneity in the brain [22,23] and increase in P 300 phase amplitude [19] all of which seems to enhance the cognitive processes. Menopausal anxiety can be a very difficult symptom to manage, but yoga therapy showed significant improvement compared to physical exercise. Several mechanisms like altered neurotransmitters, changed brain blood flow and brain metabolism and sympathetic activation seems to be responsible for this improvement brought by yoga practice. [24]

Compared to physical exercise group, yoga showed most significant effect in managing the symptoms of vasomotor domain. All the three symptoms in this domain, that is, hot flushes, night sweats and sweating were significantly reduced in the yoga group while no improvement was observed in any of the symptoms in control group. Especially, the improvement in hot flushes through yoga was very rewarding, since this is most difficult symptom to manage and affects the overall quality of life. The vasomotor symptom improvement brought about by yoga intervention seems to be due to its effect in modulating autonomous nervous system with special attention to decreased sympathetic nervous system activation [25] which in turn seems to affect the thermoregulation resulting in vasodilatation and sweating.[26]

The yoga postures used in this study are known to improve the tone of the muscles of pelvic region and enhance the blood circulation to the urogenital area.[27] Thus, yoga improved most of the symptom profile thus contributing significantly in the improvement of overall quality of life. Yoga is relatively simple to learn and is economical, non-invasive with multiple collateral lifestyle benefits. Group and individual practice may also help to improve lifestyle choices and health-related attitudes in part, by enhancing psychological well-being and thereby contributing significantly to chronic disease protection and health promotion.

Though most of the clinical effects of yoga are probably brought about by vagal stimulation and parasympathetic activation, the complete mechanisms underlying the reported benefits remain poorly understood. Clearly, additional high-quality research is warranted to confirm and further explore the putative beneficial effects of yoga in perimenopausal women.

CONCLUSION

This study clearly demonstrates the effectiveness of yoga therapy in managing the distressing perimenopausal symptoms. It is easy, safe, non-expensive alternative therapy helping the well-being of perimenopausal women and must be encouraged in the regular management of perimenopausal symptoms.

ABSTRACT

BACKGROUND: Chronic low back pain is defined as pain, muscle tension or stiffness localized below the costal margin and above the inferior gluteal folds, persists for 12 weeks or more. For treating Chronic Low back pain various techniques are available. Basic aim is to compare the effect of Pilates exercise and MFR technique in patients with chronic low back pain.

METHODOLOGY: After taking informed, written consent patients were divided into 2 groups by simple random sampling method. Group A received Pilates exercise plus conventional treatment and Group B received MFR technique plus conventional treatment. Both groups received treatment 4 sessions per week for 4 weeks. Pre and post intervention NPRS were measured. Data were analyzed with both groups.

RESULT: As the data followed normal distribution, parametric tests were used. Paired t test was applied to analyze pre and post outcome measures between both groups. Both the groups showed significant improvement in NPRS scores in within group analysis ($p<0.05$) but there was no statistically significant difference found in NPRS at the end of 4 weeks in between groups analysis ($p>0.05$).

CONCLUSIONS: The present study concludes that Pilates exercise along with conventional treatment and MFR technique along with conventional treatment, both are equally effective in reducing pain in patients with Chronic Low Back Pain.

KEY WORDS: Pilates exercise, MFR technique, Chronic low back pain.

INTRODUCTION

Chronic low back pain is defined as a pain, muscle tension or stiffness localized below the costal margin and above the inferior gluteal folds, which persists for 12 weeks or more[1] Exercise training has collectively been shown to be effective in reducing pain when compared with non-exercise training-based treatments in adults. [2] Risk factor of chronic low back are female sex, middle age, sedentary lifestyle as well as strenuous physical activity, occupational overload, smoking and obesity. [3]

Pilates exercise used for the core strengthening, posture and breathing pattern also. These exercises aim to improve static and dynamic stability, posture and ADLs. [4] The use of specialized Pilates exercise requirements are spring resistance, such as reformer has also recommended for Chronic Low Back Pain (CLBP) patients. [5] It has recommended in management of people with CLBP, this type of exercise helpful to strengthen deep and stabilizing muscle which support to the lumbar spine (transverse abdominis muscle). The muscles are inhibited in people with CLBP. [6]

Myofascial release (MFR) used for manual medicine which include the application of low-load, long duration of stretch to the myofascial complex with intent to restore optimal length of fascia-tissue, reduce pain and improve functional ability. Applied combined intervention of MFR with other therapeutic appear like muscular energy, soft tissue, high velocity-low amplitude thrust and cranial sacral techniques. [7]

Advance stage of research includes the progression towards more functional task giving to the patient to activate of deep muscle and global trunk muscles. [8] In recent years, increased interest in the issues fascia, which until recently was neglected in the etiology of LBP. At the same time as term is defined as fascial system- a network that has ability to transfer forces, where separate elements manually interact and form complex involved in traversing.

Those patients which suffering from long time CLBP gives rise to, restrictions within the fascial tissues. The combination of different structures of the complex lumbar-pelvic- hip joint may cause the source of pain is a considerable distance from the origin of pain. [9] Long standing limitation of motion occurring in people with risk factors for development of LBP, it's cause restrictions within the fascial tissue. Restrictions can cause abdominal tension which lead to an increase in excitability of receptors located in the fascia, bone structures involve in wrong direction, thus leading to excessive compression in the intervertebral joints. As a result, dysfunction and pain.[10]

NEED OF THE STUDY:

According to research done in past the Myofascial release and Pilates both methods individually when given shown beneficial effects but no studies were compared these methods. Both methods are individually effective in low back pain according to the previous research article but which one is more beneficial to reduce pain is not shown till now. Our need of the study is to compare both treatments so it is helpful in clinical practice for better treatment outcome.

AIM AND OBJECTIVES:

AIM: - To compare effects of Pilates exercise and MFR in people with CLBP.

OBJECTIVES: -

1. To find out the effects of Pilates exercise in CLBP on pain

2. To find out the effects of MFR in CLBP on pain

3. To compare effects of Pilates exercise and MFR on pain

HYPOTHESIS:

1. NULL HYPOTHESIS:

- There is no significant difference between effect of MFR and Pilates in chronic low back pain patients.

2. **ALTERNATIVE/ RESEARCH HYPOTHESIS:**

- There is significant difference between effect of MFR and Pilates in chronic low back pain patients.

METHODOLOGY:

STUDY DESIGN**:** A Comparative study

SOURCE OF DATA: OPD of Venus Institute of Physiotherapy

POPULATION: Chronic low back pain patient (Age between 30 to 50 years)

SAMPLING METHOD: Simple random sampling

DURATION OF STUDY: 4 weeks

TREATMENT DURATION**:** 4 sessions per week for 4 weeks

SAMPLE SIZE**:** 30 (Calculated via following formula) [11]

$N = 4\,\Sigma^2\,(Z_\alpha + Z_\beta)^2 / D^2$

N = Sample size

Σ = Standard Deviation

Z_α = Level of desired significance (1.96)

Z_β = Desired Power (0.84 for 80% power)

D = Effect size (Mean difference)

A) Group A: 15

B) Group B: 15

METHOD OF SELECTION OF SUBJECTS: -

INCLUSION CRITERIA:

- Patient's willingness to participate
- Both males and females
- Age group between 30-50 years
- Patient having chronic low back pain with more than 3 months
- Without identifiable specific anatomical/neurological factors

EXCLUSION CRITERIA:

- Any orthopedic or neurological condition of lumbar spine

- Patient with previous spinal injury
- Spondylolisthesis
- Past history of vertebral fractures
- Cancer of spine
- Tuberculosis of spine

MATERIALS AND TOOLS REQUIRED: -

1. Consent form
2. Pen, pencil, paper
3. Plinth and Pillow
4. Pilate mat
5. Transcutaneous electrical nerve stimulation (TENS) unit with gel, cotton and
6. Micro-pore

OUTCOME MEASURES: -

NUMERICAL PAIN RATING SCALE (NPRS): [12]

- The NPRS for pain is a Uni-dimensional measure of pain intensity in adults. Similar to visual analogue scale (VAS), the NPRS is anchored by describing pain severity extremes. The NPRS can be administered verbally on graphically for self-completion.
- A 11-point numeric scale with 0 representing one pain extreme (e.g., no pain), and 10 representing the other pain extreme (e.g., "pain as bad you can imagine" and "worse pain imaginable"). The patient is asked to indicate the numeric value on the segmented scale that best describes their pain intensity. Scores range from 0-10. Higher scores indicate greater pain intensity.
- Reliability: High test-retest reliability has been observed in both literate and illiterate patients with rheumatoid arthritis (r=0.96 and 0.95, respectively) before and after medical consultation.
- Validity: For construct validity, the NPRS was shown to be highly correlated to the VAS in patients with rheumatic and other chronic pain conditions (pain>6 months) range from 0.86 to 0.95.

CLINICAL INTERVENTIONS: -

All the participants/ patients of the study were advised to continue their normal routine activities but they should not take any pharmacological agents or other form of treatment Other than the designed protocol, during the period of study. After taking informed consent patients were divided into 2 groups by simple random sampling method and treatment was given 4 sessions per week for 4 weeks.

Group A: Patients of these group received Pilates exercise plus conventional treatment.

Group B: Patients of these group received MFR technique plus conventional treatment.

Conventional therapy for both groups:

Patients received conventional therapy in the form of Transcutaneous Electrical Nerve Stimulation [Pulse width - 50-300 µs, Frequency - 150 Hz, Pulse shape - rectangular shape, Intensity - 0 to 60 mA (Milliamps) (It can be varying from patient to patient), Duration - 10 minutes], hamstrings and calf stretching, cat and camel exercise, extension of trunk (cobra pose), static glutes and static back exercise for 4 days a week for 4 weeks.

FLOW CHART OF THE STUDY PROCEDURE

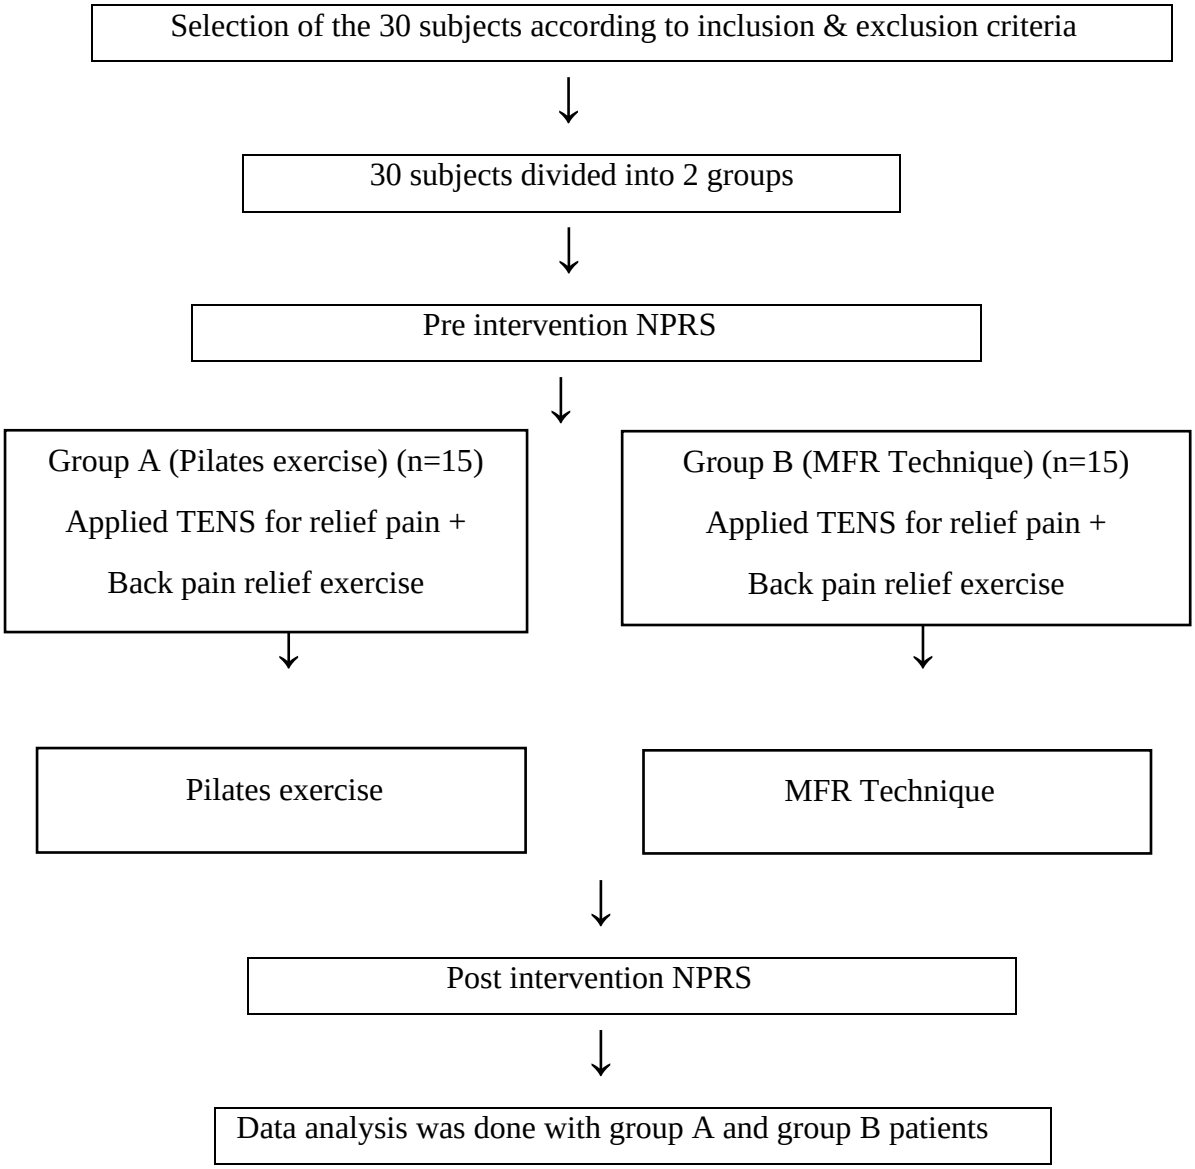

Figure 1: Flow chart of study Procedure

■ **<u>Group A [Pilates exercise plus conventional treatment]</u>:**

Pilates exercise: -

(1) <u>CURL-UPS</u>:

- Patient position: supine with knee semi-flexed
- First instruct the patient to perform the contraction of abdominal muscles and then lift the head. Progress by lifting the shoulders until the scapula and thorax clear the mat, keeping the arms horizontal.
- Hold this position as much as patient can (maximum 10 seconds) and then relax. 10 repetitions with 3 second interval.

(2) <u>BRIDGING</u>:

- Patient position: hook-lying position
- Have the patient press upper back and feet into the met, elevate the pelvis and extend the hips.
- Hold this position for 10 seconds and then relax. 10 repetitions with 3 second interval.

(3) KNEE TO CHEST:

- Patient position: supine
- Gently pull one knee up to chest until feel a stretch in lower back. Bring the knee as close to your chest as comfortably possible. Keep the opposite leg relaxed in a comfortable position, either with knee bent or with leg extended. Hold for about 5 seconds and then relax. 10 repetitions with 3 second intervals.

(4) BILATERAL STRAIGHT LEG RISING:

- Patient position: supine
- Bend the knee of one leg at 90-degree angle, planting the foot flatly on the floor. Stabilize the muscles on straight leg by contracting the quadriceps.
- Inhaling slowly, lift the straight leg at least 6 inches off the ground. Hold for 3 seconds then relax. 10 repetitions with 3 seconds interval.

(5) BIRD DOG EXERCISE:

- Patient position: Quadruped
- Place patient's knees under their hips and their hands under the shoulders. Maintain a neutral spine by using an abdominal muscles. Raise right arm and left leg, keeping shoulders and hips parallel to the floor. Hold this position for the few seconds, then lower back down to the starting position. Raise opposite arm and leg (left arm and right leg), holding this position for a few seconds. Return to the starting position. This is 1 round. Repeat this 10 times with 2 sets and each round 3 second interval time.

■ **Group B [MFR technique plus conventional treatment]:**

❖ **MFR technique: -**

- Myofascial release is a hands-on soft tissue technique that facilitates a stretch into the restricted fascia. A sustained pressure is applied into the tissue barrier, after 60 to 90 seconds. The tissue will undergo histological length changes allowing the first release to be felt. The therapist Follows the release into a new tissue barrier and holds. After a few releases the tissue will become softer and more pliable.
- Patient position: prone
- Therapist stands contra lateral to the side to be treated, at the level of patient's iliac crest. The therapist's superior hand is positioned thinner sided adjacent to the lumbar spine with extensive contact at the TFL at the level of L1 to L4 and acts as a palpation hand.
- The superior hand work as a palpation hand and initiates a direct stretch of the fascia laterally to a noticeable tissue resistance. The therapist follows the creep of myofascial tissue to initiate further stretching of the TFL and piriformis muscle. The applied force on the tissue is only moderate in the direction of the abdominal muscles.
- The duration of entire technique is 60 to 90 seconds at the same place of the lower back. [NOTE: The therapist contact (which could involve thumb, finger, knuckle or elbow) moves longitudinally along muscle fibers, distal to the proximal.]

RESULT:

Data analysis: Statistical analysis was performed on the data obtained from 30 patients. Data was analysed using SPSS (Version 16). Descriptive statistics for all outcome measures were expressed as mean, standard deviations and test of significance such as paired 't' test used for comparing data within each group and independent 't' test for comparing between the groups. Data was considered statistically significant with P<0.05. Pre and post mean difference of pain (NPRS) shows 1.46 ± 2.12 in group A and 1.73 ± 1.22 in group B. Independent "t" test values chronic LBP shows not significant difference between both groups.

Table 1: Paired "t" test values for Chronic LBP (NPRS)

Groups	Within group analysis	Mean	Mean Difference	Standard Deviation	"t" Value	"p" Value
Group A	Pre-Test Post Test	5.46 4	-1.46	2.12	-3.8977	P<0.05
Group B	Pre-Test Post Test	6.33 4.6	-1.73	1.22	-5.49	P<0.05

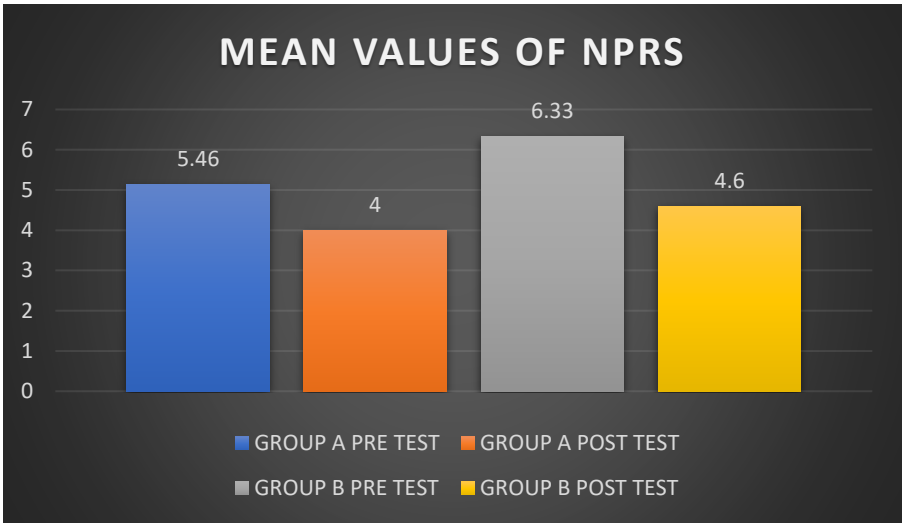

Figure 2. Mean Values of NPRS

Table 2: Independent "t" test values chronic LBP

Outcome Measures	"t" Value	"p" Value
NPRS	-1.16	0.1267

DISCUSSION:

The present study was designed to study effects of Pilates exercise and MFR technique in patients with chronic low back pain. Total 30 patients with low back pain more than 3 months were included in the study with the age group of 30 to 50 years and according to the inclusion and exclusion criteria.

After taking informed, written consent subjects were divided into two groups by simple random Sampling method. Group A received Pilates exercises plus conventional treatment and group B received MFR technique plus conventional treatment. Both groups were assessed before and after treatment duration to determine the extent of reduction of pain using Numerical pain rating scale taken as outcome measures.

At the end of 4 weeks, patients in both groups showed reduction in pain and improvement in NPRS scores on statistical analysis. The result showed that there was no statistically significant difference of effectiveness of pain between Both groups (group A and group B).

So here, both groups were improved after intervention. By comparing NPRS measure group A showed statistically significant improvement in pain equal to the group B. The mean difference of NPRS is almost equal to the both groups. So, Pilates exercise along with conventional treatment and MFR technique along with conventional treatment both are equally effective in reducing pain in patients with Chronic Low Back Pain.

CONCLUSION:

The present study concludes that Pilates exercise along with conventional treatment and Myo Fascial Release technique along with conventional treatment both are equally effective in reducing pain in patients with Chronic Low Back Pain.

LIMITATIONS

- In this study age limit is 30-50 years.
- MFR technique only assessed in chronic low back pain patients.
- Long term follow up is not taken.

FURTHER RECCOMENDATION

- Study can be done with chronic low back pain patients with other age groups.
- MFR technique effectiveness can also be determined for acute low back pain patients.
- Long term follows up of the patients can be taken to compare sustainability of treatment.

ABBREVIATIONS

- **CLBP** = Chronic low back pain
- **MFR** = Myofascial release
- **LBP** = low back pain
- **ADLs** = Activities of daily living
- **TENS** = Transcutaneous electrical nerve stimulation
- **TFL** = Tensor fascia late
- **SLR** = Straight leg raise
- **NPRS** =Numerical pain rating scale
- **VAS** = Visual Analogue Scale

INTRODUCTION

Chronic pain is a major public health problem all over the world.[1] The chronic low back pain is define as the chronic lower back pain is established by the persistence of pain beyond 3 month of symptoms.[1] CLBP can have a debilitating effect on patient's lives, resulting in disability and reducing their ability to carry out activities of daily living.[1] Acute low back pain is pain remains for less than 6 months.[2] Sub-acute back pain is back pain for between 6weeks and 3moths.[2]

Low back pain can affect all age and genders.[2] back pain is then further categorized into specific or non-specific back pain. Non-specific back pain refers to a pain is diagnosed when the cause of back pain is unknown. And specific back pain refers to a specific cause

for the pain, for example an infection or a fracture.[3] back pain is a major health issue in western countries and 60%-80% of adults are likely to experience low back pain[4]. Chronic pain is a significant health problem that leads to major consequences for the individuals afflicted, their families, and society.[4] Chronic pain can lead to various disabilities. Currently, there are in general no curative options for chronic pain, so treatments focus on reducing pain and disability.[4]

Physical activity and physical exercise are commonly prescribed as treatment for chronic pain. Physical activity is defined as any bodily movement produced by skeletal muscles that results in energy expenditure[5]. Physical exercise is described as a subset of physical activity characterized by planned, structured, and repetitive physical activities with an objective to maintain or improve physical fitness.[5] Because the terms physical activity and physical exercise are often used 3 interchangeably in the literature, the term physical activity and exercise (PA&E) is used in this study[6]. PA&E interventions for chronic pain patients can include aerobic exercises, strength exercises, and motor control exercises[6]. PA&E as treatment has shown significant improvements (up to medium effect sizes) for pain intensity, physical disability, and psychological distress in chronic neck pain, chronic low back pain.[6]

WHO defines physical activity as any bodily movement produced by skeletal muscles that requires energy expenditure – including activities undertaken while working, playing, carrying out household chores, travelling and engaging in recreational pursuits.[7] An increase in physical activity is one of the measures that is said to have the greatest positive effect on public health.[7] Physical activity plays an important role in the prevention and treatment of chronic musculoskeletal pain, but chronic pain may implicate a poor rehabilitation outcome.[7] PA increases the blood flow to the back which is important for the healing process of the soft tissues in the back.[7] Physical activity can reduce the risk of chronic disease including cancer, depression, cardiovascular diseases.[8] physical activity is reduced in the people who is suffered from chronic pain.[8]

Activity has been identified as the most important health-related behavior to change, the patients ask health care staff for support in making lifestyle changes.[8] Physical activity increases the blood flow to the back which is important for the healing process of the soft tissues in the back.[8]

The term "physical activity" should not be confused with "exercise", which is a subcategory of physical activity that planned, structured, repetitive, and aims to improve or maintain one or more components of physical fitness.[8] Physical activity to increase aerobic capacity and muscular strength, especially of the lumbar extensor muscles, is important for patients with CLBP in assisting them to complete activities to daily living.[8]

Pain is a subjective and personal experience, and its presence in the chronic form brings not only biological changes but emotional, cognitive and also behavioral changes.[8] The Back Pain Attitudes Questionnaire (Back-PAQ) was developed following these Interviews with people experiencing acute and chronic LBP. It aims to assess beliefs which underlie common attitudes about back pain[9]. Evidence showed that patients with chronic pain that had depression, anxiety and anguish have reported higher intensity of pain and disability.[10] A considerable body of research, based on cognitive-behavioral theory, has established the importance of individuals' pain-related cognitions and coping responses in their adaptation to chronic pain.[11] Beliefs and attitudes influence the acceptance, the results and the satisfaction

with treatment, also impacting the capacity of individuals to build an active and satisfactory life, despite the pain.[12]

For the beliefs facing pain, the Brief Pain Inventory (BPI-brief) was used, validated for the Portuguese language in 2006.[12] The purpose of this instrument is to evaluate the attitudes and beliefs facing pain in patients with non-oncologic chronic pain[12]. It has 30 items corresponding to seven domains: solicitude, emotion, medical cure, control, disability, physical damage, and medication.[12]

The "solicitude" domain relates to how much the patient believes that his/her family and other people should be more solicitous during the pain episodes. "Emotion" relates to the belief of the emotional effects, good or bad, in the painful experience."Medical Cure" relates to how much the patient believes in medicine to cure his/her pain. "Control" relates to how much the patient believes that he/she has control over his/her pain. "Disability" relates to how much the patient believes that the pain has disabled him/her. "Physical Damage" relates to how much, in the patient's point of view, the pain hurts him/herself, and because of it, exercises should be avoided."Medication" relates to how much the patient believes that drugs are the best treatment for chronic pain.[12]

Beliefs are culturally learned certainties; they are each individual's notion concerning its own reality, of the others and of the space, which interferes with the behavior[12]. Beliefs have been described as 'a cognitive process resulting in a concrete cognition of how we think things are'.[13] Attitudes are organized in affective arrangements, relatively stable, that reflect the trend to respond positively or negatively to something or some event. Both are formed from personal experiences[14]. Attitudes are 'a more complex cognitive state involving beliefs and feelings as well as values and predispositions to act in a certain way'.[15] Beliefs and attitudes influence the acceptance, the results and the satisfaction with treatment, also impacting the capacity of individuals to build an active and satisfactory life, despite the pain.[16]

Beliefs about a stressor such as pain, and in particular, appraisals of threat, influence an individual's coping responses (Lazarus, 1993). Coping has been defined as `constantly changing cognitive and behavioral efforts to manage specific external 6 and/or internal demands that are appraised as taxing or exceeding the resources of the person'[17]

Review question

- **What is the attitude and belief towards physical activity in chronic low back pain?**

- **What is the most appropriate treatment to cure the chronic low back pain?**

NEED OF STUDY

NEED OF STUDY

- To understand determinants of belief and attitude towards physical activity and exercise in patients with chronic low back pain.

OBJECTIVE OF REVIEW

OBJECTIVE OF REVIEW

- To identify attitude and belief towards physical activity and exercise in chronic pain.
- To identify attitudes and beliefs about LBP in the general population to analyse their association with individual characteristics and the belief that exercise is an effective treatment for LBP.

HYPOTHESIS

- ***Null Hypothesis(H0):***

There will be no effect or zero pain relief in patient with chronic low back pain.

- ***Alternative Hypothesis(H1):***

There will be significant effect or progress in pain relief in patient with chronic low back pain.

METHODOLOGY

- **KEYWORDS USED FOR SEARCH :**
  - Chronic low back pain, Attitude and belief towards physical activity and exercise

- **SEARCH STRATEGY :**
  - For the literature review, we used standard search strategies involving the querying of online databases MEDLINE (pub med) , Google scholar using key words followed by relevant articles. We included articles in overview.
  - Eligible criteria for the articles were :

Eligible criteria for the articles were:

- Duration of publication : 2013 Onwards
- Article should be in English language
- Age criteria : 45 – 65 years
- Article that assess the physical attitude and the need of exercise
- Exclusion criteria for the articles were :
- Unpublished articles
- Article which published in another language

➢ **DATA SEARCHED** :

- To identified potentially relevant articles in the medical
- Literature, we searched MEDLINE (PUBMED), Google scholar, Sci-hub data bases

➢ **DATA SYNTHESIS :**

- Narrative synthesis of data will be done.

YEAR	2018
STUDY DESIGN	Qualitative interview study
AIM& OBJECTIVE	The purpose of this study was to describe how patients with chronic pain experience physical activity and exercise (PA&E).
OUTCOME	International Physical Activity Question naire (IPAQ) Hospital, Anxiety and Depressio n Scale (HADS), Pain Self- Efficacy Questionnarie (PSEQ), Fear Avoidance Beliefs Questionnarie(FABQ), Psychological.
REMARKS	Physical activity was highly valued in daily life although experiences of PA&E were characterized by difficulties and failure. A will to engage in desired PA&E was apparent, but it was seldom successful even though the participants tried a variety of strategies. This intention– behavior gap identified might be related to the pain condition as well as to motivational aspects, self- efficacy, and action-control, a conclusion that requires careful analysis and support when PA&E is applied as treatment for chronic pain.

YEAR	2008
STUDY DESIGN	Systematic review
AIM& OBJECTIVE	To identify psychosocia l predictors of failureto return to work in non-chronic (lasting less than3 months) non-specific low back pain (NSLBP)
REMARKS	To predict work outcome in non-chronic NSLBP, psychosocial assessment should focus on recovery expectation and fear avoidance.The importance of fear avoidance beliefs in chronic pain has been established and it appears these beliefs and behaviours also play an important role in the non-chronic phase of NSLBP and can assist in predicting work outcome.

RESULT

RESULT

275 records were identified using databases searching. Duplicates screening was performed and 6 articles were removed in duplicates screening and than 3 reviews independently scanned the abstract and title or both and determined which studies were to be assessed further and if there were any discrepancies it were then further remove by the supervisor. Prisma flowchart was adapted for the study selection. Following it 275 studies were screened after the duplicates were removed out of which 6 studies were screened after the duplicates were removed. Furthermore excluded as full texts of 67 articles were screened out of which studies were excluded due to many reasons as mentioned in prisma flowchart of study selection. At last we included 13 studies in our data synthesis. The detail of study used in the data synthesis were be mentioned I the data extraction table which include the following detailed: author and year of publication, study design, aim and objective, outcome measure and remarks.

In this study we have observed that chronic low back pain often present dysfunction belief and attitude in relation to pain and that such belief showed in many cases, an association with intensity of pain anxiety and depression. A large proportion of respondents believed that they needed to protect their back to prevent injury; we theorise that this belief may result in reduced confidence to use the back and contribute to fear avoidance. People experiencing back pain may benefit from more targeted information about the positive prognosis. The provision of clear guidance about levels of activity may enable confident participation in an active recovery. According to cognitive behavior therapy altering pain beliefs and improving coping skills may modified the pain. experiecnces and thereby improve the health related quality of life

A very high proportion of respondents believed they should stay active when they have back pain. Among from all the people who are suffering from chronic low back pain, women are having a increasing complain of low back pain in compare of men. If we look most specifically than we found that age group of 41-50 years are those who are suffering from chronic low back pain. In addition to that smoking in men had no significant relationship with low back pain, because those who were found positive chronic low back pain where non smoker. The assosiation of low back pain with reproductive history is found significantly. According to that those women who has history of caesarean section more prone to have a low back pain later a time. Even those who have history of sterilization.

Some study also shows that both men and women who where household and in lower socio economical status reported more back pain than those who were in higher socio economic status. We have found that low back pain in ruler housewifes is around 83%, out of those more than 50% of housewife have severe disability with low back pain. They have also significant impact of social burden on their daily life.

Chronic fatigue syndrome is characterized by severe, disabling chronic fatigue lasting for at least six months. Other symptoms can include musculoskeletal pain, sleep disturbances, impaired concentration and headaches. Patients with chronic fatigue syndrome appear to be less physically active compared with asymptomatic controls.

There is no difference in variation of physical activity levels between patients with chronic fatigue syndrome and healthy control subjects, but the validity and reliability of some methods of measuring physical activity is questionable or unknown.

DISCUSSION

DISCUSSION

The present review was intended to understand determinants of belief and attitude towards physical activity and exercise in patients with chronic low back pain. Main aim of the review was to identify what are the multiple dimension bother the patient to perform physical activity and exercise in chronic low back pain[1]. As well as the review suggests belief may result in reduced confidence to use the back and contribute to fear avoidance[2].

We have found that the prevalence of chronic low back pain more common in aged population (41-50years). In general the prevalence of LBP was higher in women (52.9%) compared to men (28.4%). The alterations in sleep due to the chronic low back pain are very common results and show the impact of this painful syndrome on the quality of life and disability of the individual[4]. Study has also showed that a reduce the level of basic activity in patient with chronic low back pain, whereas increased their sportive and leisure time activities.

There are several studies that conform to the pattern that height is not correlated with the occurrence of low back pain in women, though in men many studies reported a positive correlation[15,17,18]. This study has also examined the association between low back pain and weight. The results conform to the pattern wherein weight does not correlate with the occurrence of low back pain and is consistent with previous studies.[24] These findings provide no evidence that a greater body mass index and waist-hip ratio is associated with an increased risk of low back pain.

The current review found that treatment orientation and fear avoidance beliefs of the physiotherapist had an influence on clinical practice and advice given to patients. A therapist with higher biomedical orientation and fear avoidance beliefs towards chronic low back pain was associated with advice to restrict return to work duties and restrict return to activity, a higher perception of risk associated with work or activity, and increased certification of sick leave. Healthcare professionals' beliefs about chronic low back pain have been shown to have an influence on patient beliefs.

The findings of the present study suggest that 83% of the non working rural housewives have low back pain and activity restriction due to their pain. They have significant impact of social burden on their low back pain. High prevalence (83%) of low back pain among rural housewives is an alarming sign for our society. Better health-care measures to enhance rural housewives education about good posture, ergonomic measures, health schemes, health awareness, and activity pacing could help rural housewives.

In this study, women who have undergone caesarean section or sterilization reported more low back pain than who have not undergone these procedures. This may be due to the sedentary life style after the caesarean section. Nevertheless, it was also observed that women who have occupation described as “Physically demanding” also have higher risk of low back pain suggesting that extremes of activity are probably not ideal.

CONCLUSION

CONCLUSION

Majority of available literature review suggest that patient with chronic low back pain often present dysfunctional beliefs and attitude in relation to pain. A large population subjects believed that they need to protect their back to prevent injury: Which shows that this belief may result in reduce confidence to use the back and contribute to fear avoidance.

Key findings of this literature review are:

- The reason for chronic low back pain are multi factorial which include reduce physical activity, food habit, occupation, under lying disease.
- Patient with low back pain often present that dysfunctional belief and attitude in relation to pain.
- Chronic pain often may lead to disability.

LIMITATIONS

Limitations

- Our review includes limited number of articles so some of the causes of attitude and belief might be missed
- Number of article were very less

ANNEXURE

	AUTHORS	YEAR	STUDY DESIGN	AIM & OBJECTIVE	OUTCOME	REMARKS
1	1. Anil Chankaramangalam Mathew, Rowther Shamna Safal, Thazhuthekudiyil Sathyam Anthadan, Moosa Saira Banu, Singanallur Lakshmanan, Ravi Shankar, Bellyur Krishna Dinakar Rai, Thomas Vengall Chacko	2013	A cross sectional study	The aim of this study was to estimate the prevalence of low back pain and its association with height, fat distribution, reproductive history and socioeconomic infl uence.	HEIGHT WEIGHT BMI WEIST CIRCUMFARANCE, WEST HIP RATIO	The Back Pain Attitudes Questionnaire (Back-PAQ) was developed following these interviews with people experiencing acute and chronic LBP.23 It aims to assess beliefs which underlie common attitudes about back pain.
2	2. GARIMA GUPTA and NUPUR NANDINI	2014	A cross sectional study	The perpose of the study was to evaluate the prevalence of low back pain in non-working rural housewivwsw. also an attempt has been made to determine thew impact of social burden on loe back pain.	Nordic Musculoskeletal Questionnaire – NMQ, Oswestry Disability Index – ODI, and Zarit Burden Interview – ZBI	The findings of the present study suggest that 83% of the non working rural housewives have low back pain and activity restriction due to their pain
3	6. Rebecca gordon and Saul Bloxham	2016	Systematic Review	This paper explores the impact of back pain on society and the role of physical activity for treatment of non-specific low back pain.		Exercise intervention programmes involving either muscularstrength,flexibility, aoraeroic, fitness is beneficial for NSCLBP but not acute low back pain. Non-specific acute low back pain patients recover in 4–6 weeks with or without a treatment , and exercising should be avoided to reduce the swelling of the affected area.
4	4. Linn Karlsson Björn Gerdle Ewa-Pekka Takala Gerhard Andersson Britt Larsson	2018	qualitative interview study	The purpose of this study was to describe how patients with chronic pain experience physical activity and exercise (PASE).	International Physical Activity Questionnaire (IPAQ) Hospital Anxiety and Depression Scale (HADS), Pain Self-Efficacy Questionnaire (PSEQ), Fear Avoidance Beliefs Questionnaire (FABQ), Psychological Inflexibility in Pain Scale (PIPS)	Physical activity was highly valued in daily life although experiences of PASE were characterized by difficulties and failure. A will to engage in desired PASE was apparent, but it was seldom successful even though the participants tried a variety of strategies. This intention–behavior gap identified might be related to the pain condition as well as to motivational aspects, self-efficacy, and action-control, a conclusion that requires careful analysis and support when PASE is applied as treatment for chronic pain.
5	5.Gerthi Persson,Annika Brörsson , Eva Ekvall Hansson,Margareta Troein and Eva Lena Brandberg	2013	qualitative study	The aim of the study was to explore and understand the meaning of prescribing physical activity from the general practitioner's perspective		There is uncertainty about using PAP as a treatment since physicians lack education in non-pharmaceutical methods, the GPs do not regard the written referral as a prioritized task and rather refer to other professionals in the health care system to prescribe PAP
7	6.Monica Joessona , Susanne Bernhardssona and Maria E. H. Larsson.	2017	qualitative study	The objective of this study was to describe the experiences of and thoughts about receiving a prescription for physical activity of people with chronic musculoskeletal pain		There is uncertainty about using PAP as a treatment since physicians lack education in non-pharmaceutical methods, the GPs do not regard the written referral as a prioritized task and rather refer to other professionals in the health care system to prescribe PAP
8	7.Fernanda Martins Barbosa, Erica Brandão de Moraes Vieira , João Batista Santos Garcia	2018	cross-sectional , quantitative study	The objective of this study was to evaluate the behavior of beliefs and attitudes in chronic low back pain and to correlate them with the intensity of pain, disicability, anxiety, and depression	NPRS, BPI, CDI, HADS	This study suggests that patients with chronic musculoskeletal pain have a greater need for information and extra support to overcome existing barriers, before or when physical activity is prescribed.
9	8.D.W. Griffin a, D.C. Harmon b, N.M. Kennede	2012	systematic review	The aim of this systematic review was to determine, based on the current body of evidence, if patients with chronic low back pain have a lower level and/or altered pattern of physical activity compared with asymptomatic, healthy individuals.	Newcastle Ottawa Scale (NOS)	there is no conclusive evidence that patients eith CLBP are less active than health individuals, based on limited number of studies , there is some evidence that the distribution of activites over the course of a day is different between patients with CLBP and controls.
10	9.Janet K. FreburgerGeorge M. Holmes, Robert P. Agans, Anne M. Jackman, Jane D. Darter, Andres S. Wallace, Liana D. Castel, William D. Kaiser and Timothy S. Carey,	February, 2009	cross-sectional, telephone survey	The objective of this study was to determine whether the prevalence of chronic LBP, and the demographic, health-related, and care-seeking characteristics of individuals with the condition have changed over the past 14 years.		The prevalence of chronic, impairing LBP has risen significantly in NC, with continuing high levels of disability and care utilization. A substantial portion of the rise in LBP care costs over the past two decades may be related to this rising prevalence
11	10.Elin Dysvik, Torill Christine Lindstrøm, Ole-Johan Eikeland, and Gerd Karin Natvig	2004	survey design	The present study focused on HRQL as measured by the Medical Outcomes Survey-Short Form (SF-36) and addressed possible relationships between pain beliefs as measured by the Pain Beliefs and Perceptions Inventory (PBAPI).	,VAS, SF-36, PBAPI, HRQL	according to CBT altering pain beliefs and improving coping skills may modified the pain exeperiences and there by improve the health related quality of life.
12	12.Ivan P.J. Huijnen a,*, Jeanine A. Verbunt a,b,c, Madelon L. Peters d, Philippe Delespaul e,Hanne P.J. Kindermans d , Jeffrey Roelofs d, Marielle Goossens d,Henk A.M. Seelen	2010	cohort study	This study evaluates whether patients with Chronic Low Back Pain (CLBP) who are more depressed and/or report more pain indeed have a lower objectively assessed daily life activity level or whether they only perceive their activity level as lower	Roland Disability Questionnaire (RDQ) Baecke Physical Activity Questionnaire (BPAQ) VAS Beck Depression Inventory II (BDI-II)	the patients with CLBP, who had a higher level of depression, underestimated their daily activity level, although their actual activity level did not differ.
13	13.Judith A. Turnera, Mark P. Jensenb, Joan M. Romanoa	October 1999			NPRS	This result of the study confirm that beliefs, coping, and catastrophizing would each be associated significantly with physical disability and depression in patients beginning a multidisciplinary pain treatment program.
14	14.Gur Prasad Dureja, Paramanand N. Jain,Naresh Bhatty,Bhyana Prasad Mandal, Ram Prabhoo Murallidhar Joshi, Subrata Goswami, Karthic Babu Natarajan, Rajagopalan Iyer, D. Tahina, Pahari Ghosh Ashok Saxena, Ganesh Kadhe, Abhay A. Phansalkar	2013	epidemiological telephonic survey	The present epidemiologic study identified point prevalence of chronic pain in India, impact on individual's QoL, unveiling current pain treatment practices, and levels of satisfaction with treatment.		A signiTcant population of India suffers from chronic pain, and their QoL is affected leading to disability. A proportion of respondents receiving pain treatment were taking nonprescription medications with a majority of respondents on NSAIDs. A very few were consulting pain management specialists.
15	15.S. Slade, S. Patel, M. Underwood J. Keating	May, 2015	systmetic review	To identify and synthesize qualitative empirical studies that explored what people with non-specific chronic low back pain believe about exercise therapy and physical activity or training for the management of their condition and make recommendations for clinical practice and research.		People are likely to prefer and participate in exercise or training programs and activities that are designed with consideration of their preferences, circumstances, fitness levels and exercise experiences. In the area of exercise and low back pain research there is a paucity of qualitative data
16	16.Geneen LJ, Moore RA, Clarke C, Martin D, Colvin LA, Smith BH	2020	cochrain review	To provide an overview of Cochrane Reviews of adults with chronic pain to determine the effectiveness of different physical activity and exercise interventions in reducing pain severity and its impact on function, quality of life, and healthcare use & the evidence for any adverse effects or harm associated with physical activity and exercise interventions.	NPRS, SF-36	There is limited evidence of improvement in pain severity as a result of exercise. There is some evidence of improved physical function and a variable effect on both psychological function and quality of life. physical activity and exercise is an intervention with few adverse events that may improve pain severity and physical function, and consequent quality of life. physical activity and exercise is an intervention with few adverse events that may improve pain severity and physical function, and consequent quality of life.
17	17.Melda Boysal,Bilge Kara, M. Nuri Arda2	2012		To investigate physical activity level in patients with chronic low back and neck pain.	Oswestry Disability Index (ODI), Physical Activity Questionnaire (IPAQ), (SF-36), Sleep Quality Index (PSQI) , Beck Depression Inventory	Physical activity modification was found in patients with chronic low back and neck pain. Physical activity level, disability, sleep, depression and quality of life scores of preoperative patients with low back pain more affected than neck patients.
18	18.Tania Gardner, Kathryn Refshauge , Lorraine Smith , James McAuley c,Markus Hübscher c, Stephen Goodall	2017	systmetic review	What influence do physiotherapists' beliefs and attitudes about chronic low back pain have on their clinical management of people with chronic low back pain	FABB-PT SCORE FEAR AVOIDANCE	Both quantitative and qualitative studies showed a relationship between treatment orientation and clinical practice. The inclusion of qualitative studies captured the influence of patient factors in clinical practice in chronic low back pain. There is a need to recognise that both beliefs and attitudes regarding treatment orientation of physiotherapists, and therapist-patient factors need to be considered when introducing new clinical practice models, so that the adoption of new clinical practice is maximised.
19	19.Tomoko Fujii, Hiroyuki Oka, Kenichiro Takano2, Fuminori Asada3, Takuo Nomura4, Kayo Kawamata1, Hiroshi Okazaki5, Sakae Tanaka6 and Ko Matsudaira	June 2015	cross-sectional study	High prevalence of low back pain (LBP) in nurses has been reported globally. Ergonomic factors and work-related psychosocial factors have been focused on as risk factors.	Fear-Avoidance Beliefs Questionnaire (FABQ), Kessler Psychological Distress Scale (K-6)	A small number of nurses had chronic disabling LBP that interfered with their work. In the nurses who had any type of LBP, high FABs were significantly associated with experiencing chronic disabling LBP. FABs about physical activity might be a potential target for LBP management in nurses.
20	20.Wing S. Wong and Richard Fielding	Feb 2011	cross-sectional study	prevalence of chronic pain in the general population of Hong Kong; evaluate the relationship of chronic pain with sociodemographic and life-style factors;	NPRS, HADS, SF-36	
21	21.Ben Darlow,Meredith Perry, James Stanley, Fiona Mathieson,Markus Melloh, G David Baxter, Anthony Dowell	2014	cross-sectional study	To explore the prevalence of attitudes and beliefs about back pain in New Zealand and compare certain beliefs based on back pain history or health professional exposure.	Back Pain Attitudes Questionnaire (Back-PAQ).	A large proportion of respondents believed that they needed to protect their back to prevent injury; we theorise that this belief may result in reduced confidence to use the back and contribute to fear avoidance. Uncertainty regarding what is a safe level of activity during an episode of back pain may limit participation
22	22.Corinna Leonhardt,Dirk Lehr, Judith Luckmann,Heinz-Dieter Basler Erika Baum,Michael Pfingsten Jan Hildebrandt Michael M. Kochen,Annette Becker	2009	Across-lagged panelanalysi	The assumption that low back pain (LBP) patients suffer from "disuse" as a consequence of high fear avoidance beliefs is currently Corinna Leonhardt Dirk Lehr under debate	international physical activity questionnaire, FBQ	study demonstrate demonstrated that a fear-avoidance based physicaltherapyonlyshowedbeneficialeffectsinpatients who scored high on a FAB-scale at the beginning

21 Ben Darlow,Meredith Perry, James Stanley, Fiona Mathieson,Markus Mellish, G David Baxter, Anthony Dowell	2014	cross-sectional study	To explore the prevalence of attitudes and beliefs about back pain in New Zealand and compare certain beliefs based on back pain history or health professions exposure.	Back Pain Attitudes Questionnaire (Back-PAQ).	A large proportion of respondents believed that they needed to protect their back to prevent injury; we theorise that this belief may result in reduced confidence to use the back and contribute to fear avoidance. Uncertainty regarding what is a safe level of activity during an episode of back pain may limit participation

Abstract

Background:
Exercise is an important component of healthy lifestyle to reduce a person's risk of developing the disease and subsequent disability. Stress, anxiety, and depression are overwhelmingly prevalent across the globe during this COVID-19 pandemic, and multiple factors can influence the rate of mental health conditions. Our factorial analysis showed notable associations and manifestations of stress, anxiety, and depressive symptoms. In Corona pandemic one can easily understand that new world order has established and many things changed drastically but importance of physical activity is still at utmost importance so one shouldn't neglect importance of same.

Objectives:
To find out the association of physical activity and mental health in college going student's and to know their mental health status.

Methodology:
This study involved 150 participants between the ages of 18 to 25 years college going students. This survey based study was conducted via mail incitation.

Results:
Self-reported PA was lower post-COVID among participants reporting being previously active (mean change: - 32.3% [95% CI: - 36.3% to - 28.1%]) but largely unchanged among previously inactive participants (+2.3% [- 3.5% to +8.1%]). Decreased PA and increased screen time were associated with worsening in depression, anxiety and stress.

Conclusion:
The current findings strongly support the mental health benefits of implementing measures that promote physical activity.

Key-words:
COVID-19, physical impact, psychological impact, university students.

INTRODUCTION

COVID-19 outbreak: As per World Health Organization (WHO) - Coronavirus disease (COVID-19) is an infectious disease caused by a newly discovered coronavirus. Most people who fall sick with COVID-19 will experience mild to moderate symptoms and recover without special treatment. It was caused by a novel coronavirus, which originated from a wet market in Wuhan, China, and has spread worldwide, earning the pandemic status by WHO on March 11, 2020.[1] As of the 3rd week of July, India has emerged as the third hardest-hit country with 10, 40,980 confirmed cases of COVID-19 and 25,602 deaths and the numbers are still increasing. According to WHO, the most common symptoms: are fever, dry cough, and tiredness. Less common symptoms: aches and pains, sore throat, diarrhoea, conjunctivitis, headache, loss of taste or smell, a rash on skin, or discoloration of fingers or toes. Serious symptoms: difficulty breathing or shortness of breath, chest pain or pressure, loss of speech or movement, Seek immediate medical attention if you have serious symptoms.[2]

Owing to COVID 19, prolonged home stay may lead to increased sedentary behaviours such as spending excessive amounts of time sitting, reclining, or lying down for screening activities (playing games, watching television, using mobile devices); reducing regular physical activity (hence lower energy expenditure); or engaging in avoidance activities that consequently, lead to inactivity and contribute to anxiety and depression and stress, which in turn can lead to a sedentary lifestyle known to result in a range of chronic health conditions. Maintaining regular physical activity and routinely exercising in a safe home environment is an important strategy for healthy living during the coronavirus crisis as an improvement in mental health status of college going students. Mental health is a state of well-being in which an individual realizes their abilities and to cope up with daily stresses of life and able to do productive work and to contribute to society.[3]

Mental health has core symptoms such as anxiety, depression and stress lead to disturbance in mental health. For accurate analysis of depression, anxiety, stress standard scale is DASS-21 (Depression, Anxiety, and Stress Scales – 21) this scale was developed by Lovibond. The three-dimensional self-reporting scales assess the presence and intensity of affective states of depression, anxiety, and stress. And to measure physical Activity standard scale is IPAQ (International physical activity questionnaire) it comprises a set of 4 questionnaires, long (5 activity domains asked independently) and short (4 generic items) versions for use by either telephone or self-administered methods are available.[4]

METHODOLOGY

Research Design: Cross-sectional Survey

Study setting: Online mode

Sampling Method: Convenient Sampling

Sample size: 150

Inclusion criteria:

- Indian college-going students between 18-25
- Able to read, write and understand English language
- Has Internet facility with e-mail

Exclusion criteria:

- Mini-mental scale less than 24
- Any systemic illness (musculoskeletal, cardiovascular, degenerative, and neurological)

Data collection tool:

- Physical activity assessed by: International Physical Activity Questionnaire (IPAQ)
- Mental health assess by DASS-21 (Depression, anxiety, stress scale)

Procedure:

The study was conducted among the college-going students of the Indian population between the ages of 18 to 25 years. Participants entered into the study from different fields of education. A random selection of the participants was used. Firstly, the Google form was created and circulated on an online platform via mail. The online consent form was taken from all the participants before they answered the questions. Secondly, with respective permission, they entered into the online survey of the DASS-21 and IPAQ along with consent and demographic details. Google form consisted of three pages and a total of 28 questions. The first page was about consent and the demographic detail of the participants. The second page was about the depression anxiety, stress scale which consisted of 21 questions and the rating scale was from 0 to 3. Whereas, 0 means did not apply at all and 3 means apply to very much and most of the time. After fillip in the second page, they entered the third page of the survey form. The third page was about the international physical activity questionnaire which consisted of 7 subparts the physical activity in different circumstances. They filled the form with tangible self-experience. The distribution of the survey form was extended to the whole country, however mostly in Gujarat where the majority of students belong. Then we waited for two days for survey collection. Initially, we received 100 responses from the first circulation. After that, we did follow up with the college-going students again via calls and messages. Moreover, we sent a new invitation to other students of the colleges. Then again we waited for the 2 days for more responses. Eventually, at the end of the survey collection, we received more than 160 responses. After the collection of the sample size, we started statistical analysis of the online survey.

DATA ANALYSIS

- Descriptive analysis was done for demographic details.

- Pearson correlation coefficient was to find out the association between physical activity and mental health of college-going students.

RESULT:

160 responses were received, out of which 10 responses were incomplete and hence excluded. The final sample size was 150. The participants were of age group 18 to 25 years with an average age of 21.6 ± 2.15 years.

Table 1: Number the participants according to Gender and Educational Status

Variables	Subgroups	No of Participants	%
Gender	**Male**	79	51.97
	Female	73	48.03
Educational Status	**Bachelor's Degree**	140	92.10
	Master's Degree	11	7.23
	PhD	1	0.65

Table 2: DASS-21 Score for number the participants

	Depression	Anxiety	Stress
Normal	89	72	108
Mild	17	13	14
Moderate	27	23	15
Severe	6	21	8
Extremely Severe	13	23	7

Table 3: IPAQ Analysis for the participants

Type of Activity	Average Days/Weeks	Average Minute/Weeks
Vigorous Physical Activity	3.85	62.5
Moderate Physical Activity	4.33	53.29
Walking	3.85	63.71
Travelling	2.88	67.38
Bicycling	4.17	43.17
Leisure Time	4.68	27.15

DISCUSSION

This research presents a timely investigation of changes in physical activity, sitting time, and screen time as a result of COVID-19 public health restrictions, and their associations with mental health in students. The current findings indicate: (1) large reductions in physical activity and increases in sedentary time across the population and particularly among previously physically active and self-isolated/quarantined individuals; (2) consistent associations between reductions in physical activity and increases in screen time with higher negative mental health and lower positive mental health; and, (3) more severe anxiety and depressive symptoms for those in self-isolation compared to less restrictive situations, which were not moderated by changes in physical activity or sedentary behaviour. We found that females were 1.7 times more likely to be present with depressive symptoms, 2.6 times as likely to show symptoms of anxiety, and twice as likely to show stress symptoms when compared to males but when adjusted for other confounding factors, females were quadruple times as likely as males to have depression and 3.5 times as likely as males to have anxiety. Our results are similar to previous studies conducted during the SARS and COVID-19 pandemic in Italy and China, where the prevalence of psychological disorders was steadily associated with the female gender[4, 5, and 6]. This trend was noted in India before the outbreak too where the prevalence of depression and anxiety disorders was more in females than males. There was no significant association between gender and the likelihood of stress which is in accordance with studies conducted during earlier epidemic/pandemic situations[7]. Gender-specific help and counselling should be offered to mitigate the psychological strain on the population. An interesting finding in our study was the variation in the association between age and depression, anxiety, and stress. Educational status influences the occupation and income of the individual, which are in turn associated with psychosocial wellbeing. The economic crisis due to lockdown might put the individuals without formal education at a higher risk of developing anxiety. Counselling, guidance, or any form of mental health help should include verbal or pictorial representations to aid this group population.

CONCLUSION

The current findings strongly support the mental health benefits of implementing measures that promote physical activity during periods of societal modification due to a pandemic. Potentially effective methods to do so may be through enhanced telehealth or public broadcasting time devoted to the promotion/implementation of home-based physical activity.

LIMITATIONS

- This cross-sectional design precludes inference of causality and the sample is predominantly well-educated.
- In particular, as this study sample is not representative of the entire Indian population, generalizations should be limited based on the sample characteristics.
- All behaviours and currently followed public health guidelines were self-reported and included a recall of pre-COVID-19 activity, which is potentially subject to misreporting. The self-selection and convenience sampling of participants to complete the survey may also affect the results, although a >70% completion rate for those who began the survey is high.

FUTURE RECOMMENDATIONS

Future research should replicate these findings in other large samples, investigate potential cross-national differences, longitudinally assess dynamic relationships between these factors, and integrate device-based measures.

Abstract

Background
Physical inactivity is a commonly observed cause of increasing incidence of lifestyle diseases like obesity which has increased the incidence of low back pain. As dancing is a physical activity that can be tailored to fit a target population's age and culture therefore, Zumba is becoming a global dance fitness activity to reduce lifestyle disease epidemic. It has a mixture of popular entertaining music, different dance styles and aerobic exercises which improves the health of all age groups. Thus, physiological effects of Zumba can be used as adjuncts to conventional medicine for prevention of various lifestyle diseases e.g., diabetes and obesity. Zumba incorporates movement of large muscle groups for aerobic endurance, strength training and flexibility thereby contributing in reducing obesity and thus decreasing back pain in all ages, especially in the geriatric population. Various researchers have also recorded the positive effect of Zumba on weight, BMI, body fat mass. To summarize, these findings reflect that Zumba intervention can be explored further as a therapeutic tool in complementary and alternative medicine for improving low back pain in obese people.

Methodology
An experimental study with a pre-test/post-test design. 30 obese participants between the ages of 18 to 45 years with low back pain were included. We evaluated changes over time (pre-test to post- test) in all outcome measures. Paired t-tests were used to analyze pain and BMI.

Result
Statistically significant improvements were seen in the Pain ($p = 0.0000005$) and BMI ($p = 0.0000002$).

Conclusion
Conclusion the current finding strongly support that Zumba has health benefits and it reduces lower back pain in obese people.

Keywords

INTRODUCTION

Low back pain is a symptom not a disease, and can result from several different known or unknown abnormalities or diseases. It is defined by the location of pain, typically between the lower rib margins and the buttock creases. It is commonly accompanied by pain in one or both legs and some people with low back pain have associated neurological symptoms in the lower limbs. For nearly all people presenting with low back pain, the specific nociceptive source cannot be identified and those affected are then classified as having so-called non-specific low back pain. People with low back pain often have concurrent pain in other body sites, and more general physical and mental health problems, when compared with people not reporting low

back pain. The combined effect on individuals of low back pain and co-morbidity is often more than the effect of the low back pain or the co-morbidity alone and results in more care, yet typically a poorer response to arrange of treatments.[1]

Obesity is one of the co morbidity which has been associated with low back pain. Obesity is defined by waist circumference was associated with increased incidence of radiating low back pain after adjustment for age, gender, educational status, occupational status, and smoking status.[2] Scientifically, obesity is caused by consuming more calories than needed by the body, they are not burnt through physical activity / exercise. One of the diseases of inactivity is obesity or overweight. Lack of physical work such as sitting for long periods will give a negative effect on health and can lead to obesity, therefore Physical exercise is vital for a healthy life and has several positive influences on the body.[3] Despite this evidence, many clinicians consider obesity to be a self-inflicted condition of little medical significance. It is thus important to focus on obesity which can decrease the incidence of low back pain immensely.[4]

In an effort to reduce rates of obesity Zumba Exercise has deliberately chosen, for reasons that it can be made in the form of weight-bearing exercise program that is homogeneous in an attempt to lose weight by exercise in the right dose. Lately, Zumba dance workout has been highly in demand by the women and young mothers, as it is evident from the increasing amount of participation in gym. In such case, it appears that high moving motivation overtake fatigue and directly influence the reduction of body fat.[3]

Zumba can be used as a physical activity which provides a large calorie burn through aerobic activities done with interval training. The average person will burn around 600 to 1,000calories in a single Zumba class. It Burn an excessive amount of calorie in compared to cardio workout and improves coordination as it is needed when you grow old. It is a full body workout besides this it help you reach your target heart rate, 145 beats per minute which can help in increasing the cardiovascular endurance.[5]

This study is necessary because the prevalence of low back pain is very high in obese people and this study will help to find the effectiveness of Zumba exercise in low back pain in obese people.

METHODOLOGY

Study Design: Experimental Study

Study setting: Community

Sampling Method: Convenient Sampling

Sample size: 30

Inclusion criteria:

- Age- 18 to 45years
- BMI- 30 or higher
- Low Back Pain

Exclusion criteria:

- Age- Below 18 years and above 45 years.
- People with active lifestyle.
- People suffering from cardiovascular, neurological and musculoskeletal conditions.

Outcome Measure:

- Numeric Pain Rating Scale (NPRS).
- Modified Oswestry low back pain disability questionnaire (MODQ)
- Body Mass Index (BMI)

Procedure:

Identification of subjects were done according to the inclusion criteria. Each of them was explained about the study and its benefits and written consent was obtained from each individual. Subjects who fulfilled inclusion and exclusion criteria along with BMI scoring were recruited and assigned into group: **Zumba Exercise group**. Each individual's weight, pain and disability level i.e. BMI, NPRS and MODQ score were taken Pre and Post Intervention.

Exercise group:

30 subjects were taken into the group for 4 weeks, each session was of 45minutes.

The Zumba Exercise schedule consists of:

a) Warm-up session- 5-10minutes

• Upper limb stretching

• Lower limb stretching

• Trunk stretching

b) Zumba exercise - 30minutes

c) Cool-down - 10minutes

• Slowly decrease the intensity of exercise

• Stretching

DATA ANALYSIS

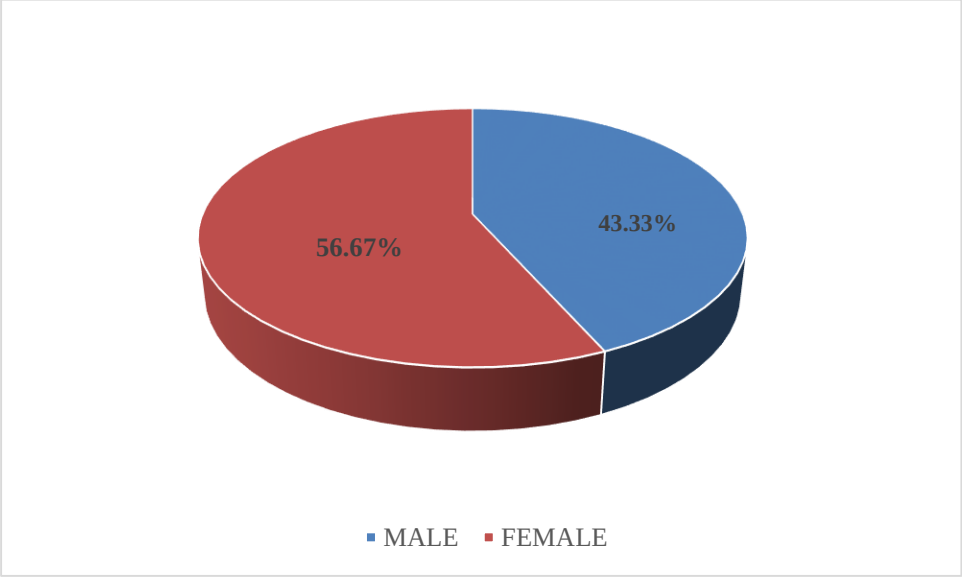
Data were analysed using SPSS statistical software using an intention-to-treat approach. Prior to all hypothesis testing, independent sample t-tests were conducted to examine whether significant mean differences existed in demographic, MODQ, BMI, NPRS scale variables among the group at baseline. We examined whether outcomes changed differentially from baseline to post intervention.

RESULT:

Demographic Profile:

1. GENDER DISTRIBUTION:

There were total 30 participants among which 17 were females and 13 were males.

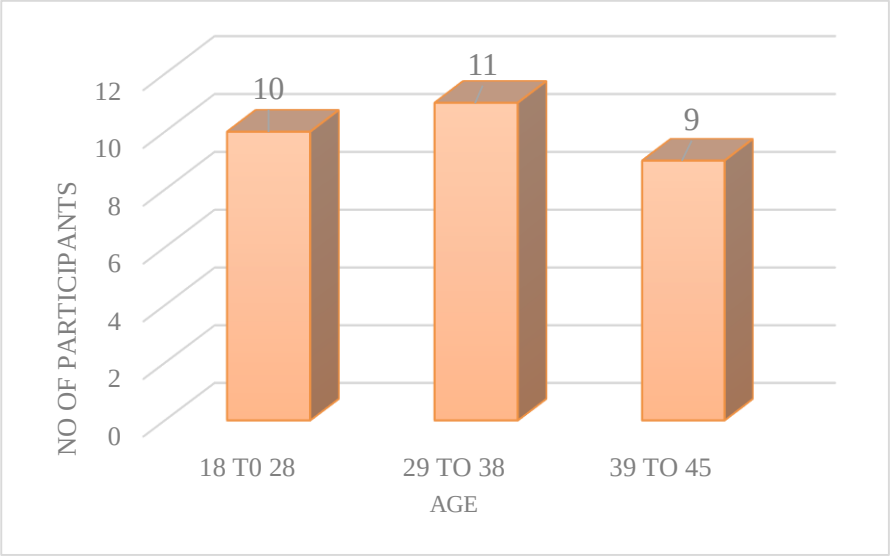


GRAPH 1: GENDER DISTRIBUTION

2. AGE DISTRIBUTION:

MEASURES	MEAN
GROUP	32

TABLE No. 1: Mean of Age Distribution within group



GRAPH 2: AGE DISTRIBUTION

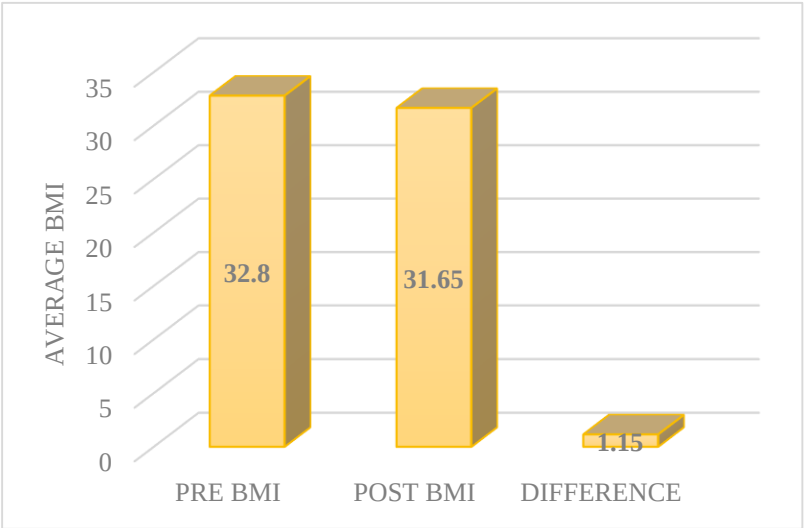
The above given age chart depicts the information about the number of participants taken in different age groups. It is apparent that the highest participant are in the age group of 29 to 38 which is 11, whereas in the age group of 18 to 28 there are 10 participants. In the age group of 39 to 45 there are 9 participants which is the lowest among all.

Clinical Parameters:

3. BMI:

MEASURES	BMI		DIFFERENCE	T-VALUE	P-VALUE
	PRE	POST			
GROUP (comparison within group)	32.70±2.86	31.65±2.39	1.05	0.00000000421308	< 0.01

TABLE No. 2: Comparison of within Groups for BMI



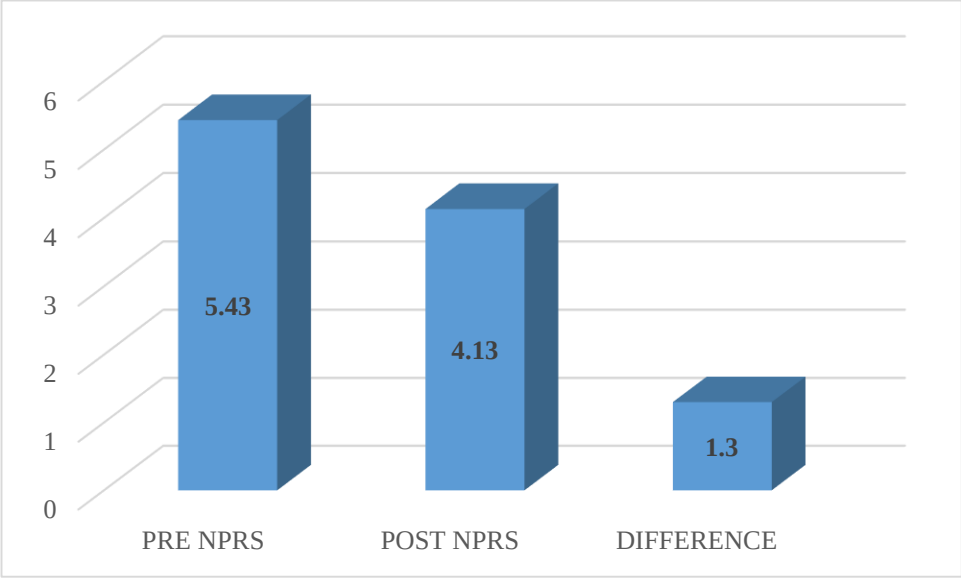
GRAPH 3: Comparison of within Groups for BMI

The above given graph shows the comparison of BMI within the groups. The average BMI were taken before the treatment and it seemed to be 32.8, whereas when the post BMI were taken it had decreased up to 31.65, hence the difference between both turns out to be 1.05.

4. NPRS (NUMERIC PAIN RATING SCALE)

MEASURES	NPRS (NUMARIC PAIN RATING SCALE)		DIFFERENCE	T-VALUE	P-VALUE
GROUP (comparison within group)	PRE	POST	1.3	0.00000000421308	< 0.01
	5.43	4.13			

TABLE No. 3: Comparison of within Groups for NPRS (NUMERIC PAIN RATING SCALE)



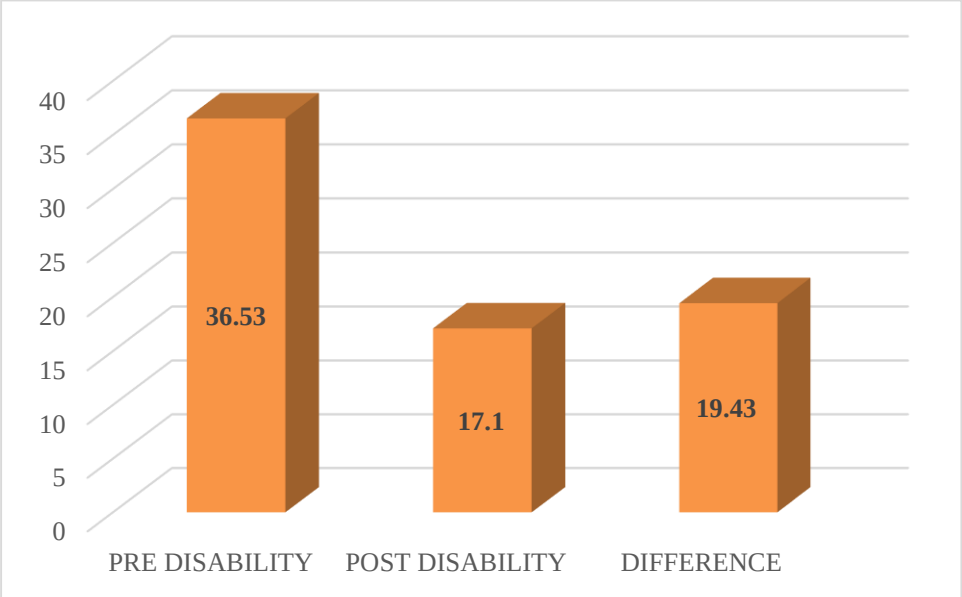
GRAPH 4: Comparison of within Groups for NPRS (NUMERIC PAIN RATING SCALE)

The above given chart shows the comparison of NPRS between the pre and post group. The pre NPRS was noted to be 5.43, however the post NPRS which was taken after the treatment was up to 4.13, hence the difference was noted to be 1.3.

5. MODIFIED OSWESTRY LOW BACK PAIN DISABILITY QUESTIONNAIRE (MODQ).

MEASURES	MODQ		DIFFERENCE	T-VALUE	P-VALUE
GROUP	PRE	POST	19.43	0.00000000000000589	< 0.01
	36.53	17.1			

TABLE No. 4: Comparison of within Groups for MODQ



GRAPH 5: Comparison of within Groups for MODQ.

The above given disability chart illustrates comparison of MODQ within the groups. The number of disability points seem to be high in pre-treatment part which is 36.53, nevertheless after the treatment a drastic change was noted and it dropped at 17.1 in the post phase of treatment, hence the difference seems to be 19.43.

DISCUSSION

The results of the study support the use of effectiveness of Zumba among obese people in low back pain. The findings obtained suggest that 4 weeks of Zumba exercise (five, forty five minute sessions a week) shows significant differences in Disability, Pain, and BMI on Obese individual.

Excessive body weight is directly related to several conditions of the spine, including the number of lumbar discs with degeneration, progression of disc disease, increased likelihood of radicular pain and neurologic symptoms and a higher prevalence of lumbar facet osteoarthritis. There are known postural changes with obesity that are likely contributing factors to an increase in mechanical load to the spine that include:

- A more flexed trunk posture leading to a decrease in flexion motion of the thoracic and thoracolumbar segments.
- An increased lordosis and decreased lateral bending of the lumbar spine.
- An increased hip joint movement.
- An increased anterior pelvic tilt.
- An increased hip-to-bench ratio for table-top work activities (a person has to stand further back from the table due to the size of the abdomen and reach farther forward). This limited spinal mobility has a negative impact on disc nutrition by limiting fluid movement and rehydration. The discs and facet joints are also affected directly by increased inflammatory responses generated by the adipose cells in the form of cytokines and acute-phase reactants.[6]

Despite these proposed and known theories of the effects of obesity on the spine, the role of obesity in directly causing LBP is still being confirmed. A review by Leboeuf-Yde of 56 research studies between 1965 and 1997 led to a conclusion that increased body weight may be a possible weak risk factor for LBP, but there were insufficient data to link it as a clear causative factor.[7]

Snow et al. randomized 54 obese patients (mean BMI 42.6 kg/m2) with musculoskeletal pain as measured by VAS (0–10 points) >5 to a physical therapy treatment program versus control group prior to a weight-loss program. The group receiving physical therapy experienced a significant reduction in VAS to 2.3 with the weight-loss program.[8]

The most recent study of nonsurgical weight loss in 46 adults with LBP and a mean BMI of 44.7 kg/m2 used a 52-week multidisciplinary program. This program included liquid meal replacements for 12 weeks (phase 1) followed by supervised caloric restriction from weeks 13–52 (phase 2). Study participants went to weekly educational meetings and group therapy sessions for the first 26 weeks, and monthly group meetings for the Second 26 weeks. During the second 26 weeks, they also participated in 60–90 min of physical activity. Over the year-long study, mean BMI was reduced to 39.6 kg/m2 (mean decrease of 5.1 kg/m2 [11.4%]) and ODI improved significantly from 31.9 to 27.1, and Numerical Pain Score (NPS) showed improvement (3.3 at baseline; 2.6 at 1 year). Weight, BMI, NPS and ODI all showed the most improvement during the initial 13 weeks of liquid meal replacements, and as the mean weight and BMI decreased, the NPS and ODI scores also decreased.[9]

Many health-associated problems are caused by the increased body fat mass and overweight. Given the global prevalence of overweight, using an accurate method is necessary to decrease overweight. Although Zumba is currently used to lose weight, this type of sport is rarely addressed in practical research as a weight loss method. Thus through this study it can be said that Zumba can be used as a conservative management to reduce weight which significantly decreases low back pain and Disability.

CONCLUSION

The current findings strongly support that Zumba exercise benefits the people having low back pain and who are suffering from obesity.

LIMITATIONS

- Small sample size.
- Limited age group of 18-45 years.
- The self-selection and convenience sampling of participants to complete the study may also influence on the result.

FUTURE RECOMMENDATIONS

- Future research should replicate these findings in other large samples, take larger age groups
- Investigate relationship between Pain and Obesity.

Abstract

Background:
Job and career satisfaction is an integral part of an individual's professional life. It affects job performance, consequently influencing growth of the profession. This study aims to assess the level of job and career satisfaction among physiotherapists of Gujarat State.
Methodology:
A cross-sectional survey was done with a self-administered e-questionnaire. 467 surveys collected were subjected to descriptive statistical analysis.
Result:
Overall job satisfaction is 39.83% (3.14±1.20) and career satisfaction is 42.84% (3.18±1.23).
Conclusions:
The majorities of physiotherapists were not satisfied with their jobs and moderately satisfied with their careers. It is essential to incorporate favourable factors in the workplace that promote professional satisfaction and there is a need to enhance opportunities for continued medical education.

INTRODUCTION

Work plays a prominent role in our lives. It occupies more time than any other single activity and provides the economical basis for our life style. Therefore, job satisfaction is a key research area for numerous specialists and is one of the most frequently studied work attitudes.[1]

Health services are affected by many factors such as human resources, delivery system and health infra structures. Among these human resources is a vital component in delivering health services. Job satisfaction of the health workers is highly important in building up employee motivation and efficiency as higher job satisfaction determine better employee performance and higher level of patients' satisfaction. Job satisfaction in health care workers has a great impact on quality, effectiveness and work efficiency and at the same time on health-care costs. Besides its importance for patients and health care system as a whole, professional satisfaction in health care workers is directly connected with absence from work, human relations and organization of work.[2, 3, 4]

Job satisfaction is how an individual feels about his or her job.[5] Job satisfaction, or dissatisfaction, not only depends on the nature of the job, but also on the individual's expectations from the job, and relies on the degree of motivation an employee has. The most common predictors for job satisfaction are leadership, interpersonal relationships, salary and promotion.[6]

Job satisfaction is under the influence of a series of factors such as: The nature of work, Salary, Advancement opportunities, Management, Work groups and Work conditions. [7] Job satisfaction is an important factor in increasing the level of work performance

and career aspirations. It is noted in the literature that there is high correlation between job satisfaction, commitment and better performance.[8, 9.]

One common research finding is that job satisfaction is correlated with life satisfaction. This correlation is reciprocal, meaning people who are satisfied with life tend to be satisfied with their job and people who are satisfied with their job tend to be satisfied with life. However, some research has found that job satisfaction is not significantly related to life satisfaction when other variables such as non-work satisfaction and core self-evaluations are taken into account.[10, 11]

There are important reasons why the researcher should be concerned with job satisfaction the first is that the people deserve to be treated fairly and with respect. Job satisfaction to some extent is a reflection of good treatment. It can also be considered as an indicator of emotional wellbeing or physiological health. The second reason is that job satisfaction can lead to behaviour of employees that affects organizational functioning .Furthermore job satisfaction can be a reflection of organizational functioning. Differences among organizational units in job satisfaction can be diagnostic of potential trouble spots.[12] Dissatisfied workers are more likely to provide inferior services, the physical and mental status and the social functioning of these workers can be affected substantially by the level of their job satisfaction.[13]

In recent years the scope of physiotherapy is also expanding to outside of medical institutions. So, that physiotherapist is increasingly expected to practice according to the social needs.[14] this necessitates practitioners to improve their quality of treatment. In order to deliver high quality of physiotherapy service it is necessary for the physiotherapist to have a firm commitment to their work, awareness of themselves as a professional & motivation & ambition to apply present and past learning and work experience to their future work.[15] One of the premises for quality treatment is job satisfaction, and this, in turn, influences employee retention in the work field, decreases absenteeism, improves work productivity and enhances performance.[16]

Knowledge about Physiotherapists job satisfaction will indirectly influence career choice and professional preferences in students for choosing Physiotherapy as a profession. One of the premises for quality treatment is job satisfaction, and this, in turn, influences employee retention in the work field, decreases absenteeism, improves work productivity and enhances performance.[17] Knowledge about Physiotherapists job satisfaction will indirectly influence career choice and professional preferences in students for choosing Physiotherapy as a profession.[18]

METHODOLOGY

Study design: A cross sectional survey study

Source of data: Physiotherapy colleges of Gujarat, Hospitals and Private Clinics of Gujarat, Social Media (Google, Facebook, Instagram, LinkedIn, and Whatsapp)

Population: Physiotherapists with more than 6 months of experience

Method of collection of data: Online survey form

Sample size: Convenient

Duration of study: 1 year

Inclusion criteria:

- Physiotherapists working in Physiotherapy Colleges of Gujarat.
- Physiotherapists having private practice or working at hospitals of Gujarat
- Physiotherapists having postal and/or email address.
- Physiotherapists having more than 6 months of work/teaching experience.

Exclusion criteria:

- Physiotherapists not willing to participate in the study.
- Physiotherapists not replying to the questionnaire in the fixed time period.
- Physiotherapists having less than 6 months of work/teaching experience.

Procedure:

The questionnaire was constructed with closed questions pertaining to job and career satisfaction. Job satisfaction included a set of questions on knowledge, work ethics, qualification, remuneration, rewards, communication among co-workers, and opportunities provided at the workplace. Career satisfaction included a set of questions on professional status, opportunities, immigration, career path, contribution, and research activity. It also covered basic demographics such as age, gender, years of experience and qualification (i.e. master‘s/bachelor‘s degree). Only the responses of individuals with more than 6 months of experience were included. The questionnaire was developed on Google Forms and consisted 15 closed questions, equally distributed on job and career satisfaction, eight of which focused on job satisfaction, and seven on career satisfaction.

STEP: 1

Identifying eligible candidates according to the inclusion criteria

STEP: 2

Selecting suitable candidates

STEP: 3

Sending consent form

STEP: 4

Sending survey form after receiving consent form

STEP: 5

Collection of data

STEP: 6

Assessment of collected data

STEP: 7

Statistical data analysis

STEP: 8

Result

DATA ANALYSIS

Statistical analysis was carried out with SPSS (v.26). Convenience sampling was used and descriptive statistics was performed. Mean, standard deviation and percentage were used and the level of satisfaction for each question was expressed in percentage. Finally, overall combined job and career satisfaction was calculated in percentage.

RESULT:

The demographic detail of the respondents is shown in the tables below. There were a total of 467 responses.

GENDER					
		Frequency	**Percent**	**Valid Percent**	**Cumulative Percent**

TABLE.22

Table 23 represents the level of job satisfaction among PTs. The results reflected that the majority of PTs were satisfied with their job in all aspects measured.

Table 23. Level of job satisfaction among physiotherapists				
	Questions	**Mean**	**Std. deviation**	**Level of satisfaction (%)**
QI	**Are you satisfied with the opportunities provided at your workplace to improve and update your knowledge and clinical skills?**	3.3919	1.17310	49.1%
Q2	**What is your level of satisfaction with the communication between your co- workers and supervisors in workplace?**	3.5268	0.93847	53.1%
Q3	**What is your level of satisfaction with work ethics at your workplace?**	3.3298	1.21614	48.9%
Q4	**Are you satisfied with your qualification matching the designation?**	3.4411	1.31933	57.4%
Q5	**Are you satisfied with remuneration for the service you provide?**	2.9615	1.22326	35.4%
Q6	**Are there regular increments in your salary in the organization/hospital you are working in?**	2.8137	1.28610	25.7%
Q7	**Are you satisfied with the criteria implemented in your organization/hospital for promotion?**	2.9829	1.19895	25.5%
Q8	**Are you satisfied with the rewards received for your performance (excluding timely promotion)?**	2.7473	1.26541	23.6%
	Overall job satisfaction	3.1493	1.2025	39.8375%
20–40% dissatisfied; 41–60 moderately satisfied; 61–80 satisfied; >80 highly satisfied				

The results were as follows for satisfaction with:

- Opportunities provided in the workplace to improve knowledge and skill level: 49.1% (3.39± 1.173)
- Communication among co-workers: 53.1% (3.526± 1.216)
- Work ethics: 48.9% (3.32±1.216)
- Qualification matching with designation: 57.4% (3.44±1.319)
- Remuneration: 35.4% (2.96 ±1.223)
- Rewards at workplace: 25.5% (2.98±1.198)
- Overall job satisfaction among physiotherapists: 39.83% (3.14± 1.202).

Table 24. Results demonstrating level of career satisfaction among physiotherapists				
		Mean	**Std deviation**	**Level of career satisfaction (%)**
Q9	**Are you satisfied with your professional status in the community and social life?**	3.224	1.39080	49.5%
Q10	**Are you satisfied with the opportunities available in India for continued professional education?**	2.6895	0.98702	20.8%
Q11	**Are you satisfied with the career path you chose?**	3.3426	1.3983	49.2%
Q12	**Are you satisfied with your contribution towards the growth of the physiotherapy profession in India?**	3.5460	1.2479	57%
Q13	**Are you satisfied with opportunities provided for research activity at your work place?**	3.1028	1.1655	37.7%
	Overall career satisfaction	3.180	1.237	42.84%
20–40% dissatisfied; 41–60 moderately satisfied; 61–80 satisfied; >80 highly satisfied				

Table 25. Results regarding qualification/income and immigration				
		Mean	**Std. Deviation**	**Level of agreement**
Q14	**Your qualification (1/2/PhD) influences your income**	3.1542	1.21410	43.1%
Q15	**Indian PTs are immigrating for better prospects**	4.0321	.30908	96.8%
20–40% disagree; 41–60% moderately disagree; 61–80% agree; >80% highly agree				

Table 24 and Table 25 represent career satisfaction level among physiotherapists

The results were as follows for satisfaction with:

- Satisfaction with professional status: 49.5% (3.224±1.390)
- Opportunities for continued medical education: 20.8% (2.68±0.987).
- Satisfied with the career path chosen: 49.2% (3.76±1.363)
- Contribution to the profession: 57% (3.546 ±1.247).
- Opportunities at work: 37.7% (3.10±1.165)
- Qualification level influences the income: 43.1% (2.74±1.439),
- Physiotherapists emigrating for better prospects: 96.8% (4.032±0.309).
- Overall career satisfaction among physiotherapists: 42.84% (3.18±1.137).

DISCUSSION:

In this state level survey, it was found that most physiotherapists surveyed were moderately dissatisfied with their job and career. The authors were unable to find literature on career satisfaction among Physiotherapists of Gujarat State.

Job satisfaction

Workplace opportunities, communication, ethics, and qualification-matching designation:

Physiotherapy is a skill-based profession where most of the techniques require a hands-on approach. Therefore, it is important for individual physiotherapists to have periodic training to update their skills and knowledge within their workplaces based upon international standards. Developing countries like India lack such opportunities. However, this study reveals that the majority of the

individual surveys were happy about the current opportunities provided to them. Interpersonal relationships, which affect communication among co-workers, is another sensitive area that has an impact on professional development[19]. The survey within this study showed that 53.1% of the physiotherapists were satisfied with their communication with co-workers and supervisors. One of the important aspects of job satisfaction is having an appropriate designation based on an individual's qualification. This is the indirect way of keeping workers effective at work. Depending on their designation, their remuneration and work responsibilities can change. In this study, 57.4% of physiotherapists were happy with their designation based on their qualification. Work ethics is also one of the important factors, which determines employee satisfaction on. This study shows that the majority of the employees reported being satisfied with their organization's work ethics.[20]

Career satisfaction

Professional status, qualification influence on income, and immigration:

In the current study, 49.5% of the physiotherapists were satisfied with their professional status in the community. The majority of the participants agree that physiotherapists are immigrating to other places for better prospects. This indirectly states that the majority of them are dissatisfied working in Gujarat, and it is presumed to be the same in other developing countries. Since this survey has been able to reach only a few of the PTs in Gujarat, however, this statement cannot be generalized. There is a need for extensive research regarding this aspect.

Remuneration, salary increments, organizational criteria and rewards:

Remuneration is another important element of job satisfaction. This survey reveals that only 35.4% of physiotherapists were happy with the remuneration they receive for the work they do. This provides some insight into the situation in India where it appears physiotherapists feel they are underpaid. Motivating the employee to improve their performance in the workplace is necessary, as is rewarding them periodically for their performance.[21]

In the current survey, 25.5% of the respondents was satisfied with the rewards they received for their work performance.

Career choice, contribution to the profession and opportunities for research activity:

The most encouraging aspect of this survey is that the majority of the participants were happy about the career they have chosen. It is essential to keep ourselves updated with recent information in order to provide safe, effective and quality care for our patients. Of the population in the current study, 79.2% expressed dissatisfaction towards the opportunities provided for continued professional education.

CONCLUSION

The majority of physiotherapists in the current study were not satisfied with their job and moderately satisfied with their career in the state of Gujarat. This study represents the scenario in state of Gujarat in India, providing insight into the situation in developing countries and also provides a global outlook when compared with developed countries.

LIMITATIONS

- Convenient sample size. Responses were collected from the physiotherapists whose contacts were possible either through email or social media.
- The main limitation of the study was the participation in the survey. As the survey was sent electronically, the response rate was solely dependent on participants 'motivation.
- The major drawback of the study was that it could only reach the major cities in Gujarat, and those who used networks. This should be a consideration for future study.
- This was a preliminary survey which does not represent the entire population; hence, a detailed study should be carried out with large sample size in order to be able to generalize the results.

FUTURE RECOMMENDATIONS:

- Other factors affecting job satisfaction can be considered.
- Individual factor for job satisfaction can be studied.
- Inclusion of all the physiotherapists in Gujarat.
- Job satisfaction of Physiotherapists can be compared with other health care professionals.
- Job satisfaction among Physiotherapists working in different health care settings can be studied.

Find Prevalence Of Osteoarthritis In Young Working Professionals A Cross-Sectional Study

1PATEL DEVANSH, 2Dr. SHIVAM AACHARYA, 3Dr. ARVIND CHAUHAN
1BACHELOR OF PHYSIOTHERAPY, 2MASTER OF PHYSIOTHERAPY IN CARDIOPULMONARY CONDITIONS, 3PhD IN PHYSIOTHERAPY
1SWARRNIM STARTUP AND INNOVATION UNIVERSITY,
2SWARRNIM STARTUP AND INNOVATION UNIVERSITY,
3SWARRNIM STARTUP AND INNOVATION UNIVERSITY

ABSTRACT

BACKGROUND AND OBJECTIVES :

This study was conducted to find the prevalence of osteoarthritis of knee in young people age between 21 to 30 years having sitting or standing work profession. The purpose of the study was to find prevalence ratio of OA in young people. Osteoarthritis (OA) is defined as a heterogeneous group of conditions that lead to joint symptoms and signs associated with a defective articular cartilage and related changes in bone morphology. It is considered the most common type of arthritis, as well as one of the most significant health problems that pervades our modern world. In 2019, it was estimated that 43 million adults suffered from arthritis. Of those, 26.9 million adults aged 25 years or older had OA. One in four people is expected to develop symptomatic OA in his or her lifetime.

INTRODUCTION :

Arthritis is a common joint problem usually associated with older adults. And there are very less study/,research Conducted on osteoarthritis in young age. According to the National Library of Medicine (NLM)Trusted Source, most people show symptoms of osteoarthritis by the time they are 70 years old, but there are also potential chances of osteoathritis in young age. So, this research helps to determine the Prevalence rate in various conditions. So this study may help to determine the prevalence ratio of OA in young people.

METHODOLOGY:

Research will be done on around 100 subjects age between 21 to 30 years with having sitting or standing profession to find Prevalence ratio for OA in young people.

Prevalence rate will be calculated by below formula.
* Prevalence percentage = OA will be found for given
Criteria / OA Will be not found for given criteria (Number of sub.) * 100 %

An observational study was conducted by using the convenient sample method. One hundred working professionals of ahmedabad and nearby area participated in this study by performa validated assessment form and clinical measures.

RESULT:

The prevalence of OA varies according to the definition of OA, the specific joint(s) under study, and the characteristics of the study population. The age standardized prevalence of radiographic knee OA in given subjects age between 21-30 years was only 5% among the all participants. Out of 100 subjects only 5 subjects primarily suspected of having OA of knee. Out of 100 subjects there was 56 female and 44 male subject in this survey. And OA was found in 3 female and 2 male subject after assessing clinical measures.

So, the prevalence percentage of OA of knee in young people age between 21 to 30 years having prolonged sitting or standing work profession would be as below:

$$\text{Prevalence percentage} = \frac{\text{OA will be found for given Criteria}}{\text{OA Will be not found for given criteria}} \times 100$$

PREVALENCE PERCENTAGE = 5/95 * 100% = **5.2631%**

A sum of 100 working professionals responded answering the questionnaire. An analysis was done by excel & calculation was done by chi square test calculator. The chi- square statistics found as **0.1695.** The p value is **0.918761**. The result is not significant at **p < .01**.

Keywords : Osteoarthritis , Prevalence , Young working professionals

Introduction

●Osteoarthritis (OA) is a common chronic condition resulting in pain, fatigue, functional limitations, increased healthcare utilization and high economic costs to society. The burden of OA is projected to increase, due in part to obesity and population aging.
●While the prevalence of OA increases with age, there is a growing recognition that OA affects people at younger ages.
●Recent US data demonstrated that half of people with symptomatic knee OA are diagnosed by age 55.

• Osteoarthritis (OA) is one of the most devastating chronic conditions that affect people around the world.
• Although the usual population associated with the condition is the elderly, who are mostly inactive, athletes and younger individuals are also susceptible.
• Depending on the population, the etiology may differ; injuries, occupational activities, and obesity appear to be the most common
causes of OA in young and athletic populations. [1]

Fig 1.1 X-RAY FINDING OF KNEE OA

Left) In this x-ray of a normal knee, the space between the bones indicates healthy cartilage (arrows). (Right) This x-ray of an arthritic knee shows severe loss of joint space.

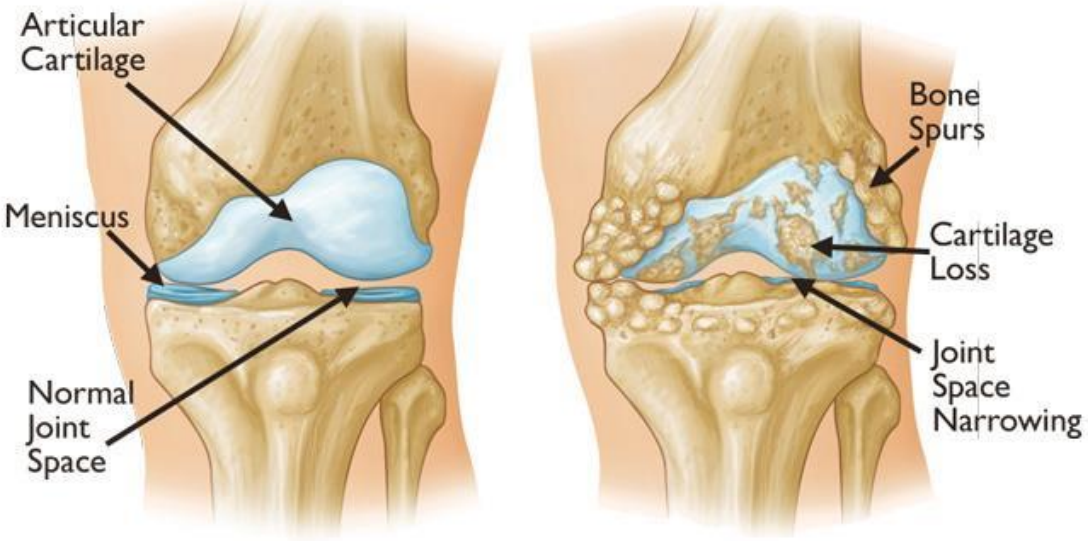

Fig 1.2 NORMAL KNEE VS OA KNEE

Osteoarthritis often results in bone rubbing on bone. Bone spurs are a common feature of this form of arthritis.

Stage 0 represents a normal joint.

- Stage 1 represents very minor wear and tear on a joint, but pain is unlikely.
- Stage 2 represents mild osteoarthritis, which is when most will typically begin experiencing pain and discomfort.
- Stage 3 is designated moderate, where there is obvious cartilage erosion. This may come with joint stiffness, more severe pain, and the experience of popping or snapping sounds.
- Stage 4 osteoarthritis is severe, where the joint space between the bones is considerably reduced. This creates greater friction, which generates more pain and discomfort.

What Are the Symptoms of Osteoarthritis?

• Symptoms of osteoarthritis most often develop gradually and include:
• Joint aching and soreness, especially with movement
• Pain after overuse or after long periods of inactivity
• Stiffness after periods of rest
• Bony enlargements in the middle and end joints of the fingers

(which may or may not be painful)

• Joint swelling
Some Of Potential Causes That Can Develop OA In Young People.
• There are several factors that increase a person's chances of developing osteoarthritis. These include:

• **Heredity**. Some people have an inherited defect in one of the genes responsible for making cartilage. This causes defective cartilage, which leads to more rapid deterioration of joints.
•People born with joint abnormalities are more likely to develop osteoarthritis, and those born with an abnormality of the spine (such as scoliosis or curvature of the spine) are more likely to develop osteoarthritis of the spine.[3]

• **Obesity** . Obesity increases the risk for osteoarthritis of the knee, hip, and spine. Maintaining ideal weight or losing excess weight may help prevent osteoarthritis of these areas or decrease the rate of progression once osteoarthritis is established.

• **Injury**. Injuries contribute to the development of osteoarthritis. For example, athletes who have knee-related injuries may be at higher risk of developing osteoarthritis of the knee. In addition, people who have had a severe back injury may
be predisposed to develop osteoarthritis of the spine. People who have had a broken bone near a joint are prone to develop osteoarthritis in that joint.[3]

• **Joint overuse**. Overuse of certain joints increases the risk of developing osteoarthritis. For example, people in jobs requiring repeated bending of the knee are at increased risk for developing osteoarthritis of the knee.
• Other diseases. People with rheumatoid arthritis, the second most common type of arthritis, are more likely to develop osteoarthritis. In addition, certain rare conditions, such as iron overload or excess growth hormone, increase the chance of developing OA.[3]

•OA isn’t restricted to older adults. Younger adults can also experience symptoms that may signify OA, including:

• morning joint stiffness
• aching pain
• tender joints
• limited range of motion
• Most often pathology develops in women but found in men.
Usually it is detected when it has already happened to
fracture, especially of the femur, which is considered the
most serious and life-threatening.[4]

• After pain, stiffness was identified as a significant
symptom that…
• impacted daily life. Other impactful symptoms included:

• - functional, walking and standing limitations
• - loss of flexibility
• - sleep disturbance
• - fatigue
• - grating (bone on bone) sensation
• - joint swelling
• - disfigurement
• - other numbness and instability (OA VOP 2017)[4]

• Diagnosing OA in athletes and young individuals is sometimes challenging because of their increased pain tolerance. However, the treatment of OA in these populations does not differ from its management in the general population.
• Several considerations need to be taken into account when choosing a treatment modality. The purpose of this review is to address OA in athletes and younger individuals and to discuss its presentation, diagnosis, and treatment.[4]

Clinical Findings for OA

X-Rays – Cartilage loss, a tell-tale sign of osteoarthritis, appears as a narrowing of the space between bones in the joint. While an X-ray image will not show the cartilage itself, your doctor can use this bone proximity to provide a diagnosis. An X-ray can also show bone spurs around a joint, which may cause pain and tenderness.

MRI – A magnetic resonance imaging test, or MRI, can produce detailed images of bone and soft tissues. This includes cartilage. This test is not typically needed for an initial diagnosis, but it can provide more information about the disease's progression.

Blood tests – Certain blood tests can help rule out other causes of joint pain, like rheumatoid arthritis, narrowing your doctor's field of potential diagnoses.

Joint fluid analysis – In this test, your doctor will use a syringe to draw fluid from the affected joint. They then test the fluid to determine whether the inflammation is caused by an infection or gout, homing in on a definitive diagnosis.

Epidemiology

●Osteoarthritis (OA) of the knee is the most common form of joint disease and prevalence of both radio graphically evident and symptomatic. The females having higher prevalence than males (11.4% vs 6.8%).

●The gender difference in prevalence has recently been emphasized in a meta-analyses, which provides evidence for a greater risk in females for prevalent and
incident knee OA.

●The meta-analysis also reported that females tend to have more severe knee OA radio graphically assessed than males and that the gender differences increase with
age > 55 years. The prevalence of OA will increase as the population of the kingdom ages, especially if the incidence of obesity remains at over 50% in the 45+ age.

• OA in adults is frequently accompanied by comorbidities that
• contribute to decreased quality of life:
• - obesity or being overweight (90 percent)
• - hypertension (40 percent)
• - depression (30 percent)
• Osteoporosis at a young age is very rare, so at the first manifestations should be sure to look for the causes of the disease.[2]
• Activity Limitation: • Arthritis limits the activities of 23.7 million US adults. Around 44% of adults with doctor-diagnosed arthritis had arthritis attributable activity limitations in 2013–2015.
• Leading Cause of Work Disability
• Arthritis and other rheumatic conditions are a leading cause of work disability among US adults.3
• In all US states, 1 in 25 working-age adults aged 18 to 64 years face work limitations they attribute to arthritis; among those with arthritis, at least 1 in 4 have work limitations. The prevalence of work limitations due to arthritis varies by state.
•Risks of revision surgery are especially pronounced in the younger patient, who may be more physically active and, consequently, subject to multiple revision surgeries over a lifetime. (DR.S.Bhandari 2012)[5]

NEED OF STUDY

• Arthritis is a common joint problem usually associated with older adults. And there are very less study/research Conducted on osteoarthritis in young age. According to the National Library of Medicine (NLM)Trusted Source, most people show symptoms of osteoarthritis by the time they are 70 years old, but there are also potential chances of osteoathritis in young age. So, this research helps to determine the Prevalence rate and percentage of OA in young working professionals who have prolonged sitting ans standing work profession. So this study may help to determine the prevalence ratio of OA in young people.

OBJECTIVE OF THE STUDY

• To find prevalence of OA in young people(Age between 21 to 30 years) having prolonged sitting or standing work profession in ahmedabad and gandhinagar area.

• *REVIEW OF LITERATURE*

1. Prevalence of osteoarthritis of knee joint among adult population in a rural area of Kanchipuram District, TN [Venkatachalam.J, Natesan.M, Bharath Z] Year -2018.[9]

•A total of 1986 adult respondents were interviewed out of which 27.1% had OA of knee. Age more than 50 years, female gender, tobacco usage, illiteracy, lower socioeconomic class, positive family history of OA, diabetes, and hypertension were found to be associated with OA knee ($P < 0.05$).

• Conclusion: The burden of osteoarthritis knee was high in this region. Hence, effective preventive strategy has to be taken to minimize this burden.

2. Osteoarthritis Affects Younger People, Too by ILANA N. ACKERMAN, PT, PhD (Article published in 2019)[10]

●Conclusion of this study

• In this article researcher found that In younger people presenting with persistent joint pain and transitory stiffness (particularly those who have sustained a previous traumatic joint injury), the early signs of OA should be suspected. Routine imaging is not indicated for the diagnosis of uncomplicated knee or hip OA.
•While X-rays are inexpensive, radiographic findings are not well correlated with symptoms and are unlikely to alter the management plan or predict future disease progression. Magnetic resonance imaging can detect early OA changes that may be useful in a research context,but the clinical significance of these changes is questionable. Overuse of MRI is costly for health systems and may lead to unwarranted surgical interventions.

• These include activity-related joint pain and either no joint-related morning stiffness or morning stiffness lasting no longer than 30 minutes.Atypical features (eg, a hot swollen joint, prolonged morning stiffness, or rapid worsening) warrant investigation, as they may indicate other diagnoses, including inflammatory or septic arthritis, or malignancy.

3. Hip and knee osteoarthritis In young age (ADAM G. CULVENOR, PT, PhD), RANA S. HINMAN, PT, PhD(Vol 2. Feb. 2017)[11]

• Hip and knee OA is not restricted to older age groups and can profoundly affect quality of life and work participation among younger people. Knee joint injury is a strong risk factor for subsequent knee OA, and early signs and symptoms may present in the decade following injury or reconstructive surgery.

•Thorough physical examination can identify key impairments, and PROMs are valuable tools for tracking changes in pain, function, and well-being. Nonsurgical management approaches relevant to younger patients include education and self-management support, physical therapist–prescribed exercise programs, and weight management.

4. Epidemiology of osteoarthritis: state of the evidence. Kelli D. Allen, Yvonne M. Golightly [2019].[12]

• This study concludes the Risk factors with strong evidence for osteoarthritis onset and/or progression include age, sex, socioeconomic status, obesity, family history, joint injury, joint alignment, and occupational joint loading.Traditional epidemiologic studies and mining of large health administrative databases show a large and increasing impact of osteoarthritis.

5. Risk Factors for Osteoarthritis and Contributing Factors to Current Arthritic Pain in South Korean Older Adults.Kyoung Min Lee, Chin Youb Chung, Ki Hyuk Sung, Seung Yeol Lee, Sung Hun Won, Tae Published online 2014 Dec 10.[13]

• The Fourth Korean National Health and Nutrition Examination Surveys was conducted in 2009. Therein, 720 males and 1008 females aged between 25 years to 45 years older were included. Comprehensive data on habitual, socioeconomic, medical, nutritional, and psychological factors were collected along with the presence of osteoarthritis and arthritic pain. After univariate analysis, binary logistic regression analysis was performed to identify risk factors for osteoarthritis and contributing
factors to current arthritic pain. And the study conclude that higher BMI, lack of weekly moderate intensity activity, and unfavorable subjective health status were significant factors contributing to current arthritic pain. More attention needs to be paid to psychiatric effects on osteoarthritis and joint related pain.

6. What Are the common risk factors that cause OA in younger athletes (Whittaker.J 2015)[14]

This study concludes some major and most common risk factors that cause OA in younger athletes that mentioned as below.

• Five common athletic injuries have been identified as placing patients at greater risk of developing post-traumatic OA:

• - anterior cruciate ligament (ACL) ruptures
• - meniscus tears (the second most common structure damaged in athletes)
• - shoulder dislocation
• - patellar dislocation
• - ankle instability (the most commonly injured joint in the body)

7.Osteoarthritis in Young, Active, and Athletic Individuals. *Adae O Amoako(2018)*[10]

This study concludes several risk factors associated with OA. In the athlete or young individual, injury, occupational activities, and obesity are the main factors that contribute to OA. Diagnosis of OA in the athlete is often delayed and difficult

because of high tolerance to pain, as well as the athlete's preference for expedited return to play. History, physical examination, laboratory tests, and radiographic findings may be used to make a definite diagnosis of OA. Exercise remains the recommended initial treatment for OA in all populations. NSAIDs, braces, and surgery are other treatment modalities for OA. The treatment of OA in the athlete or young individual should be patient specific, with consideration for the patient's expectations and the period of absence from sports activities.

8. Workplace policies and prevalence of knee osteoarthritis: the Johnston County Osteoarthritis Project. J-C Chen, L Linnan, L F Callahan, E H Yelin, and J B Renner, J M Jordan [2007 Jun 13]

The negative associations between KOA and workplace policies raise concerns about possible employment discrimination or beneficial effects of workplace policies.

Longitudinal studies are needed to clarify the dynamic complexities of KOA risks and outcomes in relation to workplace policies.

Studies on the interrelations of work and osteoarthritis (OA) remain an active area of research because of their profound implications for clinical practice and public policy. As indicated in recent reviews of epidemiological literature on the relationship between occupational factors and risks of knee OA (KOA),[1,2] both case–control and prospective cohort studies have shown the positive associations between KOA and physical exposures in the workplace, and the strength of scientific evidence is moderate.

Specifically, previous studies have shown that certain occupational activities (e.g., kneeling, squatting or climbing) increase the risk of KOA,[3,4,5,6] presumably due to increased biomechanical loads on knee joints.

However, most of the previous studies were primarily focused on individual-level attributes; very little data are available to examine the potential link between KOA and organisation-level workplace characteristics (e.g., workplace policies, employers' commitment), many of which play an important role in occupational health and safety.

HYPOTHESIS

NULL HYPOTHESIS :

There's no correlation find between knee OA and young people (Age between 21 to 30 years) having prolonged sitting or standing work profession. That's why prevalence rate is difficult to find and result is not significant.

RESEARCH HYPOTHESIS :

There's some correlation find between knee OA and young people (Age between 21 to 30 years) having prolonged sitting or standing work profession. Hens prevalence

rate can be find and significance can be find through this research.

METHODOLOGY

MATERIALS AND METHODOLOGY :-

STUDY DESIGN : Cross-sectional study

SOURCE OF DATA : Hospitals and Offices

POPULATION : Young Working professionals having age between 21 to 30 years who have prolonged sitting or standing work profession.

SAMPLING METHOD : Convenient Sampling Method

DURATION OF STUDY : 1 month

SAMPLE SIZE : 100

•Method of selection of data:

Research will be conducted on young people age between 21 to 30 years having prolonged standing or sitting work profession. An observational study was conducted by using the convenient sample method. One hundred working professionals of ahmedabad and nearby area participated in this study by perform validated assessment form and clinical measures.

• *INCLUSION CRITERIA*

• Subject having age between 21 to 30 Years.

• Both male and female subject.

• Subject who having prolonged sitting or standing work profession (Ex: Nurse, Teacher/Professor, Petrol filler man).

• *EXCLUSION CRITERIA*

• Subject having diabetes, hyperthyroidism, hypertension, osteoporosis, rickets and various type of muscular disorders.

• Subject having autoimmune disease.

• Subject with previous history OA surgery.

• Subject with history of any other neurological and cardio-thoracic conditions.

• Subject having OA of hip, wrist or hand and feet.

• OUTCOME MEASURES

• Clinical assessment forms

• Patient's X-ray, and other radiological reports

• Clinical Measures

• Excel sheet

• The Visual Analogue WOMAC 3.0 scale & VAS scale

• Goniometer

RESULT :

PROCEDURE OF RESEARCH:

Survey of the working professionals

Data collection by using the questionnaire

Data analysis

Data Interpretation

Result

Conclusion

A sum of 100 working professionals responded answering the questionnaire. An analysis was done by excel & calculation was done by chi square test calculator. The chi- square statistics found as 0.1695. The p value is 0.918761. The result is not significant at $p < .01$.

RESULTS			
	NONE	MILD	MODERATE
MALE	42 (41.80) [0.00]	1 (1.32) [0.08]	1 (0.88) [0.02]
FEMALE	53 (53.20) [0.00]	2 (1.68) [0.06]	1 (1.12) [0.01]

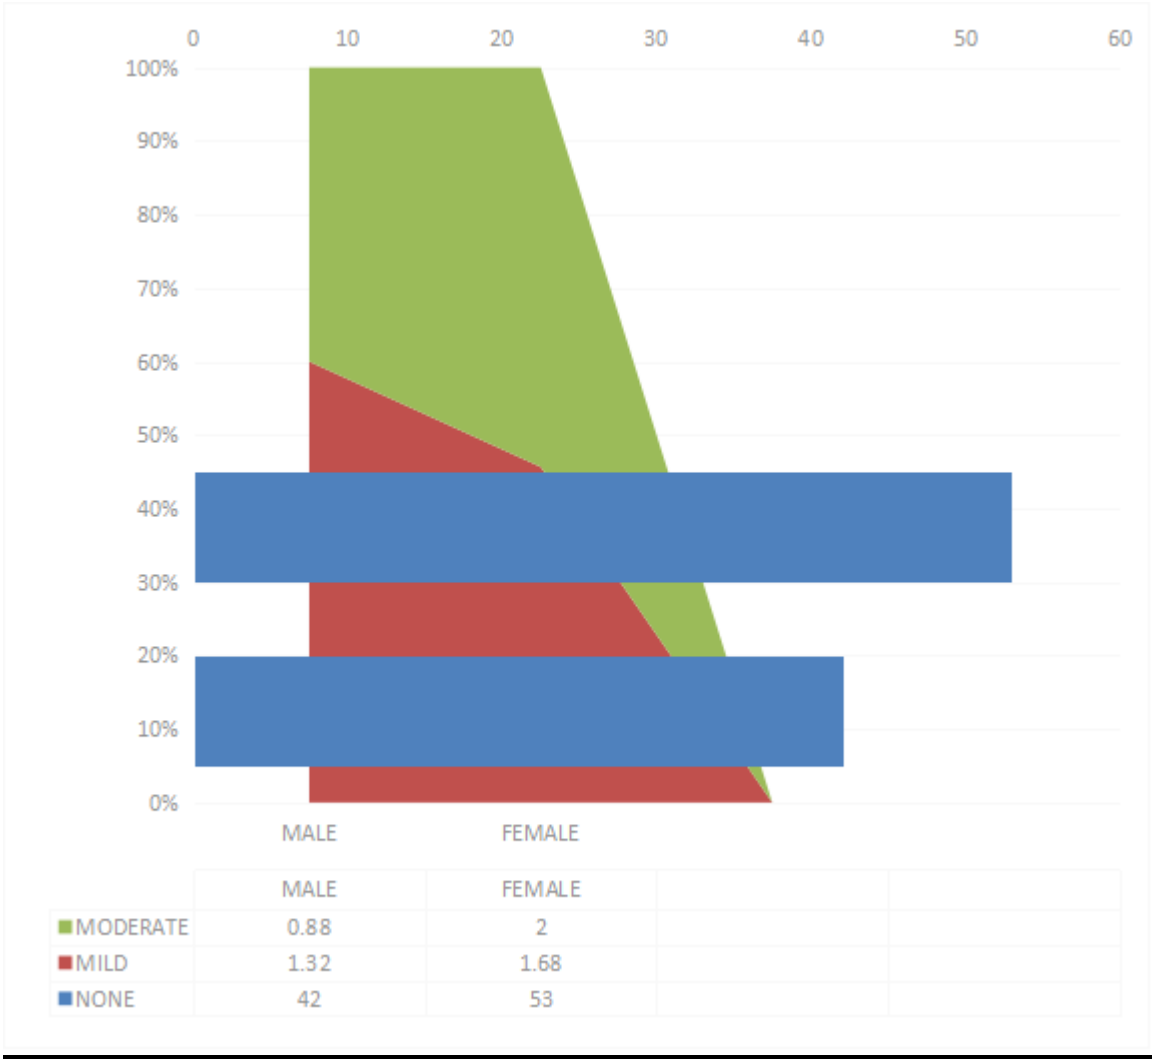
1.1 RESULT TABLE WITH P VALUE AND CHI SQUARE DATA

The prevalence of OA varies according to the definition of OA, the specific joint(s) under study, and the characteristics of the study population. The age standardized prevalence of radiographic knee OA in given subjects age between 21-30 years was only 5% among the all participants. Out of 100 subjects only 5 subjects primarily suspected of having OA of knee. Out of 100 subjects there was 56 female and 44 male subject in this survey. And OA was found in 3 female and 2 male subject after assessing clinical measures.

So, the prevalence percentage of OA of knee in young people age between 21 to 30 years having prolonged sitting or standing work profession would be as below:

Prevalence percentage = OA will be found for given Criteria **DEVIDED BY** OA Will be not found for given criteria **INTO 100%**

TOTAL PREVALENCE PERCENTAGE = **5.2631%**
PREVALANCE PERCENTAGE IN MALES = **2.10%**
PREVALANCE PERCENTAGE IN FEMALES = **3.15%**

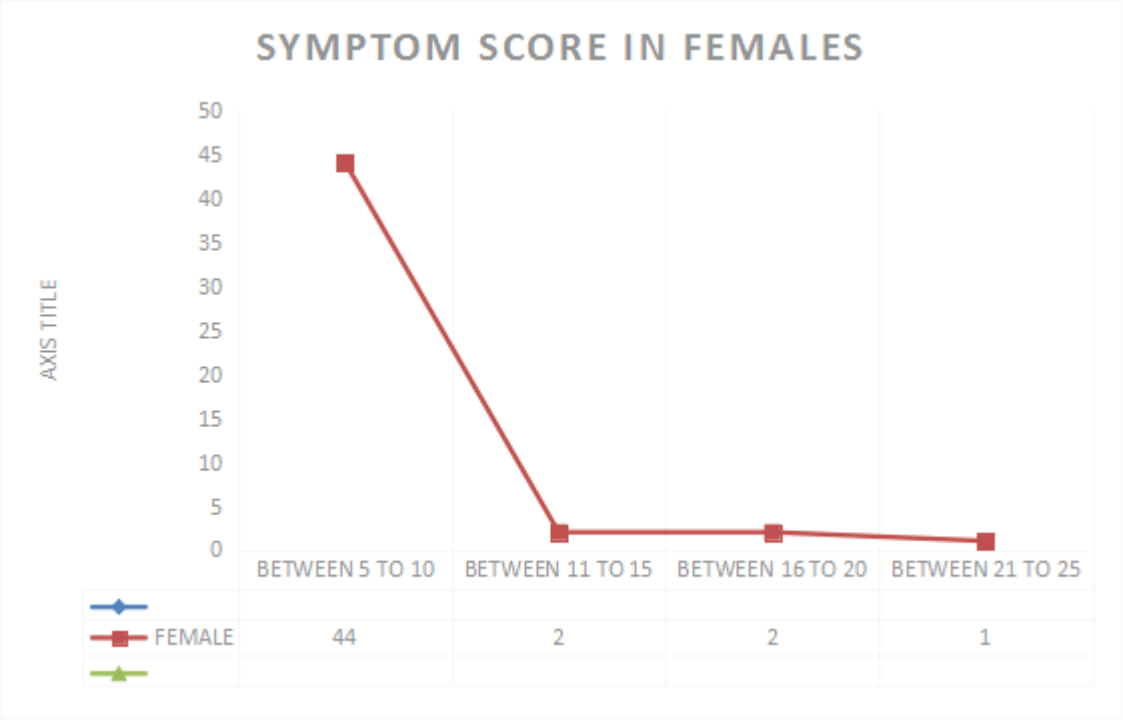


GRAPH 1.1 CHI SQUARE

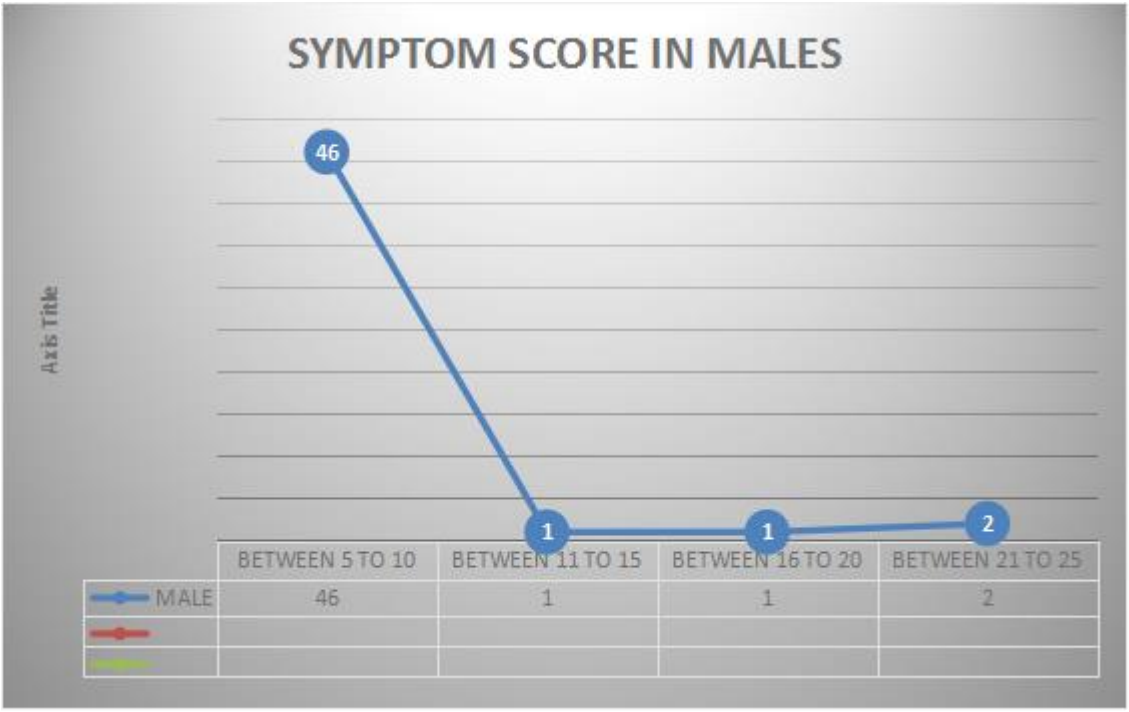
➡ ***CHI SQUARE STATISTICS WITH PREVALANCE DATA***

A chi-squared test (also chi-square or χ^2 test) is a statistical hypothesis test that is valid to perform when the test statistic is chi-squared distributed under the null hypothesis, specifically Pearson's chi-squared test and variants thereof. Pearson's chi-squared test is used to determine whether there is a statistically significant difference between the expected frequencies and the observed frequencies in one or more categories of a contingency table.

Symptoms - These questions should be answered thinking of your knee symptoms during the **last week**



GRAPH 1.2



GRAPH 1.3

Stiffness - The following questions concern the amount of joint stiffness you have experienced during the **last week** in your knee. Stiffness is a sensation of restriction or slowness in the ease with which you move your knee joint.

DISCUSSION :

The present study was carried out to find prevalence of osteoarthritis in young people (Age between 21 to 30 years) having prolonged sitting and standing profession. This study was performed in the ahmedabad and nearby areas. any damage to the joints cannot be reversed, the symptoms of osteoarthritis can be managed, allowing sufferers to live as normal a life as possible.

Treatments for osteoarthritis include lifestyle advice, medications, orthobiologics and surgery.

Lifestyle changes include taking steps to lose weight if necessary and doing low impact exercise, such as yoga, to help strengthen muscles around the joint to stabilise it. Your doctor may refer you to a physiotherapist if your job or choice of physical activity is causing your symptoms. They may also recommend topical treatments or the use of hot or cold compresses.

Osteoarthritis typically affects people over the age of 50, but young people can be affected as well.[2] The CDC estimates that about 7% of the U.S. population aged 18–44 had been diagnosed with OA from 2013–2015.

Younger people who are active in sports or other physically demanding activities, or who have sustained an injury such as a torn meniscus—a tear in the cartilage of the knee—may be more prone to developing the condition earlier in life.

Over 32 million people across the U.S. live with osteoarthritis.[3] While this condition can affect any joint, it typically affects the knees, hips, back, hands, and neck. Symptoms such as pain or swelling may not occur right away and can worsen over time.

This study was conducted to find the prevalence of osteoarthritis of knee in young people age between 21 to 30 years having sitting or standing work profession. The purpose of the study was to find prevalence ratio of OA in young people. Osteoarthritis (OA) is defined as a heterogeneous group of conditions that lead to joint symptoms and signs associated with a defective articular cartilage and related changes in bone morphology. It is considered the most common type of arthritis, as well as one of the most significant health problems that pervades our modern world. In 2019, it was estimated that 43 million adults suffered from arthritis. Of those, 26.9 million adults aged 25 years or older had OA. One in four people is expected to develop symptomatic OA in his or her lifetime.

SUMMARY & CONCLUSION

The prevalence of OA varies according to the definition of OA, the specific joint(s) under study, and the characteristics of the study population. The age standardized prevalence of radiographic knee OA in given subjects age between 21-30 years was only 5% among the all participants. Out of 100 subjects only 5 subjects primarily suspected of having OA of knee. Out of 100 subjects there was 56 female and 44 male subject in this survey. And OA was found in 3 female and 2 male subject after assessing clinical measures.

A sum of 100 working professionals responded answering the questionnaire. An analysis was done by excel & calculation was done by chi square test calculator. The chi- square statistics found as 0.1695. The p value is 0.918761. The result is not significant at $p < .01$.

This study concludes that prevalence of osteoarthritis is very less in young working professionals that's why we can conclude that young people is not very prone for OA.
But there are some potential chances for having OA is present like lifestyle, genetic factors and other factors that can cause OA in young age.

LIMITATION & FUTURE RECOMMENDATION

1. Small sample size.
2. Limited research area.
3. The self selection and convenient sampling of participates to complete the study may also influence the result.
4. Very limited access to clinical measures.
5. Very small subject group.

FUTURE RECOMMENDATION

- Future research should replicate these findings in other large samples , take larger age groups to find most accurate prevalence of OA in young working professionals.

ANNEXURE A

Clinician's name (or ref) **Patient's d.o.b :**

INSTRUCTIONS: This survey asks for your view about your knee. This information will help us keep track of how you feel about your knee and how well you are able to do your usual activities.

Answer every question by ticking the appropriate box. If you are unsure about how to answer a question, please give the best answer you can.

Symptoms - These questions should be answered thinking of your knee symptoms during the **last week.**

S1. Do you have swelling in your knee?

○ Never ○ Rarely ○ Sometimes ○ Often ○ Always

S2. Do you feel grinding, hear clicking or any other type of noise when your knee moves?

○ Never ○ Rarely ○ Sometimes ○ Often ○ Always

S3. Does your knee catch or hang up when moving?

○ Never ○ Rarely ○ Sometimes ○ Often ○ Always

S4. Can you straighten your knee fully?

○ Never ○ Rarely ○ Sometimes ○ Often ○ Always

S5. Can you bend your knee fully?

○ Never ○ Rarely ○ Sometimes ○ Often ○ Always

Stiffness - The following questions concern the amount of joint stiffness you have experienced during the **last week** in your knee. Stiffness is a sensation of restriction or slowness in the ease with which you move your knee joint.

S6. How severe is your knee joint stiffness after first wakening in the morning?

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

S7. How severe is your knee stiffness after sitting, lying or resting **later in the day?**

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

Pain[1]

P1. How often do you experience knee pain?

○ Never ○ Monthly ○ Weekly ○ Daily ○ Always

What amount of knee pain have you experienced the **last week** during the following activities?

P2. Twisting/pivoting on your knee

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

P3. Straightening knee fully

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

P4. Bending knee fully

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

P5. Walking on flat surface

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

P6. Going up or down stairs

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

P7. At night while in bed

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

P8. Sitting or lying

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

P9. Standing upright

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

Function, daily living - The following questions concern your physical function. By this we mean your ability to move around and to look after yourself. For each of the following activities please indicate the degree of difficulty you have experienced in the **last week** due to your knee.

Al. Descending stairs				
○ None	○ Mild	○ Moderate	○ Severe	○ Extreme

A2. Ascending stairs				
○ None	○ Mild	○ Moderate	○ Severe	○ Extreme

For each of the following activities please indicate the degree of difficulty you have experienced in the **last week** due to your knee.

A3. Rising from sitting				
○ None	○ Mild	○ Moderate	○ Severe	○ Extreme

A4. Standing				
○ None	○ Mild	○ Moderate	○ Severe	○ Extreme

A5. Bending to floor/pick up an object				
None	Mild	Moderate	Severe	Extreme

A6. Walking on flat surface				
○ None	○ Mild	○ Moderate	○ Severe	○ Extreme

A7. Getting in/out of car				
○ None	○ Mild	○ Moderate	○ Severe	○ Extreme

A8. Going shopping				
○ None	○ Mild	○ Moderate	○ Severe	○ Extreme

A9. Putting on socks/stockings				
○ None	○ Mild	○ Moderate	○ Severe	○ Extreme

A10. Rising from bed				
○ None	○ Mild	○ Moderate	○ Severe	○ Extreme

A11. Taking off socks/stockings

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

A12. Lying in bed (turning over, maintaining knee position)

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

A13. Getting in/out of bath

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

A14. Sitting

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

A15. Getting on/off toilet

○ None ○ Mild ○ Moderate ○ Severe ○ Extreme

For each of the following activities please indicate the degree of difficulty you have experienced in the **last week** due to your knee

A16. Heavy domestic duties (moving heavy boxes, scrubbing floors, etc)

○ Never ○ Rarely ○ Sometimes ○ Often ○ Always

A17. Light domestic duties (cooking, dusting, etc)

○ Never ○ Rarely ○ Sometimes ○ Often ○ Always

Thank you very much for completing all the questions in this questionnaire.

ABSTRACT

BACKGROUND:

Frozen Shoulder Is An Idiopathic Diseases Characterized By Fibrosis, Decrease Volume Of The Glenoid Capsule, And Progressive Pain With Loss Of ROM.

SCAPULAR PNF TECHNQUES :

PNF Is A Treatment Concept With Four Theoretical Mechanisms, Referred To As Autogenic Inhibition, Reciprocal Inhibition, Stress Relaxation, And The Gate Control Theory, That Enhance ROM And Muscle Activation. PNF Has An Positive Effect On Pain, Muscle Strength.

CLASSIC SHOULDER EXERCIES :

- **Strengthening exercises :**

- Codman Pendulum exercises.
- Wand (stick) exercises.
- Pulley exercises.

- Finger walk.
- Resisted Exercise With Theraband

- **OBJECTIVES:**

- To Determine The Acute Effect Of Scapular PNF Techniques With Tens In Patients With Adhesive Capsulitis.
- To Determine The Acute Effect Of Classic Shoulder Exercises With Tens In Patients With Frozen Shoulder.
- To Compare The Acute Effect Between The Scapular PNF Techniques With Tens And Classic Shoulder Exercises With Tens In Patients With Adhesive Capsulitis.

METHODOLOGY:

30 Patients are Allocate To 2 Groups Scapular PNF Exercise And Tens, Classic Exercise And Tens. The Intervention Were Apply In A Single Session. The Visual Analog Scale(Vas), Lateral Scapular Slide Test, Range Of Motion And Simple Shoulder Test Were Evaluate Before And After The Intervention. All The Participants Of The Study Were Be Given Treatment According To The Group For 4 Weeks.

Subjects – 30 Subjects

Groups – 2 Groups

Sampling Method – Randomized Sampling Method

	Group 1	Group 2
Treatment Method	Scapular PNF With TENS	Classic Shoulder Exercise With TENS
Subjects	15	15
Duration: 4x/W/4 Weeks	4x/W/4 Weeks	

Inclusion Criteria:

- Having A Painfull Stiff Shoulder For At Least 3 Months, And Diagnosed As Frozen Shoulder.

- Having Limited Rom Of Shoulder Joint(Rom Losses Of 25% Or Greater Compared With The Non Involved Shoulder In At Least 2 Of The Following Shoulder Motion; Glenohumeral Flexion, Abduction.

Exclusion Criteria:

- Diabetes Mellitus
- A History Of Surgery On The Particular Shoulder
- A Pain Full Stiff Shoulder After A Severe Trauma
- Fracture Of The Shoulder Complex
- Rheumatoid Arthritis
- Rotator Cuff Rupture
- Tendon Calcification

Analysis:

- Between group analysis of obtained data were be done by using Unpaired T- test.
- Within the same group analysis (pre and post) of obtain data were be done by using paired T-test.

RESULT & CONCLUSIONS:

During The Course Of The Study It Has Been Concluded That Scapular PNF Techniques And Classic Shoulder Exercises Both Are Improved Pain, Scapular Dyskinesis And Functional Impairment The Patients With Adhesive Capsulitis. There Is Significant Increase In Both Scapular PNF Techniques And Classic Shoulder Exercises After 4-Week Treatment Duration In Both Groups. But Group Receiving Scapular PNF Techniques Showed More Power Full Improvement In Pain, Scapular Dyskinesis And Functional Improvement.

INTRODUCTION

INTRODUCTION

Adhesive capsulitis, Describes The common Shoulder condition Characterized By Painful And Limited Active And Passive Range of Motion(Rom). Individuals With Primary Adhesive capsulitis Are Commonly

Between 40 and 65 Years And The Incidence Appears Higher In Females Than Males.(1)

- The Term Adhesive capsulitis Were BE Used, Because It Encompasses Both Primary Adhesive Capsulitis And Secondary Adhesive Capsulitis Related to Systemic Diseases And Extrinsic or Intrinsic Factors, Excluding Cerebral Vascular Accident, Proximal humeral #, And Causative Rotator Cuff or Labral Pathology.(1)

(FIG 1: ADHESIVE CAPSULITIS)

Adhesive capsulitis IS Estimated To Affected 2% Of The General Population, With A Cumulative Incidence Between Of 2.4 Per 1000 Person-Years. It Is Rare Before The Age Of 40,With A Peak Incidence Between 40 and 60 And Is Unsual In Patient Over 70 Years (Except Secondary Traumatic Adhesive Capsulitis) And In Manual Workers. It Affects Women Slighly More Often Than Men. The Economic Impact Of The Condition Is Underscored By Its Predilection For Adults Of Working Age(8.2% For Men And 10.1% For Women).(2)

Diabetes Mellitus Is The Common Condition Most Commonly Associated With Adhesive Capsulitis. The Combined Prevalence Of A Diabetic Predisposition And Adhesive Capsulitis Is Estimated To Be As High As 71.5% Diabetics Have A 10% to 20% Lifetime Risk Of Developing A Adhesive Capsulitis, With A 4% Point Prevalence, And A Two To Four Times Greater Risk Than The General Population.(2)

The Glenohumeral joint Is An Incongruous, Ball & Socket Triaxial Joint With A Lax Joint Capsule. Its Supported By The Tendons Of The Rotator Cuff And The Glenohumeral (Suprior, Middle, Inferior) And Coracohumeral Ligaments.(3)

ANATOMY OF SHOULDER JOINT

PRESENTOR :DR.B.VAMSHIKIRAN

(FIG 2: NORMAL SHOULDER ANATOMY)

The Coracohumeral Ligament Originated From The Base And Lateral Border Of The Coracoid Process And Runs Transversely To The Grater Tuberosity. Its Anterior Border Is Distrincts Medially And Merges Laterally. Whereas Its Posterior Border Is Indistinct. it's a Primary Restraint To The Long Head Of Biceps Tendon.(4)

Causes:

The Causes are mainly idiopathic and are due to fibrosis following chronic inflammation. This could be due to:

1}Primary shoulder

2}Secondary Non-shoulder

1 Primary shoulder cause problems directly related to shoulder joint which can give rise to adhesive capsulitis :

tendinitis of rotator cuff

bicipitaltenditis

and dislocation around the shoulder

2 Secondary Non shoulder causes problems not related to shoulder joint like

Diabetes

Hyperthyroidism

Reflex sympathetic dystrophy

Frozen hand syndrome

Complication of Collis's fracture can all leads to adhesive capsulitis.

The reason could be prolonged immobilization of the shoulder joint due to reffered pain, Etc.(5)

Classification:

The Classification System By Including Disease Such As Diabetes Mellitus, Myocardial Infraction Or Various Neurological Disorder Under Secondary Frozen Shoulder Classification Scheme Where, **Primary Adhesivecapsulitis**And Idiopathic Adhesive capsulitis Are Considered Identical And Non AssociatedWith A Systemic Condition Or History Of Injury.

1. Secondary Adhesive capsulitis Was Defined By 3 Subcategories Extrinsic Secondary Adhesive capsulitis Includes Patients Whose Pathology Is Not Directly Related To The Shoulder, And Intrinsic Secondary Adhesive capsulitis Describes Patients With A Known Pathology Of The Glenohumeral Joint Soft Tissues Or Structures. Specific Causes Of Secondary Adhesive capsulitis May Influence Prognosis. For Instance, Individuals With Secondary Adhesive capsulitis Related To Insulin-Dependent Diabetes Are More Likely To Have A More Protracted And Difficult Clinical Course.(6)

Stage Of Adhesive Capsulitis

Stage 1

- Duration Of Symptoms: 0 To 3 Months.
- Pain With Active And Passive Rom.
- Pathologic Changes: Hypertrophic, HypervascularSynovitis, Rare Inflammatory Cell
- Infiltrates, Normal Underlying Capsule.

Stage 2: Freezing stage

- Duration Of Symptoms: 3 To 9 Months
- Chronic Pain With Active And Passive Rom
- Significant Limitation Of Forward Flexion, Abduction, Internal Rotation, External Rotation
- Pathologic changes: hypertrophic, hypervascularsynovitis with perivascular and subsynovialscar ,fibroplasias and scar formation in the underlying capsule.

Stage 3: Frozen Stage

- Duration Of Symptoms: 9 To 15 Months.
- Minimal Pain Except At End Rom.
- Significant Limitation Of Rom With Rigid End Feel.
- Pathologic Changes: “Burned-Out” SynovitisWithout Significant Hypertrophy Or Hypervascularity. Underlying Capsule Shows Dense Scar Formation.

Stage 4: Thawing Phase

- Duration Of Symptoms: 15 To 24 Months.
- Minimal Pain.
- Progressive Improvement In Rom.(1)

Common Structural and Functional Impairments

- Night Pain And Disturbed Sleep During Acute Flares.
- Pain On Motion And Often At Rest During Acute Flares.
- Mobility: Decreased Joint Play And ROM, Usually Limiting External Rotation And Abduction With Some Limitation Of Internal Rotation And Elevation In Flexion.
- Posture: Possible Faulty Postural Compensations With Protracted And Anteriorly Tilted Scapula, Rounded Shoulders, And Elevated And Protected Shoulder.
- Decreased Arm Swing During Gait.

- Muscle Performance: General Muscle Weakness And Poor Endurance In the Glenohumeral Muscles With Overuse Of The Scapular Muscles Leading To Pain In The Trapezius, LevatorScapulae, And Posterior Cervical Muscles.
- Substitution For Limited Glenohumeral Motion With Increased Scapular Motion, Especially Elevation.(3)

Common Activity Limitation And Participation Restriction

- Instability To Reach Overhead, Behind Head, Out To The Side, And Behind Back; Thus, Having Difficulty Dressing (Putting On A Jacket Or Coat Or In The Case Of Women, Fastening Undergarments Behind Their Back), Reaching Hand Into Back Pocket Of Pants (To Retrieve Wallet), Reaching Out A Car Window (To Use An ATM Machine), Self-Grooming (Combing hair, Brushing Teeth, Washing Face), And Bringing Eating Utensils To The Mouth.
- Difficulty Lifting Weighted Objects, Such As Dishes Into A Cupboard.
- Limited Ability To Sustain Repetitive Activities.

Scapular Dyskinesis:

- The Scapula Is The Large Triangular-Shaped Bone At The Back Of Your Shoulder Frequency Known As The Shoulder Blade. Its Only Attachment To The Rest Of The Skeleton Is Throught The Collarbone At The Acromioclavicular Joint. Therefore, The Bone Is Primarily Held In Place By The Attached And Surrouding Muscles. Many Muscle Use The Large Area Of The Scapula For Attachment and They Enable The Vast Range Of Shoulder Motion.(7)
- At The Order Edge Of The Scapula A Shallow Socket Form And Is Where The Humeral Heads Sits Forming The Shoulder Joint. Proper Positioning And Movement Of The Scapula Is Critical For Full And Normal Shoulder Range Of Motion.(7)
- We Use The Acronym **SICK(Scapular Malposition, Inferior Medial Border Prominence, Coracoid Pain And Malposition, And Dyskinesis Of Scapular Movement)** To Refer to An Injury Resulting From Overuse And Fatigue Of The Muscle That Stabilize And Provide Motion For The Scapula.(7)

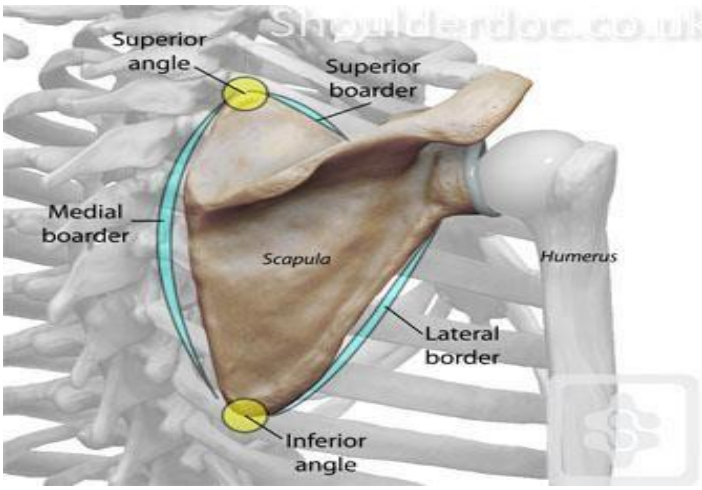

FIG 3: SICK SCAPULA

Risk Factors

- Intense, Repetitive Overhead Activity (Throwing, Tennis, Volleyball)
- Overuse Fatigue.
- Injury To Other Structure Of The Shoulder.
- Direct Trauma
- Muscle Strain
- Tense Pectoralis Major Possibly Resulting From Unbalanced Weight Training(7)

Signs And Symptoms

- Affected Shoulder Appears Dropped Or Lower Than Unaffected Shoulder
- Medial Scapular Protrusion
- Noticeable Hitches And Jumps In Scapular Motion During Arm Movements.
- Scapular Pain
- Pain At The Front, Back, Or Top Of The Shoulder.
- Pain On The Outside Of Your Upper Arm.(7)

Scapular Dyskinesis Classification System(8,9)

- **Type 1: Inferior Border**
- At Rest, The Inferior Medial Scapular Border May Be Prominent Dorsally. During Arm Motion. The Inferior Angle Tilts Dorsally And The Acromion Tilts Ventrally over The Top Of The Thorax.
- The axis Other Rotation Is In The Horizontal Plane.

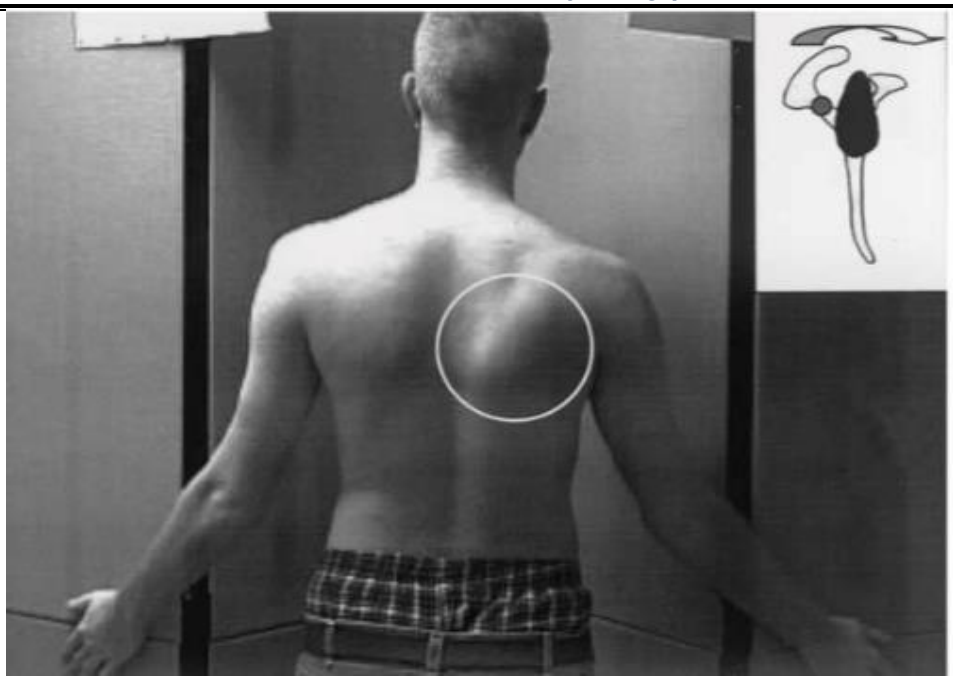

FIG 4: INFERIOR BORDER SCAPULA DYSKINESIS

TYPE 2: MEDIAL BORDER

- At Rest, The Entire Medial Border May Be Prominent Dorsally. During Arm Motion, The Medial Scapular Border Tilts Dorsally Off The Thorax. The Axis Of The Rotation Is Vertical In The Frontal Plane.

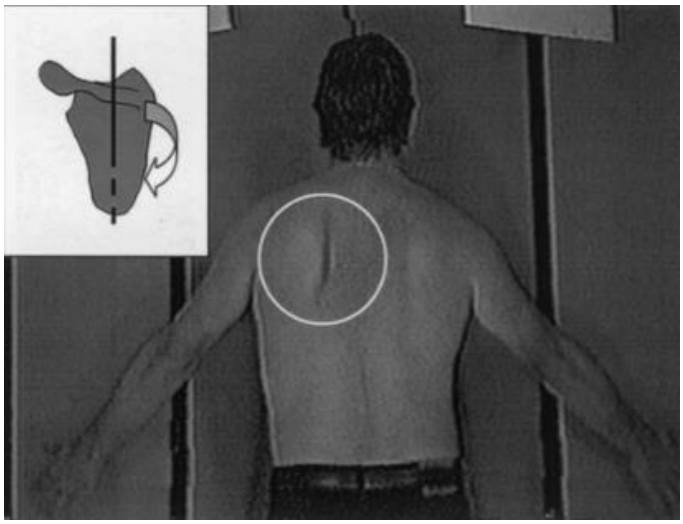

FIG 5: MEDIAL BORDER OF SCAPULAR DYSKINESIS

TYPE 3 : Superior Border

- At Rest, The Superior Border Of The Scapula May Be Elevated And The Scapula Can Also Be Anteriorly Displaced. During Arm Motion, A Shoulder Shrug Initiates Movement Without Significant Winging OF The Scapula Occurring. The Axis Of This Motion Occurs In The Sagittal Plane.

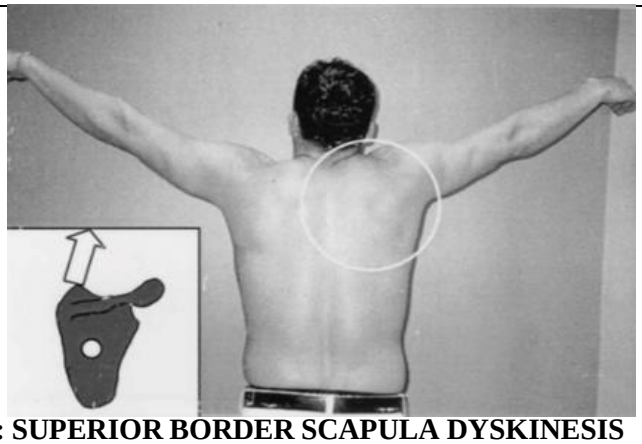

FIG 6: SUPERIOR BORDER SCAPULA DYSKINESIS

Type 4 : Symmetric Scapulohumaral

- At Rest, The Position Of Both Scapula Are Relatively Symmetrical, Taking Into Account That The Dominant Arm May Be Slightly Lower. During Arm Motion, The Scapulae Rotate Symmetrically Upward Such That The InferiorAngles Translate Laterally Away From The Midline.

FIG 7: SYMMETRIC SCAPULOHUMERAL

The Studies Cited Have Shown That Various Forms Of Exercise Are Effective In Reducing The Motion Restriction And Pain Of Patients With Adhesive Capsulitis. Physical Therapists, As Specialists Dealing With Exercise And Movement Dysfunction, Play A Major Role In Restoring Function To These Persons. After Performing The Necessary Tests To Confirm The Diagnosis Of Adhesive Capsulitis Ascertain The Current Status Of The Condition, And Identify Causative Factors, A Physical Therapist Is Prepared To Design A Treatment Program. Each Individual Case Were Dictate Whether Physical Therapy Is To Be Used Alone Or In Conjunction With Other Medical Or Surgical Treatment.

A Combination Of Exercise And Physical Modalities Helps Accomplish This Objective. Activate And Active-Assistive Exercises Such As Pedulum, Wand , And Physiologic ROM Should Be Performed For At Least One Half-Hour Three Times A Day. Passive Exercise Has Multiple Benefits. Gentle Passive Movement, Short Of Pain And The Pathological limit Of Motion, Reduces Pain. Often, Reflex Muscle Spasm Prevents A Patient From Performing Active Exercise, Whereas A TherapistCan Passively Guide The Lime Further Into The Range Without Eliciting Spasm Or A Stretch Reflex. Also , Because Many Patients Are Reluctant Psychologically To Perform Regular, Appropriate Active Exercise, Passive Exercise Becomes The Treatment Of Choice(10).

Evaluation Of The Position Of The Scapula Is Very Important In The Pathologies Of The Shoulder Because These Pathologies Are Responsible For The Second And Third most Common Causes Of Musculoskeletal Pain. Abnormal Changes In The Position Of The Scapula At Different Angles Of The Shoulder Indicate A Disturbance Of The ScapulohumeralRhythm(11,12).

Even Though Scapular Alterations Have Been Assessed In Patients With Frozen Shoulder, Treatment Programs Were Focused On Pain Relief And Improvement In ROM. Scapular Exercises Were Not Included In The Programs

Even Though The Scapula Plays Several Roles In Facilitating Optimal Shoulder Funcation(13).

SCAPULAR PNF TECHNQUES :

PNF Is A Treatment Concept With Four Theoretical Mechanisms, Referred To As Autogenic Inhibition, Reciprocal Inhibition, Stress Relaxation, And The Gate Control Theory, That Enhance ROM And Muscle Activation.(14,15)

PNF Has Been Reported To Be Effective In Relieving Pain And Improving Functional Abilities. PNF Methods, Particularly Those Involving Reciprocal Activation Of The Agonist And Antagonist To The Desired Motion, Provide The Greatest potential For Muscle Functioning.(16,17)

Among Therapeutic Approaches, Joint Mobilization Using PNA Has A Positive Effect On Pain, Muscle Strength, And ROM. Proper Function Of The Upper Extremities Requires Both Motion And Stability Of The Scapula.(19,20)

The Scapula Patterns Defined In PNF Are Activated Within The Upper Extremity Patterns And Scapular Motion Together(21). The Effects Of The Shoulder Have Been Investigated In Some Studies(22-29). However, No Previous Study Has Investigated The Effects Of Scapular PNF Exercises In AC Rehabilitation.

CLASSIC SHOULDER EXERCIES :

- **Strengthening exercises :**
- Codman Pendulum exercises.
- Wand (stick) exercises.
- Pulley exercises.
- Finger walk.
- Resisted Exercises With Theraband(30).
- Therefore, The **Aim Of This Study** Was To Compare The Acute Effects Of Scapular PNF Techniques And Classic Shoulder Exercises With TENS On Pain, Scapular Dyskinesis, Shoulder ROM, And Functionality In Patients With AC.
- In This Study, Pain, Scapular Dyskinesis And Shoulder Function Were Be Measured Using Visual Analogue Scale(VAS), Lateral Scapular Slide Test (LSST) And Simple Shoulder Test.

REVIEWOF LITERATURE

1. **Positional stretching of the coracohumeral ligament on a patient with adhesive capsulitisJose Orlando Ruiz Et Al(2009)** Performed A Study On Positional Streching Of Coracohumeral Ligament On A Patient With Adhesive Capsulitis And Concluded That the Coracohumeral Ligament Streching Is An Effective Therapeutic Strategy To Help Reduce Loss Of Joint Mobility And Function.(31)

2. **Adhesive shoulder capsulitis : Does the timing of manipulation influence outcome ?Olivia Flannery Et Al (2007)** Conducted A Study On The Adhesive Shoulder Capsulitis. In Their Study They Mentioned That Duplay Was The First To Describe A Painful, Stiffening Condition Of The Shoulder, Which He Termed **Peri** – Arthritis Scapula Humerale And Codman In 1934 Named The Condition **Adheshive Capsulitis** Conclued That It Was Characterized By Slow Onset, Pain near The Insertion Of The Deltoid, Instability To Sleep On The Affected Side, Painful And Restricted Elevation And Term **Adheshive Capsulitis** Was Introducted By Neviaser In 1945, Based Upon His Finding Of Synovial Changes In The Gleno - Humeral joint.(32)

3. **The Pathology Of Frozen ShoulderG.C.R. Hand Et Al (2007)** Studies The Pathology Of Adhesive capsulitis. Twenty Two Subjects, Diagnosed As Primary Adhesive capsulitis Was inclued In Their Study Biopsies Were Taken From This Site And Histological And Immunocyto -chemical Analysis Was Performed To Identify The Type Of Cell Present. The Tissue Was Characterized By The Presence Of Fibroblast, Profiferating, Fibroblast And Chronic Inflamatory Response With Fibroblastic Proliferation Which May be Immune Modulated(33).

4. **J.Mobilization Techniques In Subjects With Frozen Shoulder Syndrome: Randomized Multiple-Treatment Trial. PhysTher 2007 Oct;87(10):1307-15. Epub 2007 Aug 7.Jing – Ian Yang (2007)** Did A Randomized Multiple Treatment Trial Of Mobilization Technique In Subject With Adhesive capsulitis Syndrome And The Results Concluded End Range Mobilization And Movement With Mobilization Are More Effective, Than Mid Range Mobilization In Increasing Mobility And Functional Ability In Patients With Adhesive capsulitis.(34)

5. **Adhesive Capsulitis : Does The Timing Of Manipulation Infulence Outcome. AetaOrthop. Belg, 2007,73,21-25.Oliva Flannery, HanamMullett Et Al(2007)** Performed A Study On Adhesive Shoulder capsulitis. In Their Study Used VAS For The Assessment Of Pain In The Shoulder In Subjects Suffering from Adhesive capsulitis And They Concluded That VAS Was Significant To Assess Pain In The Affected Shoulder(35).

6. **Non Operative Management Of Idiopathic Adhesive Capsulitis Journal Of Shoulder And Elbow Surgery 2006.569-573.Wereiam N> Levine Et Al (2006)** Performed A Study On Non Operative Management Of Idiopathic Adhesive capsulitis. In Their study They Said That This Condition Was First Describe By Duplay In 1872 And Named As **FROZEN SHOULDER** In 1934 And Is Characterized By Pain And Restriction Of Both Active and Passive ROM. They Concluded That the Pathology Is Anatomy Was First Describe For Frozen shoulder.(36)

7. **Frozen Shoulder Richard Dias Et Al (2005)** Performed A Study On The Clinical Review Of Frozen Shoulder. They Studied The Incidence, Clinical Presentation, Diagnosis And Treatment Modalities In Adhesive capsulitis. Regarding The Incidence They Concluded That The Onset Of This Condition Before The Age Of 40 Is Very Uncommon. The Peak Age Is 56 Yrs And The Condition Occurs Slightly More Often In Women Than Men. In 6-17% Of Patients, The Other Shoulder Becomes Affected. The Non Dominant Shoulder Is Slightly More Likely To Be Affected.(37)

8. **Acromiohumeral distance in a seated position in persons with impingement syndrome Hebert LJ Et Al(2003)** Had Done A Prospective Cohort Study To Identify The Bestindicators Of The Current Disability Of Patients With Shoulder Impingement Syndrome(Sis)And The Strongest Predictors Of 3 Months SIS-Related Disability. The SPADI Score ALBaseline And The Presence Of Sis On The Dominant Side,Among Other Variables Predicted86% The Variance Of The SPADI At 3 Months And Concluded That Variables That BestExplain The Current Disability Level And Predictors Of Short-Term Leval Of DisabityShould Be Considered In SIS Treatment Planning As Well As For Establishing Prognosis.(38)

9. **Influence of Comorbidity on Self-Assessment Instrument Scores of Patients with Idiopathic Adhesive Capsulitis Jennifer Moriatis Wolf And Andrew Green(2002)** Did A Study To Determine The"Influence Of Co- Morbidity On Self - Assessment Instruments Scots Of Patients With Adhesive Capsulitis. Phase 2 Adhesive Capsulitis Were Prospectively Evaluated With The Use Of VAS And They Found That The Score On VAS Can Be Applied To The Evaluation Of The Patient And May Help To Identify Patients Who Potentially Require A Longer Treatment Course Or Those Outcome WereBe Less Satisfactory.(39)

10. **End-range mobilization techniques in adhesive capsulitis of the shoulder joint: A multiple-subject case report VermeulenHM Et Al (2000)** Did A Study On Effectiveness Of End Range Mobilization Technique In Adhesive

    Capsulitis Of Shoulder Joint In 45 Subjects And The Results Concluded End Range Mobilization Technique To Be Beneficial In Improving Joint Mobility.(40)

11. **Idiopathic adhesive capsulitis. A prospective functional outcome study of nonoperative treatment Griggs Et Al (2000)**Reported That Following A Physical Therapy Program Consisting Of Passive Stretching Exercises (Forward Elevation, External Rotation, Horizontal Adduction And Internal Rotation) At A Mean Follow - Up Of 22 Months, Patients Demonstated A Reduction In Pain Score From 1-57 To 1 -16 In Range From One To Five Points Improvements in Active Range Of Motion, And 64 Patients (20%) Reported A Satisfactory Outcome.(42)

12. **Reliability of goniometric measurements Boone DC, Azen SP Et Al(1987)** Conducted A Study To Determine The Intra - Tester And Inter-Tester Variability And Reliability Of Goniometric Measurement Taken By Four Physical Therapists On Upper And Lower Extremity Motions. Their Findings Indicated The Necessity For Using The Same Lester When Effects Of Treatment Are Evaluated.(43)

NEEDOF STUDY

NEEDOFSTUDY

NEEDOFSTUDY

- There Are Lots Of Study Available Which Suggest The Treatment Of Adhesive Capsulitis Which Includes Scapular PNF Techniques , Classic Shoulder Exercises, Strengthning Exercises , Mobilization Techniques Etc. But There Are Lack Of Evidence Which Compare The Acute Effect Of Scapular PNF Techniques And Classic Shoulder Exercises With TENS In The Effectiveness Between These Treatment Groups For Adhesive Capsulitis Patients.

OBJECTIVESOFTHESTUDY

OBJECTIVES OFTHESTUDY

OBJECTIVEOFTHESTUDY

To Determine The Acute Effect Of Scapular PNF Techniques With Tens In Patients With Adhesive Capsulitis.

To Determine The Acute Effect Of Classic Shoulder Exercises With Tens In Patients With Frozen Shoulder.

To Compare The Acute Effect Between The Scapular PNF Techniques With Tens And Classic Shoulder Exercises With Tens IN Patients With Adhesive Capsulitis.

HYPOTHESIS

HYPOTHESES

HYPOTHESIS

- **Null Hypothesis :**

  There Is No Significant Difference In Effect Of Scapular PNF Techniques And Classic Shoulder Exercises With Tens In The Patients With Adhesive Capsulitis.

- **Alternate hypothesis :**

  There Is Significant Difference In Effect Of Scapular PNF Techniques And Classic Shoulder Exercises With Tens In The Patients With Adhesive Capsulitis.

METHODOLOGY

Participants Were Allocate To Treatment Groups Using Sealed, Opaque Envelopes. The Envelopes Contained Stickers Denoting 1 Or 2. Subjects Who Picked 1 Were Included In The Groups 1 (scapular PNF techniques) And The Subjects Who Picked 2 Were Included In Group 2 (classic shoulder Exercises). Following This, Demographic Information were Conducting. Duration Of Symptoms And Side Affected Noted And Initial Evaluation Of Pain Profile Was Done Using Visual Analogue Scale (VAS).
Functional Performance Were Assessing Using The simple shoulder test scale (SST), And Lateral Scapular Slide Test (LSST).

Group 1 : Subjects Received scapular PNF techniques.
Group 2 : Subjects Received classic shoulder Exercises.

PROCEDURE:

The Purpose And The Procedure Of The Study were Explain In Details To The Patients Who Satisfied The Inclusion Criteria Both The Treatment Groups Completed With Written Informed Consent Form. Patients were Allocate To Treatment Groups Using Sealed, Opaque Envelopes. The Envelopes Contained Stickers Denoting 1 Or 2. Then Both Treatment Groups Of Each Patients Completed 2 times (Pre & Post) VAS, SST, LSST.

The Patients were Collect Along With The Routine Evaluation With Emphasis On; Pain Scores Using VAS Where A Horizontal Line (10cm Long) Was Drawn On A Paper And Patients Were Ask To Mark A Ponton The Line That Beat Defined The Present PAIN Level, Where – 0 Indicated No Pain And – 10 Indicated Severe Pain, Functional Performance were Assessed Using SST Scale. Outcome Measure Were Taken On Day 1 And After Completion Of Treatment Protocol I.E. After 4 Weeks.

SUBJECTS AND METHODS

This Study wereDesign As Randomized Control Trial. Thirty Subjects (Females, Males) Shoulder Exercises Groups And TENS (N=15),Simple Randomization And A Random-Number Table Were Used As The Method Of Sequence Generation For Patients.Same Therapist Evaluated All The Patients, While Another Therapist Applied The Intervention Methods The Therapist Who Applied The Interventions Was Experienced In Ac Treatment And Also Had A PNF Certificate.
All Patients Received An Explanation About The Purpose And Test Procedures Involved In The Study Before Enrollment. Each Patient Was Informed About The Study And Gave Written Informed Consent To Patient

GROUP 1 :

- **SCAPULAR PNF TECHNIQUES :**

In the PNF groups, scapular PNF was applied by a therapist in two diagonals, anterior elevation and posterior depression and posterior elevation and anterior depression with 20 repetitions. Patients lay on the unaffected side while the therapists stood in the line of desired motion. Firstly, the therapist gave preparatory instructions. In the beginning of the
Pattern, the therapist pulled the scapula to the elongated position and then gave instructions for the desired movement. Rhythmic initiation and repeated contractions facilitation techniques were applied in all patterns. These techniques are the best matchedmatched scapular facililation techniques of the PNF agonistic techniques.

GROUP 2 :

In the **classic Shoulder exercise group,** TENS were applied using the same procedure as describe above. After the TENS, strengthening exercises with Theraband and dumbbells were assigned to the patients. One set of want , finger walk , pulley and Codman pendulum exercises scapular elevation adduction (posture), and scapular stabilization exercises were also performed with 20 repetitions for each exercise.
wereRecruite For This Study Form The Near by Clinics In Kalol.
Subjects Werebe Randomly Allocated To Two Groups :SCAPULAR PNF TECH. And TENS (N=15), Classic

DISCUSSION

DISCUSSION

DISCUSSION

Adhesive Capsulitis Is Characterized By Painful Stiffness Of Shoulder That May Persist For Several Years. It Is A Common Disorder; With An Estimated Annual Incidence Of 3% To 5% In The General Population (Bridgman 1972, Pal Et Al 1986). Advocated Treatments Include Rest And Analgesics, Corticosteroid Injections, Acupuncture, Physical Therapy, Manipulation Under Anesthesia, And Arthroscopic Or Open Surgery. There Is No General Acceptance Of One Standard Treatment.

Adhesive Capsulitis Is A Contracture Of The Capsule And Depending On How Severe The Contracture Is (For It Varies In Intensity From Patient To Patient) The Treatment Is Decided. The First Objective In The Treatment Of Patients With Adhesive Capsulitis Is Pain Relief. This Is Essential, For It Permits Patients To More Readily Participate In An Exercise Program Aimed At Restoring Motion And Recovering Function.

The Primary Mode Of Treatment For Adhesive Capsulitis Is Prevention. Avoiding Prolonged Immobilization Of The Shoulder After Trauma Or When Shoulder Pain Develops Is Key. The Overall Goal Of Treatment Is To Relieve Pain, Restore Motion, And To Restore Function. Although Adhesive Capsulitis Is Generally Considered To Be A Self- Limiting Condition That Can Be Treated With Physical Therapy, The Best Treatment Has Been The Subject Of Extensive Investigation. A Variety Of Different Treatments Have Been Recommended.

CONCLUSIONANDSUMMARY

CONCLUSION &SUMMARY

CONCLUSION

The Study Rejects The Null Hypothesis – There Is No Significant Effect Of Scapular PNF Techniques And For Improving Pain, Scapular Dyskinesis And Functional Impairments The Patients With Adhesive Capsulitis And Accept The Experimental Hypothesis – There Is **Highly Significant Effect Of Scapular PNF Technique** And For Improving Pain, Scapular Dyskinesis And Functional Impairments The Patients With Adhesive Capsulitis .

During The Course Of The Study It Has Been Concluded That Scapular PNF Techniques And Classic Shoulder Exercises Both Are Improved Pain, Scapular Dyskinesis And Functional Impairments The Patients With Adhesive Capsulitis. There Is Significant Increase In Both Scapular PNF Techniques And Classic Shoulder Exercises After 4-Week Treatment Duration In Both Groups. But Group 1 Receiving **Scapular PNF Techniques Showed More Power Full Improvement In Pain, Scapular Dyskinesis And Functional Improvement.**

LIMITATIONS

LIMITATIONS

Limitations

- Sample Size Was Limited.
- There Is No Control Group.
- No Follow Up

Futurerecommendation

- The Same Study Can Be Done With Large Group.
- The Same Study Can Be Done With A Longer Follow- Up.
- The Same Study Can Be Done With Control Group.

Simple Shoulder Test

Answer each question by circling "Yes" or "No"

If you do not normally do the activity, try to imagine if you could. Would your shoulder restrict you. If the activity causes no pain, or rarely produces pain, then answer "Yes". If your shoulder hurts sometimes, often or always when you do the netivity, answer "No"

1.Is your shoulder comfortable with your arm at rest by your side?	Yes	No
2.Does your shoulder allow you to sleep comfortably?	Yes	No
3.Can you reach the small of your back to tuck in your shirt?	Yes	No
4.Can you place your hand behind your head with the elbow straight out to the side?	Yes	No
5.Can you place a coin on a shelf at the level of your Shoulder Without bonding your albow?	Yes	No
6.Can you lift one pound (full pint container) to the level at your shoulder without bending your elbow?	Yes	No
7.Can you lift eight pound (full gallon container) to the level of your shoulder without bending your elbow?	Yes	No
8.Can you carry twenty pounds at your side with the affected extremity?	Yes	No
9.Do you think yon can toss a softball under- hand twenty yards with the affected extremity?	Yes	No
10.Do you think you can toss a softball over hand twenty yards with the affected extremity?	Yes	No

11.Can you wash the back of your opposite shoulder with the affected extremity? Yes No

12.Would your shoulder allow you to work full-time at your regular job? Yes No

ABSTRACT

Background: Tendinopathy is a failed healing response of the tendon, with haphazard proliferation of tenocytes, intracellular abnormalities in tenocytes, disruption of collagen fibres, and a subsequent increase in non-collagenous matrix. There is always remains controversy regarding effectiveness of different treatment techniques for tendinopathy and aim of present study is to find and justify better treatment modality for management of tendinopathy. **Purpose:** To study the evidences regarding effect of Shock wave therapy versus Ultrasound therapy in tendinopathies. **Methodology:** This Evidence based study was conducted from June 2017 to June 2022. Search engines used to find appropriate articles were: PubMed, Google Scholar, PEDro, ResearchGate, ScienceDirect and Embase. Key words used were: Ultrasound, Shock wave Therapy and Tendinopathy. Articles were assessed via 2 scales: Centre for Evidence-Based Medicine's (CEBM's) Levels of Evidence and PEDro scale. **Results:** Total 156 articles were found, out of which 12 articles were relevant and from those 6 articles were included in this evidence-based study. From 6 studies, 1 Meta-analysis (Level of evidence 1a), 2 Randomized controlled trails (Level of evidence 1b) and 3 Comparative studies (Level of evidence 2b). **Conclusion:** There are moderate to strong evidences suggests the Shock wave therapy has more effect on Achilles, Gluteal, Rotator cuff and Lateral Elbow tendinopathies when compared to ultrasound.

KEYWORDS

Ultrasound, Shock wave Therapy and Tendinopathy

INTRODUCTION

Tendinopathy is a degenerative tendon disorder associated with chronic pain, swelling, and impaired physical function. Tendons are susceptible to injury as they undergo high forces during loading activities, receive little vascular blood supply, have low elasticity and decreased metabolism. Tendinopathy is thought to be caused by repetitive tendon microtrauma and subsequent failed healing responses, characterized by neovascularization, incidence of calcium deposits or calcification and increased tendon thickness or swelling.[1]

Histologically, tendinopathy is characterized by the absence of inflammatory cells, poor healing, non-inflammatory intratendinous collagen degeneration, collagen fiber disorientation and thinning, hypercellularity with high concentrations of glycosaminoglycans and proteoglycans, and neovascularization. [2][3]Although inflammatory cells are typically present in tendinopathy, tendon cell degeneration rather than inflammation is considered the pathological hallmark of the disorder, leading to the adoption of the term tendinopathy rather than the previously used diagnosis of tendinitis.

A variety of therapeutic techniques have been proposed for the appropriate management of patients with tendinopathy including exercise, orthotics, manual therapy, passive modalities, acupuncture or a combination of them. However, the effectiveness of each treatment option remains debatable.

Extracorporeal shockwave therapy is a popular method in the management of common tendinopathies and has been proposed as an effective supplement to other noninvasive therapies. The ultrasound is a commonly used modality for tendinosis. It Improves microcirculation, migration and synthesis of collagen fibers to the tendon [4]. There is growing evidence from in vitro and animal-based models that low intensity pulsed ultrasound (LIPUS) may also have beneficial effects on non-mineralized tissues, such as ligaments and tendons. For instance, using these models low intensity pulsed ultrasound (LIPUS) has been found to accelerate knee medial collateral ligament healing [5][6][7], augment tendon repair [8] and modulate tendon cell activity. Alexander et al showed that higher doses of ultrasound energy improved pain in individuals with shoulder calcific tendinitis. In contrast, Warden et al. found that lower doses of ultrasound was no better than placebo for the treatment of individuals with patellar tendinopathy.

So, there is always remains controversy regarding effectiveness of different treatment techniques for tendinopathy and aim of present study is to find and justify better treatment modality for management of tendinopathy.

METHODOLOGY

Study Design: This is an Evidence Based Study, which was conducted according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analysis) guidelines. (Figure 1).

Literature Search:

A specified literature search was performed from June 2017 to June 2022 (Last 5 years). Literature was searched using following search engines: Google Scholar, PEDro, PubMed, ResearchGate, ScienceDirect, Embase

Key Words Used For The Search Were:

Ultrasound, Shock wave Therapy and Tendinopathy

METHOD OF SELECTION OF ARTICLES:

Inclusion Criteria:

(1) Studies involving any type of Tendinopathy from June 2017 to June 2022 (Last 5 years), (2) Studies which compared Ultrasound or Shockwave Therapy in any type of Tendinopathy, (3) Articles on tendinopathy having study design of Systematic reviews, Meta-analysis and RCTs, (4) Articles published in English, (5) Studies done on Human participants.

Exclusion Criteria:

(1) Articles on tendinopathy having study design of Case Control and Cohort (2) Studies done on animals.

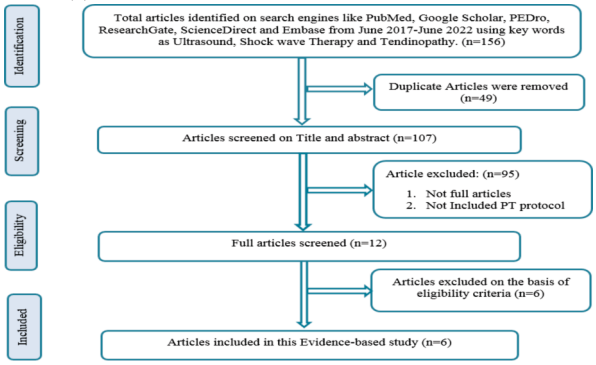

Figure 1: Preferred Reporting Items for systematic reviews and Meta-analysis (PRISMA)

Table 1: Characteristics of Included Studies

SR NO.	TITLE	Study design & Duration	Articles Or Sample Size	Outcome Measures	Pedro And Level Of Evidence
1	Analgesic Effect of Extracorporeal Shock-Wave Therapy in Individuals with Lateral Epicondylitis: A Randomized Controlled Trial [9]	A Randomized Controlled Trial (5 sessions)	40	VAS, Taiwan Version of DASH and Dynamometer	8/10 1b

3	Comparison of Radial Extracorporeal Shock Wave Therapy and Traditional Physiotherapy in Rotator Cuff Calcific Tendinitis Treatment [11]	A comparative study (4 weeks)	80	Age, height, Weight, BMI, VAS, Goniometer (Internal and external rotation ROM) and QuickDASH	4/10 2b
4	Comparison of Radial Extracorporeal Shockwave Therapy versus Ultrasound Therapy in the Treatment of Rotator Cuff Tendinopathy [12]	A comparative study (4 weeks)	115	The University of Peloponnese Pain, Functionality and Quality of life Questionnaire - the UoP-PFQ'	4/10 2b
5	Focused extracorporeal shock wave therapy for greater trochanteric pain syndrome with gluteal tendinopathy: a randomized controlled trial [13]	A randomized controlled trial (3 weeks)	50	NPRS, LEFS	7/10 1b
6	A comparative study of the efficacy of ultrasonics and extracorporeal shock wave in the treatment of tennis elbow: a meta-analysis of randomized controlled trials [14]	A meta-analysis	5 articles involving 117 participants	-	- 1a

Assessment of Methodological Quality:
Data was assessed using 2 parameters: (1) Centre for Evidence-Based Medicine's (CEBM's) Levels of Evidence and (2) PEDro scale (Appendix 1 & 2)

RESULTS

Evidences were reviewed and analysis was done on the basis of PEDro score and CEBM's Level of Evidence Scale. Risk of bias is also assessed.

Total 156 articles were found, out of which 12 articles were relevant and from those 6 articles were included in this evidence-based study and other articles were excluded as per Inclusion and Exclusion criteria.

From total 6 studies, there is 1 meta-analysis on efficacy of ultrasonics and extracorporeal shock wave in the treatment of tennis elbow and their result shown that Extracorporeal shock wave Therapy is a superior adjuvant therapy for tennis elbow compared to Ultrasound. Its level of evidence was 1a. 5 out of 6 studies (2 Randomized controlled trials and 3 Comparative studies) were shown that Shock wave (Either Extracorporeal or Radial) was effective treatment for reducing pain and improving disability in subjects with Achilles, Lateral elbow, Gluteal, Rotator cuff tendinopathies when compared to Ultrasound. Their Level of evidence was 1b and 2b.

DISCUSSION

Total 6 studies (1 Meta-analysis, 2 Randomized controlled trials and 3 comparative study) were included in this evidence-based study. The methodological qualities of included studies were moderate to high. The sample size varied from 40-117 subjects.

There are 1 strong evidence (Meta-analysis) which suggest that shock wave therapy is an effective treatment for reducing pain and disability in patients with Lateral elbow tendinopathy when compared to Ultrasound.

There are 2 moderates to high quality of evidences (2 Randomized Controlled Trials) which suggest that shock wave therapy alone or can be adjunct to other conventional treatment provide significant benefits in reducing pain and dysfunctions in patients with Lateral elbow and Gluteal tendinopathies. Total study duration varied from 3 to 5 weeks.

Furthermore, there are 3 low to moderate quality of evidences (3 Comparative Studies) having small to large sample size which compares Ultrasound with Shockwave therapy and their results confirms that Shock wave therapy effectively reduces pain and promotes healing in Rotator cuff and Achillies Tendinopathy. Total Study duration was 4 weeks.

Haupt proposed four possible phase mechanisms of ESWT effects on tissue: physical, physicochemical, chemical and biological. In the physical phase, shockwave pressures cause absorption, refection, refraction and transmission of energy into cells. These tensile forces induce cavitation, increasing cell membrane permeability and activating cell signaling pathways. These include mechano-transduction pathways and those that regulate a variety of gene expressions. In the physicochemical phase, cells release molecules such as adenosine triphosphate (ATP), activating cell signaling pathways. In the chemical phase, ion channels in cell membranes are altered allowing cell calcium mobilization. The biological phase plays host to a plethora of identified biological responses due to tissue and cell stimulation.

Tissue-healing responses are mediated by release of vascular endothelial growth factor (VEGF), endothelial progenitor cells, endothelial nitric oxide synthase (eNOS), insulin-like growth factor (IGF1) proliferating cell nuclear antigen (PCNA) and various other functional proteins.

Cellular modulation is activated by upregulation and downregulation of proteins which promotes processes such as neovascularization, anti-inflammation, anti-apoptosis, chondroprotective effects angiogenesis and regeneration of bone and tendon tissue. [15]

It should be noted that there were no any adverse effects reported from Shockwave Therapy from included articles.

CONCLUSION

From this Evidence based study, it can be concluded that there are moderate to strong evidences suggests the Shock wave therapy has more effect on Achilles, Gluteal, Rotator cuff and Lateral Elbow tendinopathies when compared to ultrasound.

Conflict Of Interest : There is no conflict of interest.

Ethical Approval
Ethical approval was not required.

Appendix 1- CEBM's Level of Evidence
It assesses quality based on study design, which categorize the studies

in a scale ranging from 1 to 5 with further subdivision for 5each.

Level	Definition
1a	Systematic reviews of randomized controlled trials
1b	Individual randomized controlled trials
1c	All-or-none studies
2b	Systematic reviews of cohort studies
2b	Individual cohort studies or low-quality randomized controlled trials
2c	Outcome research
3a	Systematic reviews of case-control studies
3b	Individual case-control studies
4	Case series, poorly designed cohort or case-control studies
5	Animal and bench research, expert opinion

Appendix 2-PEDro Scale

It assesses methodological quality and consists of a checklist of 11 criteria, 10 of which are scored. For each criterion the study met, 1 point was awarded. The points were tallied and presented as a score out of 10. The scale applies only to experimental studies. For this review, investigations with PEDro scores of 6 to 10 were considered high quality, of 4 to 5 were considered moderate quality, and of 0 to 3 were considered low quality.

No.	Description	Yes/No
1	Eligibility criteria were specified (No points awarded)	
2	Subjects were randomly allocated to groups	
3	Allocation was concealed	
4	The groups were similar at baseline regarding the most important prognostic indicators	
5	There was blinding of all subjects	
6	There was blinding of all therapists who administered the therapy	
7	There was blinding of all assessors who measured at least one key outcome	
8	Measure of at least one key outcome were obtained from more than 85% of the subjects initially allocated to groups	
9	All subjects for whom outcome measures were available received the treatment or control condition as allocated	
10	The result of between group comparisons are reported for at least one key outcome	
11	The study provides both point measures and measures of variability for at least one key outcome

ABSTRACT

Background: Neck pain is becoming increasingly common throughout the world. It has a considerable impact on individuals and their families, communities, health-care systems, and businesses. There is substantial heterogeneity between neck pain epidemiological studies, which makes it difficult to compare from different studies. The prevalence of neck pain in the general population ranges between 0.4% and 86.8% (mean: 23.1%); point prevalence ranges from 0.4% to 41.5% (mean: 14.4%); and 1 year prevalence ranges from 4.8% to 79.5% (mean: 25.8%). Northwick Park Neck Pain Questionnaire is one of the most commonly used scales that has been used by physical therapists worldwide. Also, it has already been translated into many languages such as Turkish, Indonesian, Spanish and Swedish. We would like to translate this scale into Gujarati language. Because it is more beneficial for the patient to understand the Gujarati scale and it is also helpful for the Gujarati physiotherapist. **Methodology:** The study was carried out on people aged more then 18 years in Gujarat, India. Those peoples who have knee injury.100 patients who fulfilled inclusion criteria were selected. Initially scale was translated to Gujarati by forward backward translation and patients were instructed to fill the scale at 1 week interval. **Result:** 100 patients participated. Gujarati version of The Northwick Park Neck Pain Questionnaire was given twice with 1- week interval to measure the test- retest reliability and validity. The results of the study showed moderate to high correlation in components of The Northwick Park Neck Pain Questionnaire Gujarati version (ICC =0.882) ($P<0.05$) and internal consistency (Cronbach's alpha =0.88). **Conclusions:** The Gujarati version of The Northwick Park Neck Pain Questionnaire was cross-culturally adapted and validated for use among the Gujarati- speaking populations. The translated version has acceptable reliability and internal consistency.

KEYWORDS

Northwick Park Neck Pain questionnaire, Cervical, Interclass correlation.

INTRODUCTION

Neck pain is becoming increasingly common throughout the world. It has a considerable impact on individuals and their families, communities, health-care systems, and businesses. There is substantial heterogeneity between neck pain epidemiological studies, which makes it difficult to compare or pool data from different studies.[1] The estimated 1 year incidence of neck pain from available studies ranges between 10.4% and 21.3% with a higher incidence noted in office and computer workers. While some studies report that between 33% and 65% of people have recovered from an episode of neck pain at 1 year, most cases run an episodic course over a person's lifetime and, thus, relapses are common.[2]

The overall prevalence of neck pain in the general population ranges between 0.4% and 86.8% (mean: 23.1%); point prevalence ranges from 0.4% to 41.5% (mean: 14.4%); and 1 year prevalence ranges from 4.8% to 79.5% (mean: 25.8%). Prevalence is generally higher in women, higher in high-income countries compared with low- and middle-income countries and higher in urban areas compared with rural areas. Many environmental and personal factors influence the onset and course of neck pain. Most studies indicate a higher incidence of neck pain among women and an increased risk of developing neck pain until the 35–49 year age group, after which the risk begins to decline.[3]

Pain scales usually are used in the assessment of patients with neck pain. However, the presence and severity of pain represent only a small part of the health outcome. Rainville et al suggested that pain scales correlate poorly with measures of physical function.[4] There is increasing recognition that patient perspectives are essential both in making medical decisions and in judging treatment outcomes. Questionnaires designed for completion by the patient are used increasingly as a convenient and reproducible measuring tool for assessing patients with musculoskeletal problems, especially those with low back pain. Among various disability indexes for low back pain, the Oswestry Index probably is the best index covering several distinct activities of daily living. However, only a few methods exist to assess the disability of patients with neck pain. Vernon and Mior modified the Oswestry Low Back Pain Index and produced a 10-item scaled questionnaire, namely the Neck Disability Index (NDI).[4] Offered as a self-reporting instrument for assessing activities of daily living for patients with neck pain, it was validated and found reliable. However, the sample size in some of the analyses was small, with only 10 patients in the concurrent validity study. Most of the patients (70%) had experienced “whiplash” injury. Leak et al again modified the Oswestry questionnaire and developed the self-administered Northwick Park Neck Pain Questionnaire (NPQ).[5] These authors converted some of the questions (walking, standing, and sex life items in the Oswestry questionnaire to cover many activities (carrying, reading/television, and work) likely to be affected by neck pain. The NPQ consists of nine five- part questions that assess the patient's symptoms, from which a score is obtained. Patients need to answer all the questions except the ninth one, which is an option for patients who drive. Each question is scored from 0 to 4. The responses to the questions are summed and converted to a score percentage, which ranges from 0% to 100%, with 0% representing the least disabled and100% the most severely disabled. In addition to questions 1 through 9, all follow-up questionnaires contained a 10th question asking patients how their pain compared with that reported the last time. The questionnaire was found to be valid, easy for patients to complete, and simple to score. It provides a reliable outcome measure for patients with acute or chronic neck pain.[6]

The Northwick Park Neck Pain Questionnaire is one of the most common scale that has been used by the physiotherapist all over the world. Also, it is already translated in many other languages like Turkish, Korean, Spanish, Indonesian etc. We want to translate this scale in our mother language i.e. Gujarati, because it will be more beneficial for patients to understand the scale in Gujarati and it will be helpful to physiotherapists also who are from Gujarat.

METHODOLOGY

Ethical Approval: Ethical approval for the study was taken from the institutional ethical committee
Study Design : Reliability and validity study.
Study Setting: Various committee of Gandhinagar city
Sampling Technique: Purposive Sampling
Population: Native Gujarati Patients with neck pain in North Gujarat.
Duration Of Study: 1 Year
Study Size : . N=100

Inclusion Criteria

- AGE : More than 18 years of age
- Patient diagnosed with neck pain

- Subjects willing to participate.

Exclusion Criteria

- Patients having neurological disorders
- Patient not able to read and write Guajarati
- Uncooperative patients

The Northwick Park Neck Pain Questionnaire was cross-culturally adapted into a Gujarati version in the following steps:

First stage, the English version of The Northwick Park Neck Pain Questionnaire was translated into Gujarati version through standardized procedure recommended by Beaton et al. with some modification. We translated and culturally adapted The Northwick Park Neck Pain Questionnaire according to Indian living standards to adapt/fit and use in Indian Gujarati speaking neck pain population for the evaluation of self-rated neck functional status., stage I was done by the first author with the help of online translation portal.

We skipped stages II and III recommended by Beaton et al. In stage IV, 08 experts (02 orthopaedicians, 02 rheumatologists, 02 English professors, and 02 Gujarati professors) were volunteered for the review of questionnaire developed in stage I. Overall, Gujarati professors simplified the language, whereas medical experts helped with the medical terminology used in the questionnaire.

In stage V, questionnaire developed at the end of stage IV was administered to 20 Gujarati speaking neck pain patients. All patients understood the questions and responded correctly; hence there was no modification of questionnaire at this stage.

Validation study: Experts and translators obtained face validity and content validity.

I. Test-retest reliability: The recruited patients with neck pain were asked to complete the Gujarati version of The Northwick Park Neck Pain Questionnaire twice with a one-week gap in between. As a result, that person will not copy the same data and will not forget. The readings were recorded in order to determine test-retest reliability.
II. Internal consistency: Cronbach's alpha (α), a statistic calculated from pair wise correlations measured between paired readings of the Gujarati version of The Northwick Park Neck Pain Questionnaire, was used to assess internal consistency.

After checking reliability and validity of this questionnaire, we have taken 100 individuals with neck pain.

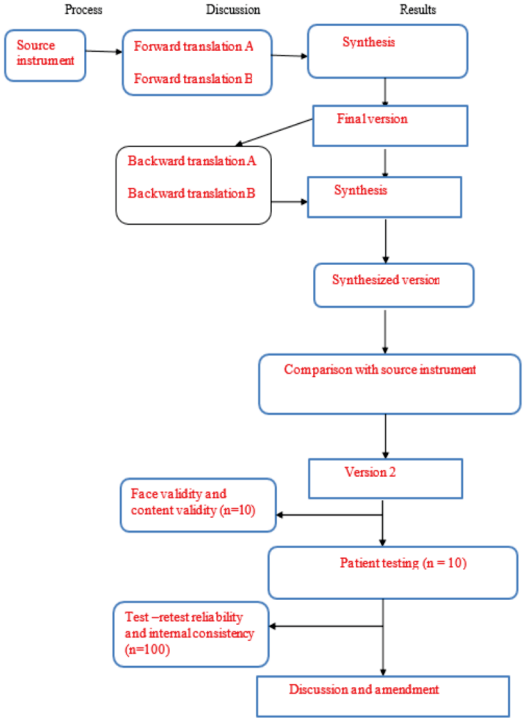

Chart:- Cross Cultural Adaption

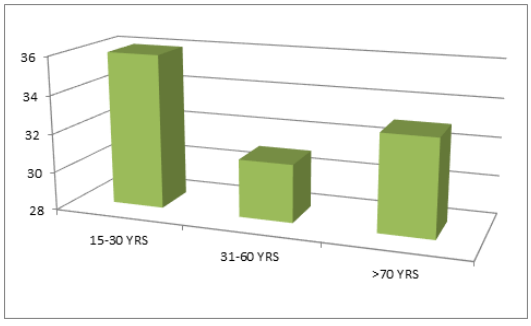
RESULT

All statistical analysis was done using SPSS 25.0 software for windows. Descriptive analysis was used to obtain mean and standard deviations. Reliability testing was done using reliability analysis. Inter class correlation coefficient, ICC(2,1) and Cronbach's α were measured. Confidence interval were set at 95%, p = 0.05 for all the analysis.

1. Age Distribution

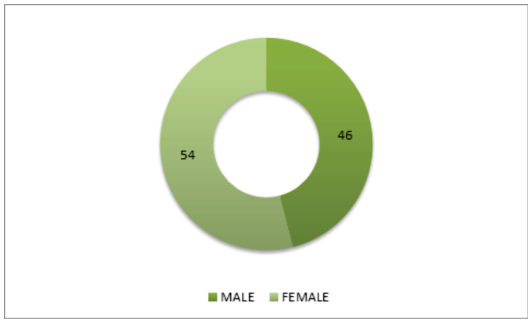
The research was performed on 100 patients with neck pain between the age of more then 18 years. There were 36 patients between the ages of 18 to 30, 31 patients between the age 31to 60, and 33 patients between the age of >70 years.



Graph : Age Distribution

2. Gender Distribution

The research was performed on 100 patient with neck pain . In which 54 are females and 46 are males.



Graph 7.2 : Gender Distribution

The content validity of Gujarati translated The Northwick Park Neck Pain Questionnaire by a 8 experts were found to be, I-CVI of individual items The Northwick Park Neck Pain Questionnaire of ≥ 0.93 and overall S-CVI for idiomatic equivalence, semantic equivalence and content relevance ≥ 0.90. For content validity equivalence all 6 experts answers were located between mostly agree and strongly agree of Gujarati version of The Northwick Park Neck Pain Questionnaire for idiomatic equivalence (average= 0.89) semantic equivalence(average = 0.91) and content relevance (average= 0.92). Test-retest reliability (n=100) was tested by using the interclass correlation coefficient, ICC (2,1) and Internal consistency (n=100) was reported in terms of Cronbach's α measured in two session after 1 week

Table 7.1:- Test- Retest Of Gujarati Version The Northwick Park Neck Pain Questionnaire

The Northwick Park Neck Pain Questionnaire	Week 1 (Mean)	Week 2 (Mean)	Cronbach's alpha	ICC	P- value
	17.5	18.73	0.88	0.882	0.01

DISCUSSION

Non-specific neck pain is very common in rheumatology patients. Of the working population, 30% aged 25-29 years and 50% over 45 years report one or more attacks of painful neck, which is the primary motive for patient presentations. In our study first report of the reliability and validity of Gujarati version of The Northwick Park Neck Pain Questionnaire for evaluating pain and function with neck pain patients.[7]

The restriction of activities of daily living caused by neck pain has an important place in the planning of treatment. Whatever the source of

the pain, the objective assessment is difficult and the evaluation should primarily be based on the patient's subjective experience of pain and disability. Instead of focusing on the examination findings for diagnostic purposes, it is more accurate for a multidisciplinary approach to evaluate the patient's performance in daily life. For this purpose, there are specific questionnaires developed for the evaluation of patients and the quantitative determination of treatment results.[8] Various features of the scale such as acceptability, ease of use, high reliability, validity and responsiveness to clinical changes can guide the evaluation and selection of an appropriate scale. Therefore, we attempted to adapt the NPQ into Gujarati. Tabachnick and Fidell reported that the sample size of 10 participants per item was sufficient for factor analysis . The present study included 100 patients with neck pain. Thus, the required sample size was sufficient.[9]

In this study 100 patients participated. Gujarati version of The Northwick Park Neck Pain Questionnaire was given twice with 1-week interval to measure the test- retest reliability and to validity. The results of the study showed good correlation neck pain scale (ICC= .815) ($P<0.01$) and internal consistency (Cronbach's alpha = . 989 and .978).

For content validity equivalence all 6 experts answer were located between mostly agree and strongly agree of Gujarati version of The Northwick Park Neck Pain Questionnaire (average=0.89) semantic equivalence (average = 0.90) and content relevance (average= 0.93). Thus, Gujarati version of The Northwick Park Neck Pain Questionnaire was content validated for idiomatic equivalence, semantic equivalence, content relevance.

Contrary to questionnaires evaluating general health, questionnaires related to regional pain and functions are considered to have higher validity because they are directed to a single body region. Therefore, the NDI was developed as the first questionnaire by Vernon et al in 1991 and then the NPQ was developed in 1994 and then the NPDS was developedin 1999. Vernon and Mior applied the NDI at a 1-week interval to patients who have had neck pain due to whiplash injury and without trauma and found the ICC score to be 0.89 . Leak et al found that ICC score was 0.84 for NPQ. They proposed that the NPQ is easy for patients to complete, simple to score and provides an objective measure for evaluating outcomes in patients with acute or chronic neck pain. Wheeler et al found that ICC score was 0.93 for NPDS. Other studies investigating the reliability of the neck questionnaires in the Turkish population, such as the Turkish version of the NPDS and the NDI, have similar ICC scores. Bicer et al conducted a study concerning chronic neck pain and reported that the value of the Cronbach's alpha coefficient for the reliability of the NPDS was 0.86. Aslanet al. conducted a study of patients with chronic neck pain who were administered with the NDI and NPDS. They found that ICC score was 0.979 at a 1-week interval for the NDI and the correlation between the NDI and the NPDS was 0.659 to 0.728.[10-11]

In previous studies, interrater reliability and interrater reliability of the Korean The Northwick Park Neck Pain Questionnaire were (ICC =(0.97) respectively. reliability and validity for level of pain and function had high sensitivity and specificity for the patient with Neck pain.

In Spanish version the concurrent validity had a high correlation (r = 0.74- 0.86) and inter and intra- rater reliability was between 0.4 to 0.6 and 0.6 to 0.8 The Northwick Park Neck Pain Questionnaire is valid and reliable for Spanish population.

It was found Gujarati version of The Northwick Park Neck Pain Questionnaire items equivalent to those in original version which is intended by translators involve in this study. The results showed that it was translate this scale into other languages without losing psychometric properties of the original English version.

CONCLUSION

The Gujarati version of The Northwick Park Neck Pain Questionnaire was cross- culturally adapted and validated for use among the Gujarati-speaking populations. The translated version has acceptable reliability and internal consistency.

ABBREVIATIONS

NPQ: Northwick Park Neck pain questionnaire
NDI: Neck Disability Index
ODI: Oswestry disability index
ICC: Interclass correlation

ABSTRACT

Background: Proper posture is considered to be a state of musculoskeletal balance that involves A minimal amount of Stress or strain to the body.it Compromises balance because of muscular Imbalance which can cause loss Of Proprioception sense in joint and decreased Balance, and trunk endurance is significantly Reduced in Reduced in forward head posture and may lead to poor muscular Control of the spine. **Aim:** To Determine the Correlation between core muscle endurance and foot posture in college Going Students. **Methodology:** An observational study Was conducted in 50 College Going Students of Ahmedabad and Convient Sampling was used. Age group 18-25 Year students Chek for Core Muscle Endurance Test and Foot Posture Analysis. The statistical evaluation become accomplished with SPSS version 29-2022, September. **Result:** Our Finding Suggest that from Descriptive analysis of data was expressed in mean and Standard Deviation for various parameters. Correlation were expressed in term of R value and P Value. P value less than 0.05 was considered to be Signifcant. **Conclusion:** Individuals with altered foot posture will have an effect on the Proximal segment through the Kinetic chain phenomenon of the body, Affecting the core endurance. Individuals with altered Foot posture have reduced core endurance.

KEYWORDS

Core Muscle,Foot Posture,College Students,Endurance

INTRODUCTION

Foot posture plays an important role in the quality of daily living.[1]The structure of the feet is such that it permits the functions of both the stability and the mobility depending on the tasks which are imposed on it.[1]

Kinetic Chain & Core

Core stability can be defined as the ability of the Lumbopelvic-Hip Complex to prevent buckling of the Vertebral Column and return it to equilibrium following perturbation by using Strength, Endurance and Motor Control in a functional manner through all the planes of motion and action despite changes in the center of gravity.[2]

Need Of Study:

1)The foot posture is important for provide stable base of support during walking, running and jumping.
2)Proximal stability is needed for distal mobility.
3)So the core provide proximal stability to perform proper distal component mobility. The affection in
4)proximal core muscle may be lead to distal component changes and visa versa.

Aims Of The Study:

To find out the Correlation between core muscle endurance and foot posture in college Going students.

OBJECTIVES:

1)To find out the Correlation between core muscle endurance and foot posture in college going students by using Flexor endurance test & FPI.
2)To find out the Correlation between core muscle endurance and foot posture in college going students by using Extensor endurance test & FPI.
3)To find out the Correlation between core muscle endurance and foot posture in college going students by using Rt. Side plank endurance test & FPI.
4)To find out the Correlation between core muscle endurance and foot posture in college going students by using Lt. Side plank endurance test & FPI.

Null hypothesis:

There is no significant Correlation between core muscle endurance and foot posture in college going students.

Alternate Hypothesis:

There is significant Correlation between core muscle endurance and foot posture in college going students. and foot posture in college going students.

MATERIAL

Pen, paper, pencil
Foot posture index questionnaire
Stop watch
Plinth or high level bed

METHODOLOGY

Sample Size: 50

Sampling Design : Convient sampling

Study Design: An observational study

Setting: Ahmedabad

Population: Age group between 18 to 25 years

Procedure

- Selection
- Fifty subjects with the age group between 18 to 25 years participate in this study.
- Core Endurance :
- 60 degree flexion endurance test,
- trunk extensor endurance test,
- Right side plank test
- left side plank test.
- Time noted in sec.
- Foot posture:
- Foot posture index.

Flexor Endurance Test Position

Extensor Endurance Test Position

Lt. & Rt. Side Plank Endurance Test Position

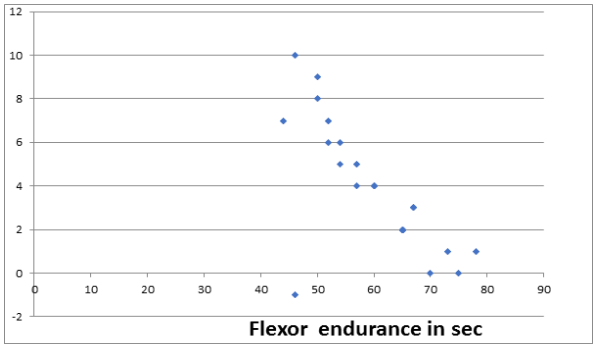
RESULTS

Descriptive analysis of data was expressed in mean and standard deviation for various parameters.Correlation were expressed in term of r value and P value.P value less than 0.05 was considered to be significant

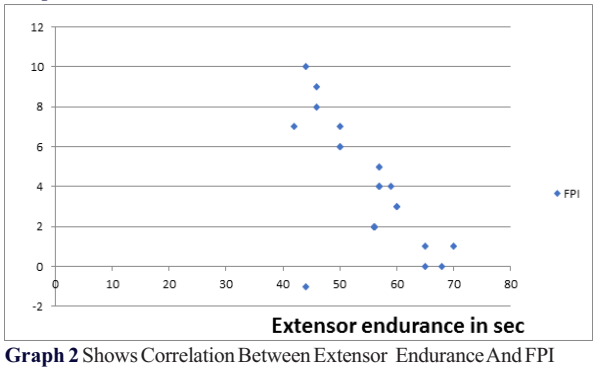
The graphical representation was done by scatter graph.

Table 1 : Descriptive Analysis

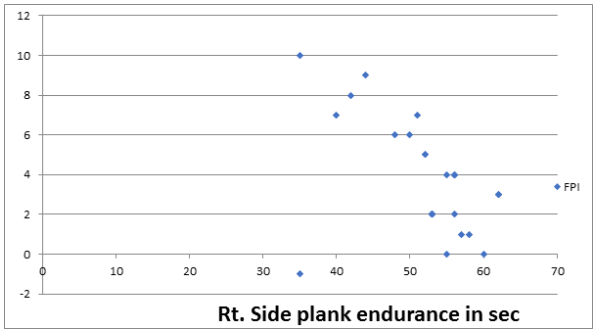
	MEAN	STANDARD DEVIATION
Age	22.34	1.7333
Flexor endurance test	60.1	9.2609
Extensor endurance test	55.34	7.3640
Rt. Side plank test	51.78	7.3326
Lt. side plank test	49.08	6.7698
Foot posture Index	3.78	2.8734



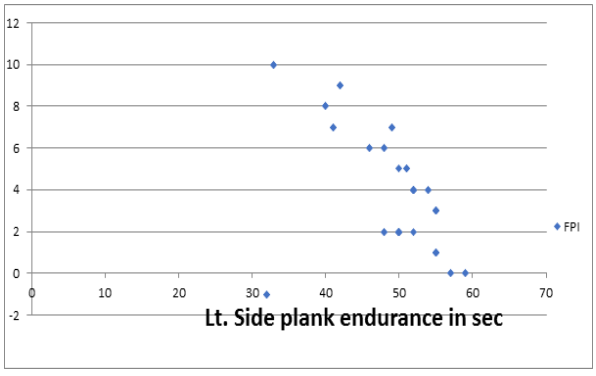
Graph 1 Shows Correlation Between Flexor Endurance And FPI



Graph 2 Shows Correlation Between Extensor Endurance And FPI



Graph 3 Shows Correlation Between Rt. Side Plank Endurance And FPI



Graph 4 Shows Correlation Between Lt. Side Plank Endurance And FPI

Table 2: Correlation Between Core Endurance & Foot Posture

Variables	r value	P value	
Flexor endurance test & FPI	-0.7231	0.04	significant
Extensor endurance test & FPI	-0.6734	0.03	significant
Rt. Side plank test & FPI	-0.5098	0.005	significant
Lt. side plank test & FPI	-0.5037	0.005	significant

RESULTS

Result shows there is a negative correlation between core endurance timing and foot posture index scoring.

DISCUSSION

The Purpose Of the Study find out correlation between core muscle endurance and foot posture in college going students. The Presents Study Suggest that changes in foot posture causes changes in the kinetic chain of the entire lower extremity upto the lumbar, pelvic and the hip region. Dr. Anvita Telang at el, Conducted study on Comparison of Core Stability in Individuals with Flexible Flat Foot and Normal Foot and conclude that Individuals with flexible flat foot have reduced core Stability.[3] Statistical significance was considered when p value was less than 0.05. The results from statistical analysis of the present study rejects the null hypothesis. There was an significant difference in Core muscle endurance in individuals with different foot posture in the age group of 18- 25 years. The reasons to the above findings are- changes in foot posture causes changes in the kinetic chain of the entire lower extremity upto the lumbar, pelvic and the hip region.

CONCLUSION

Individuals with altered foot posture will have an effect on the proximal segment through the kinetic chain phenomenon of the body, affecting the core endurance.

Individuals with altered foot posture have reduced core endurance.

DAILY TRAVELLING AND LOW BACK PREVALANCE AMONG UNDERGRADUATE STUDENTS OF A SWARRNIM STARTUP AND INNOVATION UNIVERSITY GANDHINAGAR: A CROSS-SECTIONAL STUDY.

Physiotherapy

Keshvi Padaliya* B.P.T. *Corresponding Author

Dr. Arvind Kumar M.P.T., Musculoskeletal, Ph.D., Principal and Professor, Venus Institute of Physiotherapy, Swarrnim Startup and Innovation University, Gandhinagar.

ABSTRACT

Background: Low back pain (LBP) is considered the single leading cause of disability-related musculoskeletal conditions globally.Low Back Pain is a serious problem in all the develop countries and is one of the most displayed problem at health service. The prevalence of low back pain has been reported among many people especially when resulting from work related and occupational activities. 75-84% of the general population suffer from low back pain and among them, it is estimated that 5-10% of the people experience LBP resulting in severe morbidity, increased health care costs, sick leaves and individual suffering. **Result:** NPRS score >2 and ODI score >20 were considered positive for backpain patients and it has found that it is having prevalence of 59% in participants who travel frequently.Age group of 18-24 years having prevalence of 72% and age group 25-30 having 18%. **Methodology:** A sample of students will be taken in this survey from Swarrnim startup and innovation University Gandhinagar. All students who meet the inclusion criteria will be eligible to participate in the study. The data were recorded through the semi structured questionnaire. The questions include distance of travelling, posture during travelling, type of vehicle, duration of journey and intensity of pain were reported. An online, standardized, self-administrated questionnaire to be used for data collection. The questionnaire were in English language and had three sections. **Conclusions:** This study, conducted among young adult students of swarrnim start-up and Innovation University, Gandhinagar, revealed that youth those are travelling regularly more than 30 minutes a day are prone to developing LBP, which aligns with published Western literature. This study shows that there is 59 % of prevalence of low back pain in students who travels regularly.

KEYWORDS

Low back pain, Numerical pain rating scale, Oswetry disability scale

INTRODUCTION

Musculoskeletal conditions arise throughout an individual's life at various points of time. Out of the many problems suffered, low back pain is one of the most frequently reported conditions. Low back pain is defined as "pain and discomfort, localised below the costal margin and above the inferior gluteal folds, with or without leg pain" and can be categorized into 3 typesAcute, Sub-acute and Chronic. Acute low back pain is defined as an episode of pain persisting for less than 6 weeks; sub-acute as pain persisting between 6 and 12 weeks; chronic as pain persisting for 12 weeks or more.[1]

Low back pain (LBP) is considered the single leading cause of disability-related musculoskeletal conditions globally. [1]Low Back Pain is a serious problem in all the develop countries and is one of the most displayed problem at health service. Low Back Pain is not considered an illness but a syndrome. It is considered a syndrome because one of the factors causes Low Back Pain is lumbar overload (lumbar stress condition) [2]

What makes the complaint of low back pain so frustrating for physicians is that an estimated 85 percent of patients with isolated low back pain cannot be given a precise pathoanatomical diagnosis. What makes low back pain so frustrating for patients is that primary care and emergency physicians appear perplexed in the face of it. Discouraged patients seek guidance from surgeons and pain specialists or seek alternative treatments such as spinal manipulation and acupuncture when time is often all that is needed. Indeed, recovery is generally inevitable regardless of what is done. One study demonstrated that 90 percent of patients recover within two weeks of presentation. [3]

A broad differential should be maintained when seeing a patient with low back pain, and the physician should consider three distinct categories of pathology: mechanical, nonmechanical, and visceral disease. Mechanical causes of low back pain include lumbar strain or sprain (idiopathic), degenerative processes of discs and facets, herniated discs, spinal stenosis, osteoporotic compression fractures, traumatic fractures, and spondylolisthesis (defined as anterior displacement of a vertebra on the one beneath it).[4]

Nonmechanical causes include neoplastic diseases, Paget's disease of the bone, inflammatory arthritis (often associated with HLA-B27), and infections such as shingles, osteomyelitis, epidural abscess, and septic discitis. The visceral diseases presenting as low back pain include aortic aneurysm, pancreatitis, perforated ulcer, nephrolithiasis, pyelonephritis, perinephric abscess, retroperitoneal hematoma, and prostatitis.[5]

The prevalence of low back pain has been reported among many people especially when resulting from work related and occupational activities. [6-7]75-84% of the general population suffer from low back pain and among them, it is estimated that 5-10% of the people experience LBP resulting in severe morbidity, increased health care costs, sick leaves and individual suffering.[8-9] It is also one of the common reasons for a person to seek medical help.This pathology is manifested at patient with disability, unable patient to work and low quality of life.[10]

There is a link between LBP and some risk factors, including age, education, obesity, smoking, hereditary factors, prolonged standing, injury, stress, anxiety, depression, poor interpersonal relationships and lack of social support .[11] Men and women are equally reported to be affected by this condition. 50% of adults and 30% of adolescents are said to be affected at least once. [11] Of late, there has been rising incidence of LBP among many young adults and children, which is of concern. [12] Sports and physical activity is one of the main factors causing LBP. [13] It was also reported that children below 14 year of age who experienced LBP, got it in more severity before 25 years. [14] Other risk factors which contribute towards a LBP is obesity and a positive family history apart from depression, stress and anxiety.

It is more prevalent in female gender, daily smokers, heavy job holders and have direct impact on the quality of life .[15]The relationship of travelling, chair support during travelling, travelling posture and low back pain is present and need to be precisely identified.[15]

Treatment for nonspecific low back pain, Deyo and Weinstein recommend, is nonsteroidal anti-inflammatory drugs prescribed on a regular schedule rather than on an as-needed basis. For most patients, the best recommendation is a rapid return to normal activities without overdoing exercise or lifting. Bed rest does not increase the speed of recovery from acute low back pain and may inhibit healing, and should not be recommended. For patients with chronic low back pain, aerobic exercise with strengthening exercises of the back and legs appear to be beneficial.[16]

Considering that low back pain is an important factor in limiting physical and cognitive abilities, especially among college students, and that it is costly for the health services, a study of the prevalence, associated factors, and disability rate produced by low back pain among college going students is important, as this will produce health indicators for this population, enabling the prevention of related factors and reducing the impacts of low back pain.

METHODOLOGY

Study Design: A cross sectional study
Population: College going students of swarnim startup and inovation university.

Selection Criteria
Inclusion criteria:
- Age 16 to 30 years,
- Both female and male,
- Travel through any vehicle example: Bus, 2 wheelers and other vehiclek.

Exclusion criteria:
- Having recent injury to back,
- Patients with psychological problem,
- Not willing to participate.

Sampling Method: Convenient Sampling

Sample Size: 100

Outcome Measures :
1. NPRS (NUMERICAL PAIN RATING SCALE): This scale is for assessing the pain score of a patient.
2. ODI: Oswetery Disability Index : This scale is for assessing Functional ability
3. An online, standardized, self-administrated questionnaire
- A sample of students were taken in this survey from Swarrnim startup and innovation University Gandhinagar.
- All students who meet the inclusion criteria were eligible to participate in the study.
- The data were recorded through the semi structured questionnaire. The questions include distance of travelling, posture during travelling, type of vehicle, duration of journey and intensity of pain were reported.
- An online, standardized, self-administrated questionnaire to be used for data collection.
- The questionnaire were in English language and had three sections.
- Different sections of the questionnaire were adapted from the minimal dataset and the questionnaires that were validated and used in previous study.
- One to ten scoring to be used for questions reflecting the duration of current back pain, rating of pain intensity , number of episodes of LBP suffered during the past year, whether one feels tense or anxious, feeling depressed in the past year, perceptions of the likelihood that the current episode of LBP were become persistent and attitudinal questions such as 'physical activity worsens the pain', 'one should stop working if the pain increases in intensity', and 'one should not do work when currently suffering from pain'.

RESULTS
All statistical analysis was done using SPSS 25.0 software for windows. Descriptive analysis was used to obtain mean and standard deviations.

Demographic Data
AGE:
The research was performed on 100 participants between the age of 18-30. There were 56 patients between the ages of 18 to 24, 44 patients between the age 25 to 30.

DISCUSSION

Various studies [1-3] reported that LBP is one of the most common causes of hospital visits and that it is the leading cause of activity limitations and work absences in many parts of the world. LBP poses a significant economic threat to the individual, family, workplace, and society. Initially considered to be a problem confined to developed countries, studies have now revealed an increasing prevalence in developing countries [15,16]. Although LBP can manifest at any age, LBP prevalence is the highest in the third decade of life [17]. LBP occurrence at an early age can cause disease progression, resulting in chronic LBP that has the potential to decrease an individual's quality of life [8]. Being a common health issue that affects all age groups, LBP and its risk factors have been evaluated by various authors internationally. However, data pertaining to the prevalence and risk factors for LBP in Indian subjects is scarce, particularly in young adults. This study, which included 1355 young adults, was unique as it not only examined LBP prevalence in young adults in swarnim startup and innovation university, Gandhinagar India,

According to Hestbaek et al. [18], the annual LBP prevalence in young adults is 32.4% compared with 59% annually, as observed in the current study. This study demonstrated that there is no sex predilection for LBP occurrence, which is consistent with several studies [19]. Furthermore, our results differ from those of Linton et al. [20] and Thomas et al. [21], which demonstrated a higher incidence in females and who also develop chronic backache compared with males. A meta-analysis by Hoy et al. [22] also showed an increased prevalence in females. Shiri et al.[23] conducted a meta-analysis and found that smokers have a higher prevalence and LBP incidence than non-smokers and that the pain is stronger in adolescents than in adults.

Static muscle load and flexion of the lumbar spine have been postulated as risk factors for LBP development; thus, prolonged sitting or sitting in an abnormal posture can aggravate LBP [25]. We found that posture while studying had no effect on LBP occurrence; however, the number of daily hours spent studying had a significant association with LBP.

With the increased sedentary life style, low back pain is getting common among adults as well as older people .it was observed in one study that the age of students did not mattered the younger students carried approximately the same as the oldeset one.studies on whole body vibration, as in travelling showed that unnatural posture or bad posture during travelling or work frequently adopted is the most of the people can be the source of low back pain.the truck drivers were observed in their sitting posture, frequency of such postures (bending,twisting,leaning).it was observed that such posture and other related activities were risk factors for developing of low back pain.

CONCLUSION

This study, conducted among young adult students of swarrnim start-up and Innovation University, Gandhinagar, revealed that youth those are travelling regularly more than 30 minutes a day are prone to developing LBP, which aligns with published Western literature. This study shows that there is 59 % of prevalence of low back pain in students who travels regularly.

Limitations

- Study was conducted in young adults.
- At the time of the study, these individuals often studied for long periods of time, which could be a major contributing factor to lbp occurrence. Thus, these subjects would have likely experienced high stress levels and monotony, which may have exacerbated lbp.
- Our study did not include sedentary lifestyle as a risk factor for lbp.
- this was a cross-sectional study, we could not assess LBP progression in these subjects

Future Recomendentions

Further studies are needed to evalute the possible risk factors for low back pain among students traveling from gandhinagar to swarnim university and other universities on regular basis, in order to implement forms of prevention and reduce the incidence, chronicity and impact on the individual's functionality.

ABSTRACT

Background: Forward head posture afflicts a large percentage of population and can cause significant neck pain, the estimated 1-year incidence of neck pain ranges between 10.4 and 21.3%, and the overall prevalence of neck pain in general population can be as high as 86.8%. Strong evidence was found to relate neck pain with female gender, older age, being an ex-smoker, high job demands, and low social or work support. Regarding physical work factors, neck pain was significantly associated with holding the neck in a forward bent posture for a prolonged time and making repetitive movements. **Methodology:** Individuals selected according to inclusion/exclusion criteria and were explained regarding the study. Total 100 participants (Age 30 years and above) were included in the study. Subject were assessed for Forward Head Posture, Pain and Cervical ROM. **Result:** Association testing were done using pearsons Correlation method. Among a total of 100 office workers took part in the survey 73% were female. The mean age of participants was 39±8 years. Results shows Moderately positive Correlation of forward neck with reduction of ROM of Neck and moderately positive Correlation of Pain and forward head posture seen according to pearsons Correlation at the level of P<0.01. **Conclusion:** The present study demonstrated the Correlation of forward head posture with pain and cervical range of motion in desk users it shows moderately negative Correlation between pain and tragus to wall test and it shows positive Correlation between pain and cervical range of motion.

KEYWORDS

Forward Head Posture (FHP), Neck pain and disability scale (NPDS)

INTRODUCTION

Forward head posture (FHP) is the anterior positioning of the cervical spine, this posture is called as "text neck", "scholar's neck, "wearies neck", "reading neck". Forward head posture afflicts a large percentage of population and can cause significant neck pain, the estimated 1-year incidence of neck pain ranges between 10.4 and 21.3%, and the overall prevalence of neck pain in general population can be as high as 86.8%.[1]

Forward head posture (FHP) is the most common postural deformity seen in the sagittal plane. It can be defined as any alignment in which the external auditory meatus is positioned anterior to the plumb line through the shoulder joint. In FHP, head moves anteriorly and the peak of the increased cervical lordotic curve is a noticeable distance away from center of gravity.[2-3] FHP gradually leads to abnormal compression of zygapophyseal joint, posterior vertebral disks, narrowed intervertebral foramina and shortened posterior zygapophyseal joint capsule causing nerve root compression.[3]

The FHP could lead to muscle ischemia, muscle pain, fatigue, inflammation, reduced cervical range of motion and sometimes protrusion of nucleus pulpous, rotation of mandible which cause compression and irritation of retrodiscal pad. There are various methods to evaluate FHP but many studies have declared that Craniovertebral angle (CVA) is the best indicator to measure the FHP. CVA is measured by the angle between the imaginary line which passes through C7 and tragus and a horizontal line through C7.[4-5]

Neck pain is one of the very common musculoskeletal conditions in the general population. Neck pain can vary from a small discomfort to severe disabling pain making it one of the major health problems that carries important economic costs. Less severe neck pains occur due to poor posture, neck strains, occupational and sport injuries and mental state such as anxiety and depression, while mechanical and degenerative factors are more likely to develop chronic neck pain.[6]

Strong evidence was found to relate neck pain with female gender, older age, being an ex- smoker, high job demands, and low social or work support. Regarding physical work factors, neck pain was significantly associated with holding the neck in a forward bent posture for a prolonged time and making repetitive movements.[7] In addition, the increasing use of new information and communication technologies has led to an increase in time spent texting messages on mobile phones or using computers, which might have a long-term impact on neck pain, potentially due to prolonged periods of neck flexion.

The increasing use of new information and communication technologies has led to an increase in time spent texting messages on mobile phones or using computers, which might have a long-term impact on neck pain, potentially due to prolonged periods of neck flexion. Neck flexion may facilitate forward head posture (FHP), which refers to forward placement of the head in relation to the shoulder.[8] This is the most common cervical postural fault in the sagittal plane that is found with different severity levels in almost all populations. Greater FHP has been associated with greater deficits in cervical range of motion (ROM), particularly neck rotation and flexion.[9]

There exist several methods for the evaluation of the spinal posture i.e. radiography, 3D motion analysis via electromagnetic and optical tools, raster stereography, photographic postural analysis and in manual methods (Universal goniometer). Among which Universal goniometer has excellent reliability and is cost effective.

This change in posture can lead to a spatial change between the spine and the line of gravity, causing an overload on muscles and connective tissues[10]. Neck pain or neck dysfunction is a musculoskeletal disorder caused by improper posture with physical impairment or functional limitation. The FHP is known as an internal factor that causes dysfunction with shoulder and neck pain [11]. A FHP results in a posture in which the extended head and upper cervical, and the lower cervical vertebrae flex[12].

This increases the length of the external moment (the arm) by moving the gravitational center (the head) ahead of the load bearing axis [12]. The exposure to this constant load on the craniovertebral extension muscles and the noncontractile structures causes a change in the biomechanical movement, and this increased stress can cause musculoskeletal damage or pain [13]. In addition, FHP can also limit the functional movement in the head and neck area [14]. These limitations are caused by irregular rotation and gliding movement inside the articular capsule whilst moving the joint. Moreover, it was reported that extended periods of FHP can result in a decreased number of sarcomere, as well as shortening of the muscle fibers, which can affect muscular contraction.

With normal flexion of the cervical region, there is separation of the posterior structures with an increase of the intervertebral foramina [15] However, the altered mechanics associated with forward head posture may lead to excessive compression on the facet joints and posterior surfaces of the vertebral bodies[16]. in the forward head position, there is an overriding of the articular processes and narrowing of the

intervertebral space of the mid cervical region which approaches the relationship observed in cervical extension.

The use of computers has increased dramatically over the past decade in various offices so that staffs spend a lot of time sitting behind the computer. These rapid changes may be accompanied by increased prevalence of poor posture and resultant neck pain. FHP (forward head posture) and rounded shoulders are defined as protrusion of the head and shoulders in the sagittal plane.[17]

Early diagnosis of forward head posture will help to minimize the consequences. This study aims to investigate the incidence of forward head posture in desk users using Goniometer and its association with pain and range of motion of cervical spine.[18] The objective of this study is to find the percentage of forward head posture in desk users using Goniometer and to find the associated problems of forward head posture in desktop users on Neck Pain and Disability Scale and Cervical Range of Motion.

METHODOLOGY

Research Design: Observational Study

Study Population: 30 years and above.

Source of Data: Miscellaneous

Sample Size: 100 participants

Inclusion Criteria:
- Individuals who work for >3hrs/day on Desktop for 1 year.
- Both males and females age group 30 and above.

Exclusion Criteria:
- Cervical vertebrae fracture, Deformity of spine like scoliosis\kyphosis, Medical condition like vertigo, tumor in cervical region were excluded.

Materials:
- Consent form
- Goniometer
- Ruler scale
- Pen and pencil
- Mobile phone

Outcome Measures
- Neck Pain and Disability (NDI) Scale
- Cervical Range of Motion (ROM)
- TWT (Tragus to Wall Test)

Neck Pain and Disability Scale (NPDS):
- The NPDS is a 20-item measure that was specifically developed for patients with neck pain. It measures the intensity of pain; its interference with vocational, recreational, social, and functional aspects of living; and the extent of associated emotional factors. Patients responded to each item by marking along a 10-cm visual analogue scale. Item scores range from 0 to 5, and the total score is the sum of the item scores [possible range 0 (no pain)–100 (maximal pain)].
- High test - retest reliability is 0.93
- Time Required: 5 minutes

Cervical Range of Motion

Goniometers are the measuring tool to measure the range of motion in grades base on the landmarks. For example, goniometer are myrin goniometer, Spring-T goniometer and cervical range of motion instrument.

Procedure:

i) Cervical Flexion:
- Center fulcrum of the goniometer over the external auditory meatus.
- Align proximal arm so that it is either perpendicular or parallel to the ground.
- Align distal arm with the base of the nares.

ii) Cervical Extension:
- Center fulcrum of the goniometer over the external auditory meatus.
- Align proximal arm so that it is either perpendicular or parallel to the ground.
- Align distal arm with the base of the nares.

iii) Cervical Lateral Flexion:
- Center fulcrum of the goniometer over the spinous process of the C7 vertebra.
- Align proximal arm with the spinous processes of the thoracic vertebrae so that the arm is perpendicular to the ground.
- Align distal arm with the dorsal midline of the head, using the occipital protuberance for reference.

iv) Cervical Rotation:
- Center fulcrum of the goniometer over the center of the cranial aspect of the head.
- Align proximal arm parallel to an imaginary line between the left and right acromial processes.
- Align distal arm with the tip of the nose.

Tragus to Wall Test
- To objectively measure the cervical mobility of an individual.
- Shipe et al (2013) describe the measuring the tragus to wall distance (TWD) as: "the horizontal distance between the tragus, the auricular cartilaginous flap anterior to the external auditory meatus, and a wall
- The TWD can be measured as cued or relaxed, i.e the clinician prompts the individual to assume as close to an anatomical posture as possible e.g "Stand tall.", or the clinician measures the individual in their usual or presenting posture.
- The measurement can be done standing or sitting and it is worth documenting which position has been used.
- The TWD can be measured on both the individual's right and left, and then an average can be calculated.
- Reliability: In AS, test-retest correlations have been reported at between 0.93 and 0.95. Inter-tester reliability has also been reported as "excellent" in individuals with PD.
- Validity: In PD, the TWD has shown convergent validity with similar measures (occiput to wall status, C7 to wall distance, photographically derived trunk flexion angle, and inclinometric Thoracic Hyperkyphosis measure). It has also shown the ability to discriminate between groups (those who could touch occiput to wall when prompted to stand tall) and conditions (cued or relaxed).

Procedure Of The Study:

After getting approval from Institutional Ethical Committee (IEC)., individuals selected according to inclusion/exclusion criteria and were explained regarding the study. After explaining about the study, informed consent form were taken from the participants who were willing to participate in the study. Subject were assessed for Forward Head Posture, Pain and Cervical ROM.

RESULTS

All statistical analysis was done using SPSS 25.0 software for windows. Descriptive analysis was used to obtain mean and stanard deviations. Correlation testing were done using pearsons correlation method. Among a total of 100 office workers took part in the survey 73% were female. The mean age of participants was 39±8 years.

		.069	.016
	Significance	.498	.871

Correlation between cervical Flexion TWD and NPDS and Neck ROM parameters. The correlations between NPDS and TWD with cervical ROM is moderate positive significant correlation The correlations between TWD and NECK ROM moderately positive correlation is seen. (Table 5 to 9).

Results shows Moderately positive correlation of forward neck with reduction of ROM of Neck and moderately positive correlation of Pain and forward head posture seen according to pearsons correlation at the level of P<0.01.

RESULTS DISCUSSION

The results of the present study show that among 100 office workers who was working with computers there is positive Correlation between NPDS, TWG and Neck ROM parameters. The correlations between NPDS and TWD were moderate negative significant correlation (r = -0.145, p = 0.149), The correlations between NPDS and Neck ROM is moderately positive correlation is seen.

There is also Correlation between cervical Flexion, TWD and NPDS and Neck ROM parameters The correlations between NPDS and TWD with cervical ROM is moderate positive significant correlation and the correlations between TWD and Neck ROM moderately positive correlation is seen. Results shows Moderately positive correlation of forward neck with reduction of ROM of Neck and moderately positive correlation of Pain and forward head posture seen according to pearsons correlation at the level of P<0.01.

One of study demonstrate that the prevalence of neck pain among Iranian office workers versus office workers in other countries almost is comparable so that it was reported 64% and 36.1% in sudan and sri lanka respectively [19]. Comparing comparison between the prevalence of shoulder pain among Iranian employees and employees of other countries shows that it is less common among Iranian office workers (9.3% versus 41 % and 34.3 % in Sudan and Sri Lanka respectively). In a survey on Chinese adolescents in 2008, the prevalence of forward head posture was reported as high as 25% [8]. In reviewing the literature, no data was found on the relationship between head and spinal posture during work and chronic neck pain. According to our study, office workers using computer had more forward head, kyphosis and rounded shoulder posture.[20]

The improper posture of head, cervical and thoracic spine was more common in the symptomatic group comparing the asymptomatic group during computer working that is equivalent to the results of mentioned cross-sectional studies that showed a significant relationship between individual's posture and neck pain.

Duration of computer use may have an impact on the incidence of neck pain. According to results of other cross-sectional studies, it was found that there is positive correlation between duration of sitting and neck pain prevalence. Another study showed that sitting behind desk for over 5 hours per day, is considered a risk factor for neck pain. Despite of these studies, in a systematic review, it was found that there is no significant correlation between duration of sitting and neck pain.

According to our study, there was no relationship between the duration of working with computer and neck pain (p = 0.322). In a prospective study with a 3-year follow-up by ariens et al on over 1,334 employees, it was observed that there is a strong relationship between duration of sitting in working hours and neck pain in such a way that if one is in sitting position for over 95% of his working hours, the probability of suffering from neck pain is increased (rr= 2.01%).

According to results of some studies, it was observed that FHP is more prevalent in women compared to men, while in present study it was seen that there is no difference in FHP prevalence in men and women. Another systematic review indicated that there is no correlation between participation in various sport and recreational exercises and neck pain. In a research by dimberg et al, it was found that taking part in rocket sport is a negative risk factor for neck pains . Of course, in our research on university office workers it was seen that they have no regular sport activity and a few of them may exercise a particular kind of sport at the weekends occasionally which was negligible and no positive or negative correlation was found in this regard. It needs further studies in the future. Another factor investigated in most previous studies is the relationship between driving and prevalence of neck and shoulder pain.

One of the study have revealed that office employees had a more improper posture while working with a computer versus sitting with forward looking (not a working) position, and that the defective posture in the working position was more severe in the symptomatic group. It may be due to poor ergonomics of chair, desk, computers position and also lack of attention paid to body position during work. Lack of awareness of posture while working among employees is important in causing improper posture of head and neck; so paying attention to head and neck posture during work might be a good way to decrease the poor posture. It can be introduced into the office environment by feedback methods, mirror or alarming instruments.

According to the results of Cagnie et al. study, it has been found that there is a positive correlation between duration of computer work and neck pain. Other studies that were published before 2000 showed that if duration of sitting at a desk is longer than 5 hours per day, it is considered as a risk factor for neck pain. In contrast to these findings, a systematic review of the 3 studies has found that there was no significant relationship between the duration of sitting and neck pain.[21,22]Based on our findings, there was no relationship between hours of work with a computer and neck pain (p = 0.322).

CONCLUSION

The present study demonstrated the Association of forward head posture with pain and cervical range of motion in desk users. It shows moderately negative correlation between pain and tragus to wall test and it shows positive correlation between pain and cervical range of motion.

ABSTRACT

Background: The Knee injury and Osteoarthritis Outcome Score (KOOS) was originally developed in 1995 by Ewa M Roos and colleagues at the Departments of Orthopedics at Lund University in USA. Thus, the American-English and Swedish versions were developed simultaneously. Also, it has already been translated into many languages such as Hindi, Turkish, Indonesian, Spanish and Swedish. Translation of this scale into Gujarati can be more beneficial for Gujarati physiotherapist to find out better outcome. **Methodology:** The study was carried out on people aged 15 to 50 years in North Gujarat, India, those peoples who have knee pain.116 patients who fulfilled inclusion criteria were selected. Initially scale was translated to Gujarati by forward backward translation and patients were instructed to fill the scale at 1 week interval. Reliability and validity were found out. **Result:** The results of the study showed moderate to high correlation in components of The Knee Injury and Osteoarthritis Outcome Score (KOOS) Gujarati version (ICC= .851,0.835,0.814,0.891 and .977) (P<0.05) and internal consistency (cronbach's alpha = 0.868, 0.834, 0.814, 0.907 and 0.905). The Knee Injury and Osteoarthritis Outcome Score (KOOS) Gujarati version was content validated for idiomatic equivalence, semantic equivalence, content relevance. Face validity were established 100% as all participants answered the scale. For construct validity pearson correlation was done with lower extremity function scale and the pearson correlation value for all five component were -0.143 to 0.185. Correlation is significant at the 0.05 level. **Conclusion:** Gujarati version of the KOOS being a valid, reliable and responsive outcome measure in young patients having knee pain.

KEYWORDS

Knee Injuries and Osteoarthritis Outcome Score (KOOS), Reliability, Validity

INTRODUCTION

The knee is the largest joint in the body and it is a compound synovial joint. [1] The knee consists of two main joints: the femorotibial joint and the patellofemoral joint, which allow the knee to move in three different planes (sagittal, transverse, and frontal).

Patient-reported outcomes are an important element to evaluate the quality and the results of clinical practice as they directly and without any interpretation report a patient's health status.[2] Patients with ACL or meniscus injury have a higher than average risk of developing osteoarthritis, and about 50% have radiological signs of osteoarthritis 10-15 years after injury.

For the elderly population with knee osteoarthritis, well validated outcome measures exist-WOMAC-Western Ontario and McMaster Universities Arthritis Index. However, no outcome measure has been validated for use in younger or physically more active subjects with knee osteoarthritis. It may not be appropriate to use outcome measures assessing function as activities of daily living alone in younger and more active subjects with post traumatic osteoarthritis.

The Knee injury and Osteoarthritis Outcome Score (KOOS) was originally developed in 1995 by Ewa M Roos and colleagues at the Departments of Orthopedics at Lund University, Sweden and at the University of Vermont, USA.

Thus, the American-English and Swedish versions were developed simultaneously. It includes 42 items in 5 separately scored subscales; Pain, other Symptoms, Function in daily living (ADL), Function in Sport and Recreation (Sport/ Recreation), and knee-related Quality of Life (QOL).

The main reason for developing a single instrument with the purpose of covering several types of knee injury and including osteoarthritis (OA), was that traumatic knee injuries often causes concomitant damage to multiple structures (ligaments, menisci, cartilage, etc.) and frequently lead to the later development of OA.

The KOOS evaluates both short-term and long-term consequences of knee injury and include assessing pain; symptoms, such as swelling and restricted range of motion; activities of daily living; sport and recreation function; and knee-related quality of life in young and middle-aged subjects with ACL injury, meniscus injury, or posttraumatic osteoarthritis. The KOOS is self- administered and takes approximately 10 minutes to fill out as well as it is a feasible instrument.[3]

The Knee Injury and Osteoarthritis Outcome Score (KOOS) is one of the most commonly used scales that has been used by physical therapists worldwide. Also, it has already been translated into many languages such as Hindi, Turkish, Indonesian, Spanish and Swedish. Translation of this scale into Gujarati can be more beneficial for Gujarati physiotherapist to find out better outcome. So, there is a need to conduct this study.

METHODOLOGY

Study Design: A cross-sectional Study

Study Population: The study was carried out on people with knee pain in past 10 years from age group 15-50 Years in North Gujarat, India

Study Setting: Native Gujarati patients with knee pain in north Gujarat.

Sample size: 116

Sample Technique: Convenient sampling.

Inclusion criteria:

- Patients willing to participate.
- Both Male and Female
- Age: Between 15-50 years in north Gujarat
- Patient having knee pain with OA, RA and Meniscus injury and Ligament injury in past 10 years.
- Native Gujarati language and can able to read and write Gujarati.

Exclusion criteria:

- Patients having neurological disorders.
- Patient having musculoskeletal disorders other than OA, RA and Meniscus injury.
- Patients having visual problem that cannot be corrected by lenses.
- Non cooperative patients.

Figure 1: Flow Chart of the study Procedure

The Knee injury and osteoarthritis outcome score (KOOS) had been cross-culturally adapted into Gujarati version of Knee injury and osteoarthritis outcome score (KOOS) in following steps:

Step 1: Forward translation:
Two translators (one with the background of medical field and other with no background of medical field) who knew both English and Gujarati language were chosen to translate the questionnaire from English to Gujarati language.

Step 2: Synthesis:
Both the Gujarati versions were combined and two professionals who had knowledge of medical terminologies and were known to both the languages (English & Gujarati) developed a synthesized version.

Step 3: Back-translation:
The synthesized version of the questionnaire was back translated into English language by an independent translator, who knew both English and Gujarati language and had no information of the original questionnaire which was in English language.

Step 4: Expert panel:
A bilingual (in English and the Gujarati language) expert panel was convened which included the forward translator, health experts, as well as professionals with skill in questionnaire development and translation. The changes were done in the translated questionnaire based on the suggestions of the expert panel.

Step 5: Testing of the questionnaire:
A Pre Final Gujarati version of KOOS was given to participants who fulfilled the inclusion and exclusion criteria to find out the reliability and validity of the questionnaire.

Reliability Testing
Test-retest reliability:
The recruited patients with knee pain were asked to fill Gujarati version of Knee injury and osteoarthritis outcome score (KOOS) by themselves twice with minimum gap of one week duration. So that person may not copy the same data as well as he/she will not forgot. The readings were recorded to report test-retest reliability.

Internal consistency:
Internal consistency was measured with Cronbach's alpha (α), a statistic which was calculated from the pair wise correlations measured between paired readings of Gujarati version of Knee injury and osteoarthritis outcome score (KOOS).

Validity Testing
Construct Validity:
Convergent and divergent construct validity was determined by comparison of the administrations of the five subscales of the KOOS and the Lower extremity functional scale. It is expected the highest correlations when comparing the scales that are supposed to measure the same or similar constructs.

Content Validity:
Content equivalence was assessed under two headings: 1. Are the words in the translated Gujarati version of KOOS presented fluently and correctly as in the original version? 2. Do the words and phrase in the translated Gujarati version of KOOS have the same semantic meaning compared with the original version? For this answers from expert panel member's fall between "mostly agree" to "strong agree". This was assessed by an expert panel and they assessed the KOOS-G for content equivalence and content relevance on 5 point likert scale. Content relevance was evaluated by expert judges or panels: How the Gujarati version of KOOS statement is relevant to assess function in knee pain subjects? For this answers from expert panel members' fall between "mostly agree" to "strong agree".

Face Validity:
Face Validity was assessed by asking one question to each of the, 'Do you think this scale is relevant to your condition.' The answer was noted as 'yes' or 'no'. Face validity of the KOOS was established when all the patients questioned about the relevance of the scale to their condition.

RESULTS

All statistical analysis was done using SPSS 25.0 software for windows. Descriptive analysis was used to obtain mean and standard deviations. Reliability testing was done using **reliability analysis**. Inter class correlation coefficient, ICC (2,1) and cronbach's α were measured. Validity testing was done using **Pearson's correlation.** Confidence interval were set at 95%, p = 0.05 for all the analysis.

Age distribution:
The research was performed on 116 patients with knee pain between the age of 15-50. There were 46 patients between the ages of 15 to 30 and 70 patients between the age 31 to 50.

Gender distribution:
The research was performed on 116 patients with Knee pain. In which 55 are Females and 61 are Males.

Test-Retest Reliability:
Test-retest reliability (n=116) was tested by using the interclass correlation coefficient, ICC(2,1) and Internal consistency (n=116) was reported in terms of cronbach's α measured in two session after 1 week is reported.

Table 1: Test- Retest Reliability of Gujarati Version Knee Injury and Osteoarthritis Outcome Score (KOOS)

Knee injury and osteoarthritis outcome score (KOOS)	Session 1 (Mean)	session 2 (Mean)	Cronbach's alpha	ICC	P-value
Pain	19.34	17.22	.868	.851	0.01
Symptoms	14.67	14.29	.834	.835	0.01
Activities of daily living	34.88	36.47	.814	.814	0.04
Sport and recreation function	10.74	11.92	.907	.891	0.01
Knee-related quality of life	9.17	9.91	.905	.897	0.04

Face Validity:
Face validity of the KOOS G was established when all the 116 patients questioned about the relevance of the scale answered YES. i.e. 100%

Construct Validity:

In convergent validity there was a positive correlation of QOL with LEFS. There was a positive correlation between LEFS and ADL (r=0.185).

Content Validity:

The content validity of Gujarati translated knee injury and osteoarthritis outcome score (KOOS) by a 6 experts were found to be, I-CVI of individual items knee injury and osteoarthritis outcome score (KOOS) of ≥ 0.89 and overall S-CVI for idiomatic equivalence, semantic equivalence and content relevance ≥ 0.90. For content validity equivalence all 6 experts answers were located between mostly agree and strongly agree of Gujarati version of knee injury and osteoarthritis outcome score (KOOS).

Table 7: Content Validity of Gujarati Version Knee Injury and Osteoarthritis Outcome Score (KOOS)

Scale Component	I-CVI	S-CVI
Pain	0.89	0.918
Symptoms	0.94	
ADL	0.92	
Sports	0.92	
QOL	0.90	

DISCUSSION

This is a cross-sectional study of translation and measurement of psychometric properties of Gujarati version of Knee Injury and Osteoarthritis Outcome Score (KOOS) on patient with Knee pain.

In this study 116 patients participated. Gujarati version of The Knee Injury and Osteoarthritis Outcome Score (KOOS) was given twice with 1- week interval to measure the test- retest reliability and to validity. The results of the study showed moderate to high correlation in components of The Knee Injury and Osteoarthritis Outcome Score (KOOS) Gujarati version (ICC= .851,0.835,0.814,0.891 and .977) (P<0.05) and internal consistency (cronbach's alpha = 0.868, 0.834, 0.814, 0.907 and 0.905).

Both the internal consistency and the test-retest reliability results confirmed the reliability of the Gujarati version of the KOOS. We found that all the KOOS subscales on the Gujarati version have adequate internal consistency, with all Cronbach α values >0.70 (range, 0.86-0.90). These values are comparable to those for the Finnish version (Cronbach α range, 0.79-0.96) and the Malaysian version (Cronbach α range, 0.78-0.95). Our test-retest reliability analysis showed that the Gujarati version of the KOOS has excellent reliability, with all ICC values >0.90 (range, 0.91-0.99). Our results are similar to those for the Italian version (ICC range 0.85-0.95)

For content validity equivalence all 6 experts answer were located

between mostly agree and strongly agree of The Knee Injury and Osteoarthritis Outcome Score (KOOS) Gujarati version for idiomatic equivalence (average=0.89) semantic equivalence (average = 0.92) and content relevance (average= 0.93). Thus, The Knee Injury and Osteoarthritis Outcome Score (KOOS) Gujarati version was content validated for idiomatic equivalence, semantic equivalence, content relevance. Face validity were established 100% as all participants answered the scale.

For construct validity pearson correlation was done with lower extremity function scale and the pearson correlation value for all five component were -0.143 to 0.185. Correlation is significant at the 0.05 level.

In previous studies, interrater reliability and intrarater reliability of the The Knee Injury and Osteoarthritis Outcome Score (KOOS) of Turkish version were (ICC & cronbach's alpha = (0.839 and 0.904) respectively.[4]

In Indonesian version for the construct validity, moderate Pearson correlation coefficients were found between the KOOS subscales and the SF36. Cronbach α was 0.84 to 0.97 for all subscales, indicating adequate internal consistency. The test-retest reliability was excellent, with intraclass correlation coefficients ranging from 0.91 to 0.99 for all subscales.[5]

Swedish version of the scale was applied on the participants at 2 week intervals. Test-retest reliability. For the five subscales of the KOOS, the random effects intra class correlation coefficients (ICC) were: Pain 0.86, Symptoms 0.84, Activities of Daily Living (ADL) 0.91, Sport and Recreation Function 0.78, and for Knee-related Quality of Life (QOL) 0.83. Internal consistency, as measured by Cronbach's alpha, was for the subscale Pain 0.84, Symptoms 0.74, ADL 0.95, Sport/Rec 0.85, and for QOL 0.71 [6]

It was found The Knee Injury and Osteoarthritis Outcome Score (KOOS) Gujarati version items equivalent to those in original version which is intended by translators involve in this study. The results showed that it was translated this scale into other languages without losing psychometric properties of the original English version.

CONCLUSION

The present study demonstrated the Gujarati version of the KOOS being a valid, reliable and responsive outcome measure in patients having knee pain. The Gujarati KOOS can be applied as a patient-reported and disease specific instrument in future studies including Knee pain subjects in Gujarat.

ABSTRACT

Background: Flexible flatfoot is defined as the postural appearance of the foot, with depressed medial longitudinal arch and pronated subtalar joint and the calcaneus assuming a valgus position under weight bearing conditions. About 10% to 25% population exhibits a flatfoot to varying degrees. In clinical practice, some subjects become symptomatic with foot pain or lower extremity soreness and limitation in their functional activities such as limitation of long distance walking or running and high-impact sports. **Methodology:** Total 100 Subjects will be assessed on basis of following 2 tests and analysis will be done accordingly. First patients will diagnosed for plantar fasciitis with the help of windlass test and then they will be assessed for the flat foot with the help of Navicular drop test. **Result:** Out of 100 participants 68 participants showed increase in pronation of foot according to navicular drop test mean distance were 12.3mm distance more then 9mm can be considered as reduction in arch so the prevalence of flat foot is 68%. **Conclusions:** There is 68% of prevalence of flat foot in patient with plantar fasciitis.

KEYWORDS

Flat foot, Navicular drop test, Plantar fascitis

INTRODUCTION

Flexible flatfoot is defined as the postural appearance of the foot, with depressed medial longitudinal arch and pronated subtalar joint and the calcaneus assuming a valgus position under weight bearing conditions.[1] About 10% to 25% population exhibits a flatfoot to varying degrees.[2]In clinical practice, some subjects become symptomatic with foot pain or lower extremity soreness and limitation in their functional activities such as limitation of long distance walking or running and high-impact sports.

This is a foot with less developed longitudinal arches. Relevant anatomy: A normal foot has longitudinal and transverse arches. The longitudinal arch consists of medial and lateral components resting on a common pillar posteriorly - the tuberosity of the calcaneum. The talus is the keystone of the arches. It receives the body weight and transmits it to the arches below. Through the arches, the weight is transmitted to the ground via the tuberosity of the calcaneum and the heads of first and fifth metatarsals.[3] The integrity of the arches is maintained by the plantar ligaments, the plantar aponeurosis, the extrinsic and intrinsic muscles and the structure of the bones of the foot[4]

Anatomically, the major medial longitudinal arch is formed by the calcaneus, talus, and navicular; the medial, middle, and lateral cuneiforms in addition to the 1st, 2nd, 3rd metatarsals. In dynamic structures, the plantar fascia is essential to the maintenance of the medial longitudinal arch.[5] Kitaoka and associates demonstrated that the posterior tibial tendon owns significant influence as an arch stabilizer during in vitro studies.[5,6] The intrinsic musculature of the foot was also proven to have a significant role in dynamic arch maintenance.

In adult population,pesplanus foot type exist about 10–25% and has been related to musculoskeletal symptoms like back and knee jointpain.[7] Presence of an averted rear foot, lowered medial longitudinal arch (MLA),abducted and dorsi flexed mid foot are the characteristic feature of the flat foot.[8] The cause of pes planus depends on the direct effect between external and internal forces at the articular surfaces, supporting ligaments, joint capsules, extrinsic and intrinsic muscles .Fatigue, paralysis of the intrinsic muscles of the foot due to anaesthesia can also results in reduced height of the MLA[9].

There are few reports which indicate that, plantar fascia contributes in supporting the MLA along with flexor digitorum brevis and abductor hallucis muscles(ABH)[10,11]. There are reports that the paralysis of ABH lowers medial arch height because it is the active elevator of the MLA[12] . About 80% of the resistance for lowering of MLA is furnished by tension in the plantar fascia in the final stage of the swing [13] .Persons with pesplanus tend to develop plantar fasciitis and plantar fascia becomes thicker and rigid due to excessive load .In pesplanus, the altered nature of the plantar fascia is not well understood in the mid and forefoot area where it divides into digital slips, however there reports suggesting studies at its calcaneal attachment[14,15,16] . In the foot,after skeletal maturity if the medial longitudinal arch undergoes a complete or partial collapse then it is referred as flat foot according to foot and ankle specialists[17] .The prevalence of flat feet is not well established. Most of the studies on prevalence of flat foot were done on children below 10 year age.

Plantar fasciitis is the most common cause of the inferior heel pain and may affect up to 10% of running athletes It is associated with biomechanical factors such as pes cavus, foot pronation, heel valgus, sudden gain in body weight or obesity, increased running distance or intensity, shoes with poor cushioning, change in the walking or running surface, and tightness of the Achilles tendon.[18]

In one study, 83% of patients seen with plantar fasciitis were active, working adults ranging from twenty-five to sixty-four years of age^ Often referred to as painful heel syndrome or chronic plantar heel pain, this disorder is diagnosed on the basis of a history of pain on taking the first few steps in the morning,[19] worsening pain with weight-bearing, and pain and tenderness to palpation over the medial calcaneal tubercle'"\ Two large national datasets of ambulatory care data (excluding visits to podiatrists or federal, military, or Veterans Administration facilities) from the National Center for Health Statistics at the U.S. Centers for Disease Control and Prevention found that plantar fasciitis accounts for an average of one million patient visits per year to medical doctors'. Sixty-two percent of these visits were made to general medicine clinics, while 31% of patients were evaluated by orthopaedic or general surgeons.[20]

Study Design And Setting

Study Design: CROSS SECTIONAL STUDY
Population: Patients with plantar fasciitis
Sample Size: 100

Selection Criteria

Inclusion criteria:

- Age group between 20 to 40 years.
- Both genders– male and female.
- Subject willing to participate in study.
- Vendors with 6 to 8 hours of duty.

Exclusion criteria:

- Subject with any systemic illness and other musculoskeletal disorders specifically in lower limb like foot injuries, degenerative changes of hip and knee.

- Subject with any recent surgeries of lower limb.

MATERIALS REQUIRED

- Paper, Pen and Pencil
- Inch Tape
- Marker
- Step Stool

METHEDOLOGY

Subjects will be assessed on basis of following 2 tests and analysis will be done accordingly. First patients will diagnosed for plantar fasciitis with the help of windlass test and then they will be assessed for the flat foot with the help of Navicular drop test.

Windlass Test:

Maintaining the sitting position and then coming in standing position. In high sitting position, the ankle will be stabilized and the great toe will dorsi-flexed (no-weight bearing). In standing position, the subject will be asked to stand on toes of both the foot (weight bearing). In both the positions the subject will be asked if there is any unpleasant pain in the sole or heel of the foot. Both the plantar fascia passive stretching test and the windlass test (in non- weight bearing position) were supposed to be performed on the both the limbs (foot) simultaneously. If the subject will complain for any pain then the respective test will be marked positively and there will be no pain then the respective test will be marked negative.

Navicular drop test.

Purpose: To assess the height of navicular bone.
Test position: Standing
First mark the navicular tuberosity next measure the height of the navicular bone with the subtalar joint in neutral and the patient bearing most of the weight on the contralateral limb. Finally have the patient assume equal weight on both feet and re-measure the first and second measurement is the navicular drop. A difference of > 10mm is considered significant excessive foot pronation.

RESULTS

All statistical analysis was done using SPSS 25.0 software for windows. Descriptive analysis was used to obtain mean and standard deviations.

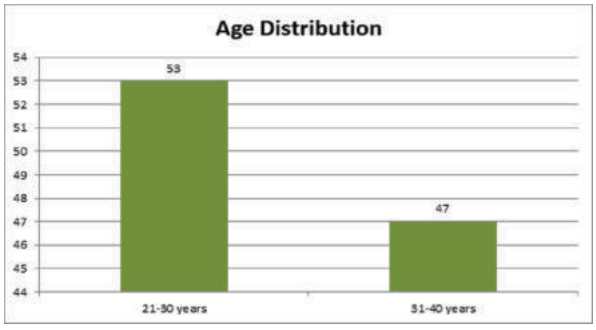
Demographic Data

AGE:

The research was performed on 100 participants between the age of 20-40. There were 53 patients between the ages of 20 to 30, 47 patients between the age 31to 40.

Table 1: Age Distribution

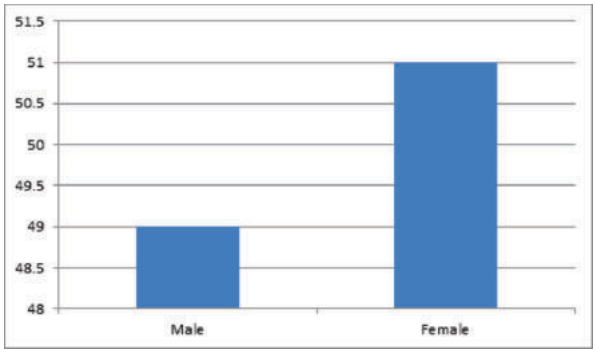
Age Distribution	
21-30 years	31-40 years
53	47



Graph 1: Age Distribution

Gender Distribution:

The research was performed on 100 participants between the age of 20-40. There were 49 Male participants and 51 female participants.



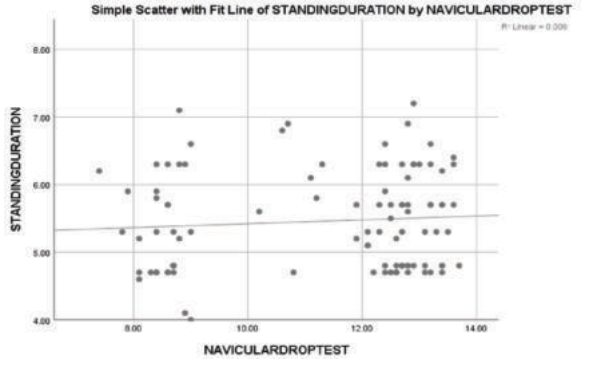
Graph 2: Gender Distribution

Table 2: Mean Value Of Fpi & Standing Duration

	Mean + SD
Age	27.8+4.6
Navicular drop test	12.3+5.2 mm
Standing Duration	5.8+ 0.8 hours

Table 3: Incidence Of Flatfoot Using Navicular Drop Test

Test Name	Positive	Negative
Windlass test	100	0
Navicular drop test	68	32



Graph 3 : Corelation Between Standing Duration And Flat Foot

Out of 100 participants 68 participants showed increase in pronation of foot according to navicular drop test mean distance were 12.3mm distance more then 9mm can be considered as reduction in arch so the prevalence of flat foot is 68% it also shows positive correlation between standing duration and flat foot.

DISCUSSION

Flatfoot is a biomechanical disorder frequently seen in clinical practice. one study reveals that the prevalence of flat foot was 26.62%.

Described finding is practically identical to a study conducted in Japan on a sample of 242 women and 98 men, in which a prevalence of 26.5% was observed, along with how said finding is related with obesity and the effects of pain and functionality . Similar findings regarding the prevalence of flat foot can be found in other publications. In other population studies (Springfield, Massachusetts) the prevalence of flat foot was 19.0% (20.1% in females and 17.2% in males) . Another study conducted in the Boston area found a prevalence of 20% in women 17% in men. There are even studies, conducted in a diabetic population on a sample of 230 patients, which refer to a prevalence as high as 37%

The present study was performed on 100 participants between the age of 20-40. There were 53 patients between the ages of 20 to 30, 47 patients between the age 31to 40. It was having mean Navicular drop test score of 12.3±5.2 mm and mean standing hours were 5.8±0.8 hours and they show positive correlation of standing hours with flat foot. Prevalence of flat foot among plantar fasciitis is 68%.

Previous studies of plantar fasciitis have found that up to 10% of the population is affected during their lifetime^ and over one million Americans per year' have this condition. The incidence rate of plantar fasciitis in our population was 10.5 per 1000 person-years, with a rate of 9.2 for men and 18.0 for women per 1000 person-years. Although we are aware of no known studies in the literature with incidence rates, prevalence rates of plantar fasciitis ranging between 4% and 22% have been reported among a population of runners.

Another study conducted in India reveals how the use of footwear at early ages, along with obesity and ligamentous laxity, increases the prevalence of flat foot

Another study conducted in Nigeria on 560 children aged between six and 12 years shows that although in the univariate analysis an association was found with type of footwear and age, after taking both into consideration, only age remained as a variable associated the presence of flat foot . Urban residence as a risk factor for the prevalence of flat foot has also been described in a study conducted on children in the Congo, where, after studying 1,851 footprints from 906 girls and 945 boys aged between three and 12 years, it was observed that prevalence diminishes with age, is higher in urban areas and in the masculine sex, and that the use of footwear has little influence on said prevalence . This study shows how the BMI, comorbidity and foot size are associated with the prevalence of flat foot. There are variability in the literature review. A number of studies describe how this foot disorder increases with age , other studies describe how flat foot diminishes with age, after adjusting for other covariates , and others indicate that neither age, gender nor BMI are related with flat foot.

Also in another study, the prevalence of flat foot was assessed where in it was found that real prevalence of symptomatic flatfoot is not very high in adolescents due to its nature of spontaneous correction as age increasesAlso in another study, the prevalence of flat foot was assessed where in it was found that real prevalence of symptomatic flatfoot is not very high in adolescents due to its nature of spontaneous correction as age increases [18,19]. According to age, the subjects between age 20-29 years were suffering 31.8% of flat foot, 30-39 years were having 42% flat foot, 40-49 years were having 16.7% flat foot, above 50 years were having 37.5% flat foot. similarly subjects between age 20-29 years were suffering 47.7% of high arched foot, 30-39 years were having 50% high arched foot, 40-49 years were having 61.1% high arched foot, above 50 years were having 50 % high arched foot.

According to gender it was found that high arched foot had higher incidences in males (55.2%) whereas flat feet were found to have higher incidences in females (38.7%).

A number of studies also describe different radiological findings in the morphology of the foot according to different ethnic groups. Others indicate how the different radiological morphology (angle of the talus with the first metatarsal) is related with the symptomatic presence or absence of flat foot. Even though obesity has repeatedly been associated with the presence of flat foot , not all studies point towards this association . In some articles, not only is the association of flat foot with characteristics (e.g., age, sex, BMI and concomitant illness) indicated, but also as a modifier of health . Thus, there are studies of 97,279 military recruits which associate flat foot with localised knee pain . As we have previously mentioned, in the article which finds a prevalence of flat foot identical that in our study it can also be seen how said alteration is also associated with the presence of pain and fatigue in women.

CONCLUSION

This study, conducted among adults of Gujarat state, revealed that youth those are having plantar fasciitis prone to developing flat foot, which aligns with published Western literature. This study shows that there is 68 % of prevalence of flat foot in adults who had plantar fasciitis. this study also suggest standing duration was positively correlated with pronation of foot in persons with plantar fasciitis.

ABSTRACT

Background: Back pain is the leading cause of activity limitation and work absence throughout much of the world, and it causes an enormous economic burden on individuals, families, communities, industry and governments. High Intensity Laser Therapy (HILT) has photochemistry effects that stimulate oxidation of mitochondria and ATP creation by delivering high energy output inside tissues. HILT can cause quick absorption of edema and removal of exudates through increased metabolism and blood circulation. Although many nonsurgical treatments for chronic back pain have been introduced so far, there is a paucity of research on HILT. **Methodology:** This Evidence based study was conducted from 2011 to 2023. Search engines used to find appropriate articles were: PubMed, Google Scholar, PEDro, ResearchGate, ScienceDirect. Key words used were: Back pain, HILT, High Intensity Laser Therapy, Laser Therapy. Articles were assessed via 2 scales: Centre for Evidence-Based Medicine's (CEBM's) Levels of Evidence and PEDro scale. **Result:** Total 136 articles were found, out of which 15 articles were relevant and from those 9 articles were included in this evidence-based study. From total 9 studies, there is 2 Systematic review and meta-analysis, 1 Systematic review, 3 Randomized controlled trials and 2 Comparative studies. Their Level of evidence was 1a, 1b and 2a. **Conclusions:** High intensity laser therapy can be considered a complimentary modality for effective management of low back pain to improve pain and function. When compared or combined with other modalities such as ultrasound and tens it improves pain and function more efficiently.

Back Pain, HILT, High Intensity Laser Therapy , Laser Therapy

INTRODUCTION

Low back pain is the leading cause of activity limitation and work absence throughout much of the world, and it causes an enormous economic burden on individuals, families, communities, industry and governments. Until 10 years ago, it was largely thought of as a problem confined to Western countries; however, since that time an increasing amount of research has demonstrated that low back pain is also a major problem in low and middle income countries.

Studies suggest that low back pain may arise from any one of a number of anatomical structures, including bones, intervertebral discs, joints, ligaments, muscles, neural structures and blood vessels. In a minority of instances, approximately 5–15%, low back pain can be attributed to a specific cause such as an osteoporotic fracture, neoplasm or infection .[1] For the remaining 85–95% of cases, the specific cause of low back pain is unclear.

The search for causes of low back pain continues through causal inference, which is a process whereby several criteria are examined to assess causation. These include assessment of bias and confounding; demonstrating a temporal relationship (i.e., the cause must precede the effect); plausibility; consistency with other studies; the strength of the association (i.e., the relative risk); the dose– response relationship (i.e., does increased exposure lead to increased effect); and reversibility (i.e., does removal of the exposure reduce the disease risk)[2]. Due to methodological heterogeneity in studies that have investigated causation of low back pain, it is difficult to draw any conclusions about causality.

Many studies have significant bias and confounding and relatively few cohort studies have been conducted. It has also been difficult to determine a temporal relationship between risk factors and low back pain (e.g., depression and low back pain), and it has been difficult to quantify exposure variables (e.g., in the occupational setting: the frequency/amount of lifting).[3]

There are a number of psychosocial factors associated with low back pain, including stress, anxiety, depression and certain types of pain behaviour; however, the direction for these relationships is often unclear. Evidence shows that psychosocial factors are also significantly associated with the transition from acute to chronic low back pain. Psychosocial workplace factors have also been shown to be important risk factors for low back pain. In two systematic reviews, it was found that job dissatisfaction, monotonous tasks, poor work relations, lack of social support in the workplace, demands, stress and perceived ability were associated with an increased occurrence of low back pain. Job dissatisfaction has also been shown to be associated with transition from acute to chronic low back pain.[4]

Other occupational factors have been shown to be associated with low back pain. One study demonstrated a clear correlation between physical demands of work and the prevalence of low back pain (with the exception of lifetime prevalence in female workers). They found the point prevalence of low back pain was 39% in manual workers, but only 18.3% in male sedentary workers. More recently, a systematic review found that manual handling, bending, twisting and whole-body vibration are risk factors for low back pain. Although the data on occupational risk in low-income countries are relatively limited, it has been estimated that 80–90% of the population in these areas are involved in 'heavy work', which suggests this may have a significant impact on the occurrence of low back pain.[5]

More recently, the pulsed neodymium-doped yttrium aluminium garnet (Nd:YAG) laser, a form of high-intensity laser therapy (HILT), was introduced to the field of physical therapy. This laser works with high peak power (3 kW), and a wavelength of 1,064 nm, and is considered to be a nonpainful and noninvasive therapeutic modality. It is able to stimulate areas that are difficult to reach with the low-power laser, such as the large and/or deep joints . The use of the pulsed Nd:YAG laser has been increasing, with patients reporting significant pain reduction. Studies have documented the anti-inflammatory, anti-oedematous, and analgesic effects of the Nd:YAG laser, justifying its use in patients with pain issues.

High Intensity Laser Therapy (HILT) has photochemistry effects that stimulate oxidation of mitochondria and ATP creation by delivering high energy output inside tissues. HILT can cause quick absorption of edema and removal of exudates through increased metabolism and blood circulation. Although many nonsurgical treatments for chronic back pain have been introduced so far, there is a paucity of research on HILT.[6]

METHODOLOGY

Study Design:

An Evidence Based Study. This was conducted according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analysis) guidelines. (Figure 1).

Literature Search:

A specified literature search was performed from 2011 to 2023 (12 years). Literature was searched using following search engines: Google Scholar, PEDro, PubMed, ResearchGate, ScienceDirect

KEY WORDS USED FOR THE SEARCH WERE:
Back Pain, HILT, High Intensity Laser Therapy, Laser Therapy

ASSESSMENT OF METHODOLOGICAL QUALITY:
Data was assessed using 2 parameters: (1) Centre for Evidence-Based Medicine's (CEBM's) Levels of Evidence and (2) PEDro scale

1. The CEBM Levels of Evidence scale: It assesses quality based on study design, which categorize the studies in a scale ranging from 1 to 5 with further subdivision for each

2. The PEDro scale: It assesses methodological quality and consists of a checklist of 11criteria, 10 of which are scored. For each criterion the study met, 1 point was awarded. The points were presented as a score out of 10. For this review, investigations with PEDro scores of 6 to 10 were considered high quality, of 4 to 5 were considered moderate quality, and of 0 to 3 were considered low quality.

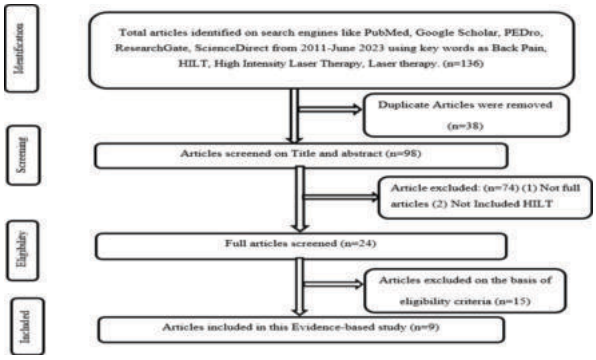

Figure 1: Preferred Reporting Items For Systematic Reviews And Meta-analysis (PRISMA)

Table 1: Characteristics Of Included Studies

Sr No.	TITLE	Study design & Duration	Articles Or Sample Size	Pedro And Level Of Evidence
1	The effectiveness of high intensity laser therapy in management of spinal disorders	Systemic review and meta-analysis	6	1a
2	The effectiveness of laser therapy on the management of chronic low back pain	Systemic review	397	1a
3	Effectiveness of high intensity laser therapy in the treatment of musculoskeletal disorders	Systemic review meta-analysis of randomized controlled trial	12 studies selected including 736 participants	1a
4	Short-term effect of high intensity laser therapy versus ultrasound therapy in treatment of low back pain	A randomized controlled trial	30	8/10 1b
5	Comparison of two different electrotherapy methods in low back pain treatment	Comparative study	40	5/10 2a
6	Long-term effect of high –intensity laser therapy in the treatment of patients with chronic low back pain	A randomized blinded placebo-controlled trial	72	5/10 2a
7	Effect of high intensity laser therapy on pain and function of patients with chronic back pain	Comparative study	20	3/10 2b
8	Comparison of high intensity laser therapy and combination of transcutaneous nerve stimulation and ultrasound treatment in patients with chronic lumbar radiculopathy	A randomized single-blinded study	54	5/10 2a
9	Laser photo biomodulation is more effective than ultrasound therapy in patients with chronic non-specific low back pain	Comparative study	45	4/10 2a

RESULTS
Evidences were reviewed and analysis was done on the basis of PEDro score and CEBM's Level of Evidence Scale. Risk of bias is also assessed.

Total 136 articles were found, out of which 15 articles were relevant and from those 9 articles were included in this evidence-based study and other articles were excluded.

From total 9 studies, there is 3 meta-analysis and systematic reviews, 3 comparative study, 3 Randomized controlled trial. All studies shown that High Intensity Laser Therapy is effective in management of Low back pain.

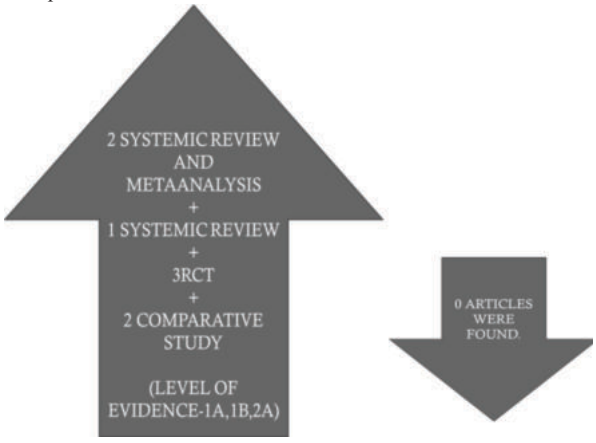

Figure 2: Result of Evidence Based Study

DISCUSSION
This evidence-based study included total 9 studies, there is 2 Systematic review and meta-analysis, 1 Systematic review, 3 Randomized controlled trials and 2 Comparative studies.

Laser treatment is noninvasive, painless, and can be easily administered in primary care settings for a wide range of conditions [7]. It has been reported that the use of laser therapy significantly reduces pain levels in both acute and chronic conditions such as rheumatoid arthritis, chronic osteoarthritis, carpal tunnel syndrome, fibromyalgia, knee injury, shoulder pain, and postoperative pain [8]. Although low level laser therapy does not elevate tissue temperatures more than a few degrees [9], studies have found that the treatment has the potential to reduce inflammation, pain and improve function [10]. Low level laser therapy significantly increases microcirculation, activates angiogenesis, and stimulates immunological processes and nerve regeneration. Moreover, it has an analgesic effect through stimulating an increased production of endorphins. More recently, the pulsed neodymium-doped yttrium aluminum garnet (Nd:YAG) laser, a form of high-intensity laser therapy (HILT), was introduced to the field of physical therapy. This laser works with high peak power (3 kW), and a wavelength of 1,064 nm, and is considered to be a nonpainful and noninvasive therapeutic modality. It is able to stimulate areas that are difficult to reach with the low-power laser, such as the large and/or deep joints. The use of the pulsed Nd:YAG laser has been increasing, with patients reporting significant pain reduction [37]. Studies have documented the anti-inflammatory, anti-oedematous, and analgesic effects of the Nd:YAG laser, justifying its use in patients with pain issues [11].

HILT has been known to reduce heat accumulation in tissues and to have photothermal and photochemical effects in deep tissues for limited periods.[12] These properties favor treatment of deep tissues and structures by increasing cell metabolism, vascular permeability, and blood flow.[13] The pain control effect achieved by HILT might be attributed to multiple mechanisms. In the central nervous system, the secretion of endogenous opioids such as b-endorphins is increased by

laser therapy and these could centrally inhibit pain sensations.[14] In the peripheral nervous system, substance P sensitizes pain transmitting neurons and leads to hyperalgesia; however, laser therapy has been reported to decrease the secretion of substance P by peripheral receptors.[15] Laser therapy might increase the latency and decrease the conduction velocity of sensory nerves by inhibiting Ae- and C-fiber transmission; these in turn may decrease the transmission of pain signals.[16] In tissues, laser therapy may also reduce the release of histamine and bradykinin in injured tissues and increase the pain threshold.[17] These multiple actions of laser therapy may represent the underlying mechanisms involved in the control the pain in MSD. In addition, a decrease in pain sensation has a significant effect on the increase of range of motion and the quality of life of the patient.[18] Thus, functional ability in patients with MSD could also be also improved.

According to the Arndt-Schulz principle, excessive energy delivered to tissues may produce adverse effects to the human body [19]. There was no definite HILT protocol existing for the treatment of spinal disorders, with the frequency of sessions as well as the duration of study varying between studies; one session daily was given for patients for one week [20], for two weeks, three weeks or two sessions/week for 4–6 weeks [21]. The current systematic review showed variation in laser source, wavelength, power, fluency, radiant exposure, application area, energy and time delivered to patients. Furthermore, there were variations in terms of treatment protocol, frequency and duration. All these variations may explain the heterogeneity in the meta-analysis. Some studies used the term intensity or the power density, that is the power per unit area, which may considered as incorrect terminology used to describe the laser type [22]. There is no definite limit to differentiate between LLLT and HILT. In addition, the term intensity does not distinguish between the radiant exitance (emitted light) from the energy density of irradiance, which is the irradiated light arriving that depends on the beam area (light exit) [23]. Such a term may lead to confusion and may be an improper laser description or title. Therefore, future studies should use such terms with caution.

CONCLUSION

High intensity laser therapy can be considered a complimentary modality for effective management of low back pain to improve pain and function. When compared or combined with other modalities such as ultrasound and tens it improves pain and function more efficiently.

Conflict Of Interest:

ABSTRACT

Background: Proper posture is considered to be a state of musculoskeletal balance that involves A minimal amount of Stress or strain to the body.it Compromises balance because of muscular Imbalance which can cause loss Of Proprioception sense in joint and decreased Balance, and trunk endurance is significantly Reduced in Reduced in forward head posture and may lead to poor muscular Control of the spine. **Aim:** To Determine the Correlation between core muscle endurance and foot posture in college Going Students. **Methodology:** An observational study Was conducted in 50 College Going Students of Ahmedabad and Convient Sampling was used. Age group 18-25 Year students Chek for Core Muscle Endurance Test and Foot Posture Analysis. The statistical evaluation become accomplished with SPSS version 29-2022, September. **Result:** Our Finding Suggest that from Descriptive analysis of data was expressed in mean and Standard Deviation for various parameters. Correlation were expressed in term of R value and P Value. P value less than 0.05 was considered to be Signifcant. **Conclusion:** Individuals with altered foot posture will have an effect on the Proximal segment through the Kinetic chain phenomenon of the body, Affecting the core endurance. Individuals with altered Foot posture have reduced core endurance.

KEYWORDS

Core Muscle,Foot Posture,College Students,Endurance

INTRODUCTION

Foot posture plays an important role in the quality of daily living.[1]The structure of the feet is such that it permits the functions of both the stability and the mobility depending on the tasks which are imposed on it.[1]

Kinetic Chain & Core

Core stability can be defined as the ability of the Lumbopelvic-Hip Complex to prevent buckling of the Vertebral Column and return it to equilibrium following perturbation by using Strength, Endurance and Motor Control in a functional manner through all the planes of motion and action despite changes in the center of gravity.[2]

Need Of Study:

1)The foot posture is important for provide stable base of support during walking, running and jumping.
2)Proximal stability is needed for distal mobility.
3)So the core provide proximal stability to perform proper distal component mobility. The affection in
4)proximal core muscle may be lead to distal component changes and visa versa.

Aims Of The Study:

To find out the Correlation between core muscle endurance and foot posture in college Going students.

OBJECTIVES:

1)To find out the Correlation between core muscle endurance and foot posture in college going students by using Flexor endurance test & FPI.
2)To find out the Correlation between core muscle endurance and foot posture in college going students by using Extensor endurance test & FPI.
3)To find out the Correlation between core muscle endurance and foot posture in college going students by using Rt. Side plank endurance test & FPI.
4)To find out the Correlation between core muscle endurance and foot posture in college going students by using Lt. Side plank endurance test & FPI.

Null hypothesis:

There is no significant Correlation between core muscle endurance and foot posture in college going students.

Alternate Hypothesis:

There is significant Correlation between core muscle endurance and foot posture in college going students. and foot posture in college going students.

MATERIAL

Pen, paper, pencil
Foot posture index questionnaire
Stop watch
Plinth or high level bed

METHODOLOGY

Sample Size: 50

Sampling Design : Convient sampling

Study Design: An observational study

Setting: Ahmedabad

Population: Age group between 18 to 25 years

Procedure

- Selection
- Fifty subjects with the age group between 18 to 25 years participate in this study.
- Core Endurance :
- 60 degree flexion endurance test,
- trunk extensor endurance test,
- Right side plank test
- left side plank test.
- Time noted in sec.
- Foot posture:
- Foot posture index.

Flexor Endurance Test Position

Extensor Endurance Test Position

Lt. & Rt. Side Plank Endurance Test Position

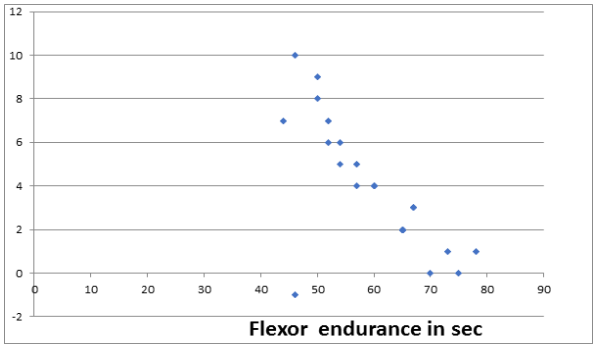
RESULTS

Descriptive analysis of data was expressed in mean and standard deviation for various parameters.Correlation were expressed in term of r value and P value.P value less than 0.05 was considered to be significant

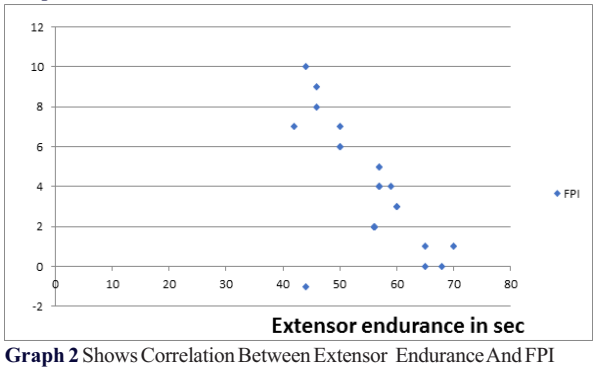
The graphical representation was done by scatter graph.

Table 1 : Descriptive Analysis

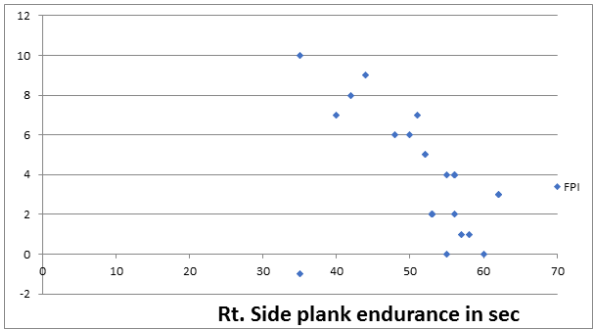
	MEAN	STANDARD DEVIATION
Age	22.34	1.7333
Flexor endurance test	60.1	9.2609
Extensor endurance test	55.34	7.3640
Rt. Side plank test	51.78	7.3326
Lt. side plank test	49.08	6.7698
Foot posture Index	3.78	2.8734



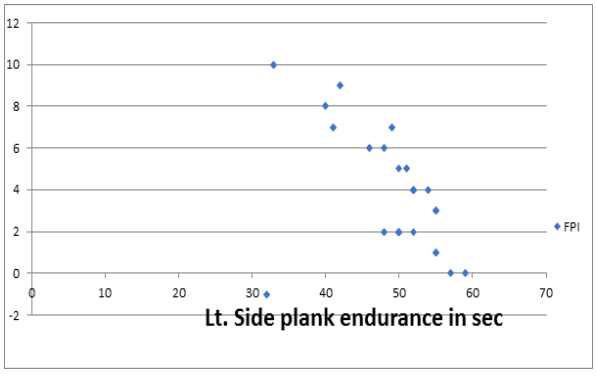
Graph 1 Shows Correlation Between Flexor Endurance And FPI



Graph 2 Shows Correlation Between Extensor Endurance And FPI



Graph 3 Shows Correlation Between Rt. Side Plank Endurance And FPI



Graph 4 Shows Correlation Between Lt. Side Plank Endurance And FPI

Table 2: Correlation Between Core Endurance & Foot Posture

Variables	r value	P value	
Flexor endurance test & FPI	-0.7231	0.04	significant
Extensor endurance test & FPI	-0.6734	0.03	significant
Rt. Side plank test & FPI	-0.5098	0.005	significant
Lt. side plank test & FPI	-0.5037	0.005	significant

RESULTS

Result shows there is a negative correlation between core endurance timing and foot posture index scoring.

DISCUSSION

The Purpose Of the Study find out correlation between core muscle endurance and foot posture in college going students. The Presents Study Suggest that changes in foot posture causes changes in the kinetic chain of the entire lower extremity upto the lumbar, pelvic and the hip region. Dr. Anvita Telang at el, Conducted study on Comparison of Core Stability in Individuals with Flexible Flat Foot and Normal Foot and conclude that Individuals with flexible flat foot have reduced core Stability.[3] Statistical significance was considered when p value was less than 0.05. The results from statistical analysis of the present study rejects the null hypothesis. There was an significant difference in Core muscle endurance in individuals with different foot posture in the age group of 18- 25 years. The reasons to the above findings are- changes in foot posture causes changes in the kinetic chain of the entire lower extremity upto the lumbar, pelvic and the hip region.

CONCLUSION

Individuals with altered foot posture will have an effect on the proximal segment through the kinetic chain phenomenon of the body, affecting the core endurance.

Individuals with altered foot posture have reduced core endurance.

ABSTRACT

Background: Coronary artery bypass graft (CABG) Surgery is Known to induce significant muscle wasting. Thus, vast no of patients is facing reduces endurance after surgery with the help of this study. The resultant significant treatment can be beneficial to help vast no of patients with endurance problems. **Methodology:** Participants' subjects meeting inclusion criteria will be included in the study. The sample will be initially selected then randomly divided into 2 groups, group A and group B Treatment with aerobic exercise group A n=30 patients. Treatment with deep breathing exercise with positive expiratory pressure breathing exercise group B n=30 patients. consent form will be signed by both groups. **Result:** The research was performed on 60 participants between the age of 35-65 years. There were group(A) 30 patients between age 35-55, group(B) 30 patients between age 35-60. The statistical software SPSS 25.0 version was used to analyze the data. Before taking statistical data, outcome measure by the six-minute walk test. All outcome measures were analyzed using suitable statistical analysis at baseline and after (4to8) weeks of intervention level ofsignificance was kept at 95% changes in the outcome measures were analyzed within group as well as between. **Conclusions:** Aerobic exercise is better than deep breathing exercise with positive expiratory pressure breathing exercise in post CABG patients in recovery phase.

INTRODUCTION-

It is a surgical procedure in which the chest is opened, and surgery is performed on the heart. The term "open" refers to the chest, not to the heart itself. Two types of cardiac surgery are closed and open-heart surgery. (1) (2) The heart is a muscular organ that pumps blood throughout the circulatory system. It is situated between two lungs in the mediastinum. It is made up of four chambers, right atrium, right ventricle, left atrium, left ventricle. Heart beats 72/min. CABG (coronary artery bypass grafting) is done when there is multiple severe coronary stenosis associated with unstable or uncontrolled angina. CABG is a surgical procedure used to treat coronary artery disease. The blocked or narrowed coronary arteries are simply bypassed, replacing the blocked portion of the coronary artery with a piece of patent blood vessels taken from any other less sensitive area of the body. Such vascular grafts may be pieces of a vein taken from the legs or mammary artery in the chest. One end of the graft is attached above the blockage and the other end is attached below the blockage through the new graft to reach the heart muscle. CABG can also be performed off pump and on pump. (3)(4)(5) Aerobic exercise is submaximal, rhythmic, repetitive exercise of large muscle groups, during which the needed energy is supplied by inspired oxygen. Aerobic exercise training is augmentation of the energy utilization of the muscles by means of an exercise program. The improvement of the muscles ability to use energy is a direct result of increased levels of oxidative enzymes in the muscles, increased mitochondrial density and size and an increased muscle fiber capillary supply. Training is dependent on exercise of sufficient intensity, duration, and frequency. Training produced cardiovascular and /or muscular adaptation and is reflected in an individual's endurance. Aerobic exercise is any type of cardiac conditioning. It can include activities like brisk walking, swimming, running, or cycling. Aerobic exercise can be effective in increasing endurance of cardio-respiratory system by improving stroke volume at rest, lowering resting heart rate, lowering blood pressure, aerobic exercise is critical component of cardiac rehabilitation following cardiac rehabilitation.

Aerobic exercise traditionally commenced two to six weeks following hospital discharge and most commonly includes stationary cycling or treadmill walking. (6)(7)(8) INTRODUCTION 4 Deep breathing exercise is a fundamental intervention for the prevention or comprehensive management of impairments related to acute or chronic pulmonary disorders and Post Surgical patients. Deep breathing exercises come in many forms including diaphragmatic, breathing, segmental breathing, inspiratory resistance training incentive spirometry, pursed-lip breathing. (9) When the diaphragm is functioning effectively in its role as the primary muscles of inspiration, ventilation is efficient and the oxygen consumption of the muscle of ventilation is low during relaxed (tidal) breathing. When a patient relies substantially on the accessory muscles of inspiration the mechanical work of breathing (oxygen consumption) increases and the efficiency of ventilation decreases. Although at an involuntary level, a patient with primary or secondary pulmonary dysfunction can be taught how to control breathing by optimal use of the diaphragm and decreased use of accessory muscles. Diaphragmatic breathing is designed to improve the efficiency of ventilation, decrease the work of breathing, increase the excursion (descent or ascent) of the diaphragm, and improve gas exchange and oxygenation. (10) (11). Pursed-lip breathing is a strategy that involves lightly pursing the lips together during controlled exhalation. Many therapists breathing and controlled expiration is a useful procedure, particularly to relieve dyspnea if it is performed appropriately. Pursed-lip breathing decreases the respiratory rate and the work of breathing (oxygen consumption), increases the tidal volume, and improves exercise tolerance. (12)

Positive expiratory pressures breathing is a technique in which resistance to airflow is applied during exhalation, similar to what occurs during pursed-lip breathing, except that the patient breathes through a specially designed mouthpiece or mask that controls resistance to airflow. This breathing technique is used to hold airways open during exhalation to mobilize accumulated secretions and improve their clearance. Positive expiratory pressure breathing provides an alternative or adjunct to postural drainage which a patient can perform independently. (13) Following coronary artery bypass graft (CABG), the main cause of postoperative morbidity and mortality are postoperative pulmonary complications, respiratory dysfunction, and arterial hypoxemia. Incentive spirometry is a treatment technique that uses a mechanical device (an incentive spirometry) to reduce such pulmonary INTRODUCTION 5 complications during postoperative care. An incentive spirometry is a device that measures the volume of the air inhales into the lungs during inspiration when breathing in through an incentive spirometry, a piston rises inside the device and measures the volume of the inspired air. Here we used flow-oriented incentive spirometry (Tri-flow device) has three chambers with one ball in each chamber capacity up to 1200ml. (14) (15) (16) The 6-minute walk test (6-MWT) is an assessment that a

doctor may use to determine a person's exercise tolerance. It may be useful for measuring the functional ability and fitness of people with certain health conditions. (17) The Borg rating of perceived exertion (RPE) scale is an objective reassure of fatigue. This scale can also be used to monitor exercise intensity. (18)

METHODOLOGY

Study Design And Setting

Study Design: Comparative Study

Source Of Data: Zydus Hospital, and Trisha Heart Care and Physiotherapy center.

Population: Post CABG Patients in Recovery Phase.

Sampling Method: Random Sampling (fish bowel method)

Sample Size: 60 Patients (Treatment with Aerobic Exercise n=30 Patients, Treatment with Deep Breathing exercise With Positive expiratory pressure breathing exercise n=30 Patients)

Duration Of the Study: One Year.

MATERIAL & TOOLS USED:

Paper Pen
Assessment sheet Consent Form Incentive spirometry
Positive expiratory pressure breathing device. Cycle ergometer
Stopwatch Pulse oximeter
Blood pressure instrument

DATA COLLECTION PROCEDURE:

Participants who were meeting the inclusion and exclusion criteria have been selected for the study followed by the signature of participants on their consent form. The sampling was done randomly followed by convenient allocation within 2 groups: group A and group B. Treatment of aerobic exercise was given to the participants of group A (n=30 patients). Treatment of deep breathing exercise with positive expiratory pressure breathing exercise was given to the subjects of group B (n=30 patients).

CASE STUDY

Worldwide approximately 400,000 people have undergone CABG in 2021-2022. Thus, vast numbers of patients are facing reduced endurance after surgery. With the help of this study, the resultant significant treatment can be beneficial to help vast number of patients with endurance problem. (4)(5)(6)

CONCLUSIONS

According to this study, Aerobic exercise is better than deep breathing exercise with positive expiratory pressure breathing exercise in post CABG patients in recovery phase. SUMMARY This study compared aerobic exercise and deep breathing exercise with positive expiratory pressure breathing exercise in post CABG patients in recovery phase. They were randomly allocated into groups or outcome was measured pre and post after 4 to 8 weeks of intervention. Both treatments were significantly effective in post CABG patients in the recovery phase but, more effective was in group A.

Limitations Limited age group may be applicable to larger age group. Limited sample size. Before recovery phase further study done with different age group geriatric group population. Future recommendation Further study can be done with large sample size. Study can be done with long term follow up.

ABSTRACT

Background: Flexible flatfoot is defined as the postural appearance of the foot, with depressed medial longitudinal arch and pronated subtalar joint and the calcaneus assuming a valgus position under weight bearing conditions. About 10% to 25% population exhibits a flatfoot to varying degrees. In clinical practice, some subjects become symptomatic with foot pain or lower extremity soreness and limitation in their functional activities such as limitation of long distance walking or running and high-impact sports. **Methodology:** Total 100 Subjects will be assessed on basis of following 2 tests and analysis will be done accordingly. First patients will diagnosed for plantar fasciitis with the help of windlass test and then they will be assessed for the flat foot with the help of Navicular drop test. **Result:** Out of 100 participants 68 participants showed increase in pronation of foot according to navicular drop test mean distance were 12.3mm distance more then 9mm can be considered as reduction in arch so the prevalence of flat foot is 68%. **Conclusions:** There is 68% of prevalence of flat foot in patient with plantar fasciitis.

Flat foot, Navicular drop test, Plantar fascitis

INTRODUCTION

Flexible flatfoot is defined as the postural appearance of the foot, with depressed medial longitudinal arch and pronated subtalar joint and the calcaneus assuming a valgus position under weight bearing conditions.[1] About 10% to 25% population exhibits a flatfoot to varying degrees.[2]In clinical practice, some subjects become symptomatic with foot pain or lower extremity soreness and limitation in their functional activities such as limitation of long distance walking or running and high-impact sports.

This is a foot with less developed longitudinal arches. Relevant anatomy: A normal foot has longitudinal and transverse arches. The longitudinal arch consists of medial and lateral components resting on a common pillar posteriorly - the tuberosity of the calcaneum. The talus is the keystone of the arches. It receives the body weight and transmits it to the arches below. Through the arches, the weight is transmitted to the ground via the tuberosity of the calcaneum and the heads of first and fifth metatarsals.[3] The integrity of the arches is maintained by the plantar ligaments, the plantar aponeurosis, the extrinsic and intrinsic muscles and the structure of the bones of the foot[4]

Anatomically, the major medial longitudinal arch is formed by the calcaneus, talus, and navicular; the medial, middle, and lateral cuneiforms in addition to the 1st, 2nd, 3rd metatarsals. In dynamic structures, the plantar fascia is essential to the maintenance of the medial longitudinal arch.[5] Kitaoka and associates demonstrated that the posterior tibial tendon owns significant influence as an arch stabilizer during in vitro studies.[5,6] The intrinsic musculature of the foot was also proven to have a significant role in dynamic arch maintenance.

In adult population,pesplanus foot type exist about 10–25% and has been related to musculoskeletal symptoms like back and knee jointpain.[7] Presence of an averted rear foot, lowered medial longitudinal arch (MLA),abducted and dorsi flexed mid foot are the characteristic feature of the flat foot.[8] The cause of pes planus depends on the direct effect between external and internal forces at the articular surfaces, supporting ligaments, joint capsules, extrinsic and intrinsic muscles .Fatigue, paralysis of the intrinsic muscles of the foot due to anaesthesia can also results in reduced height of the MLA[9].

There are few reports which indicate that, plantar fascia contributes in supporting the MLA along with flexor digitorum brevis and abductor hallucis muscles(ABH)[10,11]. There are reports that the paralysis of ABH lowers medial arch height because it is the active elevator of the MLA[12] . About 80% of the resistance for lowering of MLA is furnished by tension in the plantar fascia in the final stage of the swing [13] .Persons with pesplanus tend to develop plantar fasciitis and plantar fascia becomes thicker and rigid due to excessive load .In pesplanus, the altered nature of the plantar fascia is not well understood in the mid and forefoot area where it divides into digital slips, however there reports suggesting studies at its calcaneal attachment[14,15,16] . In the foot,after skeletal maturity if the medial longitudinal arch undergoes a complete or partial collapse then it is referred as flat foot according to foot and ankle specialists[17] .The prevalence of flat feet is not well established. Most of the studies on prevalence of flat foot were done on children below 10 year age.

Plantar fasciitis is the most common cause of the inferior heel pain and may affect up to 10% of running athletes It is associated with biomechanical factors such as pes cavus, foot pronation, heel valgus, sudden gain in body weight or obesity, increased running distance or intensity, shoes with poor cushioning, change in the walking or running surface, and tightness of the Achilles tendon.[18]

In one study, 83% of patients seen with plantar fasciitis were active, working adults ranging from twenty-five to sixty-four years of age^ Often referred to as painful heel syndrome or chronic plantar heel pain, this disorder is diagnosed on the basis of a history of pain on taking the first few steps in the morning,[19] worsening pain with weight-bearing, and pain and tenderness to palpation over the medial calcaneal tubercle'"\ Two large national datasets of ambulatory care data (excluding visits to podiatrists or federal, military, or Veterans Administration facilities) from the National Center for Health Statistics at the U.S. Centers for Disease Control and Prevention found that plantar fasciitis accounts for an average of one million patient visits per year to medical doctors'. Sixty-two percent of these visits were made to general medicine clinics, while 31% of patients were evaluated by orthopaedic or general surgeons.[20]

Study Design And Setting

Study Design: CROSS SECTIONAL STUDY
Population: Patients with plantar fasciitis
Sample Size: 100

Selection Criteria

Inclusion criteria:

- Age group between 20 to 40 years.
- Both genders– male and female.
- Subject willing to participate in study.
- Vendors with 6 to 8 hours of duty.

Exclusion criteria:

- Subject with any systemic illness and other musculoskeletal disorders specifically in lower limb like foot injuries, degenerative changes of hip and knee.

- Subject with any recent surgeries of lower limb.

MATERIALS REQUIRED

- Paper, Pen and Pencil
- Inch Tape
- Marker
- Step Stool

METHEDOLOGY

Subjects will be assessed on basis of following 2 tests and analysis will be done accordingly. First patients will diagnosed for plantar fasciitis with the help of windlass test and then they will be assessed for the flat foot with the help of Navicular drop test.

Windlass Test:

Maintaining the sitting position and then coming in standing position. In high sitting position, the ankle will be stabilized and the great toe will dorsi-flexed (no-weight bearing). In standing position, the subject will be asked to stand on toes of both the foot (weight bearing). In both the positions the subject will be asked if there is any unpleasant pain in the sole or heel of the foot. Both the plantar fascia passive stretching test and the windlass test (in non- weight bearing position) were supposed to be performed on the both the limbs (foot) simultaneously. If the subject will complain for any pain then the respective test will be marked positively and there will be no pain then the respective test will be marked negative.

Navicular drop test.

Purpose: To assess the height of navicular bone.
Test position: Standing
First mark the navicular tuberosity next measure the height of the navicular bone with the subtalar joint in neutral and the patient bearing most of the weight on the contralateral limb. Finally have the patient assume equal weight on both feet and re-measure the first and second measurement is the navicular drop. A difference of > 10mm is considered significant excessive foot pronation.

RESULTS

All statistical analysis was done using SPSS 25.0 software for windows. Descriptive analysis was used to obtain mean and standard deviations.

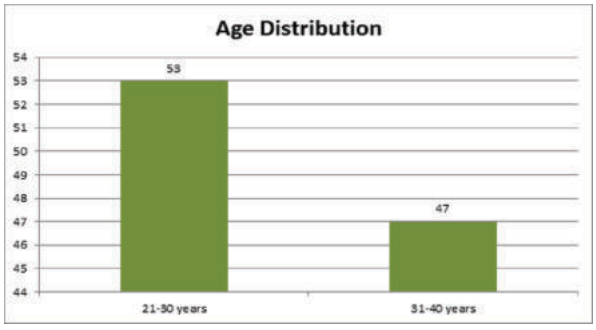
Demographic Data

AGE:

The research was performed on 100 participants between the age of 20-40. There were 53 patients between the ages of 20 to 30, 47 patients between the age 31to 40.

Table 1: Age Distribution

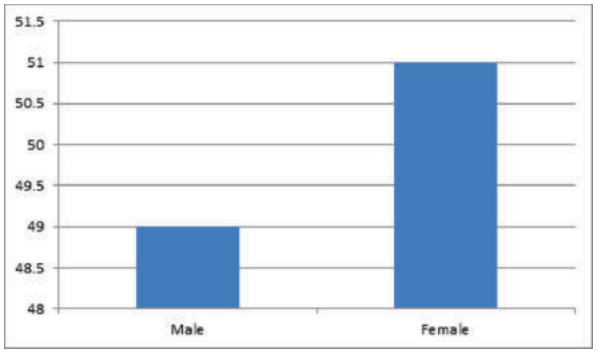
Age Distribution	
21-30 years	31-40 years
53	47



Graph 1: Age Distribution

Gender Distribution:

The research was performed on 100 participants between the age of 20-40. There were 49 Male participants and 51 female participants.



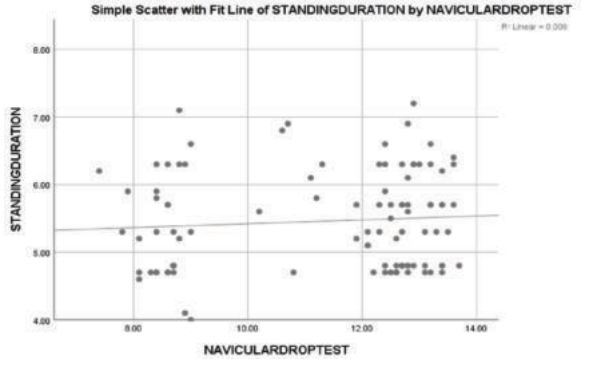
Graph 2: Gender Distribution

Table 2: Mean Value Of Fpi & Standing Duration

	Mean + SD
Age	27.8+4.6
Navicular drop test	12.3+5.2 mm
Standing Duration	5.8+ 0.8 hours

Table 3: Incidence Of Flatfoot Using Navicular Drop Test

Test Name	Positive	Negative
Windlass test	100	0
Navicular drop test	68	32



Graph 3 : Corelation Between Standing Duration And Flat Foot

Out of 100 participants 68 participants showed increase in pronation of foot according to navicular drop test mean distance were 12.3mm distance more then 9mm can be considered as reduction in arch so the prevalence of flat foot is 68% it also shows positive correlation between standing duration and flat foot.

DISCUSSION

Flatfoot is a biomechanical disorder frequently seen in clinical practice. one study reveals that the prevalence of flat foot was 26.62%.

Described finding is practically identical to a study conducted in Japan on a sample of 242 women and 98 men, in which a prevalence of 26.5% was observed, along with how said finding is related with obesity and the effects of pain and functionality . Similar findings regarding the prevalence of flat foot can be found in other publications. In other population studies (Springfield, Massachusetts) the prevalence of flat foot was 19.0% (20.1% in females and 17.2% in males) . Another study conducted in the Boston area found a prevalence of 20% in women 17% in men. There are even studies, conducted in a diabetic population on a sample of 230 patients, which refer to a prevalence as high as 37%

The present study was performed on 100 participants between the age of 20-40. There were 53 patients between the ages of 20 to 30, 47 patients between the age 31to 40. It was having mean Navicular drop test score of 12.3±5.2 mm and mean standing hours were 5.8±0.8 hours and they show positive correlation of standing hours with flat foot. Prevalence of flat foot among plantar fasciitis is 68%.

Previous studies of plantar fasciitis have found that up to 10% of the population is affected during their lifetime^ and over one million Americans per year' have this condition. The incidence rate of plantar fasciitis in our population was 10.5 per 1000 person-years, with a rate of 9.2 for men and 18.0 for women per 1000 person-years. Although we are aware of no known studies in the literature with incidence rates, prevalence rates of plantar fasciitis ranging between 4% and 22% have been reported among a population of runners.

Another study conducted in India reveals how the use of footwear at early ages, along with obesity and ligamentous laxity, increases the prevalence of flat foot

Another study conducted in Nigeria on 560 children aged between six and 12 years shows that although in the univariate analysis an association was found with type of footwear and age, after taking both into consideration, only age remained as a variable associated the presence of flat foot . Urban residence as a risk factor for the prevalence of flat foot has also been described in a study conducted on children in the Congo, where, after studying 1,851 footprints from 906 girls and 945 boys aged between three and 12 years, it was observed that prevalence diminishes with age, is higher in urban areas and in the masculine sex, and that the use of footwear has little influence on said prevalence . This study shows how the BMI, comorbidity and foot size are associated with the prevalence of flat foot. There are variability in the literature review. A number of studies describe how this foot disorder increases with age , other studies describe how flat foot diminishes with age, after adjusting for other covariates , and others indicate that neither age, gender nor BMI are related with flat foot.

Also in another study, the prevalence of flat foot was assessed where in it was found that real prevalence of symptomatic flatfoot is not very high in adolescents due to its nature of spontaneous correction as age increasesAlso in another study, the prevalence of flat foot was assessed where in it was found that real prevalence of symptomatic flatfoot is not very high in adolescents due to its nature of spontaneous correction as age increases [18,19]. According to age, the subjects between age 20-29 years were suffering 31.8% of flat foot, 30-39 years were having 42% flat foot, 40-49 years were having 16.7% flat foot, above 50 years were having 37.5% flat foot. similarly subjects between age 20-29 years were suffering 47.7% of high arched foot, 30-39 years were having 50% high arched foot, 40-49 years were having 61.1% high arched foot, above 50 years were having 50 % high arched foot.

According to gender it was found that high arched foot had higher incidences in males (55.2%) whereas flat feet were found to have higher incidences in females (38.7%).

A number of studies also describe different radiological findings in the morphology of the foot according to different ethnic groups. Others indicate how the different radiological morphology (angle of the talus with the first metatarsal) is related with the symptomatic presence or absence of flat foot. Even though obesity has repeatedly been associated with the presence of flat foot , not all studies point towards this association . In some articles, not only is the association of flat foot with characteristics (e.g., age, sex, BMI and concomitant illness) indicated, but also as a modifier of health . Thus, there are studies of 97,279 military recruits which associate flat foot with localised knee pain . As we have previously mentioned, in the article which finds a prevalence of flat foot identical that in our study it can also be seen how said alteration is also associated with the presence of pain and fatigue in women.

CONCLUSION

This study, conducted among adults of Gujarat state, revealed that youth those are having plantar fasciitis prone to developing flat foot, which aligns with published Western literature. This study shows that there is 68 % of prevalence of flat foot in adults who had plantar fasciitis. this study also suggest standing duration was positively correlated with pronation of foot in persons with plantar fasciitis.

ABSTRACT

Background: Tendinopathy is a failed healing response of the tendon, with haphazard proliferation of tenocytes, intracellular abnormalities in tenocytes, disruption of collagen fibres, and a subsequent increase in non-collagenous matrix. There is always remains controversy regarding effectiveness of different treatment techniques for tendinopathy and aim of present study is to find and justify better treatment modality for management of tendinopathy. **Purpose:** To study the evidences regarding effect of Shock wave therapy versus Ultrasound therapy in tendinopathies. **Methodology:** This Evidence based study was conducted from June 2017 to June 2022. Search engines used to find appropriate articles were: PubMed, Google Scholar, PEDro, ResearchGate, ScienceDirect and Embase. Key words used were: Ultrasound, Shock wave Therapy and Tendinopathy. Articles were assessed via 2 scales: Centre for Evidence-Based Medicine's (CEBM's) Levels of Evidence and PEDro scale. **Results:** Total 156 articles were found, out of which 12 articles were relevant and from those 6 articles were included in this evidence-based study. From 6 studies, 1 Meta-analysis (Level of evidence 1a), 2 Randomized controlled trails (Level of evidence 1b) and 3 Comparative studies (Level of evidence 2b). **Conclusion:** There are moderate to strong evidences suggests the Shock wave therapy has more effect on Achilles, Gluteal, Rotator cuff and Lateral Elbow tendinopathies when compared to ultrasound.

KEYWORDS

Ultrasound, Shock wave Therapy and Tendinopathy

INTRODUCTION

Tendinopathy is a degenerative tendon disorder associated with chronic pain, swelling, and impaired physical function. Tendons are susceptible to injury as they undergo high forces during loading activities, receive little vascular blood supply, have low elasticity and decreased metabolism. Tendinopathy is thought to be caused by repetitive tendon microtrauma and subsequent failed healing responses, characterized by neovascularization, incidence of calcium deposits or calcification and increased tendon thickness or swelling.[1]

Histologically, tendinopathy is characterized by the absence of inflammatory cells, poor healing, non-inflammatory intratendinous collagen degeneration, collagen fiber disorientation and thinning, hypercellularity with high concentrations of glycosaminoglycans and proteoglycans, and neovascularization. [2][3]Although inflammatory cells are typically present in tendinopathy, tendon cell degeneration rather than inflammation is considered the pathological hallmark of the disorder, leading to the adoption of the term tendinopathy rather than the previously used diagnosis of tendinitis.

A variety of therapeutic techniques have been proposed for the appropriate management of patients with tendinopathy including exercise, orthotics, manual therapy, passive modalities, acupuncture or a combination of them. However, the effectiveness of each treatment option remains debatable.

Extracorporeal shockwave therapy is a popular method in the management of common tendinopathies and has been proposed as an effective supplement to other noninvasive therapies. The ultrasound is a commonly used modality for tendinosis. It Improves microcirculation, migration and synthesis of collagen fibers to the tendon [4]. There is growing evidence from in vitro and animal-based models that low intensity pulsed ultrasound (LIPUS) may also have beneficial effects on non-mineralized tissues, such as ligaments and tendons. For instance, using these models low intensity pulsed ultrasound (LIPUS) has been found to accelerate knee medial collateral ligament healing [5][6][7], augment tendon repair [8] and modulate tendon cell activity. Alexander et al showed that higher doses of ultrasound energy improved pain in individuals with shoulder calcific tendinitis. In contrast, Warden et al. found that lower doses of ultrasound was no better than placebo for the treatment of individuals with patellar tendinopathy.

So, there is always remains controversy regarding effectiveness of different treatment techniques for tendinopathy and aim of present study is to find and justify better treatment modality for management of tendinopathy.

METHODOLOGY

Study Design: This is an Evidence Based Study, which was conducted according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analysis) guidelines. (Figure 1).

Literature Search:

A specified literature search was performed from June 2017 to June 2022 (Last 5 years). Literature was searched using following search engines: Google Scholar, PEDro, PubMed, ResearchGate, ScienceDirect, Embase

Key Words Used For The Search Were:

Ultrasound, Shock wave Therapy and Tendinopathy

METHOD OF SELECTION OF ARTICLES:

Inclusion Criteria:

(1) Studies involving any type of Tendinopathy from June 2017 to June 2022 (Last 5 years), (2) Studies which compared Ultrasound or Shockwave Therapy in any type of Tendinopathy, (3) Articles on tendinopathy having study design of Systematic reviews, Meta-analysis and RCTs, (4) Articles published in English, (5) Studies done on Human participants.

Exclusion Criteria:

(1) Articles on tendinopathy having study design of Case Control and Cohort (2) Studies done on animals.

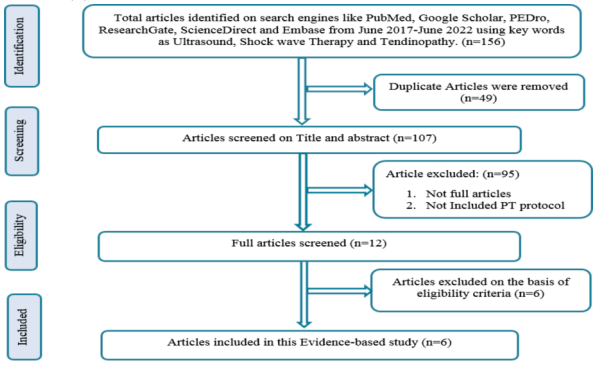

Figure 1: Preferred Reporting Items for systematic reviews and Meta-analysis (PRISMA)

Table 1: Characteristics of Included Studies

SR NO.	TITLE	Study design & Duration	Articles Or Sample Size	Outcome Measures	Pedro And Level Of Evidence
1	Analgesic Effect of Extracorporeal Shock-Wave Therapy in Individuals with Lateral Epicondylitis: A Randomized Controlled Trial [9]	A Randomized Controlled Trial (5 sessions)	40	VAS, Taiwan Version of DASH and Dynamometer	8/10 1b
2	Achilles tendinopathy: Comparison between shockwave and ultrasound therapy [10]	A comparative study (4 weeks)	130	The University of Peloponnese Pain, Functionality and Quality of life Questionnaire - the UoP-PFQ'	4/10 2b
3	Comparison of Radial Extracorporeal Shock Wave Therapy and Traditional Physiotherapy in Rotator Cuff Calcific Tendinitis Treatment [11]	A comparative study (4 weeks)	80	Age, height, Weight, BMI, VAS, Goniometer (Internal and external rotation ROM) and QuickDASH	4/10 2b
4	Comparison of Radial Extracorporeal Shockwave Therapy versus Ultrasound Therapy in the Treatment of Rotator Cuff Tendinopathy [12]	A comparative study (4 weeks)	115	The University of Peloponnese Pain, Functionality and Quality of life Questionnaire - the UoP-PFQ'	4/10 2b
5	Focused extracorporeal shock wave therapy for greater trochanteric pain syndrome with gluteal tendinopathy: a randomized controlled trial [13]	A randomized controlled trial (3 weeks)	50	NPRS, LEFS	7/10 1b
6	A comparative study of the efficacy of ultrasonics and extracorporeal shock wave in the treatment of tennis elbow: a meta-analysis of randomized controlled trials [14]	A meta-analysis	5 articles involving 117 participants	-	- 1a

Assessment of Methodological Quality:
Data was assessed using 2 parameters: (1) Centre for Evidence-Based Medicine's (CEBM's) Levels of Evidence and (2) PEDro scale (Appendix 1 & 2)

RESULTS

Evidences were reviewed and analysis was done on the basis of PEDro score and CEBM's Level of Evidence Scale. Risk of bias is also assessed.

Total 156 articles were found, out of which 12 articles were relevant and from those 6 articles were included in this evidence-based study and other articles were excluded as per Inclusion and Exclusion criteria.

From total 6 studies, there is 1 meta-analysis on efficacy of ultrasonics and extracorporeal shock wave in the treatment of tennis elbow and their result shown that Extracorporeal shock wave Therapy is a superior adjuvant therapy for tennis elbow compared to Ultrasound. Its level of evidence was 1a. 5 out of 6 studies (2 Randomized controlled trials and 3 Comparative studies) were shown that Shock wave (Either Extracorporeal or Radial) was effective treatment for reducing pain and improving disability in subjects with Achilles, Lateral elbow, Gluteal, Rotator cuff tendinopathies when compared to Ultrasound. Their Level of evidence was 1b and 2b.

DISCUSSION

Total 6 studies (1 Meta-analysis, 2 Randomized controlled trials and 3 comparative study) were included in this evidence-based study. The methodological qualities of included studies were moderate to high. The sample size varied from 40-117 subjects.

There are 1 strong evidence (Meta-analysis) which suggest that shock wave therapy is an effective treatment for reducing pain and disability in patients with Lateral elbow tendinopathy when compared to Ultrasound.

There are 2 moderates to high quality of evidences (2 Randomized Controlled Trials) which suggest that shock wave therapy alone or can be adjunct to other conventional treatment provide significant benefits in reducing pain and dysfunctions in patients with Lateral elbow and Gluteal tendinopathies. Total study duration varied from 3 to 5 weeks.

Furthermore, there are 3 low to moderate quality of evidences (3 Comparative Studies) having small to large sample size which compares Ultrasound with Shockwave therapy and their results confirms that Shock wave therapy effectively reduces pain and promotes healing in Rotator cuff and Achillies Tendinopathy. Total Study duration was 4 weeks.

Haupt proposed four possible phase mechanisms of ESWT effects on tissue: physical, physicochemical, chemical and biological. In the physical phase, shockwave pressures cause absorption, refection, refraction and transmission of energy into cells. These tensile forces induce cavitation, increasing cell membrane permeability and activating cell signaling pathways. These include mechano-transduction pathways and those that regulate a variety of gene expressions. In the physicochemical phase, cells release molecules such as adenosine triphosphate (ATP), activating cell signaling pathways. In the chemical phase, ion channels in cell membranes are altered allowing cell calcium mobilization. The biological phase plays host to a plethora of identified biological responses due to tissue and cell stimulation.

Tissue-healing responses are mediated by release of vascular endothelial growth factor (VEGF), endothelial progenitor cells, endothelial nitric oxide synthase (eNOS), insulin-like growth factor (IGF1) proliferating cell nuclear antigen (PCNA) and various other functional proteins.

Cellular modulation is activated by upregulation and downregulation of proteins which promotes processes such as neovascularization, anti-inflammation, anti-apoptosis, chondroprotective effects angiogenesis and regeneration of bone and tendon tissue. [15]

It should be noted that there were no any adverse effects reported from Shockwave Therapy from included articles.

CONCLUSION

From this Evidence based study, it can be concluded that there are moderate to strong evidences suggests the Shock wave therapy has more effect on Achilles, Gluteal, Rotator cuff and Lateral Elbow tendinopathies when compared to ultrasound.

Conflict Of Interest : There is no conflict of interest.

Ethical Approval
Ethical approval was not required.

Appendix 1- CEBM's Level of Evidence
It assesses quality based on study design, which categorize the studies

in a scale ranging from 1 to 5 with further subdivision for 5each.

Level	Definition
1a	Systematic reviews of randomized controlled trials
1b	Individual randomized controlled trials
1c	All-or-none studies
2b	Systematic reviews of cohort studies
2b	Individual cohort studies or low-quality randomized controlled trials
2c	Outcome research
3a	Systematic reviews of case-control studies
3b	Individual case-control studies
4	Case series, poorly designed cohort or case-control studies
5	Animal and bench research, expert opinion

Appendix 2-PEDro Scale

It assesses methodological quality and consists of a checklist of 11 criteria, 10 of which are scored. For each criterion the study met, 1 point was awarded. The points were tallied and presented as a score out of 10. The scale applies only to experimental studies. For this review, investigations with PEDro scores of 6 to 10 were considered high quality, of 4 to 5 were considered moderate quality, and of 0 to 3 were considered low quality.

No.	Description	Yes/No
1	Eligibility criteria were specified (No points awarded)	
2	Subjects were randomly allocated to groups	
3	Allocation was concealed	
4	The groups were similar at baseline regarding the most important prognostic indicators	
5	There was blinding of all subjects	
6	There was blinding of all therapists who administered the therapy	
7	There was blinding of all assessors who measured at least one key outcome	
8	Measure of at least one key outcome were obtained from more than 85% of the subjects initially allocated to groups	
9	All subjects for whom outcome measures were available received the treatment or control condition as allocated	
10	The result of between group comparisons are reported for at least one key outcome	
11	The study provides both point measures and measures of variability for at least one key outcome

ABSTRACT

Background: The Knee injury and Osteoarthritis Outcome Score (KOOS) was originally developed in 1995 by Ewa M Roos and colleagues at the Departments of Orthopedics at Lund University in USA. Thus, the American-English and Swedish versions were developed simultaneously. Also, it has already been translated into many languages such as Hindi, Turkish, Indonesian, Spanish and Swedish. Translation of this scale into Gujarati can be more beneficial for Gujarati physiotherapist to find out better outcome. **Methodology:** The study was carried out on people aged 15 to 50 years in North Gujarat, India, those peoples who have knee pain.116 patients who fulfilled inclusion criteria were selected. Initially scale was translated to Gujarati by forward backward translation and patients were instructed to fill the scale at 1 week interval. Reliability and validity were found out. **Result:** The results of the study showed moderate to high correlation in components of The Knee Injury and Osteoarthritis Outcome Score (KOOS) Gujarati version (ICC= .851,0.835,0.814,0.891 and .977) (P<0.05) and internal consistency (cronbach's alpha = 0.868, 0.834, 0.814, 0.907 and 0.905). The Knee Injury and Osteoarthritis Outcome Score (KOOS) Gujarati version was content validated for idiomatic equivalence, semantic equivalence, content relevance. Face validity were established 100% as all participants answered the scale. For construct validity pearson correlation was done with lower extremity function scale and the pearson correlation value for all five component were -0.143 to 0.185. Correlation is significant at the 0.05 level. **Conclusion:** Gujarati version of the KOOS being a valid, reliable and responsive outcome measure in young patients having knee pain.

KEYWORDS

Knee Injuries and Osteoarthritis Outcome Score (KOOS), Reliability, Validity

INTRODUCTION

The knee is the largest joint in the body and it is a compound synovial joint. [1] The knee consists of two main joints: the femorotibial joint and the patellofemoral joint, which allow the knee to move in three different planes (sagittal, transverse, and frontal).

Patient-reported outcomes are an important element to evaluate the quality and the results of clinical practice as they directly and without any interpretation report a patient's health status.[2] Patients with ACL or meniscus injury have a higher than average risk of developing osteoarthritis, and about 50% have radiological signs of osteoarthritis 10-15 years after injury.

For the elderly population with knee osteoarthritis, well validated outcome measures exist-WOMAC-Western Ontario and McMaster Universities Arthritis Index. However, no outcome measure has been validated for use in younger or physically more active subjects with knee osteoarthritis. It may not be appropriate to use outcome measures assessing function as activities of daily living alone in younger and more active subjects with post traumatic osteoarthritis.

The Knee injury and Osteoarthritis Outcome Score (KOOS) was originally developed in 1995 by Ewa M Roos and colleagues at the Departments of Orthopedics at Lund University, Sweden and at the University of Vermont, USA.

Thus, the American-English and Swedish versions were developed simultaneously. It includes 42 items in 5 separately scored subscales; Pain, other Symptoms, Function in daily living (ADL), Function in Sport and Recreation (Sport/ Recreation), and knee-related Quality of Life (QOL).

The main reason for developing a single instrument with the purpose of covering several types of knee injury and including osteoarthritis (OA), was that traumatic knee injuries often causes concomitant damage to multiple structures (ligaments, menisci, cartilage, etc.) and frequently lead to the later development of OA.

The KOOS evaluates both short-term and long-term consequences of knee injury and include assessing pain; symptoms, such as swelling and restricted range of motion; activities of daily living; sport and recreation function; and knee-related quality of life in young and middle-aged subjects with ACL injury, meniscus injury, or posttraumatic osteoarthritis. The KOOS is self- administered and takes approximately 10 minutes to fill out as well as it is a feasible instrument.[3]

The Knee Injury and Osteoarthritis Outcome Score (KOOS) is one of the most commonly used scales that has been used by physical therapists worldwide. Also, it has already been translated into many languages such as Hindi, Turkish, Indonesian, Spanish and Swedish. Translation of this scale into Gujarati can be more beneficial for Gujarati physiotherapist to find out better outcome. So, there is a need to conduct this study.

METHODOLOGY

Study Design: A cross-sectional Study

Study Population: The study was carried out on people with knee pain in past 10 years from age group 15-50 Years in North Gujarat, India

Study Setting: Native Gujarati patients with knee pain in north Gujarat.

Sample size: 116

Sample Technique: Convenient sampling.

Inclusion criteria:

- Patients willing to participate.
- Both Male and Female
- Age: Between 15-50 years in north Gujarat
- Patient having knee pain with OA, RA and Meniscus injury and Ligament injury in past 10 years.
- Native Gujarati language and can able to read and write Gujarati.

Exclusion criteria:

- Patients having neurological disorders.
- Patient having musculoskeletal disorders other than OA, RA and Meniscus injury.
- Patients having visual problem that cannot be corrected by lenses.
- Non cooperative patients.

Figure 1: Flow Chart of the study Procedure

The Knee injury and osteoarthritis outcome score (KOOS) had been cross-culturally adapted into Gujarati version of Knee injury and osteoarthritis outcome score (KOOS) in following steps:

Step 1: Forward translation:
Two translators (one with the background of medical field and other with no background of medical field) who knew both English and Gujarati language were chosen to translate the questionnaire from English to Gujarati language.

Step 2: Synthesis:
Both the Gujarati versions were combined and two professionals who had knowledge of medical terminologies and were known to both the languages (English & Gujarati) developed a synthesized version.

Step 3: Back-translation:
The synthesized version of the questionnaire was back translated into English language by an independent translator, who knew both English and Gujarati language and had no information of the original questionnaire which was in English language.

Step 4: Expert panel:
A bilingual (in English and the Gujarati language) expert panel was convened which included the forward translator, health experts, as well as professionals with skill in questionnaire development and translation. The changes were done in the translated questionnaire based on the suggestions of the expert panel.

Step 5: Testing of the questionnaire:
A Pre Final Gujarati version of KOOS was given to participants who fulfilled the inclusion and exclusion criteria to find out the reliability and validity of the questionnaire.

Reliability Testing
Test-retest reliability:
The recruited patients with knee pain were asked to fill Gujarati version of Knee injury and osteoarthritis outcome score (KOOS) by themselves twice with minimum gap of one week duration. So that person may not copy the same data as well as he/she will not forgot. The readings were recorded to report test-retest reliability.

Internal consistency:
Internal consistency was measured with Cronbach's alpha (α), a statistic which was calculated from the pair wise correlations measured between paired readings of Gujarati version of Knee injury and osteoarthritis outcome score (KOOS).

Validity Testing
Construct Validity:
Convergent and divergent construct validity was determined by comparison of the administrations of the five subscales of the KOOS and the Lower extremity functional scale. It is expected the highest correlations when comparing the scales that are supposed to measure the same or similar constructs.

Content Validity:
Content equivalence was assessed under two headings: 1. Are the words in the translated Gujarati version of KOOS presented fluently and correctly as in the original version? 2. Do the words and phrase in the translated Gujarati version of KOOS have the same semantic meaning compared with the original version? For this answers from expert panel member's fall between "mostly agree" to "strong agree". This was assessed by an expert panel and they assessed the KOOS-G for content equivalence and content relevance on 5 point likert scale. Content relevance was evaluated by expert judges or panels: How the Gujarati version of KOOS statement is relevant to assess function in knee pain subjects? For this answers from expert panel members' fall between "mostly agree" to "strong agree".

Face Validity:
Face Validity was assessed by asking one question to each of the, 'Do you think this scale is relevant to your condition.' The answer was noted as 'yes' or 'no'. Face validity of the KOOS was established when all the patients questioned about the relevance of the scale to their condition.

RESULTS

All statistical analysis was done using SPSS 25.0 software for windows. Descriptive analysis was used to obtain mean and standard deviations. Reliability testing was done using **reliability analysis**. Inter class correlation coefficient, ICC (2,1) and cronbach's α were measured. Validity testing was done using **Pearson's correlation.** Confidence interval were set at 95%, p = 0.05 for all the analysis.

Age distribution:
The research was performed on 116 patients with knee pain between the age of 15-50. There were 46 patients between the ages of 15 to 30 and 70 patients between the age 31 to 50.

Gender distribution:
The research was performed on 116 patients with Knee pain. In which 55 are Females and 61 are Males.

Test-Retest Reliability:
Test-retest reliability (n=116) was tested by using the interclass correlation coefficient, ICC(2,1) and Internal consistency (n=116) was reported in terms of cronbach's α measured in two session after 1 week is reported.

Table 1: Test- Retest Reliability of Gujarati Version Knee Injury and Osteoarthritis Outcome Score (KOOS)

Knee injury and osteoarthritis outcome score (KOOS)	Session 1 (Mean)	session 2 (Mean)	Cronbach's alpha	ICC	P-value
Pain	19.34	17.22	.868	.851	0.01
Symptoms	14.67	14.29	.834	.835	0.01
Activities of daily living	34.88	36.47	.814	.814	0.04

In convergent validity there was a positive correlation of QOL with LEFS. There was a positive correlation between LEFS and ADL (r=0.185).

Content Validity:

The content validity of Gujarati translated knee injury and osteoarthritis outcome score (KOOS) by a 6 experts were found to be, I-CVI of individual items knee injury and osteoarthritis outcome score (KOOS) of ≥ 0.89 and overall S-CVI for idiomatic equivalence, semantic equivalence and content relevance ≥ 0.90. For content validity equivalence all 6 experts answers were located between mostly agree and strongly agree of Gujarati version of knee injury and osteoarthritis outcome score (KOOS).

Table 7: Content Validity of Gujarati Version Knee Injury and Osteoarthritis Outcome Score (KOOS)

Scale Component	I-CVI	S-CVI
Pain	0.89	0.918
Symptoms	0.94	
ADL	0.92	
Sports	0.92	
QOL	0.90	

DISCUSSION

This is a cross-sectional study of translation and measurement of psychometric properties of Gujarati version of Knee Injury and Osteoarthritis Outcome Score (KOOS) on patient with Knee pain.

In this study 116 patients participated. Gujarati version of The Knee Injury and Osteoarthritis Outcome Score (KOOS) was given twice with 1- week interval to measure the test- retest reliability and to validity. The results of the study showed moderate to high correlation in components of The Knee Injury and Osteoarthritis Outcome Score (KOOS) Gujarati version (ICC= .851,0.835,0.814,0.891 and .977) (P<0.05) and internal consistency (cronbach's alpha = 0.868, 0.834, 0.814, 0.907 and 0.905).

Both the internal consistency and the test-retest reliability results confirmed the reliability of the Gujarati version of the KOOS. We found that all the KOOS subscales on the Gujarati version have adequate internal consistency, with all Cronbach α values >0.70 (range, 0.86-0.90). These values are comparable to those for the Finnish version (Cronbach α range, 0.79-0.96) and the Malaysian version (Cronbach α range, 0.78-0.95). Our test-retest reliability analysis showed that the Gujarati version of the KOOS has excellent reliability, with all ICC values >0.90 (range, 0.91-0.99). Our results are similar to those for the Italian version (ICC range 0.85-0.95)

For content validity equivalence all 6 experts answer were located

between mostly agree and strongly agree of The Knee Injury and Osteoarthritis Outcome Score (KOOS) Gujarati version for idiomatic equivalence (average=0.89) semantic equivalence (average = 0.92) and content relevance (average= 0.93). Thus, The Knee Injury and Osteoarthritis Outcome Score (KOOS) Gujarati version was content validated for idiomatic equivalence, semantic equivalence, content relevance. Face validity were established 100% as all participants answered the scale.

For construct validity pearson correlation was done with lower extremity function scale and the pearson correlation value for all five component were -0.143 to 0.185. Correlation is significant at the 0.05 level.

In previous studies, interrater reliability and intrarater reliability of the The Knee Injury and Osteoarthritis Outcome Score (KOOS) of Turkish version were (ICC & cronbach's alpha = (0.839 and 0.904) respectively.[4]

In Indonesian version for the construct validity, moderate Pearson correlation coefficients were found between the KOOS subscales and the SF36. Cronbach α was 0.84 to 0.97 for all subscales, indicating adequate internal consistency. The test-retest reliability was excellent, with intraclass correlation coefficients ranging from 0.91 to 0.99 for all subscales.[5]

Swedish version of the scale was applied on the participants at 2 week intervals. Test-retest reliability. For the five subscales of the KOOS, the random effects intra class correlation coefficients (ICC) were: Pain 0.86, Symptoms 0.84, Activities of Daily Living (ADL) 0.91, Sport and Recreation Function 0.78, and for Knee-related Quality of Life (QOL) 0.83. Internal consistency, as measured by Cronbach's alpha, was for the subscale Pain 0.84, Symptoms 0.74, ADL 0.95, Sport/Rec 0.85, and for QOL 0.71 [6]

It was found The Knee Injury and Osteoarthritis Outcome Score (KOOS) Gujarati version items equivalent to those in original version which is intended by translators involve in this study. The results showed that it was translated this scale into other languages without losing psychometric properties of the original English version.

CONCLUSION

The present study demonstrated the Gujarati version of the KOOS being a valid, reliable and responsive outcome measure in patients having knee pain. The Gujarati KOOS can be applied as a patient-reported and disease specific instrument in future studies including Knee pain subjects in Gujarat.

ABSTRACT

Background: Neck pain is becoming increasingly common throughout the world. It has a considerable impact on individuals and their families, communities, health-care systems, and businesses. There is substantial heterogeneity between neck pain epidemiological studies, which makes it difficult to compare from different studies. The prevalence of neck pain in the general population ranges between 0.4% and 86.8% (mean: 23.1%); point prevalence ranges from 0.4% to 41.5% (mean: 14.4%); and 1 year prevalence ranges from 4.8% to 79.5% (mean: 25.8%). Northwick Park Neck Pain Questionnaire is one of the most commonly used scales that has been used by physical therapists worldwide. Also, it has already been translated into many languages such as Turkish, Indonesian, Spanish and Swedish. We would like to translate this scale into Gujarati language. Because it is more beneficial for the patient to understand the Gujarati scale and it is also helpful for the Gujarati physiotherapist. **Methodology:** The study was carried out on people aged more then 18 years in Gujarat, India. Those peoples who have knee injury.100 patients who fulfilled inclusion criteria were selected. Initially scale was translated to Gujarati by forward backward translation and patients were instructed to fill the scale at 1 week interval. **Result:** 100 patients participated. Gujarati version of The Northwick Park Neck Pain Questionnaire was given twice with 1- week interval to measure the test- retest reliability and validity. The results of the study showed moderate to high correlation in components of The Northwick Park Neck Pain Questionnaire Gujarati version (ICC =0.882) ($P<0.05$) and internal consistency (Cronbach's alpha =0.88). **Conclusions:** The Gujarati version of The Northwick Park Neck Pain Questionnaire was cross-culturally adapted and validated for use among the Gujarati- speaking populations. The translated version has acceptable reliability and internal consistency.

INTRODUCTION

Neck pain is becoming increasingly common throughout the world. It has a considerable impact on individuals and their families, communities, health-care systems, and businesses. There is substantial heterogeneity between neck pain epidemiological studies, which makes it difficult to compare or pool data from different studies.[1] The estimated 1 year incidence of neck pain from available studies ranges between 10.4% and 21.3% with a higher incidence noted in office and computer workers. While some studies report that between 33% and 65% of people have recovered from an episode of neck pain at 1 year, most cases run an episodic course over a person's lifetime and, thus, relapses are common.[2]

The overall prevalence of neck pain in the general population ranges between 0.4% and 86.8% (mean: 23.1%); point prevalence ranges from 0.4% to 41.5% (mean: 14.4%); and 1 year prevalence ranges from 4.8% to 79.5% (mean: 25.8%). Prevalence is generally higher in women, higher in high-income countries compared with low- and middle-income countries and higher in urban areas compared with rural areas. Many environmental and personal factors influence the onset and course of neck pain. Most studies indicate a higher incidence of neck pain among women and an increased risk of developing neck pain until the 35–49 year age group, after which the risk begins to decline.[3]

Pain scales usually are used in the assessment of patients with neck pain. However, the presence and severity of pain represent only a small part of the health outcome. Rainville et al suggested that pain scales correlate poorly with measures of physical function.[4] There is increasing recognition that patient perspectives are essential both in making medical decisions and in judging treatment outcomes. Questionnaires designed for completion by the patient are used increasingly as a convenient and reproducible measuring tool for assessing patients with musculoskeletal problems, especially those with low back pain. Among various disability indexes for low back pain, the Oswestry Index probably is the best index covering several distinct activities of daily living. However, only a few methods exist to assess the disability of patients with neck pain. Vernon and Mior modified the Oswestry Low Back Pain Index and produced a 10-item scaled questionnaire, namely the Neck Disability Index (NDI).[4] Offered as a self-reporting instrument for assessing activities of daily living for patients with neck pain, it was validated and found reliable. However, the sample size in some of the analyses was small, with only 10 patients in the concurrent validity study. Most of the patients (70%) had experienced “whiplash” injury. Leak et al again modified the Oswestry questionnaire and developed the self-administered Northwick Park Neck Pain Questionnaire (NPQ).[5] These authors converted some of the questions (walking, standing, and sex life items in the Oswestry questionnaire to cover many activities (carrying, reading/television, and work) likely to be affected by neck pain. The NPQ consists of nine five- part questions that assess the patient's symptoms, from which a score is obtained. Patients need to answer all the questions except the ninth one, which is an option for patients who drive. Each question is scored from 0 to 4. The responses to the questions are summed and converted to a score percentage, which ranges from 0% to 100%, with 0% representing the least disabled and100% the most severely disabled. In addition to questions 1 through 9, all follow-up questionnaires contained a 10th question asking patients how their pain compared with that reported the last time. The questionnaire was found to be valid, easy for patients to complete, and simple to score. It provides a reliable outcome measure for patients with acute or chronic neck pain.[6]

The Northwick Park Neck Pain Questionnaire is one of the most common scale that has been used by the physiotherapist all over the world. Also, it is already translated in many other languages like Turkish, Korean, Spanish, Indonesian etc. We want to translate this scale in our mother language i.e. Gujarati, because it will be more beneficial for patients to understand the scale in Gujarati and it will be helpful to physiotherapists also who are from Gujarat.

METHODOLOGY

Ethical Approval: Ethical approval for the study was taken from the institutional ethical committee
Study Design : Reliability and validity study.
Study Setting: Various committee of Gandhinagar city
Sampling Technique: Purposive Sampling
Population: Native Gujarati Patients with neck pain in North Gujarat.
Duration Of Study: 1 Year
Study Size : . N=100

Inclusion Criteria

- AGE : More than 18 years of age
- Patient diagnosed with neck pain

- Subjects willing to participate.

Exclusion Criteria

- Patients having neurological disorders
- Patient not able to read and write Guajarati
- Uncooperative patients

The Northwick Park Neck Pain Questionnaire was cross-culturally adapted into a Gujarati version in the following steps:

First stage, the English version of The Northwick Park Neck Pain Questionnaire was translated into Gujarati version through standardized procedure recommended by Beaton et al. with some modification. We translated and culturally adapted The Northwick Park Neck Pain Questionnaire according to Indian living standards to adapt/fit and use in Indian Gujarati speaking neck pain population for the evaluation of self-rated neck functional status., stage I was done by the first author with the help of online translation portal.

We skipped stages II and III recommended by Beaton et al. In stage IV, 08 experts (02 orthopaedicians, 02 rheumatologists, 02 English professors, and 02 Gujarati professors) were volunteered for the review of questionnaire developed in stage I. Overall, Gujarati professors simplified the language, whereas medical experts helped with the medical terminology used in the questionnaire.

In stage V, questionnaire developed at the end of stage IV was administered to 20 Gujarati speaking neck pain patients. All patients understood the questions and responded correctly; hence there was no modification of questionnaire at this stage.

Validation study: Experts and translators obtained face validity and content validity.

I. Test-retest reliability: The recruited patients with neck pain were asked to complete the Gujarati version of The Northwick Park Neck Pain Questionnaire twice with a one-week gap in between. As a result, that person will not copy the same data and will not forget. The readings were recorded in order to determine test-retest reliability.
II. Internal consistency: Cronbach's alpha (α), a statistic calculated from pair wise correlations measured between paired readings of the Gujarati version of The Northwick Park Neck Pain Questionnaire, was used to assess internal consistency.

After checking reliability and validity of this questionnaire, we have taken 100 individuals with neck pain.

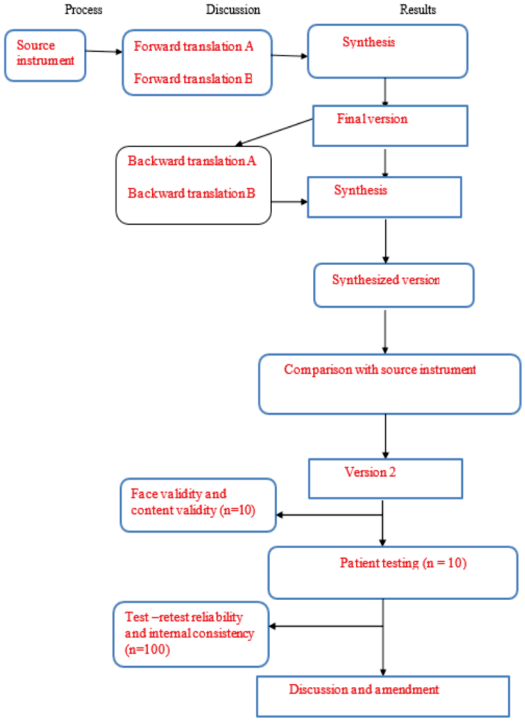

Chart:- Cross Cultural Adaption

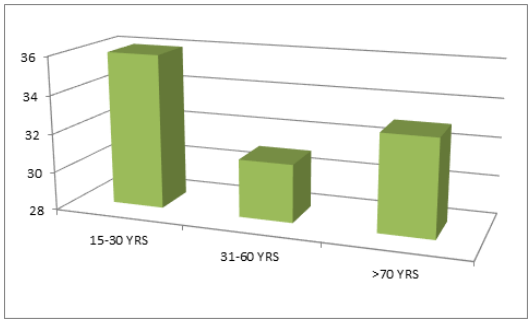
RESULT

All statistical analysis was done using SPSS 25.0 software for windows. Descriptive analysis was used to obtain mean and standard deviations. Reliability testing was done using reliability analysis. Inter class correlation coefficient, ICC(2,1) and Cronbach's α were measured. Confidence interval were set at 95%, p = 0.05 for all the analysis.

1. Age Distribution

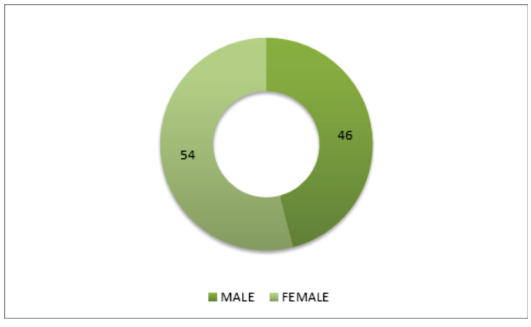
The research was performed on 100 patients with neck pain between the age of more then 18 years. There were 36 patients between the ages of 18 to 30, 31 patients between the age 31to 60, and 33 patients between the age of >70 years.



Graph : Age Distribution

2. Gender Distribution

The research was performed on 100 patient with neck pain . In which 54 are females and 46 are males.



Graph 7.2 : Gender Distribution

The content validity of Gujarati translated The Northwick Park Neck Pain Questionnaire by a 8 experts were found to be, I-CVI of individual items The Northwick Park Neck Pain Questionnaire of ≥ 0.93 and overall S-CVI for idiomatic equivalence, semantic equivalence and content relevance ≥ 0.90. For content validity equivalence all 6 experts answers were located between mostly agree and strongly agree of Gujarati version of The Northwick Park Neck Pain Questionnaire for idiomatic equivalence (average= 0.89) semantic equivalence(average = 0.91) and content relevance (average= 0.92). Test-retest reliability (n=100) was tested by using the interclass correlation coefficient, ICC (2,1) and Internal consistency (n=100) was reported in terms of Cronbach's α measured in two session after 1 week

Table 7.1:- Test- Retest Of Gujarati Version The Northwick Park Neck Pain Questionnaire

The Northwick Park Neck Pain Questionnaire	Week 1 (Mean)	Week 2 (Mean)	Cronbach's alpha	ICC	P- value
	17.5	18.73	0.88	0.882	0.01

DISCUSSION

Non-specific neck pain is very common in rheumatology patients. Of the working population, 30% aged 25-29 years and 50% over 45 years report one or more attacks of painful neck, which is the primary motive for patient presentations. In our study first report of the reliability and validity of Gujarati version of The Northwick Park Neck Pain Questionnaire for evaluating pain and function with neck pain patients.[7]

The restriction of activities of daily living caused by neck pain has an important place in the planning of treatment. Whatever the source of

the pain, the objective assessment is difficult and the evaluation should primarily be based on the patient's subjective experience of pain and disability. Instead of focusing on the examination findings for diagnostic purposes, it is more accurate for a multidisciplinary approach to evaluate the patient's performance in daily life. For this purpose, there are specific questionnaires developed for the evaluation of patients and the quantitative determination of treatment results.[8] Various features of the scale such as acceptability, ease of use, high reliability, validity and responsiveness to clinical changes can guide the evaluation and selection of an appropriate scale. Therefore, we attempted to adapt the NPQ into Gujarati. Tabachnick and Fidell reported that the sample size of 10 participants per item was sufficient for factor analysis . The present study included 100 patients with neck pain. Thus, the required sample size was sufficient.[9]

In this study 100 patients participated. Gujarati version of The Northwick Park Neck Pain Questionnaire was given twice with 1-week interval to measure the test- retest reliability and to validity. The results of the study showed good correlation neck pain scale (ICC= .815) ($P<0.01$) and internal consistency (Cronbach's alpha = . 989 and .978).

For content validity equivalence all 6 experts answer were located between mostly agree and strongly agree of Gujarati version of The Northwick Park Neck Pain Questionnaire (average=0.89) semantic equivalence (average = 0.90) and content relevance (average= 0.93). Thus, Gujarati version of The Northwick Park Neck Pain Questionnaire was content validated for idiomatic equivalence, semantic equivalence, content relevance.

Contrary to questionnaires evaluating general health, questionnaires related to regional pain and functions are considered to have higher validity because they are directed to a single body region. Therefore, the NDI was developed as the first questionnaire by Vernon et al in 1991 and then the NPQ was developed in 1994 and then the NPDS was developedin 1999. Vernon and Mior applied the NDI at a 1-week interval to patients who have had neck pain due to whiplash injury and without trauma and found the ICC score to be 0.89 . Leak et al found that ICC score was 0.84 for NPQ. They proposed that the NPQ is easy for patients to complete, simple to score and provides an objective measure for evaluating outcomes in patients with acute or chronic neck pain. Wheeler et al found that ICC score was 0.93 for NPDS. Other studies investigating the reliability of the neck questionnaires in the Turkish population, such as the Turkish version of the NPDS and the NDI, have similar ICC scores. Bicer et al conducted a study concerning chronic neck pain and reported that the value of the Cronbach's alpha coefficient for the reliability of the NPDS was 0.86. Aslanet al. conducted a study of patients with chronic neck pain who were administered with the NDI and NPDS. They found that ICC score was 0.979 at a 1-week interval for the NDI and the correlation between the NDI and the NPDS was 0.659 to 0.728.[10-11]

In previous studies, interrater reliability and interrater reliability of the Korean The Northwick Park Neck Pain Questionnaire were (ICC =(0.97) respectively. reliability and validity for level of pain and function had high sensitivity and specificity for the patient with Neck pain.

In Spanish version the concurrent validity had a high correlation (r = 0.74- 0.86) and inter and intra- rater reliability was between 0.4 to 0.6 and 0.6 to 0.8 The Northwick Park Neck Pain Questionnaire is valid and reliable for Spanish population.

It was found Gujarati version of The Northwick Park Neck Pain Questionnaire items equivalent to those in original version which is intended by translators involve in this study. The results showed that it was translate this scale into other languages without losing psychometric properties of the original English version.

CONCLUSION

The Gujarati version of The Northwick Park Neck Pain Questionnaire was cross- culturally adapted and validated for use among the Gujarati-speaking populations. The translated version has acceptable reliability and internal consistency.

ABBREVIATIONS

NPQ: Northwick Park Neck pain questionnaire
NDI: Neck Disability Index
ODI: Oswestry disability index
ICC: Interclass correlation

ABSTRACT

Background: Proper posture is considered to be a state of musculoskeletal balance that involves A minimal amount of Stress or strain to the body.it Compromises balance because of muscular Imbalance which can cause loss Of Proprioception sense in joint and decreased Balance, and trunk endurance is significantly Reduced in Reduced in forward head posture and may lead to poor muscular Control of the spine. **Aim:** To Determine the Correlation between core muscle endurance and foot posture in college Going Students. **Methodology:** An observational study Was conducted in 50 College Going Students of Ahmedabad and Convient Sampling was used. Age group 18-25 Year students Chek for Core Muscle Endurance Test and Foot Posture Analysis. The statistical evaluation become accomplished with SPSS version 29-2022, September. **Result:** Our Finding Suggest that from Descriptive analysis of data was expressed in mean and Standard Deviation for various parameters. Correlation were expressed in term of R value and P Value. P value less than 0.05 was considered to be Signifcant. **Conclusion:** Individuals with altered foot posture will have an effect on the Proximal segment through the Kinetic chain phenomenon of the body, Affecting the core endurance. Individuals with altered Foot posture have reduced core endurance.

KEYWORDS

Core Muscle,Foot Posture,College Students,Endurance

INTRODUCTION

Foot posture plays an important role in the quality of daily living.[1]The structure of the feet is such that it permits the functions of both the stability and the mobility depending on the tasks which are imposed on it.[1]

Kinetic Chain & Core

Core stability can be defined as the ability of the Lumbopelvic-Hip Complex to prevent buckling of the Vertebral Column and return it to equilibrium following perturbation by using Strength, Endurance and Motor Control in a functional manner through all the planes of motion and action despite changes in the center of gravity.[2]

Need Of Study:

1)The foot posture is important for provide stable base of support during walking, running and jumping.
2)Proximal stability is needed for distal mobility.
3)So the core provide proximal stability to perform proper distal component mobility. The affection in
4)proximal core muscle may be lead to distal component changes and visa versa.

Aims Of The Study:

To find out the Correlation between core muscle endurance and foot posture in college Going students.

OBJECTIVES:

1)To find out the Correlation between core muscle endurance and foot posture in college going students by using Flexor endurance test & FPI.
2)To find out the Correlation between core muscle endurance and foot posture in college going students by using Extensor endurance test & FPI.
3)To find out the Correlation between core muscle endurance and foot posture in college going students by using Rt. Side plank endurance test & FPI.
4)To find out the Correlation between core muscle endurance and foot posture in college going students by using Lt. Side plank endurance test & FPI.

Null hypothesis:

There is no significant Correlation between core muscle endurance and foot posture in college going students.

Alternate Hypothesis:

There is significant Correlation between core muscle endurance and foot posture in college going students. and foot posture in college going students.

MATERIAL

Pen, paper, pencil
Foot posture index questionnaire
Stop watch
Plinth or high level bed

METHODOLOGY

Sample Size: 50

Sampling Design : Convient sampling

Study Design: An observational study

Setting: Ahmedabad

Population: Age group between 18 to 25 years

Procedure

- Selection
- Fifty subjects with the age group between 18 to 25 years participate in this study.
- Core Endurance :
- 60 degree flexion endurance test,
- trunk extensor endurance test,
- Right side plank test
- left side plank test.
- Time noted in sec.
- Foot posture:
- Foot posture index.

Flexor Endurance Test Position

Extensor Endurance Test Position

Lt. & Rt. Side Plank Endurance Test Position

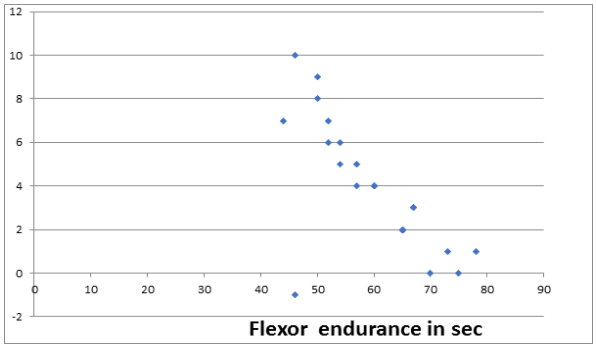
RESULTS

Descriptive analysis of data was expressed in mean and standard deviation for various parameters.Correlation were expressed in term of r value and P value.P value less than 0.05 was considered to be significant

The graphical representation was done by scatter graph.

Table 1 : Descriptive Analysis

	MEAN	STANDARD DEVIATION
Age	22.34	1.7333
Flexor endurance test	60.1	9.2609
Extensor endurance test	55.34	7.3640
Rt. Side plank test	51.78	7.3326
Lt. side plank test	49.08	6.7698
Foot posture Index	3.78	2.8734



Graph 1 Shows Correlation Between Flexor Endurance And FPI

Table 2: Correlation Between Core Endurance & Foot Posture

Variables	r value	P value	
Flexor endurance test & FPI	-0.7231	0.04	significant
Extensor endurance test & FPI	-0.6734	0.03	significant
Rt. Side plank test & FPI	-0.5098	0.005	significant
Lt. side plank test & FPI	-0.5037	0.005	significant

RESULTS

Result shows there is a negative correlation between core endurance timing and foot posture index scoring.

DISCUSSION

The Purpose Of the Study find out correlation between core muscle endurance and foot posture in college going students. The Presents Study Suggest that changes in foot posture causes changes in the kinetic chain of the entire lower extremity upto the lumbar, pelvic and the hip region. Dr. Anvita Telang at el, Conducted study on Comparison of Core Stability in Individuals with Flexible Flat Foot and Normal Foot and conclude that Individuals with flexible flat foot have reduced core Stability.[3] Statistical significance was considered when p value was less than 0.05. The results from statistical analysis of the present study rejects the null hypothesis. There was an significant difference in Core muscle endurance in individuals with different foot posture in the age group of 18- 25 years. The reasons to the above findings are- changes in foot posture causes changes in the kinetic chain of the entire lower extremity upto the lumbar, pelvic and the hip region.

CONCLUSION

Individuals with altered foot posture will have an effect on the proximal segment through the kinetic chain phenomenon of the body, affecting the core endurance.

Individuals with altered foot posture have reduced core endurance.

ABSTRACT

Background: Flat foot can lead to many unpleasant problems including heel pain, bunions, hammertoes, shin splints and even knee, hip or back pain [9]. Most cases of flat foot are caused by loose joint connections. This develops with repetitive stress on the main supporting tendon of the arch over a long period of time [3]. It is believed that Asians have less ligament laxity and accordingly lower prevalence of flat foot than Europeans and Americans [10]. The prevalence of flat feet has been investigated by many researchers in different parts of the world. Higher prevalence (21 to 57%) is reported among children of two to six years which declines (13.4% to 27.6%) in primary school children [14]. In adult population, it is reported to be approximately 5 to 14% by different researchers. The true prevalence of flat foot is uncertain due to lack of exact clinical or radiographic criteria for defining flat foot **Methodology:** Street vendors of Ahmedabad were selected for the study and asked for total standing hours in their day and flat feet were assessed by the FPI-6 score. FPI-6 is a clinical tool that classifies foot posture according to six items (Redmond, 2005): (i) palpation of the head of the talus; (ii) curvatures above and below the lateral malleolus; (iii) position of the calcaneus in the frontal plane; (iv) prominence in the talo-navicular joint; (v) the medial longitudinal arch's congruence; and (vi) abduction/adduction of the forefoot on the rear-foot. Each item is scored from −2 to 2, resulting in a total score of −12 to 12. Negative values indicate supinated foot posture and positive values indicate pronated foot posture. **Result:** The research was performed on 100 participants between the age of 20-40. There were 56 patients between the ages of 20 to 30, 44 patients between the age 31to 40. Moderately negative correlation seen in standing duration and pronation of foot. **Conclusions:** There is no correlation between standing time and flat foot in street vendors of Ahmedabad.

Foot posture index, Medial Longitudinal Ach, Flat foot, Pes Plano-Valgus, Adult Flatfoot.

INTRODUCTION

The structure and dynamicity of foot arches are essential for functions of foot like shock absorption, body weight transmission and to act as a lever for propelling the body forward during locomotion. Medial Longitudinal Arch (MLA) of foot is higher than the Lateral longitudinal arch and its curvature flattens to variable degree during weight bearing[1]. Pes planus is a medical condition where the curvature of MLA is more flat than normal and entire sole of the foot comes into near complete or complete contact with the ground [2]. The height of MLA is most important measurement in determining the degree of pes planus. The feet appear to be flat in infants due to presence of fat. The arches become prominent when the child starts walking and the foot starts bearing the weight. The arches of foot rapidly develop between two to six years and become structurally mature around 12-13 years. [3]

Prevalence of flat feet is higher in children due to ligament laxity and declines with age. Early shoe wearing in children impairs the development of longitudinal arches[4]. The true prevalence of flat foot is uncertain due to lack of exact clinical or radiographic criteria for defining flat foot.

Flatfoot can also be acquired in adulthood. In the adult-acquired condition, patients typically present with an insidious onset of vague pain in the medial foot and behind the medial malleolus along the course of the tibialis posterior tendon [4]. As the condition progresses, these patients have more complaints related to loss of function and changes in the shape of the foot. In the late stages, rigidity, arthritic changes, and ankle valgus may also be observed. In adulthood, the tibialis posterior tendon should maintain its integrity between the medial malleolus and navicular tuberosity When the tendon is elongated, the plantar structures such as the spring ligament stretch excessively, leading to joint subluxation.

A cross-sectional study in 24 subjects with tibialis posterior tendon abnormality and 48 sex- and age-matched controls showed that advanced tibialis posterior tendon pathology was statistically significantly associated with adult-acquired flatfoot deformity and spring ligament pathology[5]. As the pathology progresses, the medial arch collapses. This leads to compensation of the foot by forefoot supinatus and calcaneal valgus, resulting in the deformity of pes planovalgus[6]. An ankle equinus may also present as either a primary deforming force or a secondary adaptation in such patients.

Adult flatfoot is defined as a foot condition that persists or develops after skeletal maturity and is characterized by partial or complete loss or collapse of medial longitudinal arch. Adult flatfoot may present as an incidental finding or as a symptomatic condition with clinical consequences ranging from mild limitations to severe disability and pain causing major impediments. It is often a complex disorder with variety of symptoms and various degrees of deformity[7].

The human foot is designed in the form of elastic arches or springs. These arches are segmented, so that they can best sustain the stresses of weight and of thrusts. An arched foot is a distinctive feature of man[8]. Absence or collapse of the arches leads to flatfoot (pes planus), which may be congenital or acquired. The effects of a flat foot are as follows Loss of spring in the foot leads to a clumsy, shuffling gait, b) Loss of the shock absorbing function makes the foot more liable to trauma and osteoarthritis, c) Loss of the concavity of the sole leads to compression of the nerves and vessels of the sole[9].

Flat foot deformity was classified into three subtypes, rigid flat foot, Flexible Flat Foot (FFF) and Flexible Flat Foot with Short Tendo-Achilles (FFF-STA)[10]. FFF is generally asymptomatic while FFF-STA gives rise to pain and functional disability. Rigid flat foot is often symptomatic and associated with tarsal coalitions and reduced range of motion at subtalar joint.

There are many different causes of flat foot, which can be separated into 2 main categories. The first category, congenital flat foot, includes the completely asymptomatic, pediatric flexible flat foot, by far the most common form of congenital flat foot. Flexible means that an arch is present until weight is put on the foot, at which time the arch disappears. The second category, acquired flat foot, develops over time, rather than at birth, and many different factors contribute to its development. These include the type of shoes a child wears[11], rheumatic arthritis, compensation for other abnormalities further up the leg, or more severe factors such as rupture of the ligaments or tendons in the foot. The most common acquired flat foot in adults is due to posterior tibial tendon dysfunction.[12]

Flat foot can lead to many unpleasant problems including heel pain, bunions, hammertoes, shin splints and even knee, hip or back pain. Most cases of flat foot are caused by loose joint connections. This develops with repetitive stress on the main supporting tendon of the arch over a long period of time. It is believed that Asians have less

ligament laxity and accordingly lower prevalence of flat foot than Europeans and Americans.[13]

The prevalence of flat feet has been investigated by many researchers in different parts of the world. Higher prevalence (21 to 57%) is reported among children of two to six years which declines (13.4% to 27.6%) in primary school children. In adult population, it is reported to be approximately 5 to 14% by different researchers. The true prevalence of flat foot is uncertain due to lack of exact clinical or radiographic criteria for defining flat foot.[14]

Studies have found relation between these indices and their validity has been determined using diagnosis carried out with a pod scope on children as a reference group. Prevalence changes with age, the type of population studied and the presence of other pathologies. Some studies show prevalence between 26.5% and 19.0% and other studies on patients with associated comorbidity report a prevalence of 37%. Flat foot has been associated to family history, the use of footwear in infancy, obesity and urban residence, and it has also been associated with age, gender and foot length. The presence of flat foot has also been associated with the presence of different states of health, the presence of pain, and the fatigue in women. Other studies, however, find no relationship of pain or functionality with the changes in the foot. [15]

Flat foot can lead to many unpleasant problems including heel pain, bunions, hammertoes, shin splints and even knee, hip or back pain. Most cases of flat foot are caused by loose joint connections. This develops with repetitive stress on the main supporting tendon of the arch over a long period of time. It is believed that Asians (including Arabs) have less ligament laxity and accordingly lower prevalence of flat foot than Europeans and Americans.[16]

METHODOLOGY

Study Design And Setting

Study Design: CORRELATION STUDY

Population: STREET VENDORS IN AHEMDABAD

Sampling Method: CONVENIENT SAMPLING

Sample Size: 100

Selection Criteria

Inclusion criteria:

- Age group between 22 to 40 years.
- Both genders– male and female.
- Subject willing to participate in study.
- Vendors with 6 to 8 hours of duty.

Exclusion criteria:

- Subject with any systemic illness and other musculoskeletal disorders specifically in lower limb like foot injuries, degenerative changes of hip and knee.
- Subject with any recent surgeries of lower limb.

Outcome Measures:

Foot Pressure Index

THE FOOT POSTURE INDEX (FPI) is a novel, foot-specific outcome measure that was developed in order to quantify variation in the position of the foot easily and quickly in a clinical setting. It is particularly intended for large sample studies where complex instrumented assessment (e.g., gait laboratory assessment) is impractical or unnecessary. It has already been used in studies of risk factors for injury in athletes and naval recruits, treatment of plantar heel pain, and response to orthotic therapy in different foot types. The FPI consists of a series of criterion-based observations that combine to provide a quantification of postural variation in 3 major regions of the foot (rear-foot, mid-foot, forefoot) in the 3 cardinal body planes. FPI-6 is a clinical tool that classifies foot posture according to six items (Redmond, 2005): (i) palpation of the head of the talus; (ii) curvatures above and below the lateral malleolus; (iii) position of the calcaneus in the frontal plane; (iv) prominence in the talo-navicular joint; (v) the medial longitudinal arch's congruence; and (vi) abduction/adduction of the forefoot on the rear-foot. Each item is scored from −2 to 2, resulting in a total score of −12 to 12. Negative values indicate supinated foot posture and positive values indicate pronated foot posture.

Reliability And Validity Of Foot Posture Index:

Mariana R.C. Aquino et al in their study of Reliability of Foot Posture Index individual and total scores for adults and older adults concluded that The relatively low reliability in light of this high level of agreement suggest that the current version of FPI-6 can be a useful tool to assess foot posture for adults and should be further examined. On the other hand, FPI- 6 should be cautiously used for older adults.

Data Collection Procedure:

After receiving the ethical committee clearance to study research from institute, participants who fulfill the selection criteria were evaluated clinically through assessment and the purpose and procedure of the study was explained to the subjects and requested to sign the consent form. Prior to study the entire subject's demographic data including age, sex, height, weight, Body Mass Index, occupation, address, etc., will be noted.Outcome measures were taken. Result was analyzed statistically using SPSS 25.0 software.

Procedure:

The participant stood on a step, with the arms by the side and looking straight ahead the examiners were not allowed to see the participant's contralateral foot during the evaluation of foot posture (Fig.2). The entire procedure was performed at a clinic. Each FPI-6 item was independently evaluated and scored by each examiner in separate sheets. First, the examiners evaluated the left foot, and then, the right foot.

RESULTS

All statistical analysis was done using SPSS 25.0 software for windows. Descriptive analysis was used to obtain mean and standard deviations.

Demographic Data

Age:

The research was performed on 100 participants between the age of 20-40. There were 56 patients between the ages of 20 to 30, 44 patients between the age 31to 40.

Table 1: Age Distribution

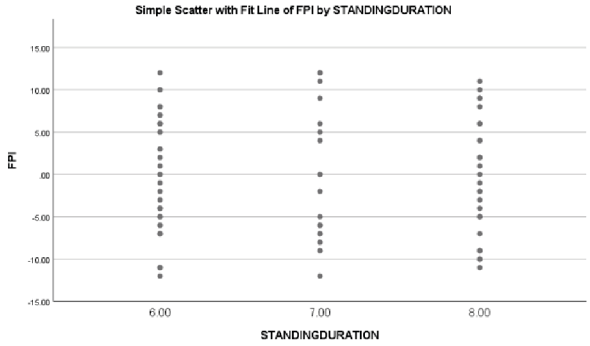

Graph 3: Correlation of FPI &standing duration

- As results are showing the person's correlation between standing hours and FPI was -0.013 that shows the moderately negative correlation seen in standing duration and pronation of foot.

DISCUSSION

Flatfoot is a biomechanical disorder frequently seen in clinical practice. This study reveals that the prevalence of flat foot was 26.62%. Described finding is practically identical to a study conducted in Japan on a sample of 242 women and 98 men, in which a prevalence of 26.5% was observed, along with how said finding is related with obesity and the effects of pain and functionality. Similar findings regarding the prevalence of flat foot can be found in other publications. In other population studies (Springfield, Massachusetts) the prevalence of flat foot was 19.0% (20.1% in females and 17.2% in males). Another study conducted in the Boston area found a prevalence of 20% in women 17% in men. There are even studies, conducted in a diabetic population on a sample of 230 patients, which refer to a prevalence as high as 37% The present study was performed on 100 participants between the age of 20-40. There were 56 patients between the ages of 20 to 30, 44 patients between the age 31to 40. It was having mean FPI of 12.5±2.5 and mean standing hours were 6.3±0.8 hours and they show moderately positive correlation of standing hours with flat foot.

Another study conducted in India reveals how the use of footwear at early ages, along with obesity and ligamentous laxity, increases the prevalence of flat foot Another study conducted in Nigeria on 560 children aged between six and 12 years shows that although in the univariate analysis an association was found with type of footwear and age, after taking both into consideration, only age remained as a variable associated the presence of flat foot. Urban residence as a risk factor for the prevalence of flat foot has also been described in a study conducted on children in the Congo, where, after studying 1,851 footprints from 906 girls and 945 boys aged between three and 12 years, it was observed that prevalence diminishes with age, is higher in urban areas and in the masculine sex, and that the use of footwear has little influence on said prevalence. This study shows how the BMI, comorbidity and foot size are associated with the prevalence of flat foot. There is variability in the literature review. A number of studies describe how this foot disorder increases with age, other studies describe how flat foot diminishes with age, after adjusting for other covariates, and others indicate that neither age, gender nor BMI are related with flat foot. Also in another study, the prevalence of flat foot was assessed where in it was found that real prevalence of symptomatic flatfoot is not very high in adolescents due to its nature of spontaneous correction as age increases also in another study, the prevalence of flat foot was assessed where in it was found that real prevalence of symptomatic flatfoot is not very high in adolescents due to its nature of spontaneous correction as age increases [18, 19]. According to age, the subjects between age 20-29 years were suffering 31.8% of flat foot, 30-39 years were having 42% flat foot, 40-49 years were having 16.7% flat foot, above 50 years were having 37.5% flat foot. similarly subjects between age 20-29 years were suffering 47.7% of high arched foot, 30-39 years were having 50% high arched foot, 40-49 years were having 61.1% high arched foot, above 50 years were having 50 % high arched foot.

According to gender it was found that high arched foot had higher incidences in males (55.2%) whereas flat feet were found to have higher incidences in females (38.7%).

A number of studies also describe different radiological findings in the morphology of the foot according to different ethnic groups. Others indicate how the different radiological morphology (angle of the talus with the first metatarsal) is related with the symptomatic presence or absence of flat foot. Even though obesity has repeatedly been associated with the presence of flat foot, not all studies point towards this association. In some articles, not only is the association of flat foot with characteristics (e.g., age, sex, BMI and concomitant illness) indicated, but also as a modifier of health. Thus, there are studies of 97,279 military recruits which associate flat foot with localized knee pain. As we have previously mentioned, in the article which finds a prevalence of flat foot identical that in our study it can also be seen how said alteration is also associated with the presence of pain and fatigue in women.

CONCLUSION

According this study, standing duration was negatively correlated with pronation of foot in vendors of Ahmedabad city. Its suggest that flat foot is not correlated with long standing duration in vendors.

ABSTRACT

Background: Coronary artery bypass graft (CABG) Surgery is Known to induce significant muscle wasting. Thus, vast no of patients is facing reduces endurance after surgery with the help of this study. The resultant significant treatment can be beneficial to help vast no of patients with endurance problems. **Methodology:** Participants' subjects meeting inclusion criteria will be included in the study. The sample will be initially selected then randomly divided into 2 groups, group A and group B Treatment with aerobic exercise group A n=30 patients. Treatment with deep breathing exercise with positive expiratory pressure breathing exercise group B n=30 patients. consent form will be signed by both groups. **Result:** The research was performed on 60 participants between the age of 35-65 years. There were group(A) 30 patients between age 35-55, group(B) 30 patients between age 35-60. The statistical software SPSS 25.0 version was used to analyze the data. Before taking statistical data, outcome measure by the six-minute walk test. All outcome measures were analyzed using suitable statistical analysis at baseline and after (4to8) weeks of intervention level ofsignificance was kept at 95% changes in the outcome measures were analyzed within group as well as between. **Conclusions:** Aerobic exercise is better than deep breathing exercise with positive expiratory pressure breathing exercise in post CABG patients in recovery phase.

Aerobic exercise, CABG, Deep breathing exercise, spirometry, positive expiratory pressure breathing (PEEP)

INTRODUCTION-

It is a surgical procedure in which the chest is opened, and surgery is performed on the heart. The term "open" refers to the chest, not to the heart itself. Two types of cardiac surgery are closed and open-heart surgery. (1) (2) The heart is a muscular organ that pumps blood throughout the circulatory system. It is situated between two lungs in the mediastinum. It is made up of four chambers, right atrium, right ventricle, left atrium, left ventricle. Heart beats 72/min. CABG (coronary artery bypass grafting) is done when there is multiple severe coronary stenosis associated with unstable or uncontrolled angina. CABG is a surgical procedure used to treat coronary artery disease. The blocked or narrowed coronary arteries are simply bypassed, replacing the blocked portion of the coronary artery with a piece of patent blood vessels taken from any other less sensitive area of the body. Such vascular grafts may be pieces of a vein taken from the legs or mammary artery in the chest. One end of the graft is attached above the blockage and the other end is attached below the blockage through the new graft to reach the heart muscle. CABG can also be performed off pump and on pump. (3)(4)(5) Aerobic exercise is submaximal, rhythmic, repetitive exercise of large muscle groups, during which the needed energy is supplied by inspired oxygen. Aerobic exercise training is augmentation of the energy utilization of the muscles by means of an exercise program. The improvement of the muscles ability to use energy is a direct result of increased levels of oxidative enzymes in the muscles, increased mitochondrial density and size and an increased muscle fiber capillary supply. Training is dependent on exercise of sufficient intensity, duration, and frequency. Training produced cardiovascular and /or muscular adaptation and is reflected in an individual's endurance. Aerobic exercise is any type of cardiac conditioning. It can include activities like brisk walking, swimming, running, or cycling. Aerobic exercise can be effective in increasing endurance of cardio-respiratory system by improving stroke volume at rest, lowering resting heart rate, lowering blood pressure, aerobic exercise is critical component of cardiac rehabilitation following cardiac rehabilitation.

Aerobic exercise traditionally commenced two to six weeks following hospital discharge and most commonly includes stationary cycling or treadmill walking. (6)(7)(8) INTRODUCTION 4 Deep breathing exercise is a fundamental intervention for the prevention or comprehensive management of impairments related to acute or chronic pulmonary disorders and Post Surgical patients. Deep breathing exercises come in many forms including diaphragmatic, breathing, segmental breathing, inspiratory resistance training incentive spirometry, pursed-lip breathing. (9) When the diaphragm is functioning effectively in its role as the primary muscles of inspiration, ventilation is efficient and the oxygen consumption of the muscle of ventilation is low during relaxed (tidal) breathing. When a patient relies substantially on the accessory muscles of inspiration the mechanical work of breathing (oxygen consumption) increases and the efficiency of ventilation decreases. Although at an involuntary level, a patient with primary or secondary pulmonary dysfunction can be taught how to control breathing by optimal use of the diaphragm and decreased use of accessory muscles. Diaphragmatic breathing is designed to improve the efficiency of ventilation, decrease the work of breathing, increase the excursion (descent or ascent) of the diaphragm, and improve gas exchange and oxygenation. (10) (11). Pursed-lip breathing is a strategy that involves lightly pursing the lips together during controlled exhalation. Many therapists breathing and controlled expiration is a useful procedure, particularly to relieve dyspnea if it is performed appropriately. Pursed-lip breathing decreases the respiratory rate and the work of breathing (oxygen consumption), increases the tidal volume, and improves exercise tolerance. (12)

Positive expiratory pressures breathing is a technique in which resistance to airflow is applied during exhalation, similar to what occurs during pursed-lip breathing, except that the patient breathes through a specially designed mouthpiece or mask that controls resistance to airflow. This breathing technique is used to hold airways open during exhalation to mobilize accumulated secretions and improve their clearance. Positive expiratory pressure breathing provides an alternative or adjunct to postural drainage which a patient can perform independently. (13) Following coronary artery bypass graft (CABG), the main cause of postoperative morbidity and mortality are postoperative pulmonary complications, respiratory dysfunction, and arterial hypoxemia. Incentive spirometry is a treatment technique that uses a mechanical device (an incentive spirometry) to reduce such pulmonary INTRODUCTION 5 complications during postoperative care. An incentive spirometry is a device that measures the volume of the air inhales into the lungs during inspiration when breathing in through an incentive spirometry, a piston rises inside the device and measures the volume of the inspired air. Here we used flow-oriented incentive spirometry (Tri-flow device) has three chambers with one ball in each chamber capacity up to 1200ml. (14) (15) (16) The 6-minute walk test (6-MWT) is an assessment that a

doctor may use to determine a person's exercise tolerance. It may be useful for measuring the functional ability and fitness of people with certain health conditions. (17) The Borg rating of perceived exertion (RPE) scale is an objective reassure of fatigue. This scale can also be used to monitor exercise intensity. (18)

METHODOLOGY

Study Design And Setting

Study Design: Comparative Study

Source Of Data: Zydus Hospital, and Trisha Heart Care and Physiotherapy center.

Population: Post CABG Patients in Recovery Phase.

Sampling Method: Random Sampling (fish bowel method)

Sample Size: 60 Patients (Treatment with Aerobic Exercise n=30 Patients, Treatment with Deep Breathing exercise With Positive expiratory pressure breathing exercise n=30 Patients)

Duration Of the Study: One Year.

MATERIAL & TOOLS USED:

Paper Pen
Assessment sheet Consent Form Incentive spirometry
Positive expiratory pressure breathing device. Cycle ergometer
Stopwatch Pulse oximeter
Blood pressure instrument

DATA COLLECTION PROCEDURE:

Participants who were meeting the inclusion and exclusion criteria have been selected for the study followed by the signature of participants on their consent form. The sampling was done randomly followed by convenient allocation within 2 groups: group A and group B. Treatment of aerobic exercise was given to the participants of group A (n=30 patients). Treatment of deep breathing exercise with positive expiratory pressure breathing exercise was given to the subjects of group B (n=30 patients).

CASE STUDY

Worldwide approximately 400,000 people have undergone CABG in 2021-2022. Thus, vast numbers of patients are facing reduced endurance after surgery. With the help of this study, the resultant significant treatment can be beneficial to help vast number of patients with endurance problem. (4)(5)(6)

CONCLUSIONS

According to this study, Aerobic exercise is better than deep breathing exercise with positive expiratory pressure breathing exercise in post CABG patients in recovery phase. SUMMARY This study compared aerobic exercise and deep breathing exercise with positive expiratory pressure breathing exercise in post CABG patients in recovery phase. They were randomly allocated into groups or outcome was measured pre and post after 4 to 8 weeks of intervention. Both treatments were significantly effective in post CABG patients in the recovery phase but, more effective was in group A.

Limitations Limited age group may be applicable to larger age group. Limited sample size. Before recovery phase further study done with different age group geriatric group population. Future recommendation Further study can be done with large sample size. Study can be done with long term follow up.

ABSTRACT

Background: Forward head posture afflicts a large percentage of population and can cause significant neck pain, the estimated 1-year incidence of neck pain ranges between 10.4 and 21.3%, and the overall prevalence of neck pain in general population can be as high as 86.8%. Strong evidence was found to relate neck pain with female gender, older age, being an ex-smoker, high job demands, and low social or work support. Regarding physical work factors, neck pain was significantly associated with holding the neck in a forward bent posture for a prolonged time and making repetitive movements. **Methodology:** Individuals selected according to inclusion/exclusion criteria and were explained regarding the study. Total 100 participants (Age 30 years and above) were included in the study. Subject were assessed for Forward Head Posture, Pain and Cervical ROM. **Result:** Association testing were done using pearsons Correlation method. Among a total of 100 office workers took part in the survey 73% were female. The mean age of participants was 39±8 years. Results shows Moderately positive Correlation of forward neck with reduction of ROM of Neck and moderately positive Correlation of Pain and forward head posture seen according to pearsons Correlation at the level of P<0.01. **Conclusion:** The present study demonstrated the Correlation of forward head posture with pain and cervical range of motion in desk users it shows moderately negative Correlation between pain and tragus to wall test and it shows positive Correlation between pain and cervical range of motion.

KEYWORDS

Forward Head Posture (FHP), Neck pain and disability scale (NPDS)

INTRODUCTION

Forward head posture (FHP) is the anterior positioning of the cervical spine, this posture is called as "text neck", "scholar's neck, "wearies neck", "reading neck". Forward head posture afflicts a large percentage of population and can cause significant neck pain, the estimated 1-year incidence of neck pain ranges between 10.4 and 21.3%, and the overall prevalence of neck pain in general population can be as high as 86.8%.[1]

Forward head posture (FHP) is the most common postural deformity seen in the sagittal plane. It can be defined as any alignment in which the external auditory meatus is positioned anterior to the plumb line through the shoulder joint. In FHP, head moves anteriorly and the peak of the increased cervical lordotic curve is a noticeable distance away from center of gravity.[2-3] FHP gradually leads to abnormal compression of zygapophyseal joint, posterior vertebral disks, narrowed intervertebral foramina and shortened posterior zygapophyseal joint capsule causing nerve root compression.[3]

The FHP could lead to muscle ischemia, muscle pain, fatigue, inflammation, reduced cervical range of motion and sometimes protrusion of nucleus pulpous, rotation of mandible which cause compression and irritation of retrodiscal pad. There are various methods to evaluate FHP but many studies have declared that Craniovertebral angle (CVA) is the best indicator to measure the FHP. CVA is measured by the angle between the imaginary line which passes through C7 and tragus and a horizontal line through C7.[4-5]

Neck pain is one of the very common musculoskeletal conditions in the general population. Neck pain can vary from a small discomfort to severe disabling pain making it one of the major health problems that carries important economic costs. Less severe neck pains occur due to poor posture, neck strains, occupational and sport injuries and mental state such as anxiety and depression, while mechanical and degenerative factors are more likely to develop chronic neck pain.[6]

Strong evidence was found to relate neck pain with female gender, older age, being an ex- smoker, high job demands, and low social or work support. Regarding physical work factors, neck pain was significantly associated with holding the neck in a forward bent posture for a prolonged time and making repetitive movements.[7] In addition, the increasing use of new information and communication technologies has led to an increase in time spent texting messages on mobile phones or using computers, which might have a long-term impact on neck pain, potentially due to prolonged periods of neck flexion.

The increasing use of new information and communication technologies has led to an increase in time spent texting messages on mobile phones or using computers, which might have a long-term impact on neck pain, potentially due to prolonged periods of neck flexion. Neck flexion may facilitate forward head posture (FHP), which refers to forward placement of the head in relation to the shoulder.[8] This is the most common cervical postural fault in the sagittal plane that is found with different severity levels in almost all populations. Greater FHP has been associated with greater deficits in cervical range of motion (ROM), particularly neck rotation and flexion.[9]

There exist several methods for the evaluation of the spinal posture i.e. radiography, 3D motion analysis via electromagnetic and optical tools, raster stereography, photographic postural analysis and in manual methods (Universal goniometer). Among which Universal goniometer has excellent reliability and is cost effective.

This change in posture can lead to a spatial change between the spine and the line of gravity, causing an overload on muscles and connective tissues[10]. Neck pain or neck dysfunction is a musculoskeletal disorder caused by improper posture with physical impairment or functional limitation. The FHP is known as an internal factor that causes dysfunction with shoulder and neck pain [11]. A FHP results in a posture in which the extended head and upper cervical, and the lower cervical vertebrae flex[12].

This increases the length of the external moment (the arm) by moving the gravitational center (the head) ahead of the load bearing axis [12]. The exposure to this constant load on the craniovertebral extension muscles and the noncontractile structures causes a change in the biomechanical movement, and this increased stress can cause musculoskeletal damage or pain [13]. In addition, FHP can also limit the functional movement in the head and neck area [14]. These limitations are caused by irregular rotation and gliding movement inside the articular capsule whilst moving the joint. Moreover, it was reported that extended periods of FHP can result in a decreased number of sarcomere, as well as shortening of the muscle fibers, which can affect muscular contraction.

With normal flexion of the cervical region, there is separation of the posterior structures with an increase of the intervertebral foramina [15] However, the altered mechanics associated with forward head posture may lead to excessive compression on the facet joints and posterior surfaces of the vertebral bodies[16]. in the forward head position, there is an overriding of the articular processes and narrowing of the

intervertebral space of the mid cervical region which approaches the relationship observed in cervical extension.

The use of computers has increased dramatically over the past decade in various offices so that staffs spend a lot of time sitting behind the computer. These rapid changes may be accompanied by increased prevalence of poor posture and resultant neck pain. FHP (forward head posture) and rounded shoulders are defined as protrusion of the head and shoulders in the sagittal plane.[17]

Early diagnosis of forward head posture will help to minimize the consequences. This study aims to investigate the incidence of forward head posture in desk users using Goniometer and its association with pain and range of motion of cervical spine.[18] The objective of this study is to find the percentage of forward head posture in desk users using Goniometer and to find the associated problems of forward head posture in desktop users on Neck Pain and Disability Scale and Cervical Range of Motion.

METHODOLOGY

Research Design: Observational Study

Study Population: 30 years and above.

Source of Data: Miscellaneous

Sample Size: 100 participants

Inclusion Criteria:
- Individuals who work for >3hrs/day on Desktop for 1 year.
- Both males and females age group 30 and above.

Exclusion Criteria:
- Cervical vertebrae fracture, Deformity of spine like scoliosis\kyphosis, Medical condition like vertigo, tumor in cervical region were excluded.

Materials:
- Consent form
- Goniometer
- Ruler scale
- Pen and pencil
- Mobile phone

Outcome Measures
- Neck Pain and Disability (NDI) Scale
- Cervical Range of Motion (ROM)
- TWT (Tragus to Wall Test)

Neck Pain and Disability Scale (NPDS):
- The NPDS is a 20-item measure that was specifically developed for patients with neck pain. It measures the intensity of pain; its interference with vocational, recreational, social, and functional aspects of living; and the extent of associated emotional factors. Patients responded to each item by marking along a 10-cm visual analogue scale. Item scores range from 0 to 5, and the total score is the sum of the item scores [possible range 0 (no pain)–100 (maximal pain)].
- High test - retest reliability is 0.93
- Time Required: 5 minutes

Cervical Range of Motion

Goniometers are the measuring tool to measure the range of motion in grades base on the landmarks. For example, goniometer are myrin goniometer, Spring-T goniometer and cervical range of motion instrument.

Procedure:

i) Cervical Flexion:
- Center fulcrum of the goniometer over the external auditory meatus.
- Align proximal arm so that it is either perpendicular or parallel to the ground.
- Align distal arm with the base of the nares.

ii) Cervical Extension:
- Center fulcrum of the goniometer over the external auditory meatus.
- Align proximal arm so that it is either perpendicular or parallel to the ground.
- Align distal arm with the base of the nares.

iii) Cervical Lateral Flexion:
- Center fulcrum of the goniometer over the spinous process of the C7 vertebra.
- Align proximal arm with the spinous processes of the thoracic vertebrae so that the arm is perpendicular to the ground.
- Align distal arm with the dorsal midline of the head, using the occipital protuberance for reference.

iv) Cervical Rotation:
- Center fulcrum of the goniometer over the center of the cranial aspect of the head.
- Align proximal arm parallel to an imaginary line between the left and right acromial processes.
- Align distal arm with the tip of the nose.

Tragus to Wall Test
- To objectively measure the cervical mobility of an individual.
- Shipe et al (2013) describe the measuring the tragus to wall distance (TWD) as: "the horizontal distance between the tragus, the auricular cartilaginous flap anterior to the external auditory meatus, and a wall
- The TWD can be measured as cued or relaxed, i.e the clinician prompts the individual to assume as close to an anatomical posture as possible e.g "Stand tall.", or the clinician measures the individual in their usual or presenting posture.
- The measurement can be done standing or sitting and it is worth documenting which position has been used.
- The TWD can be measured on both the individual's right and left, and then an average can be calculated.
- Reliability: In AS, test-retest correlations have been reported at between 0.93 and 0.95. Inter-tester reliability has also been reported as "excellent" in individuals with PD.
- Validity: In PD, the TWD has shown convergent validity with similar measures (occiput to wall status, C7 to wall distance, photographically derived trunk flexion angle, and inclinometric Thoracic Hyperkyphosis measure). It has also shown the ability to discriminate between groups (those who could touch occiput to wall when prompted to stand tall) and conditions (cued or relaxed).

Procedure Of The Study:

After getting approval from Institutional Ethical Committee (IEC)., individuals selected according to inclusion/exclusion criteria and were explained regarding the study. After explaining about the study, informed consent form were taken from the participants who were willing to participate in the study. Subject were assessed for Forward Head Posture, Pain and Cervical ROM.

RESULTS

All statistical analysis was done using SPSS 25.0 software for windows. Descriptive analysis was used to obtain mean and stanard deviations. Correlation testing were done using pearsons correlation method. Among a total of 100 office workers took part in the survey 73% were female. The mean age of participants was 39±8 years.

Descriptive Statistics:

Table 1: Mean Values and Standard Deviation

Table 9: Correlation of Right Rotation with NPDS & TWD

Rotation (Rt)	Correlation	NPDS	TWD
		.069	.016
	Significance	.498	.871

Correlation between cervical Flexion TWD and NPDS and Neck ROM parameters. The correlations between NPDS and TWD with cervical ROM is moderate positive significant correlation The correlations between TWD and NECK ROM moderately positive correlation is seen. (Table 5 to 9).

Results shows Moderately positive correlation of forward neck with reduction of ROM of Neck and moderately positive correlation of Pain and forward head posture seen according to pearsons correlation at the level of P<0.01.

RESULTS DISCUSSION

The results of the present study show that among 100 office workers who was working with computers there is positive Correlation between NPDS, TWG and Neck ROM parameters. The correlations between NPDS and TWD were moderate negative significant correlation (r = -0.145, p = 0.149), The correlations between NPDS and Neck ROM is moderately positive correlation is seen.

There is also Correlation between cervical Flexion, TWD and NPDS and Neck ROM parameters The correlations between NPDS and TWD with cervical ROM is moderate positive significant correlation and the correlations between TWD and Neck ROM moderately positive correlation is seen. Results shows Moderately positive correlation of forward neck with reduction of ROM of Neck and moderately positive correlation of Pain and forward head posture seen according to pearsons correlation at the level of P<0.01.

One of study demonstrate that the prevalence of neck pain among Iranian office workers versus office workers in other countries almost is comparable so that it was reported 64% and 36.1% in sudan and sri lanka respectively [19]. Comparing comparison between the prevalence of shoulder pain among Iranian employees and employees of other countries shows that it is less common among Iranian office workers (9.3% versus 41 % and 34.3 % in Sudan and Sri Lanka respectively). In a survey on Chinese adolescents in 2008, the prevalence of forward head posture was reported as high as 25% [8]. In reviewing the literature, no data was found on the relationship between head and spinal posture during work and chronic neck pain. According to our study, office workers using computer had more forward head, kyphosis and rounded shoulder posture.[20]

The improper posture of head, cervical and thoracic spine was more common in the symptomatic group comparing the asymptomatic group during computer working that is equivalent to the results of mentioned cross-sectional studies that showed a significant relationship between individual's posture and neck pain.

Duration of computer use may have an impact on the incidence of neck pain. According to results of other cross-sectional studies, it was found that there is positive correlation between duration of sitting and neck pain prevalence. Another study showed that sitting behind desk for over 5 hours per day, is considered a risk factor for neck pain. Despite of these studies, in a systematic review, it was found that there is no significant correlation between duration of sitting and neck pain.

According to our study, there was no relationship between the duration of working with computer and neck pain (p = 0.322). In a prospective study with a 3-year follow-up by ariens et al on over 1,334 employees, it was observed that there is a strong relationship between duration of sitting in working hours and neck pain in such a way that if one is in sitting position for over 95% of his working hours, the probability of suffering from neck pain is increased (rr= 2.01%).

According to results of some studies, it was observed that FHP is more prevalent in women compared to men, while in present study it was seen that there is no difference in FHP prevalence in men and women. Another systematic review indicated that there is no correlation between participation in various sport and recreational exercises and neck pain. In a research by dimberg et al, it was found that taking part in rocket sport is a negative risk factor for neck pains . Of course, in our research on university office workers it was seen that they have no regular sport activity and a few of them may exercise a particular kind of sport at the weekends occasionally which was negligible and no positive or negative correlation was found in this regard. It needs further studies in the future. Another factor investigated in most previous studies is the relationship between driving and prevalence of neck and shoulder pain.

One of the study have revealed that office employees had a more improper posture while working with a computer versus sitting with forward looking (not a working) position, and that the defective posture in the working position was more severe in the symptomatic group. It may be due to poor ergonomics of chair, desk, computers position and also lack of attention paid to body position during work. Lack of awareness of posture while working among employees is important in causing improper posture of head and neck; so paying attention to head and neck posture during work might be a good way to decrease the poor posture. It can be introduced into the office environment by feedback methods, mirror or alarming instruments.

According to the results of Cagnie et al. study, it has been found that there is a positive correlation between duration of computer work and neck pain. Other studies that were published before 2000 showed that if duration of sitting at a desk is longer than 5 hours per day, it is considered as a risk factor for neck pain. In contrast to these findings, a systematic review of the 3 studies has found that there was no significant relationship between the duration of sitting and neck pain.[21,22]Based on our findings, there was no relationship between hours of work with a computer and neck pain (p = 0.322).

CONCLUSION

The present study demonstrated the Association of forward head posture with pain and cervical range of motion in desk users. It shows moderately negative correlation between pain and tragus to wall test and it shows positive correlation between pain and cervical range of motion.

ABSTRACT

Background: Frozen shoulder (FS) is signified by pain and stiffness in the shoulder joint; limited range of motion and pain are the most common symptoms. It is also known as adhesive capsulitis or periarthritis (PA). FS has a prevalence of approximately 2 to 5 % in the general population. The incidence among women is 1.6 to 4-fold higher than in men. Functional impairments caused by FS consist of Limited Reaching, particularly during Overhead or to the side activities. **Methodology:** Patients were analyzed pre and post treatment for frozen shoulder by SPADI and range of motion (ROM) of the shoulder joint by using goniometer. Total 40 Patients were taken and divided in two group. Group A received ultrasound with conventional physiotherapy and Group B received cryotherapy ultrasound with conventional physiotherapy for 6 days a week for 4 weeks. **Result:** The research was performed on 100 participants between the age of 20-40. There were 56 patients between the ages of 20 to 30, 44 patients between the age 31to 40. Moderately negative correlation seen in standing duration and pronation of foot. **Conclusions:** In conclusion the treatment program consisting of Ultrasound with Conventional Physiotherapy is more effective in frozen shoulder to reduce Pain, Functional disability and improve Shoulder range of motion.

Frozen shoulder, Ultrasound therapy, Cryotherapy, Rang of motion, Shoulder Pain And Disability Index

INTRODUCTION

1.1 Shoulder Complex

The shoulder joint, also known as the glenohumeral joint, is a dynamic articulation between the glenoid of the scapula and the proximal humerus, with functions like abduction, adduction, flexion, extension, and rotation. It is supported by the primary four rotator cuff muscles.[1,2] The shoulder joint is one of the most mobile joints in the human body due to its loose capsule and humeral head size. It is commonly dislocated due to its increased mobility. The upper extremity is connected to the axial skeleton via the sternoclavicular joint. The pectoral girdle consists of three joints.[3,4]

"Frozen shoulder" was first introduced by Codman in 1934, a painful shoulder condition with stiffness, difficulty sleeping, and reduced forward elevation and external rotation. This condition was formerly known as 'periarthritis' by Duplay in 1872, and later redefined as 'adhesive capsulitis' by Julius Naviaser in 1945. The disease is distinct from arthritis and preserves the joint.[5,6,7]

1.2 Frozen Shoulder

"Frozen shoulder" was first introduced by Codman in 1934, a painful shoulder condition with stiffness, difficulty sleeping, and reduced forward elevation and external rotation. This condition was formerly known as 'periarthritis' by Duplay in 1872, and later redefined as 'adhesive capsulitis' by Julius Naviaser in 1945. The disease is distinct from arthritis and preserves the joint.[5,6,7]

1.3 Etiology

Frozen shoulder (FS) is often associated with diabetes mellitus, affecting 10-36% of diabetics. Insulin-dependent diabetics are at the highest risk, and the primary cause is unknown, making them 2-4 times more likely to develop the condition.[8,9]

Frozen shoulder is common in thyroid disorders, Parkinson's disease, and cardiac and pulmonary diseases, often triggered by surgical procedures or shoulder injuries.[10,11]

1.4 Epidemiology:

Frozen Shoulder prevalence in general population is 2-5%, with increased rates in diabetics and thyroid gland pathologies, particularly hypothyroidism, up to 10-38%.[12,13]

Type 1 diabetes significantly increases the risk of developing FS, with a lifetime prevalence of 76%, particularly in patients over 45 years old.[14]

1.5 Pathophysiology:

FS is a condition characterized by synovial inflammation and capsular fibrosis, often resulting from cytokines like TNF-alpha and ILs. The cause is unclear, but potential triggers include chronic inflammation, tendon damage, Tendon Fiber rupture, or inflammatory mediators.[15,16,17] Figure 1 Summarizes the pathological event and pathogenesis of FS.[18]

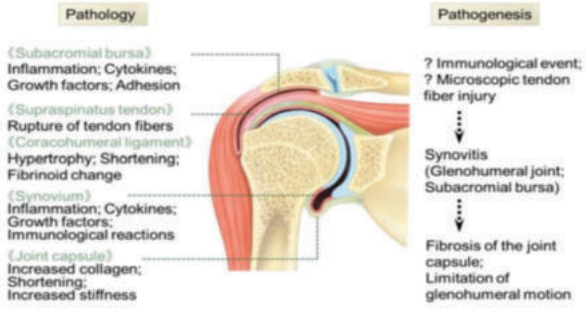

Fig. 1 Pathological event and Pathogenesis of FS

1.6 Stages:

Clinical presentation is typically in three overlapping phases: [19] The clinical presentation of a condition is divided into three phases: Stage 1, which is a gradual onset of pain with movement, Stage 2, which is persistent and intense pain, and Stage 3, which is pain only with movement, significant adhesions, and limited GH motions. Stage 4 of a joint condition, known as Thawing, involves minimal pain, no synovitis, but significant capsular restrictions from adhesions, with gradual motion improvement. The "freezing" stage of treatment for FS should focus on pain control, inflammation reduction, and patient education. Home self-exercise is effective, and daily programs should be given. Other treatments include anesthesia manipulation and surgical procedures.[5,20]

1.7 METHODOLOGY

STUDY DESIGN AND SETTING

Research Design: A COMPARATIVE STUDY

Population: Subjects with Frozen shoulder

Sample Design: Convenient sampling

Sample Size: The study was done on 40 patients. Subjects were divided in to 2 groups.

- Group 1=20 subjects (n=20)
- Group 2= 20 subjects (n=20)

Selection Criteria
Inclusive Criteria:
- Age between 30 to 60 year.
- Painful and limited passive shoulder joint mobility
- FS patients with and without type 2 diabetes mellitus
- More restricted lateral rotation relative to abduction and medial rotation.
- No clear sign (eg. painful arc, positive resistance testing, or loss of power)
- Illness time ranging between 2-15 months
- Stage of frozen shoulder: 1-3 stages

Exclusive Criteria:
- Any previous shoulder surgeries.
- Frozen shoulder Stage 4
- Glenohumeral or Acromioclavicular arthiritis.
- Any condition other than frozen shoulder
- Any Fracture around the shoulder complex
- Patient know to have uncontrolled diabetes mellitus or type 1, orthopedic condition or deformities around shoulder joint and any neuromuscular disorder.

OUTCOME MEASURES:
Shoulder Pain and Disability Index (SPADI) and Shoulder Range of Motion (ROM) Overview

SPADI:
- Self-administered questionnaire with 13 items assessing pain and functional activities.
- Assesses 5 questions on pain severity and 8 questions on difficulty with daily activities.
- High test-retest reliability of 0.92.
- Requires 5-10 minutes of time.

ROM:
- Measured using Universal Goniometer, a highly reliable tool conducted by the same therapist.
- Test-retest reliability of 0.94–0.98.

Patient Positioning and Movement Shoulder Flexibility:
- Patient is supine lying with shoulder and elbow 90º position.
- Axis: Greater tuberosity of the humerus.
- Movable arm placed over the midline of the lateral arm.
- Stable arm placed either perpendicular or parallel to the ground.

Shoulder Extension:
- Patient is prone lying with shoulder and elbow 90º position.
- Axis: One inch below the acromion process of the scapula.
- Movable arm placed over the midline of the anterior arm.
- Stable arm placed perpendicular or parallel to the clavicle.

Shoulder External & Internal Rotation:
- Patient is supine lying with shoulder and elbow 90º position.
- Axis: Olecranon process of the ulna.
- Movable arm placed over the midline of the posterior forearm.

Procedure:
- Approval from Institutional Ethical Committee (IEC) for study.
- Individuals selected based on inclusion/exclusion criteria.
- Informed consent form obtained from willing participants.
- Patients' anamnesis and demographic characteristics recorded.
- SPADI, VAS, and Shoulder joint ROM taken.
- Subjects assigned into two groups:

Group 1(n=20) Ultrasound with Conventional Physiotherapy and Group 2(n=20) Cryotherapy with Conventional Physiotherapy.

Outcome measures taken at baseline, after 2 weeks, and 4 weeks of treatment.

Statistical analysis using SPSS 25.0 software. P value less than 0.05 considered statistically significant.

RESULTS
The study used SPSS 25.0 software for Windows to compare the success of ultrasound and cryotherapy treatment for Frozen shoulder in 40 subjects, with 20 in each group meeting inclusion criteria.

Demographic Data
TABLE 1. Gender distribution

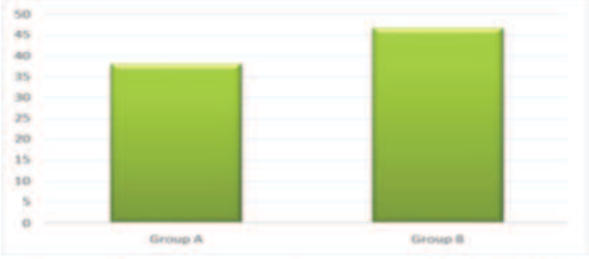
Graph 1: Graph of Gender distribution

Interpretation of Result:
1) Inter Group Analysis:
The table compares shoulder disability in Group A & B using independent T test. At baseline, no significant difference exists, but post-treatment p value of 0.03 suggests significant improvement between groups.

2) Intra Group Analysis:
The table compares shoulder disability in group A and B using paired t-test, showing significant differences in pain scores, indicating effective treatment for both groups.

Graph 2: Intragroup comparison of mean values of SPADI for Group A

Graph 3: Intragroup comparison of mean values of SPADI for Group B

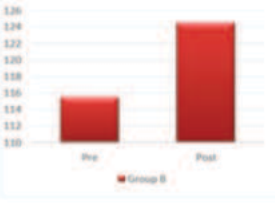


Graph 4: Intergroup comparison of mean values of SPADI

Interpretation of Results:
1) Inter group Analysis:
The study compared shoulder flexion ROM scores between Group A and B using an independent T test, finding no significant difference at baseline but significant improvement post-treatment.

2) Intra group analysis:
The table compares shoulder flexion ROM and pain scores in groups A and B, showing significant differences, indicating effective treatment for both groups.

Graph 5: Intragroup comparison of mean values of Flexion ROM for Group A



Graph 6: Intragroup comparison of mean values of Flexion ROM for Group B

Graph 7: Intergroup comparison of mean values of Flexion ROM

Interpretation of Results:

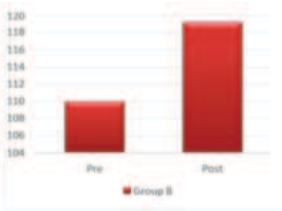
1) Inter group analysis:

The table compares shoulder Abduction ROM scores between Group A and B, showing no significant difference at baseline and a 0.03 post-treatment improvement.

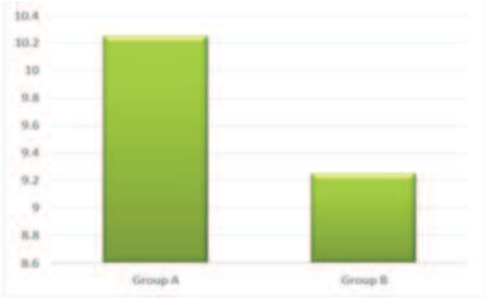
2) Intra group analysis:

The table compares shoulder abduction ROM and pain scores in groups A and B, showing significant differences, indicating effective treatment for both groups.

Graph 8: Intra group comparison of mean values of Abduction ROM for Group A



Graph 9: Intra group comparison of mean values of Abduction ROM for Group B



Graph 10: Intergroup comparison of mean values of Abduction ROM

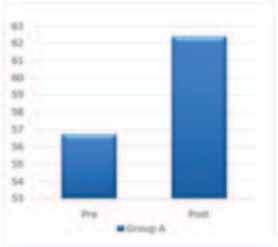
Interpretation of Result:

1) Inter group analysis:

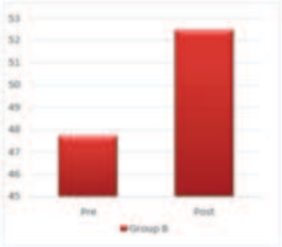
The table compares shoulder External ROM scores between Group A and B, showing no significant difference at baseline and a 0.04 post-treatment improvement.

2) Intra group analysis:

The table compares shoulder external ROM and pain scores in groups A and B, showing significant differences, indicating effective treatment for both groups.



Graph 11: Intragroup comparison of mean values of External rotation ROM for Group A



Graph 12: Intragroup comparison of mean values of External rotation ROM for Group B

Graph 13: Intergroup comparison of mean values of External rotation ROM

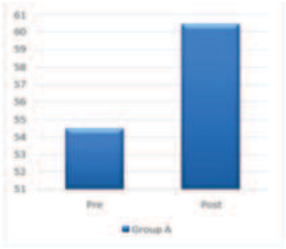
Interpretation of Result:

1) Inter group analysis:

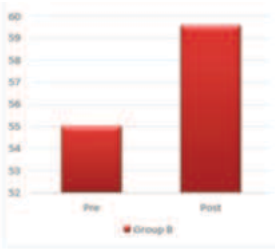
The table compares shoulder Internal ROM scores between Group A and B, showing no significant difference at baseline and a 0.03 post-treatment improvement, suggesting significant improvement between groups.

2) Intra group analysis:

The table compares shoulder Internal ROM and pain scores in group A and B, showing significant differences, indicating effective treatment for both groups.



Graph 14: Intragroup comparison of mean values of Internal Rotation ROM for Group A



Graph 15: Intragroup comparison of mean values of Internal Rotation ROM for Group B

Graph 16: Intergroup comparison of mean values of Internal Rotation ROM

DISCUSSION

The study investigates the effectiveness of ultrasound therapy and cryotherapy in reducing pain, range of motion, and disability in patients with frozen shoulder. Both groups received conventional physiotherapy for 4 weeks. Results showed significant differences in ROM improvement for both groups. However, the group receiving ultrasound therapy showed improvement in flexion extension, internal and external rotation, but not abduction and adduction ROM. The study highlights the self-limiting nature of frozen shoulder symptoms. [21,22] Ultrasound therapy reduces pain, increases blood flow, and aids tissue repair. It's used in rehabilitation for frozen shoulder patients. Connective tissue stretches promote elastic and plastic responses. Crystaltherapy controls pain by altering perception and controlling transmission to higher centers, making it useful for treating shoulder pain. [23] Cold exposure increases norepinephrine, providing calming effects. High-level mobilization improves frozen shoulder treatment in primary patients, while stretching programs relieve symptoms in stage 2 patients. [24,25] The study found that combining cryotherapy with conventional physiotherapy effectively reduced pain, functional disability scores, and improved range of motion in patients with frozen shoulder. Ultrasound therapy, produced using quartz, reduces pain,

increases blood flow, and aids in tissue repair. It's used in rehabilitation for frozen shoulder patients and promotes soft tissue healing. Connective tissue stretches promote elastic and plastic responses.

CONCLUSION

In conclusion the treatment program consisting of Ultrasound with Conventional Physiotherapy is more effective in frozen shoulder to reduce Pain, Functional disability and improve Shoulder range of motion.

Limitations:

✓ Small sample size

✓ No control group was included in the study

Future Recommendation:

✓ The study can be done on a larger number of populations.

✓ The study can be done with control group along with only conventional physiotherapy given in frozen shoulder

Dr. Mitrangikuvarba Vaghela M.P.T. (Cardiopulmonary Sciences), Assistant Professor, Venus Institute of Physiotherapy, Swarnim Startup and Innovation University, Gandhinagar.

Dr. Arvind Kumar M.P.T. (Musculoskeletal), Ph.D., Principal and Professor, Venus Institute of Physiotherapy, Swarnim Startup and Innovation University, Gandhinagar.

ABSTRACT

Background: Plantar fasciitis is a prevalent condition affecting 10% of the general population, particularly active working adults aged 25 to 65. This study aimed to assess the efficacy of intrinsic and extrinsic muscle-strengthening exercises in individuals with plantar fasciitis, considering age-specific responses. **Methods:** A randomized controlled trial was conducted involving 30 participants (18 females, 12 males) aged above 18, distributed into Group-A (intrinsic exercises) and Group-B (extrinsic exercises) for a 4-week intervention. Age distribution mirrored the typical age range of plantar fasciitis patients. **Results:** In participants aged above 40, intrinsic exercises demonstrated a statistically significant improvement in foot function and pain reduction compared to extrinsic exercises. No significant differences were observed in participants below 40. Overall, intrinsic exercises showed superiority in both age groups. **Conclusion:** This study highlights the importance of tailoring exercise interventions for plantar fasciitis based on age. Intrinsic exercises, particularly for individuals above 40, proved more effective in enhancing foot function and reducing pain. These findings underscore the need for individualized rehabilitation plans and warrant further research to explore long-term effects and refine treatment strategies.

KEYWORDS

Planter Fasciitis, Ultrasound, Intrinsic Exercise, Extrinsic Exercise, Foot Function Index, Numeric Pain Rating Scale.

INTRODUCTION

BACKGROUND

- Plantar fasciitis is a prevalent source of heel pain among adults. The discomfort typically results from collagen degeneration, often mischaracterized as "chronic inflammation," occurring at the point where the plantar fascia originates on the medial tubercle of the calcaneus. This degeneration shares similarities with the persistent necrosis seen in tendonosis. Tendonosis is characterized by the loss of collagen continuity, heightened levels of ground substance (the connective tissue matrix), increased vascularity, and the presence of fibroblasts, in contrast to the inflammatory cells typically associated with the acute inflammation seen in tendonitis.[1,2]
- This condition commonly results from overuse, primarily attributed to repetitive strain causing micro-tears in the plantar fascia. However, it can also manifest due to trauma or a combination of various factors. Predisposing factors include pes planus, pes cavus, restricted ankle dorsiflexion, and abnormal pronation or supination. Pes planus may increase strain at the plantar fascia's origin, while pes cavus can impose excessive strain on the heel due to inadequate foot eversion and shock absorption.
- Tightness in the gastrocnemius, soleus, and other posterior leg muscles is frequently observed in individuals with this condition, potentially altering normal walking biomechanics. While around 50% of patients may exhibit heel spurs, these spurs are not the root cause but are often present. Plantar fasciitis is commonly associated with runners and older adults, with additional risk factors including obesity, heel pad atrophy, aging, occupations involving prolonged standing, and weight-bearing activities. Although there is an association with certain seronegative spondyloarthropathies, approximately 85% of cases do not have identifiable systemic factors.[3,4]

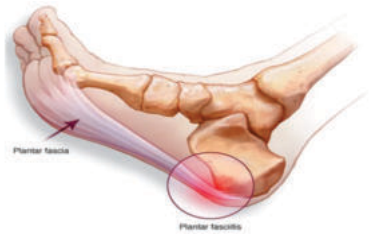

Figure 1: Diagram of Planter Fasciitis

Plantar fasciitis stands as the predominant cause of heel pain encountered in outpatient settings. While the precise incidence and prevalence across different age groups remain elusive, estimations suggest that approximately one million patient visits annually are attributed to plantar fasciitis. This condition contributes to around 10% of injuries related to running and necessitates professional medical care for 11% to 15% of all foot symptoms. It is believed to afflict approximately 10% of the general population, with the majority (83%) of affected individuals falling within the active working age group of 25 to 65 years. Bilateral presentation occurs in about a third of cases. Some literature indicates even higher prevalence rates, reaching up to 22%, particularly within populations of runners.[5,6]

- Management of plantar fasciitis involves a phased approach, with initial emphasis on conservative measures. Relative rest from the causative activity, tailored to the pain level, is recommended. Post-activity application of ice and the use of oral or topical NSAIDs can help alleviate pain.
- Patients are encouraged to modify work-related activities, and a night splint may be beneficial for those with persistent pain. Surgery is considered the final option and may involve fasciotomy through an open or endoscopic approach. However, it's important to note that surgical release does not guarantee a successful outcome. Potential complications include nerve injury, plantar fascia rupture, and flattening of the longitudinal arch. Careful consideration of the risks and benefits is imperative when contemplating surgical intervention for plantar fasciitis.[7,8,9]

Methodology

Study Place

OPD of Venus Institute of Physiotherapy, Bhoyan Rathod, Gandhinagar and Hi-Tech Multispecialty Hospital, Gandhinagar

Study Duration

4 weeks

Study Design

- Exprimental Study

Inclusion Criteria

1. Patients willing to participate
2. Both male and female subjects
3. Age between 25-60 years
4. Diagnosed with Plantar Fasciitis

Exclusion Criteria

1. Subjects with neurological disorders affecting the foot
2. Subjects with any previous heel or foot surgeries
3. Subjects with Peripheral Vascular disease
4. Subjects with pain at great toe and not around heel pain.

MATERIALS REQUIRED

Intervention

Intervention Group

1. Group A (Intrinsic Foot Muscle Strengthening + Ultrasound)
Participants will engage in a structured program including exercises such as toe curls, big toe extension *(Figure : 10)*, marble pick-up, towel gathering curls*(Figure : 9)*, toe spread, and tennis ball exercises. Each exercise is designed to target intrinsic foot muscles.
The intervention will include ultrasound therapy in addition to the exercise regimen.

2. Group B (Extrinsic Foot Muscle Strengthening + Ultrasound)
Participants in this group will follow exercises focused on extrinsic foot muscle strengthening, including calf muscle stretch*(Figure :5)*, resisted plantar flexion*(Figure : 6)*, foot supination-sitting, foot adduction, hip external rotation-side lying, and hip abduction.

Similar to Group A, participants in this group will receive ultrasound therapy *(Figure : 12)* as part of the intervention.

Exercise Protocol

Each exercise session will consist of 10–20 repetitions.
Participants will perform the exercises three times per day.

Figure 2 : Calf Muscle Stretching

Figure 3 : Resisted Plantar Flexion

Figure 4: Resisted Inversion Of Foot

Figure 5 : Abduction Of Foot Finger

Figure 6 : Towel Gathering (Curls) Exercise

Figure 7 : Big Toe Extension Exercise

Figure 8 : Big Toe Extension Exercise

Figure 9 : Apply Ultrasound Therapy

Outcome Measures

1. Foot Function Index (FFI) [13]

The FFI is a self-administered index comprising 23 items categorized into three subscales: pain, disability, and activity limitation. Participants rate each item on a scale from 0 (no pain or difficulty) to 10 (worst pain imaginable or requiring assistance) based on their foot condition over the past week. The pain subcategory consists of 9 items, disability subcategory consists of 9 items, and the activity limitation subcategory consists of 5 items. The FFI demonstrates good test-retest reliability for both total and subscale scores (ranging from 0.87 to 0.69) and high internal consistency (ranging from 0.96 to 0.73)

2. Numeric Pain Rating Scale (NPRS) [14]

The NPRS is a unidimensional measure of pain intensity in adults, comparable to the visual analogue scale (VAS). Administered verbally or graphically for self-completion, it employs a 10-point numeric scale ranging from 0 (no pain) to 10 (worst pain imaginable). Participants indicate the numeric value on the segmented scale that best describes their pain intensity. Higher scores signify greater pain intensity. The NPRS exhibits high test-retest reliability in literate and illiterate patients with rheumatoid arthritis (r=0.96 and 0.95, respectively). Additionally, for construct validity, the NPRS correlates highly with the VAS in patients with chronic pain conditions (ranging from 0.86 to 0.95). The scale provides a reliable and valid measure of pain intensity.

Data Collection

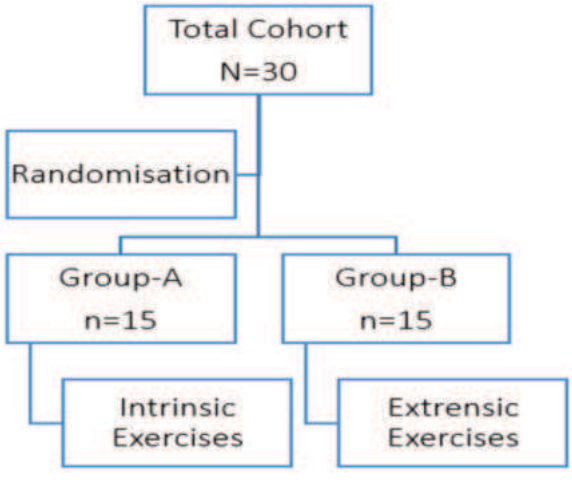
Data of all the patients were collected a data collection form.

Statistical Analysis

Descriptive statistics will be employed for demographic data, and inferential statistics will be used to compare changes in FFI and NPRS scores between the two intervention groups. The significance level will be set at $p < 0.05$.

RESULTS

This study involved a total of 30 patients diagnosed with plantar fasciitis were randomly allocated into two groups, Group-A and Group-B, each prescribed a distinct type of exercise regimen aimed at muscle strengthening—Intrinsic and Extrinsic, respectively—for a duration of 4 weeks. Among the total population, 18 patients were female and 12 were male, spanning ages from 18 to 59 years.



Baseline Characters

Table 1: Age group of Study Population

Age Group	Group-A		Group-B	
	Number	Percentage	Number	Percentage
20-29 Years	2	13.33%	2	13.33%
30-39 Years	6	40.00%	7	46.67%
40-49 Years	4	26.67%	6	40.00%
50-59 Years	3	20.00%	0	0.00%

The participant distribution across different age groups in Groups A and B, engaged in intrinsic and extrinsic exercises, respectively, reveals interesting insights. In the 20-29 age group, both groups have an equal representation of 13.33%. In the 30-39 age range, Group A constitutes 40.00% of participants, slightly less than the 46.67% in Group B. The 40-49 age group sees 26.67% in Group A compared to 40.00% in Group B. Notably, in the 50-59 age group, Group A has 20.00% representation, while Group B has none. These demographic variations underscore the importance of considering age differences in the interpretation of intervention outcomes, as the efficacy of intrinsic and extrinsic exercises may vary across different age cohorts.

Comparative Analysis of Group-A and Group-B

Table 2: Post-Baseline Full Set Descriptive Data (Group-A vs Group-B)

Post-Baseline Full Set Descriptive Data (Group-A vs Group-B)								
	Foot Function Index (FFI)				Numeric Pain Rating Scale (NPRS)			
	Group-A	Group-B	CFB	%CFB	Group-A	Group-B	CFB	%CFB
N	15.00	15.00	15.00	15.00	15.00	15.00	15.00	15.00
Minimum	90.00	120.00	11.00	10.09	3.00	4.00	0.00	0.00
Maximum	110.00	138.00	38.00	40.00	5.00	6.00	3.00	100.00
Mean	99.07	126.90	27.87	28.57	3.67	4.73	1.07	32.78
SD	6.46	5.66	7.90	9.09	0.62	0.80	1.03	33.85
SEM	1.67	1.46	2.04	2.04	0.16	0.21	0.27	8.74
P-value	<0.0001				<0.05			
Note: CFB- Change From Baseline/ %CFB- Percentage Change From Baseline								

In the post-baseline full set analysis comparing Group-A (Intrinsic Exercises) to Group-B (Extrinsic Exercises), significant differences are observed in both the Foot Function Index (FFI) and Numeric Pain Rating Scale (NPRS). In terms of FFI, Group-A exhibited a mean score of 99.07, significantly lower than Group-B's mean of 126.90, resulting in a substantial change from baseline (CFB) of 27.87 and a percentage change (%CFB) of 28.57%. This indicates that participants in Group-A experienced a more significant improvement in foot function compared to Group-B. In the NPRS, Group-A also showed a lower mean pain score of 3.67 compared to Group-B's 4.73, resulting in a CFB of 1.07 and a %CFB of 32.78%. While both groups experienced improvements in pain, Group-A demonstrated a larger reduction. The statistical significance for both FFI and NPRS differences is indicated by p-values of <0.0001 and <0.05, respectively. These results suggest that intrinsic exercises (Group-A) may be more effective in improving foot function and reducing pain compared to extrinsic exercises (Group-B).

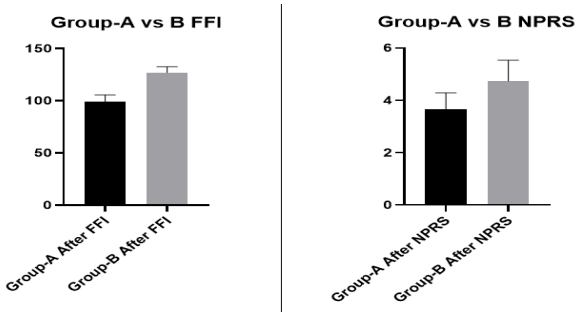

Figure 12: Post-Baseline Full Set Descriptive Data (Group-A vs Group-B)

DISCUSSION

Comparison with Previous Studies

The present study significantly contributes to our understanding of the relevance of intrinsic and extrinsic muscle strengthening in individuals diagnosed with plantar fasciitis [10]. The research cohort comprised a total of 30 participants, all above the age of 18, which aligns with the demographic characteristics of plantar fasciitis patients, a condition that notably affects around 10% of the general population. Within this demographic, a substantial majority consists of active working adults aged between 25 and 65 years, with a peak incidence occurring in the 40 to 60 years age range and a higher prevalence in women compared to men. Remarkably, a similar age distribution was observed in the present study, with the majority falling between the ages of 30 and 49[11].

Building on existing literature, a prior study involving 36 individuals focused on comparing the effectiveness of exercises targeting extrinsic and intrinsic foot muscles in enhancing the medial longitudinal arch, particularly in adolescents with flat feet. In this investigation, Group 1 engaged in intrinsic muscle exercises, while Group 2 performed extrinsic muscle exercises. The outcomes of this study resonate with the findings of the present research, where the group undertaking intrinsic exercises exhibited a statistically significant improvement compared to the group assigned extrinsic exercises for managing plantar fasciitis. These parallel results further support the notion that intrinsic exercises may be more effective than their extrinsic counterparts in addressing the complexities of plantar fasciitis. The implications of these findings are particularly relevant in informing targeted intervention strategies for individuals grappling with this prevalent foot condition [12].

CONCLUSION

In conclusion, the comprehensive analysis of participants undergoing intrinsic (Group-A) and extrinsic (Group-B) exercises, particularly when stratified by age, reveals noteworthy findings. Both intrinsic and extrinsic interventions resulted in statistically significant improvements in foot function and pain levels, with Group-A consistently demonstrating a more pronounced effect across various parameters. When examining age-specific data, the distribution of participants varies, with Group-B having a higher representation in the 30-39 age group, while Group-A displays a more balanced distribution across the 30-39, 40-49, and 50-59 age groups. Notably, Group-A consistently outperforms Group-B in improving foot function and reducing pain, especially among participants above 40 years. These results underscore the potential efficacy of intrinsic exercises, particularly for individuals above 40 years old, in enhancing foot function and alleviating pain. However, the diverse age distribution emphasizes the need for careful consideration of age-related factors in interpreting and applying these intervention outcomes. Further research and exploration of age-specific responses to intrinsic and extrinsic exercises would contribute to a more nuanced understanding of their effectiveness in improving foot health.

Limitations

- Despite the insightful findings, it is important to acknowledge several limitations in this study. Firstly, the relatively small sample size within each age group may limit the generalizability of the results to broader populations.
- The unequal distribution of participants across age groups could introduce potential bias, especially in the 50-59 age range where Group-B lacks representation. Additionally, the study's duration and follow-up period are crucial factors to consider, as they may

impact the long-term sustainability of the observed improvements. The lack of a control group or alternative intervention group further limits the ability to attribute the observed changes specifically to intrinsic or extrinsic exercises.

Dr. Kosha Gor M.P.T. (Cardiopulmonary Sciences), Assistant Professor, Venus Institute of Physiotherapy, Swarrnim Startup and Innovation University, Gandhinagar.

Dr. Arvind Kumar (Musculoskeletal), Ph.D., Principal and Professor, Venus Institute of Physiotherapy, Swarrnim Startup and Innovation University, Gandhinagar.

ABSTRACT

Background: This study evaluates Matrix Rhythm Therapy (MRT) alongside traditional massage to assess their impact on peripheral circulation. While massage therapy is widely used to enhance blood flow and tissue healing, the effectiveness of MRT in this regard remains unclear. By comparing these modalities, the study aims to provide clarity on their therapeutic benefits, potentially guiding treatment choices in clinical practice. **Methods:** A systematic review following PRISMA guidelines will compare Matrix Rhythm Therapy (MRT) and traditional massage effects on peripheral circulation. Studies will be assessed using PEDro score and CEBM's Level of Evidence scale. Data synthesis, including potential meta-analysis, aims to inform clinical decisions on therapeutic interventions for peripheral circulation. **Results:** Matrix Rhythm Therapy (MRT) demonstrated significant efficacy across various conditions, including pain reduction, enhanced functional activities, and improved quality of life. Studies highlighted its effectiveness in addressing chronic low back pain, peripheral circulation, diabetic peripheral neuropathy, and hand pain in excessive smartphone users. While some comparisons favored alternative treatments like stretching exercises for specific conditions, overall, MRT emerged as a promising therapeutic modality with broad applicability in healthcare settings. **Conclusion:** Matrix Rhythm Therapy (MRT) shows significant promise in addressing a wide range of conditions, offering pain relief, improving functional outcomes, and enhancing quality of life.

Musculoskeletal disorder, Matrix Rhythm Therapy, Systematic review, pain reduction.

INTRODUCTION

Background

Patients experiencing musculoskeletal issues often activate anaerobic metabolism due to reduced blood circulation and microcirculation. The compromised regulation of microcirculation in muscles is associated with the generation of nociceptive pain. Circulation plays a crucial role in tissue healing, with enhanced blood circulation facilitating the delivery of proteins, nutrients, and oxygen, consequently promoting improved tissue healing Recent studies have focused on comparing the efficacy of various conservative treatment approaches on bloodstream dynamics.[1,2,3]

Massage, a widely adopted physiotherapeutic technique, is employed to enhance blood circulation. Defined as soft tissue manipulation for therapeutic purposes, massage therapy is administered by trained therapists. While some sports medicine practitioners advocate for the benefits of massage, including increased blood circulation, reduced muscle tension, and enhanced neural excitability, conflicting opinions exist in the literature. Some authors posit that massage positively impacts blood circulation, while others assert that it has no effect.[4,5,6,7]

Various massage techniques, such as effleurage, petrissage, tapotement, friction, and vibration, are employed.[8] Vibration massage, specifically, aims to enhance circulation and facilitate muscle relaxation. Mechanical devices allow for the safe and localized application of vibration treatment. Adjustable speed and frequency in vibration devices cater to diverse indications, with some used in beauty salons for fat burning, hand-held devices for musculoskeletal pain, and whole-body vibration devices for exercise.[9]

While hand-held devices exhibit a strong placebo effect, low-magnitude mechanical vibration is believed to boost local blood flow. Matrix Rhythm Therapy (MRT) represents a novel form of vibromassage utilized in various settings, including special education and rehabilitation centers, sports clubs, and neurologic, orthopedic, physical therapy, and rehabilitation centers.[10,11,12]

Limited studies and clinical experiences suggest the effectiveness of MRT, yet the evidence level is considered low. To elucidate the therapeutic efficacy of MRT, it is imperative to explore its impact on peripheral circulation. [13]As MRT is a novel vibromassage method, no studies have yet assessed its influence on circulation, and existing literature presents conflicting results regarding the effect of massage on peripheral circulation[14]. Notably, MRT requires a device for application, distinguishing it from traditional massage methods. If the findings of the current study reveal comparable increases in peripheral blood circulation between massage and MRT, it may suggest a preference for traditional massage over MRT. This approach deviates from previous studies that compared MRT to a placebo, as therapists have shown a preference for manual hand massage over handheld devices.[15]

MRT represents a groundbreaking approach in cellular therapy, utilizing rhythmic oscillations within the 8-12 Hz range to rejuvenate cellular energy metabolism and rebalance physiological functions.[16] By intricately stimulating cells and synchronizing tissue, it promotes heightened circulation, increased oxygenation, and enhanced ATP synthesis, fostering deep-seated muscle and tissue relaxation. This advanced technique orchestrates cellular regeneration and healing through precise micro-process modulation, ensuring enduring relaxation and optimized tissue metabolism, thereby offering comprehensive therapeutic benefits at the cellular level.

METHODOLOGY

Study Duration

6 - 8 Month.

Study Design

This will be an Evidence Based Study and will conduct according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analysis) guidelines.

Figure 7: Flowchart for PRISMA

Figure 8 : Flowchart for Review Article

Inclusion Criteria

1. Articles published during last 10 years. (2012- May 2022)
2. Articles having study design as Systematic reviews, Meta-analysis and Randomized controlled trial.
3. Articles published in English.
4. Articles in which studies done on Human.

Exclusion Criteria

1. Articles having study design as case control or cohort.
2. Studies done on animals.
3. Studies design case reports.

Data Analysis

- ❖ Physiotherapy Evidence Database (PEDro)
  - ➢ It assesses methodological quality and consists of a checklist of 11criteria, 10 of which are scored.
  - ➢ For each criterion the study met, 1 point was awarded.
  - ➢ The points were presented as a score out of 10.
  - ➢ PEDro scores of 6 to 10 were considered high quality, of 4 to 5 were considered moderate quality, and of 0 to 3 were considered low quality

- ❖ Centre for Evidence-Based Medicine's (CEBM's) Levels of Evidence scale:
  - ➢ It assesses quality based on study design, which categorize the studies in a scale ranging from 1 to 5 with further subdivision for each.

Figure 09: Hierarchy of Evidence

RESULTS

The review article synthesized findings from multiple studies on Matrix Rhythm Therapy (MRT), highlighting its diverse applications and therapeutic efficacy across various pathological conditions. Dr. Sonali Shrivastava's review emphasized MRT's ability to induce oscillations within the physiological frequency range, thereby restoring disrupted rhythms at the cellular level and enhancing oxygen supply, leading to tissue relaxation and pain reduction.

Dr. med. Ulrich G. Randoll underscored MRT's successful application in rehabilitation, sports medicine, and veterinary medicine, noting its role in preventive measures and rehabilitation efforts, as well as its effectiveness in addressing various types of pain and degenerative diseases.

Nadir et al.'s study focused on chronic low back pain and found that MRT, when integrated into a comprehensive physiotherapy program, led to significant improvements in pain, disability, and quality of life compared to the control group.

Taspinar et al.'s research demonstrated MRT's ability to enhance peripheral blood circulation, particularly in young women, compared to massage therapy.

Figure 10: PEDro Score

- We have taken PEDro score for our study for MRT and concluded that approximately 76.8% of study from 2012 to 2023 were shows that MRT is more beneficial than conventional therapy.
- Evidence shows that MRT is more effective compare to conventional therapy such as Non-healing wounds, Arthritis, Osteoporosis, Spasticity, Ligaments tear, Tendinitis and Bone degeneration.

DISCUSSION

1. The study by F Taspinar et al. in the year (2013), "engages with the outcomes derived from a randomized, double-blind, controlled trial, investigating and contrasting the effects of matrix rhythm therapy and massage on peripheral blood circulation" in a cohort of fifteen healthy women aged 19–23 years. The interventions, administered as single 30-minute sessions on the left lower extremity with a minimum one-week interval, were executed by the same physiotherapist.[17]
2. Derya et al. in Dec, (2016), investigates "the comparative short-term effectiveness of Matrix Rhythm Therapy and stretching exercises in individuals with frozen shoulder." Forty-three patients, with an average age of 52.6 years, were randomly assigned to either the Matrix Rhythm Therapy or stretching exercises group, both undergoing a 6-week treatment accompanied by a similar home exercise program. Various outcome measures, including range of motion, Constant score, Disabilities of the Arm, Shoulder, and Hand score, Short Form Health Survey-36, and Global Rating of Change score, were assessed at different intervals.[18]
3. T. Palekar in the year (2019), proposes "Matrix Rhythm Therapy (MRT), an emerging electrotherapy modality, demonstrating effectiveness in managing pain and restoring cellular frequency" within the 8-12Hz range. This study focuses on evaluating the impact of MRT on hand pain in excessive smartphone users.[19]
4. Dr. Sonali Shrivastava's review (2019) highlights that "Matrix Rhythm Therapy induces oscillations within the physiological frequency range of 8-1 HZ. This frequency synchronization with the body aims to restore disrupted rhythms at the cellular level." The therapy demonstrates a positive impact on oxygen supply by enhancing microcirculation, consequently boosting energy production. Notably, immediate effects manifest as the relaxation of tissues, muscles, and fascia, with this relaxation enduring for an extended period.[20]
5. Dr. med. Ulrich G. Randoll (2019) underscores "the successful application of Matrix-Rhythm-Therapy, particularly in the realms of rehabilitation, high-performance sports, and veterinary medicine." The therapy has undergone rigorous testing and validation over the past decade, originating from the University of Erlangen. Its application is particularly noteworthy for both preventive measures, involving the prophylactic avoidance of disease development, and rehabilitation efforts, aimed at preventing and mitigating damages resulting from strain, trauma, accidents, and surgeries. Sports medicine, in particular, recognizes the therapy's merit in significantly expediting the regeneration time between training periods, especially after instances of hyper-distension, injuries, hardening, tendonitis, and other impairments. This acceleration allows for the intensification of training cycles and facilitates a swifter return to peak performance following injuries.[21]
6. In the experimental study published in (2019), by Naik et al., aimed to assess "the effectiveness of a single session of Matrix Rhythm Therapy (MaRhyThe) in individuals diagnosed with Plantar Fasciitis (PF), a prevalent musculoskeletal condition often associated with limitations in daily activities." Seventeen subjects within the age range of 18-35 years participated in the study, receiving one session of MaRhyThe targeting the calf and plantar aspect of the foot, lasting 45–60 minutes. The pre and post-intervention outcomes were measured using a pressure algometer (PPA) for pain assessment, a non-contact infrared thermometer (IRT) for local skin temperature, and the Foot and Ankle Ability Measures (FAAM) scale for evaluating functional activities.[22]
7. Nadir et al. (2021) assess "the impact of Matrix Rhythm Therapy (MRT) on chronic low back pain, specifically concentrating on parameters such as pain intensity, levels of disability, and overall quality of life." A cohort of thirty-two participants underwent random assignment into either the intervention or control group. Both groups underwent a comprehensive ten-session combined physiotherapy program, with the intervention group receiving an additional six sessions of MRT.[23]
8. Anand et al. (2022) proposes diabetic peripheral neuropathy (DPN), a prevalent complication of diabetes, adversely impacting the quality of life by affecting balance and gait, leading to an increased risk of falls. Matrix Rhythm Therapy (MaRhyThe) is an innovative approach utilized in various musculoskeletal and neurological conditions to manage pain and enhance functionality.[24]
9. Taj Afreen Sheikh (Oct, 2022) underscores "the Matrix Rhythm Therapy (MRT) approach in the fundamental understanding that cellular processes, whether preventive, therapeutic, regenerative or degenerative, operate predominantly within the cellular environment." Crucial to these processes is the muscle pulsation frequency, identified at 8-12 Hertz, with deviations outside this range linked to ailments such as aches, muscle tension and broader health concerns.[25]
10. The study by Munjewar et al. in the year (2022), examines "the effectiveness of Matrix Rhythm Therapy (MRT) as a novel development in physiotherapy." MRT serves as a non-invasive method for relieving pain, enhancing microcirculation, promoting relaxation, and increasing blood oxygenation. Operated within a frequency range of 8-12 Hz, MRT stimulates the body's self-healing powers, employing vibromassage through a resonating head to release muscular tension.[26]

CONCLUSION

- MRT's non-invasive nature makes it a valuable therapeutic option with broad applications in musculoskeletal health, presenting opportunities for improved well-being.Matrix Rhythm Therapy (MRT) exhibits promising efficacy in managing various musculoskeletal disorders. Studies highlight its ability to induce physiological oscillations, restore disrupted cellular rhythms and enhance microcirculation, contributing to improved oxygen supply. Applications in rehabilitation, sports, and diverse musculoskeletal conditions demonstrate positive outcomes, including pain relief and functional improvements.
- Evidence shows that MRT is more effective compare to conventional therapy such as Non-healing wounds, Arthritis, Osteoporosis, Spasticity, Ligaments tear, Tendinitis and Bone degeneration.

Limitations

- Limitations of this study include potential constraints arising from the availability and quality of existing scientific data on Matrix Rhythm Therapy (MRT) in musculoskeletal disorders, as well as the heterogeneity of included studies in terms of design, participant characteristics, and outcome measures.
- The study's scope may be limited to the disorders covered in the available literature, potentially overlooking other musculoskeletal conditions.
- It includes other factors like patient comorbidities, and variations in practitioner expertise could act as confounders, influence on the effects of MRT.

ABSTRACT

Background: Increasing rate of musculoskeletal dysfunction due to backpack is matter of concern. Prevalence varies regionally as it depends on many variables. Heavy backpack is one of the important underlying causes. Adolescent spine is in the critical stage of development in the age group of 07-15 years. This study was carried out to decide regional cutoffs of heavy relative weights of backpacks in male and female children. **Methodology:** For this survey, a sample of students from Ahmedabad's New Education School was used. Every student who satisfies the inclusion requirements is welcome to take part in the research. Through the semi-structured questionnaire, the data were collected. The length of the trip, the type of vehicle, and the distance traveled, the posture taken while traveling, and the level of pain were all mentioned in the questionnaires. Every outcome that was measured was obtained at baseline. NDI, SPADI & NPRS. **Result:** In present study we found that from total 60 students 34 students shows highest upper cross syndrome and students with upper cross syndrome were having mean pain score of NPRS 4.52±2.18 and disability as per NDI & SPADI as 50.79 &51.28.overall prevalence of musculoskeletal dysfunction is 55.66%. **Conclusions:** Majority of the School going students are exposed to the risk of adopting poor postures which can lead to musculoskeletal dysfunction. The results of this study suggesting the importance of postural awareness among school going students.

KEYWORDS

Upper Cross Syndrome, Neck Disability Index, Shoulder Pain And Disability Index, Musculoskeletal Disorder.

INTRODUCTION

The World Health Organization states that musculoskeletal disorders—which are primarily linked to Students and cause headaches and chronic neck pain, which are the most common complaints worldwide—are one of the main causes of disability among persons between the ages of 20 and 50. It is acknowledged that disabilities result in severe medical conditions as well as socioeconomic problems; the loss of GDP from absenteeism and low productivity has been estimated to be as high as 2%. Numerous studies found that almost 90% of rehabilitation specialists suffer from musculoskeletal conditions, with 50% of physiotherapists reporting a tendency to develop Work-Related Musculoskeletal Disorders (WMSDs) throughout the course of their five-year careers. This might be because of the nature of their employment, which entails extended periods of sitting, standing, and lifting as well as the use of manual techniques in academic or clinical settings. The high prevalence (66%) in lower limb, particularly in the low back and neck region (61%), may be related to their line of work, which involves extended standing, sitting, lifting, or using manual procedures in clinical or academic settings[1].

Upper Cross Syndrome (UCS), also known as cervical cross syndrome, is defined as a pattern of alternative tightness and weakness of the neck's Serratus Anterior, Pectorals Major, Levator Scapulae, Rhomboids, and Deep Flexors, especially the Scalene muscles. This pattern is thought to be caused by improper body ergonomics, poor work habits, or low self-esteem. Rather than only affecting one muscle, Upper Cross Syndrome is typified by an imbalance in the activation and inhibition of skeletal muscles. Muscular insufficiencies arise from any inability of the tonic and phasic muscles to activate coherently. Thus, the most common symptom of UCS is neck and upper back pain, which is typically diagnosed as Cervicogenic Vertigo with shoulder pathology in a number of patients. This bad posture causes hypnosis, forward head posture, loss of cervical lordosis, and some postural patterning of the front shoulders[2]. The upper portion of the body experiences general pattern changes as a result of these anomalies.

This pattern alteration results in strain to the shoulder blade and muscle attachments of the shoulder, giving the impression of a rounded shoulder. While extended use of this position does not always result in pain, people frequently report upper back and neck pain various factors including musculoskeletal structures, body changes regarding age, cultural customs, motor performances and occupation affects the head position of the person while sitting. The patients may develop forward head posture because of this poor sitting posture along with rounded shoulder which occurs due to the increased hypnosis in thoracic region[2].

When seated, the forward head position causes the upper cervical region to extend, the lower cervical region to flex, and the shoulders to round. This reduces the length of muscle fibers on average, which causes extensor torque around the upper cervical region's joints. This aberrant state leads to a number of musculoskeletal problems, such as increased internal rotation, anterior tilt, and decreased scapular upward rotation. It makes it even harder to keep an erect posture[3].

Upper crossed syndrome is what occurs when rounded shoulders and forward head posture occur at the same time. Students enrolled in college typically adopt a range of positions throughout class and exams. Therefore, it is necessary to determine if these aberrant postures are learned or inherited. It is also necessary to ascertain whether any of the elements of a muscle imbalance are present at this point and to identify the reason for the change in upper back posture[4].

Work related segments, for instance, postponed static muscle load and dismal work might be a hotspot for hurt headway. Physical activity and masculinity are two further characteristics that may be linked to musculoskeletal pain. Issues with posture, vision, or mental health might also bring about musculoskeletal issue, particularly affecting the cervical and thoracic locale. As demonstrated by Janda's farsighted clarification of muscle ponderousness, significant cervical flexors and lower scapular stabilizers get the opportunity to be subdued in a foreseen illustration (upper crossed disorder)[5].

Proximal or shoulder support crossed confusion is another term used to describe Upper-Crossed Syndrome (UCS). Coziness of the levator scapula and upper trapezius on the dorsal side of the UCS intersects with coziness of the genuine and minor pectoralis muscles. Significant cervical flexor weakness ventrally crosses with insufficient middle and lower trapezius; this unevenness causes joint fractures, especially at the glen humeral joint, atlantooccipital joint, C4-5 area, cervicothoracic joint, and T4-T5[6].

Janda observed a discrepancy between these concentrated areas of discomfort inside the spine and the transitional zones where the morphology of the adjoining vertebrae changes. This study aimed to identify the key factors that contribute to students' upper-crossed issues changing. Certain particular postural motions are observed in upper cross problem, such as forward head carriage, thoracic hypnosis and extended cervical lordosis, elevated and developed shoulders, and

scapular winging and discontent. Due to Serratus front weakness, which causes the scapulae to grasp, turn, and wing, these postural movements decrease glen humeral quality by allowing the glenoid fosse to become more vertical[7].

Purpose Of the study to find Prevalence Musculoskeletal Dysfunction Due to backpacks in students with upper cross syndrome.

METHODOLOGY

Study Design: Observational study

Duration of Study: 6 months to 1 year.

Sample Size: 60 students (both male and female)

Selection Criteria

Inclusion criteria:

- Age of students (07 to 15) Years.
- Students suffering from Upper Cross Syndrome.
- Subject willing participate.

Exclusion criteria:

- Developmental disorders,
- Neurological disorders,
- Surgical interventions and previous spinal fractures

For this survey, a sample of students from Ahmedabad's New Education School was used.

Every student who satisfies the inclusion requirements is welcome to take part in the research. Through the semi-structured questionnaire, the data were collected. The student's posture, the weight of the bag, and the level of pain were all noted. Every outcome that was measured was obtained at baseline.

- SPADI
- NDI
- NPRS

RESULT:

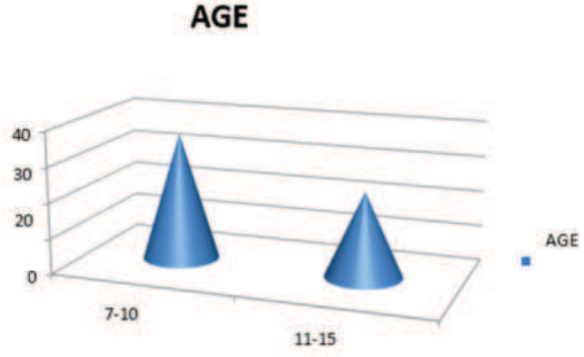
Descriptive analysis for Windows was used for all statistical studies. The mean and standard deviations were obtained using descriptive analysis. Demographic Data

AGE:

The research was performed on 60 participants between the age of 7-15 years. There were 36 participants between the ages of 7 to 10, 24 participants between the age 11 to 15.

Table1: Age Distribution

Age Distribution	
7-10 years	11-15 years
36	24

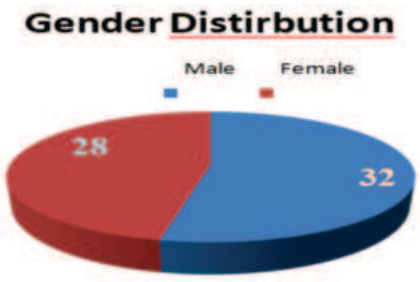


Graph 1: Age Distribution

Gender Distribution:

The research was performed on 60 students with upper cross syndrome, in which 32 Male & 28 Female.

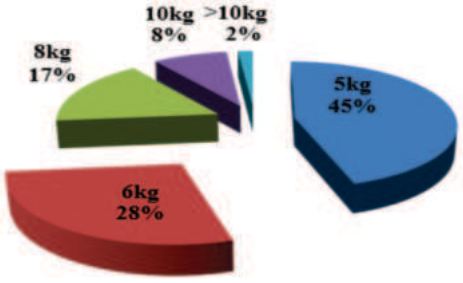
Gender Distribution	
Male	Female
32	28



Weight of bag:

Table 3: Weight of Bag.

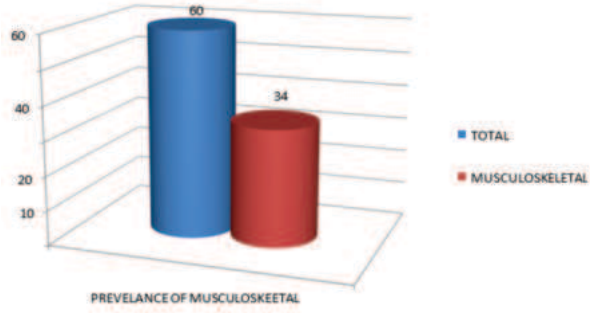
Mode	Number	Percentage
5Kg	27	45%
6Kg	17	28%
8Kg	10	17%
10Kg	5	8%
>10Kg	1	2%



Mean value of Outcome measures

Table 2: Mean value of Outcome measures

	Mean + SD
Age	9.6+4.46 years
NPRS	4.51+2.18
NDI	50.79 + 19.98
SPADI	51.28 ± 17.84



Graph 2: Prevelence Of Musculoskeletal Dysfunction

DISCUSSION:

The goal of the current study was to determine how common upper crossed syndrome is among school-age children. We had classified two diagonal muscles—the neck flexors and scapular retractors being weak, or the neck extensors and pectoralis minor being tight—as weak or tight for the purpose of the prevalence analysis. The cervical spine and shoulder girdle biomechanics may change as a result of a muscle imbalance in any one of the two diagonal muscles.

Present study conducted on 60 school going students with age of 07 to 15 years among that 34 students showed positive impact of musculoskeletal dysfunction with mean pain score 4.51±2.18, NDI mean & sd 50.79 ± 19.98 & SPADI 51.28 ± 17.84 Overall prevalence of musculoskeletal dysfunction is 55.66%.

A study on Neck, Shoulder, and Back Pain Associated with Carrying Heavy Backpacks among Spirit School Children in Lahore was undertaken by Rubina Khan et al. They came to the conclusion that children's back, shoulder, and neck pain was significantly correlated

with the weight of their school bags. Less symptoms were displayed by students who carried their bags over both shoulders and used twin straps[8].

Mayank Mohan et al done An experimental study on the Effect of backpack loading on cervical and shoulder posture in Indian school children and examining the effects of backpack loading on posture[9].

Sheir-Neiss, et al conducted study on The Association of Backpack Use and Back Pain in Adolescents and concluded that The use of backpacks during the school day and backpack weights are independently associated with back pain[10].

Mubeen et al done investigate on primary indicators of upper cross syndrome, which include forward head position, rounded shoulders, and neck stiffness and pain. The results of the study showed that 36.07% of students had neck pain when studying or using any kind of electronic device. Additionally, it was shown that 76.39% of students believed that when using a device or studying, they needed to support their head and upper back. However, 23.60% of the pupils felt otherwise.In their investigation on the prevalence of upper cross syndrome results showed that 52.1% of pupils found it challenging and 48.7% of students felt neck pain[11].

Clare Haselgrove et al had done study on Perceived school bag load, duration of carriage, and method of transport to school are associated with spinal pain in adolescents: an observational study and concluded that Neck pain is as common as back pain amongst adolescents. Perceived school bag load, duration of carriage and method of transport to school are associated with back and neck pain. Physical activity in the form of walking or riding to school may offset the potentially provocative effects of prolonged bag carriage and warrants further investigation.[12].

Therefore, it is imperative that people of all ages, especially students, take some action to improve their postural awareness.

CONCLUSION

Majority of the School going student are exposed to the risk of adopting poor postures which can lead to musculoskeletal dysfunctions. The results of this study suggesting the importance of postural awareness among school going students.

ABSTRACT

Introduction: Chronic neck pain is a prevalent issue among Ola/Uber drivers in Gujarat, adversely impacting their daily functioning and overall well-being. Despite its significance, research focusing on the prevalence and impact of chronic neck pain in this occupational group remains limited. This study aims to address this gap by examining the prevalence, severity, and associated factors of chronic neck pain among Ola/Uber drivers in Gujarat. **Participants:** A total of 300 Ola/Uber drivers from various regions of Gujarat participated in the study, providing valuable insights into the prevalence and impact of chronic neck pain in this population. **Results:** Analysis of the data revealed that a significant proportion of Ola/Uber drivers experienced chronic neck pain, with 66% of the participants reporting some degree of disability according to the Neck Disability Index (NDI). Additionally, varying levels of pain intensity were observed, highlighting the considerable burden of chronic neck pain on the drivers' well-being and work performance. **Conclusion:** The findings underscore the urgent need for targeted interventions and ergonomic improvements to alleviate the burden of chronic neck pain among Ola/Uber drivers in Gujarat. By addressing the underlying factors contributing to neck pain and implementing strategies to improve driver well-being, we can enhance the overall quality of life and safety for Ola/Uber drivers in Gujarat.

Chronic Neck Pain, Ola/uber Drivers, Prevalence, Impact, Interventions.

INTRODUCTION:

About Anatomy Of Neck

The neck serves as a crucial anatomical region connecting the head to the trunk, housing vital structures responsible for various physiological functions. Understanding the intricate anatomy of the neck is fundamental for medical practitioners across multiple specialties.

The neck comprises several layers, including skin, superficial fascia, platysma muscle, deep cervical fascia, and numerous structures such as blood vessels, nerves, lymph nodes, and viscera. The cervical vertebrae provide structural support while facilitating movement of the head and neck.

Muscles:
Key muscles in the neck include the sternocleidomastoid, scalene, trapezius, and suprahyoid muscles. These muscles play crucial roles in head movement, respiration, swallowing, and speech.1

Blood Supply:
The neck receives arterial blood supply primarily from the common carotid arteries, which bifurcate into internal and external carotid arteries. The vertebral arteries also contribute to cerebral circulation, branching off from the subclavian arteries.

Nerves:
Nerves of the neck include the cervical plexus, brachial plexus, vagus nerve, phrenic nerve, and sympathetic chain. These nerves innervate various structures in the neck and regulate autonomic functions.2

Lymphatics:
The neck contains an extensive network of lymph nodes organized into chains, including the superficial and deep cervical lymph nodes. These nodes play a crucial role in immune surveillance and lymphatic drainage from the head and neck region.

Clinical Significance:
An understanding of neck anatomy is essential for diagnosing and treating various conditions, including neck trauma, infections, tumors, and neurological disorders. Surgical procedures in the neck region require precise knowledge of anatomy to minimize complications. 3951

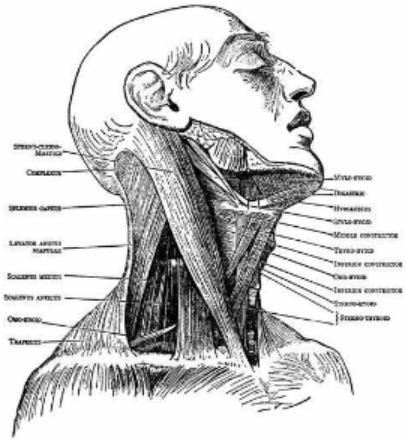

Fig: 1 Anatomy Of Neck

About Neck Pain

Neck pain is a common complaint encountered in clinical practice, affecting individuals of all ages and backgrounds. Understanding the various types of neck pain is essential for accurate diagnosis and appropriate management.

Types of Neck Pain:

1. Mechanical Neck Pain:

- Mechanical neck pain typically results from musculoskeletal causes such as poor posture, muscle strain, or degenerative changes in the cervical spine.
- It is often exacerbated by certain activities or positions and may improve with rest, activity modification, and physical therapy.4

2. Cervical Radiculopathy:

- Cervical radiculopathy occurs when a nerve root in the cervical spine becomes compressed or irritated, leading to pain, weakness, and sensory changes along the distribution of the affected nerve.
- Common causes include herniated discs, spinal stenosis, or foraminal narrowing.

3. Cervical Myelopathy:

- Cervical myelopathy refers to compression or injury to the spinal cord in the cervical region, resulting in motor, sensory, and reflex abnormalities.
- Causes include degenerative disc disease, cervical spondylosis, or spinal cord tumors.

4. Whiplash-Associated Disorder (WAD):
- WAD occurs following sudden acceleration-deceleration forces on the neck, commonly seen in motor vehicle accidents.
- Symptoms may include neck pain, stiffness, headache, and sometimes neurological deficits.5

5. Non-Specific Neck Pain:
- Non-specific neck pain refers to pain in the neck region without a specific identifiable cause.
- It may result from a combination of factors including poor posture, stress, muscle tension, and psychosocial factors.

Clinical Considerations:
- A thorough history and physical examination are essential for evaluating neck pain and determining its underlying cause.
- Diagnostic imaging studies such as X-rays, MRI, or CT scans may be indicated to further evaluate the cervical spine and surrounding structures.
- Treatment options for neck pain vary depending on the underlying cause and may include medications, physical therapy, injections, or surgical intervention in severe 6

Neck Pain Due To Bad Posture And Stress

Neck pain attributed to bad posture and stress is a common complaint encountered in clinical practice, affecting individuals of all ages and occupations. Understanding the underlying mechanisms and management strategies for this type of neck pain is essential for healthcare professionals.

Etiology:

1. Bad Posture:
- Prolonged periods of sitting or standing with poor posture can lead to excessive strain on the muscles, ligaments, and joints of the neck.
- Common postural deviations contributing to neck pain include forward head posture, rounded shoulders, and excessive cervical lordosis.

2. Over Stress:
- Psychological stress and tension can manifest physically as muscle tightness and increased muscle tone in the neck and shoulder region.
- Chronic stress can lead to the development of trigger points, muscle imbalances, and reduced pain threshold, exacerbating neck pain symptoms.

Pathophysiology:
- Poor posture and stress can result in muscular imbalances, leading to altered biomechanics of the cervical spine and surrounding structures.
- Chronic tension and strain on the neck muscles can cause microtrauma, inflammation, and decreased blood flow, contributing to the development of neck pain.7

Neck Disability Index

The Neck Disability Index (NDI) is a validated tool used to assess the impact of neck pain on daily functioning and quality of life. It consists of 10 items covering various aspects of physical and functional impairment related to neck pain. 8

Numeric Pain Rating Scale (NPRS)

The Numeric Pain Rating Scale (NPRS) is a commonly used tool for quantifying pain intensity on a numerical scale from 0 to 10, where 0 represents no pain and 10 represents the worst pain imaginable. It provides a quick and simple method for patients to communicate their pain levels to healthcare providers.9

AIM OF THE STUDY

The aim of this study is to investigate the prevalence and factors associated with chronic neck pain among Ola/Uber drivers in Gujarat, India.

Specifically, the study seeks to:
1. Determine the prevalence of chronic neck pain among Ola/Uber drivers in Gujarat.
2. Identify demographic, occupational, and psychosocial factors contributing to chronic neck pain in this population.
3. Assess the impact of chronic neck pain on the quality of life, work performance, and driving safety of Ola/Uber drivers.
4. Explore potential interventions and preventive strategies to alleviate neck pain and improve the overall well-being of Ola/Uber drivers in Gujarat.

This study aims to provide valuable insights into the burden of chronic neck pain among Ola/Uber drivers and inform the development of targeted interventions to address this occupational health issue.

Need Of The Study

The need for investigating the prevalence of chronic neck pain among Ola/Uber drivers in Gujarat arises from several key factors:
1. Occupational Health Concerns: Ola/Uber drivers spend prolonged periods driving, often in non-ergonomic positions, which may predispose them to musculoskeletal disorders such as chronic neck pain. Understanding the extent of this issue is crucial for addressing their occupational health needs.
2. Lack of Research: Despite the growing reliance on ridesharing services like Ola and Uber, there is limited research focusing on the musculoskeletal health of drivers, particularly regarding chronic neck pain. This study will fill a critical gap in the literature.
3. Impact on Quality of Life: Chronic neck pain can significantly impact the quality of life, work productivity, and overall well-being of individuals. Assessing the prevalence of neck pain among Ola/Uber drivers will shed light on the magnitude of this problem and its implications.
4. Driver Safety: Neck pain can impair mobility and concentration, potentially compromising driver safety and increasing the risk of accidents. Understanding the association between neck pain and driving performance is essential for ensuring road safety.
5. Intervention Development: By identifying the factors contributing to chronic neck pain among Ola/Uber drivers, this study will inform the development of targeted interventions and preventive measures to alleviate pain and improve the health outcomes of drivers.

In summary, there is a pressing need to investigate the prevalence of chronic neck pain among Ola/Uber drivers in Gujarat to address their occupational health concerns, improve their quality of life, ensure driver safety, and inform the development of effective interventions.

Objective Of The Study

The objective of this study is to determine the prevalence of chronic neck pain among Ola/Uber drivers in Gujarat, India, and to explore associated risk factors and impact on drivers' quality of life and work performance. Specifically, the study aims to:
1. Assess the prevalence of chronic neck pain among Ola/Uber drivers in Gujarat through a cross-sectional survey.
2. Identify demographic, occupational, and psychosocial factors associated with chronic neck pain in this population.
3. Evaluate the impact of chronic neck pain on drivers' quality of life, work productivity, and driving safety.
4. Investigate coping strategies and healthcare-seeking behaviors adopted by Ola/Uber drivers in response to chronic neck pain.
5. Provide recommendations for interventions and preventive measures to alleviate neck pain and improve the overall well-being of Ola/Uber drivers in Gujarat.

Study Design And Study Setting

Study Design:

The study will employ a cross-sectional design to investigate the prevalence of chronic neck pain among Ola/Uber drivers in Gujarat.

Study Duration:

The study will be conducted over a period of 6 months, from [10 October, 2023] to [12 March, 2024].

Population:

The target population will consist of Ola and Uber drivers operating in various cities and towns across Gujarat.

Selection Criteria:

a. Inclusion Criteria:
1. Licensed Ola/Uber drivers.
2. Currently active in driving for Ola/Uber services.
3. Willing to participate in the study.
4. Able to understand and respond to the questionnaire in Gujarati or English.

b. Exclusion Criteria:
1. Drivers with a history of traumatic neck injury in the past 6 months.
2. Drivers currently undergoing treatment for neck-related disorders.
3. Drivers with pre-existing chronic conditions affecting the neck, such as cervical spondylosis or rheumatoid arthritis.

Sampling Method:
A convenience sampling method will be employed to recruit participants. Researchers will approach Ola/Uber drivers at various pick-up and drop-off points, rest areas, and driver hubs across different cities in Gujarat.

Sampling Size:
Based on previous studies and considering an estimated prevalence rate of chronic neck pain among Ola/Uber drivers in Gujarat, a sample size of 300 drivers will be targeted to achieve a sufficient level of statistical power and precision in estimating the prevalence rate with a 95% confidence interval and a 5% margin of error.

Outcome Measures:
Numeric Pain Rating Scale (NPRS)
Neck Disability Index (NDI)

METHODOLOGY

Table: 1 Flow Chart Of Procedure

1. Participant Recruitment:
- Identify and approach Ola/Uber drivers at various locations such as taxi stands, transportation hubs, and rest areas across different cities in Gujarat.
- Provide a brief explanation of the study aims, procedures, and benefits to potential participants.
- Obtain informed consent from eligible drivers willing to participate in the study.

2. Demographic Information:
- Collect demographic data including age, gender, educational level, years of driving experience, average daily driving hours, and any previous history of neck pain or related conditions.

3. Numeric Pain Rating Scale (NPRS):
- Explain the NPRS to participants, emphasizing that it is a simple tool used to assess the intensity of their neck pain on a scale from 0 to 10, with 0 representing no pain and 10 representing the worst possible pain.
- Provide a numerical scale to the participants.
- Ask participants to rate their current neck pain intensity by selecting a number on the scale that best represents their level of pain.
- Record the participant's NPRS score.

4. Neck Disability Index (NDI) Scale:
- Introduce the NDI scale to participants, explaining that it is a questionnaire designed to assess the impact of neck pain on their daily activities and functioning.
- Provide a printed or electronic copy of the NDI questionnaire to participants.
- Instruct participants to read each question carefully and select the response that best reflects their current level of disability or limitation due to neck pain.
- Assist participants in completing the questionnaire if necessary, ensuring that they understand each item.
- Collect the completed NDI questionnaire from the participants.

5. Data Collection and Recording:
- Enter the demographic information, NPRS scores, and NDI questionnaire responses into a secure database or electronic spreadsheet.
- Ensure accuracy and consistency in data entry by double-checking entries against the original forms.
- Assign unique identifiers or codes to participants to maintain confidentiality and anonymity of their data.

IMAGE: 2 DATA COLLECTION

IMAGE: 3 DATA COLLECTION

6. Quality Control:
- Periodically review a subset of data entries to identify any errors or inconsistencies.
- Address any discrepancies by verifying the original data sources and making necessary corrections.
- Conduct regular checks to ensure compliance with ethical guidelines and data protection regulations.

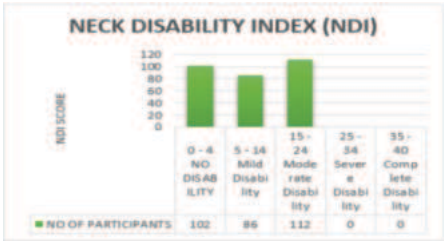
7. Data Analysis:
- Analyze the collected data using appropriate statistical methods to determine the prevalence of chronic neck pain among Ola/Uber drivers in Gujarat.
- Calculate descriptive statistics such as mean NPRS scores, NDI scores, and prevalence rates of neck pain severity and disability.
- Explore potential associations between demographic variables, driving characteristics, and neck pain outcomes using inferential statistics if applicable.

8. Reporting and Dissemination:
- Prepare a comprehensive report summarizing the study findings, methodology, and conclusions

RESULT

1. Neck Disability Index (NDI) Scores:
- No Disability (0-4 score): 102 participants
- Mild Disability (5-14 score): 86 participants
- Moderate Disability (15-24 score): 112 participants
- Severe Disability (25-34 score): 0 participants
- Complete Disability (35-40 score): 0 participants

Table : 2 Neck Disability Score



2. Numeric Pain Rating Scale (NPRS) Scores:
- Score 1: 0 participants
- Score 2: 66 participants
- Score 3: 36 participants
- Score 4: 86 participants
- Score 5: 60 participants
- Score 6: 52 participants
- Score 7, 8, 9, 10: 0 participants

Table: 3 Numeric Pain Rating Scale Score

3. Individuals with Disability:
- Individuals with disability: 198 participants (66%)
- Individuals without disability: 102 participants (34%)
- Total number of participants: 300

Table: 4 Disability Evaluation

The prevalence of chronic neck pain among Ola/Uber drivers in Gujarat is significant, with a total of 198 participants (66%) reporting some level of disability according to the Neck Disability Index (NDI). Among these, the majority exhibit moderate disability, indicating a considerable impact on daily functioning. Numeric Pain Rating Scale (NPRS) scores reveal varying levels of pain intensity, with a notable proportion of participants reporting scores ranging from 2 to 6. These findings underscore the need for targeted interventions and ergonomic improvements to mitigate the burden of chronic neck pain among Ola/Uber drivers in Gujarat and enhance their overall well-being.

DISCUSSION

Chronic neck pain is a complex and multifaceted issue that poses significant challenges for Ola/Uber drivers in Gujarat. This comprehensive discussion will delve into the various facets of chronic neck pain among this occupational group, including its prevalence, impact, contributing factors, and potential avenues for intervention.

Prevalence and Impact of Chronic Neck Pain:

The findings of this study underscore the high prevalence and considerable impact of chronic neck pain among Ola/Uber drivers in Gujarat. **With 66% of participants reporting some degree of disability** according to the Neck Disability Index (NDI), it is evident that chronic neck pain significantly affects the daily functioning of these drivers. Moreover, the distribution of NDI scores highlights the diverse spectrum of disability experienced by drivers, ranging from mild to moderate impairment in performing daily activities. This not only impacts their ability to work effectively but also has implications for their overall quality of life and well-being.

Factors Contributing to Chronic Neck Pain:

Several factors contribute to the development and exacerbation of chronic neck pain among Ola/Uber drivers. Prolonged periods of driving, often in non-ergonomic conditions, can lead to muscle fatigue, tension, and poor posture, all of which are known risk factors for neck pain. Additionally, the repetitive nature of driving, combined with frequent use of mobile devices and navigation systems, can further strain the neck muscles and exacerbate existing pain. Furthermore, psychosocial factors such as stress, anxiety, and job dissatisfaction may also play a role in the development and persistence of chronic neck pain among drivers.

Impact on Work Performance and Well-being:

Chronic neck pain not only affects the physical health of Ola/Uber drivers but also has significant implications for their work performance and overall well-being. The moderate to severe pain intensity reported by a substantial proportion of drivers, as indicated by Numeric Pain Rating Scale (NPRS) scores, can impair their ability to concentrate, make quick decisions, and react to changing road conditions, thereby compromising driving safety. Moreover, the discomfort and disability associated with chronic neck pain may lead to decreased job satisfaction, increased absenteeism, and financial strain, further exacerbating the drivers' overall stress and dissatisfaction.

Potential Avenues for Intervention:

Addressing the burden of chronic neck pain among Ola/Uber drivers requires a multifaceted approach that addresses both individual and systemic factors. Ergonomic improvements in vehicle design, including adjustable seats, lumbar support, and headrests, can help alleviate strain on the neck muscles and promote better posture during driving. Additionally, education and training programs on proper ergonomics, stretching exercises, and relaxation techniques can empower drivers to proactively manage their neck pain and prevent its recurrence. Furthermore, access to timely and affordable healthcare services, including physiotherapy, chiropractic care, and pain management interventions, is essential to address the underlying causes of neck pain and improve the drivers' overall musculoskeletal health

CONCLUSION

In conclusion, the findings of this study shed light on the significant prevalence and impact of chronic neck pain among Ola/Uber drivers in Gujarat. The high percentage of drivers reporting some degree of disability underscores the profound burden of neck pain on their daily functioning and overall quality of life. Moreover, the varying levels of pain intensity reported by drivers further emphasize the complexity of this issue and the urgent need for effective interventions to alleviate their suffering. Addressing the multifaceted factors contributing to chronic neck pain, including ergonomic improvements, education on proper posture and stretching techniques, and access to healthcare services, is paramount to improving the musculoskeletal health and well-being of Ola/Uber drivers in Gujarat.

Moving forward, concerted efforts from policymakers, healthcare professionals, and stakeholders in the transportation industry are essential to implement sustainable solutions that prioritize the health and safety of Ola/Uber drivers. By addressing the root causes of chronic neck pain and promoting proactive measures to mitigate its impact, we can create a supportive environment that empowers drivers to manage their pain effectively and continue their vital role in providing transportation services to the community. Ultimately, by prioritizing the musculoskeletal health of Ola/Uber drivers, we can enhance their overall well-being and contribute to a safer and more sustainable transportation system in Gujarat.

ABSTRACT

Background: This research focuses on assessing work-related musculoskeletal disorder among recreational cricket players using modified Nordic musculoskeletal questionnaire. Using MNMQs, the aim is to gather detailed information on the prevalence, severity and location of musculoskeletal problems experienced by recreational cricket players during their participation in the sport. **Methods:** A Cross sectional study was carried out on 105 recreational cricket players using Modified Nordic Musculoskeletal Questionnaire to find the prevalence of work-related Musculoskeletal disorder among recreational cricket players. **Results:** Out of 105 cricket players 73 (69.5%) players experienced work-related musculoskeletal problem in last 12 months. Shoulder, low back and Hips/thighs were the most common areas of problem in last 12 months. Hips/thighs, low back were the most common areas of problem in last 12 months in Batsmen. Shoulder and Ankles/feet were the most common areas of problem in last 12 months in bowlers. Low back, shoulders were the most common area of problem in last 12 months in All-rounders. Sprain (38%) and Strain (33%) were the most common type of injury among recreational cricket players. **Conclusion:** This study concludes that the work-related musculoskeletal disorder in recreational cricket players were more. Shoulders and Lower back were the most common injured body parts followed by Hips/thighs, Ankles/Feet and Knees. According to role of cricket, Bowlers were more affected than Batsmen and All-rounder. The study conclude that Hips/thighs and low back are the common site of injury in batsmen. Shoulder and Ankles/feet are the common site of injury in bowlers and Low back and shoulder were the most common site of injury in All-rounders. The study also concludes that due to the Low back Injury or pain players had affected from doing their daily activity of living in last 12 months. This research findings indicate that sprain and strains rank as the predominant injuries experienced by cricket players.

KEYWORDS

Work-related musculoskeletal disorder, Modified Nordic Musculoskeletal Questionnaire, recreational cricket players.

INTRODUCTION

Work-related injuries pose a significant burden on individuals, organizations, and society at large, with musculoskeletal disorders (MSDs) being one of the primary causes and contributors to workers' compensation claims. The lack of specific data on work-related musculoskeletal diseases in developing nations complicates efforts to identify prevalent issues and occupations at high risk, though occupations requiring heavy physical exertion, such as construction, stone work, mining, and cleaning, are likely the most vulnerable. Additionally, musculoskeletal disorders (MSDs) are defined as soft tissue disorders not resulting from sudden events, and are deemed work-related when the work environment significantly contributes to their development. [1]

Cricket is a major international sport played in more than 60 countries. The laws of cricket were drawn up by the London Club in 1944 formalizing a game that had been played for a hundred of years ago.[2] Cricket is regarded as a leisurely, gentlemen's game.[3] In cricket, bowlers deliver a hard ball at a high speed directly to the batsman.[4] Now cricket is played in more than sixty countries and regarded as major international team sport. Cricket also played in many commonwealth countries as popular sport. Cricket is the most popular team sport in Indian subcontinent that consists India, Pakistan, Afghanistan, Bangladesh, Sri Lanka. The popularity for cricket in India was started after its success in 1983 world cup in which it was the champion; this led to a greater number of people participating in cricket. There are various clubs and centres with skilful coaches to train them. Injuries are inevitable when one player is training and compete. There are numerous studies available at international level, but in India there is a lack of research in cricket.[5]

The ICC Trophies Won by India:

India's cricket legacy began with the 1983 ICC Cricket World Cup victory, where Kapil Dev's team triumphed against the odds, defeating Clive Lloyd's West Indies, marking India's first ICC trophy. Until then, the Indian cricket team held little significance in the sporting world, but this underdog victory transformed the perception of cricket in India. The 2002 Champions Trophy stands as a unique event in ICC history, being the solitary tournament where a definitive champion wasn't determined, resulting in Sri Lanka and India being declared joint winners. This marked a significant milestone, breaking a nearly two-decade drought for India in ICC trophy victories. Sri Lanka, considered pre-tournament favourites, secured their spot in the final through dominant performances in the group stage, culminating in a convincing seven-wicket win over Ricky Ponting's formidable Australian team. Conversely, India, fielding a relatively youthful squad, earned their place in the final after a hard-fought 10-run victory against South Africa. However, unforeseen rain disruptions plagued the finals, forcing two washouts and ultimately leading to both Asian cricket powerhouses sharing the trophy. The inaugural ICC T20 World Cup introduced both a new competition and a fresh captain, sparking apprehension over India's performance. With MS Dhoni, then 26 years old, assuming leadership, following Rahul Dravid, Sourav Ganguly, and Sachin Tendulkar's self-exclusion from T20I cricket's premier event in 2007, the team faced the challenge with a predominantly inexperienced roster. As a result, the burden fell on Dhoni, hailing from Ranchi, to orchestrate a remarkable feat. India's 28-year wait for another ICC Cricket World Cup ended in 2011, with MS Dhoni's iconic six in the final against Sri Lanka, while Yuvraj Singh's stellar performance anchored the victorious campaign, marking a fitting farewell for cricket legends Sachin Tendulkar and Virender Sehwag. The 2013 edition of the ICC Champions Trophy, India beat England in finals and MS Dhoni becomes only captain in world cricket to will all three ICC trophies. Currently the men's Indian cricket team is ranked 1st in test cricket, 1st in one-day international and 1st in T20 (as of 26/03/2024 - ICC rankings). There is a lot of crazes for cricket in India. Many children here like or even play cricket. There is a big cricket player in every street here. People love cricket a lot. Cricket is not just a sport but an emotion for the children of India. There is no shortage of talent in India, there is a dangerous player in every street regarding cricket. Every child here dreams of becoming a successful cricketer and playing for his country.[6]

Cricket, characterized by its dynamism, encompasses a plethora of abstract skills and movements. To refine these intricacies, many players prioritize maintaining peak physical fitness and strength. The game's three distinct facets (bowling, batting, and fielding) each pose unique injury risks. [7,8,9] Musculoskeletal discomfort may manifest in diverse scenarios during cricket matches, including impacts from balls or bats, swift rotational actions, sliding and diving maneuvers, collisions with fellow players, and the cumulative effects of overuse. [10,11,12,13]

Running is a common thing in cricket, whether it is batting or bowling or fielding, running has to be done by all, hence lower limb is more

affected in cricket. After that, the second task is to throw the ball because all the players do field and hence upper limb injuries also occur. After that, injuries to the upper and lower trunk occur, due to twisting or overstretch of the trunk.

The stance of a batsman while batting is somewhat like this, it can be differed from batsmen to batsmen. This is a normal stance of the batsman, after that the bowler bowls the ball and the batsman hits the stroke according to the ball. The posture of batsmen is different in every stroke, sometimes extra force is applied on the body or if the body gets twisted too much than the injury can occur. And also, when the batsmen take run, he will run fast so the batsmen have chances to get injured while running. That's why batsmen suffer more injuries to their back and hips.

The ideal bowling action of the player. While bowling, a bowler runs, then makes a jump, rotates his arm in a circular motion and delivers the ball. And experts believe that while delivering the ball, 7 to 8 times more force is applied to the bowler's ankles/feet and the repetitive movement of the shoulder is happens while bowling. That's why bowlers suffer more ankle/feet and shoulder injuries.

Fielding is another role in cricket. So, while doing this, a player gives extra efforts to save runs for the team. During this, his chances of getting injured are increased because he runs, slides, dives, throws and catches the ball and players even collide with each other. Therefore, fielders are at greater risk of hip/thigh injuries, knee injuries, low back and shoulder injuries.

According to Sathya et al., 61% of players encountered musculoskeletal issues linked to cricket. Stretch et al.'s findings indicated that South African cricketers predominantly suffered lower limb injuries (50%), followed by upper limb (23%) and back/trunk injuries (23%). [14] Musculoskeletal pain (Injury) is defined as 'A sensation of agony that inhibits the individual from participating in cricket or practice for a minimum of 24 hours'[15]

There are many studies available at domestic and international level on injuries faced by cricket players. Thus, the purpose of the study is to find the work-related musculoskeletal disorder among recreational cricket players.

Methodology

Study Place

Tanman Cricket Ground, Galaxy Cricket Ground, Samarpan Cricket Ground, Norada 108 Cricket Ground.

Sampling Design

Convenience sampling

Study Design

A cross-sectional survey studies.

Duration of Study

6 months

Sample Size: 105

Inclusion Criteria

- Male cricket players of age 19-27 years
- Playing experience of minimum 3-4 years with regular practices

Exclusion Criteria

- Recent fracture or injury.
- Any recent cardiovascular surgery.
- Any Neurological condition.
- Alter mental illness.
- Players who do not play regularly

Materials Required

- Consent form
- Assessment form
- Modified Nordic Musculoskeletal Questionnaire (MNMQ)
- Pen

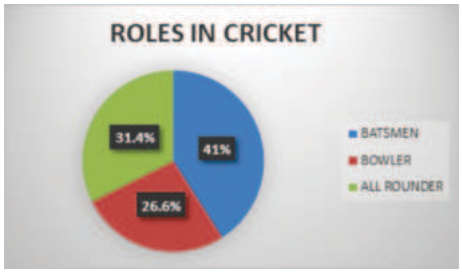
Method

- A sample of cricket players was taken in this survey from various cricket ground located in Ahmedabad.
- All players who meet the inclusion criteria were eligible to participate in the study.
- The data collection was done involving the questionnaire is based on MNMQs.
- Firstly, players were made aware about the purpose of the study. Each component of Modified Nordic Musculoskeletal Questionnaire was explained to each and every player. And consent of each player was taken.
- Then, General demographic data was taken Name, age, gender, occupation, role they play in cricket from the player and asked them to recall their injuries from last one year from April 2023 to March 2024.
- Afterward, the questionnaire content six component.
- The questionnaire content binary questions and player have to fill the answers respectively.
- Then data was collected from 105 player and analyzed in simple percentage and graphs.

RESULTS

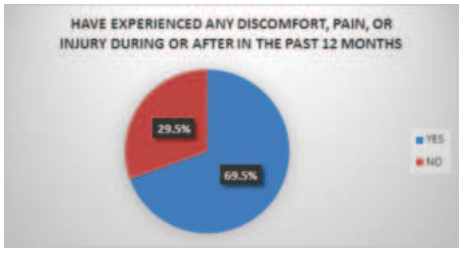
- The analysis was done using excel.
- Total 105 player are taken for the study

A. The above graph shows, out of 105 players 43(41%) were batsmen, 28(26.6%) were bowler, 34(31.4%) were all-rounder.



Graph 1

B. The above graph shows, out of 105 players, 73(69.5%) players had experienced any discomfort, pain, or injury during or after cricket activities in the past 12 months.

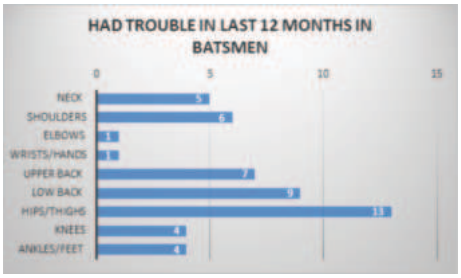


Graph 2

C. The above Graph show the trouble held to cricket players during the last 12 months according to anatomical site. The commonest site for pain or injury among the players is Shoulder and low back (41%) followed by Upper back and Hips/thighs (35%), Ankles/feet (31%), Neck (23%), Wrists/hands (16%), Knees (15%), Elbows (11%).

Graph 3

D. The above graph shows the trouble held to Batsmen during last 12 months according to anatomical site. Out of 43 batsmen 24 (55%) experienced pain or discomfort during or after cricket in last 12 months. The commonest site for batsmen is Hips/Thighs (54%), followed by low back (37%), upper back (29%), shoulder (25%), Neck (20%), Knees and Ankles/Feet (16%), Elbow and Wrists/Hands (4%).



Graph 4

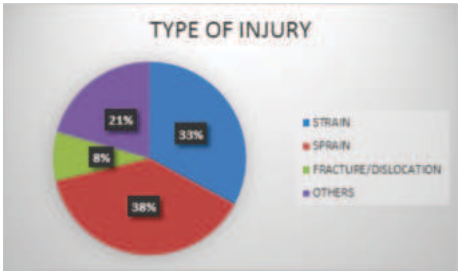
E. The above graph shows the trouble held to Bowler during last 12 months according to anatomical site. Out of 28 bowlers 23 (82%) experienced pain or discomfort during or after cricket in last 12 months. The commonest site for bowler is Shoulders and Ankles/Feet (60%) followed by Wrists/Hand (30%), Hips/Thighs (26%), Neck (21%), Elbows and Kness (17%), Low back (13%), Upper back (8%)

Graph 5

F. The above graph shows the trouble held to All-rounder during last 12 months according to anatomical site. Out of 34 all-rounder 25 (73%) experienced pain or discomfort during or after cricket in last 12 months. The commonest site for all-rounder is Low back (72%), followed by Shoulder (48%), Upper back (36%), Neck and Hips/Thighs (28%), Ankles/feet (20%), Wrists/Hands (16%), Elbows (12%), Knees (8%).

Graph 6

G. The above graph shows types of injuries in cricket players. Out of 105 players investigated 73 (69.5%) experienced work-related musculoskeletal problem within last 12 months. Out of 73 players 28 (38%) had Sprain, 24 (33%) had strain, 15 (21%) had other injuries and 6 (8%) had fracture/dislocation.



Graph 7

DISCUSSION

The study was done on 105 recreational cricket players (males) of age group of 19-27 years with minimum experience of 3-4 years. The Aim and objective of the study was to find work-related musculoskeletal disorder among recreational cricket player. Modified Nordic Musculoskeletal Questionnaire was used to find the work-related musculoskeletal problem in recreational cricket players in last one year. Out of 105 players 73 (69.5%) experienced work -related musculoskeletal problem. According to Graph -3, the most common site of injury or pain is in shoulders and low back (41%), followed by Ankles/feet, upper back, hips/thighs. Because of repetitive movement of shoulder and trunk. Fielder throws the ball, bowler runs and deliver the ball with maximum effort so the movement of shoulder is much more that's why the risk of shoulder injuries is more on other hand repetitive hyperextension, rotation of trunk while batting or deliver the ball by bowlers.

The Graph-4 shows the prevalence of work-related musculoskeletal problem in last 12 months in Batsmen. Out of 43 batsmen 24 (55%) experienced musculoskeletal problem. Hips/thighs, low back, upper back these 4 sites are most commonly affected in batsmen because more use of trunk and lower extremities is there. That's why trunk and lower limb is most commonly affected. The Graph-5 shows the prevalence of work-related musculoskeletal problem in last 12 months in Bowler. Out of 28 bowler 23 (82%) experienced musculoskeletal problem. Shoulder, Ankles/Feet these 3 sites are most commonly affected in bowler because of repetitive movement of shoulder for delivering the ball and also when the bowler delivers the ball, the whole weight of the body came to ankles/feet. Hence shoulder, ankles/feet are most commonly affected. The Graph-6 shows the prevalence of work-related musculoskeletal problem in last 12 months in All-rounder. Out of 34 All-rounder 25 (73%) experienced musculoskeletal problem. Low back, Shoulder, Upper back, Hips/thighs these 4 are the most common site of injury or pain in all-rounder because they have to play all the roles in cricket (Batting, Bowling and Fielding).

Player who prevented from doing normal work in the last 12 months due to work-related musculoskeletal problem: The most common site for preventing from doing normal work during last 12 months are Low back and Upper back followed by Shoulder. Player who had trouble at any time during last 7 days: The most common site causing trouble in last 7 days are Hips/Thighs followed by Upper back and Low back. Out of 105 players only 18 (17%) players had ever hurt themselves body part in an accident. Shoulder and Ankle/feet are hurt more in an accident followed by Hips/thighs and Knees. When the players were asked about the total length of time that had trouble during the last 12 months. The most common answered was 1-7 days followed by 8-30 days and very few were for more than 30 days. The last component of the MNMQs was about the type of the Injury. As the Graph 7 shows, 28 players were affected with Sprain, 24 Players were affected with Strain and 21 players were affected with Other and Fracture/dislocation.

Chandrasekhar Bodanki et al. conducted a study on Prevalence of cricket-related musculoskeletal pain among Indian junior club cricketers and finds that CIPP should be implemented and strictly followed from the early stages of sports life. Pre-training warm-up and post-training cool-down sessions into their regular training regimen is essential. It's crucial to steer clear of overuse, such as prolonged play beyond scheduled times, and to refrain from disregarding any pain experienced during practice or matches. A supervised training and regular screening of players by orthopaedician or sports physician will keep them fit to play with full potential.[16]

P. Sathya et al. conducted a study on Prevalence of Musculoskeletal Problems in Cricket Players and finds that the findings revealed a 61% prevalence of musculoskeletal problems among cricket players. The lower back emerged as the most frequently affected area, followed by ankles/feet, knees, and hips/thighs. Musculoskeletal problems were more prevalent among all-rounders than batsmen and bowlers. Specifically, ankles/feet were frequently affected in all-rounders, while bowlers and batsmen commonly experienced issues in the low back area, alongside other regions. Furthermore, strain and sprain were identified as the predominant types of injuries among cricket players, regardless of their specific role in the game. [14]

Sumit Kumar et al. conducted a study on One year prevalence of musculoskeletal disorder among cricket Players in Haryana: A retrospective study: - Injury data was gathered using a modified Nordic Musculoskeletal Injury Questionnaire. Frequency of musculoskeletal injuries is more among cricket players. Conditioning by coaches and early rehabilitation by physiotherapists are essential to reduce the

injury rate in this population. [5]

Present study was conducted on 105 recreational cricket player and the prevalence of Musculoskeletal problem was 69.5% and shoulder and Low back (41%) were the most commonly injured body part followed by Ankles/feet, upper back, hips/thighs.

CONCLUSION

This study concludes that the work-related musculoskeletal disorder in recreational cricket players were more. Shoulders and Lower back were the most common injured body parts followed by Hips/thighs, Ankles/Feet and Knees. According to role of cricket, Bowlers were more affected than Batsmen and All-rounder. The study conclude that Hips/thighs and low back are the common site of injury in batsmen. Shoulder and Ankles/feet are the common site of injury in bowlers and Low back and shoulder were the most common site of injury in All-rounders. The study also concludes that due to the Low back Injury or pain players had affected from doing their daily activity of living in last 12 months. This research findings indicate that sprain and strains rank as the predominant injuries experienced by cricket players.

Limitations

- Collecting accurate data in recreational cricket player is difficult due to factors such as player recall bias on injuries and the absence of official records or statistics.
- This study is only conducted on male cricket players.

Future Recommendation

- Future studies can be done with a larger sample size to get the more appropriate result.
- The study should be conduct specially for professional cricket players.
- Explore the use of technology, such as mobile applications, to collect real-time data on recreational cricket gameplay.
- The study can be done on another sports like football, volley ball, Tennis, etc.
- The study can be conducted on Female cricket players.

ABSTRACT

Background: Given that physiotherapists receive education on injury prevention and body mechanics as part of their entry-level training, it might be expected that their rates of work-related musculoskeletal disorders (WRMSDs) would be lower compared to other professionals who perform patient handling tasks, such as nurses and massage therapists. Previous research has shown that psychosocial working conditions significantly affect mental distress and overall well-being.[10] Based on the literature, occupational stress has been identified as having a detrimental impact on the development of work-related musculoskeletal disorders (WRMSDs), with these cases posing substantial risks to both physical and mental health. Therefore, this study was undertaken to investigate the prevalence of WRMSDs and their correlation with mental health. **Methodology:** Subjects were qualified physiotherapists those who were based on the inclusion & exclusion criteria and participants who willingly wants to participate. 2 Questionnaire was used in this study for the outcome measures were: (1) Nordic musculoskeletal questionnaire to assess the WRMSD, (2) General health questionnaire (GHQ-12) for the assessment of the mental health. The form was administered through Email or WhatsApp to physiotherapists across the city. **Results:** There is 67% prevalence of musculoskeletal disorders among physiotherapists and there is perfect negative correlation with WRMSD with their mental health. **Conclusion:** WRMSDs are exacerbated by patient handling and demanding work conditions, not only affect physical health but also impact therapists' mental well-being. Despite the significant prevalence, many therapists do not seek timely treatment or take necessary breaks, potentially exacerbating their conditions. Addressing ergonomic practices, reducing repetitive tasks, and enhancing support systems are crucial steps in mitigating WRMSDs and promoting overall occupational health in the physiotherapy profession.

Musculoskeletal disorders, Physiotherapists, Mental Health, Nordic Musculoskeletal Questionnaire, Working Posture

INTRODUCTION

Background

According to the World Health Organization, work-related musculoskeletal disorders (WRMSDs) are defined as injuries encompassing a broad spectrum of inflammatory or degenerative diseases and disorders that lead to pain or functional impairment.[1] These disorders affect the muscles, tendons, ligaments, joints, peripheral nerves, and supporting blood vessels.[2] They include clinical conditions like tendon inflammations (such as tenosynovitis, epicondylitis, bursitis), nerve compression disorders (like carpal tunnel syndrome, sciatica), and osteoarthrosis. Additionally, they cover less well-defined conditions such as myalgia, low back pain, and other regional pain syndromes that cannot be attributed to known pathology.[3]

Physiotherapists have already taken advantage of opportunities to take on new responsibilities, including more advanced and initial practitioner roles. While they are well-positioned to tackle future healthcare challenges, there is a need for unified support within the profession to embrace significant changes in practice, including a reassessment of their role. Healthcare workers who have direct contact with patients experience the highest rates of work-related diseases, attributed to the demands of their profession and the physical positions they must maintain throughout the day.[4]

The main risk factors associated with WRMSDs include repetitive tasks, uncomfortable postures, and high levels of force. Physiotherapists frequently undertake tasks like transferring dependent patients, assisting with mat activities, and lifting heavy equipment, which increase their susceptibility to both acute and chronic work-related musculoskeletal disorders (WRMSDs).[5] A considerable number of physiotherapists suffer from work-related musculoskeletal disorders, with upper back pain, lower back pain, and hip pain being the most common issues they face.[6]

According to the results of a longitudinal study investigating the effects of musculoskeletal pain on work performance, regular musculoskeletal discomfort was associated with decreased performance. Work-related factors contributing to this include job dissatisfaction, job strain (involving psychologically demanding tasks with time pressure and low job control), time constraints, high mental pressure, relationships with coworkers, support at work, and overall stress levels [7,8].

A Literature has highlighted that high-level workplace stress can negatively impact both the body and mind, leading to reduced productivity, absenteeism, job changes, and exhaustion. Stress arising from pain or discomfort can also affect an individual's mental well-being and quality of life. [9] According to Karasek's model, which has been prominent in research on WRMSDs, four key work-related psychosocial factors high psychological job demands, low decision-making authority, inadequate social support, and job insecurity—contribute to psychological strain. This strain increases the likelihood of stress-related health issues.[12]

Methodology

Study Place

Government and private hospitals and clinics of Gandhinagar and Ahmedabad

Study Duration

1 Year

Study Design

A Cross sectional Study

Inclusion Criteria

1. Willing to participate
2. Clinical working Physiotherapist
3. Age group (25-55 years)
4. Both male and female
5. Minimum 5-6 hours of working
6. Physiotherapist with minimum 6 months - 1 year of clinical work experience

Exclusion Criteria

1. Physiotherapists who are in the administrative duty
2. Academics or performing non-clinical work

3. Female physiotherapists who are pregnant
4. Recent trauma or surgery
5. Physiotherapists who have full time working assistants

Materials required

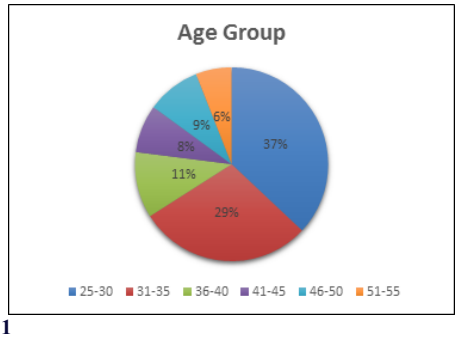
1. Mobile Phone
2. Consent form
3. Assessment form

METHOD

- Subjects were qualified physiotherapists those who meet inclusion and exclusion criteria and who are willing to participate.
- The consent was taken from all the subjects and detailed explanation of the study was also given to the subjects.
- 2 questionnaire was used in the study for the outcome measures were:
- Nordic Musculoskeletal Questionnaire (NMQ) to assess the WRMSD
- General Health Questionnaire (GHQ-12) for the assessment of the mental health
- The 1ST questionnaire consists of 2 parts. In the first part each subject were required to fill the assessment form consisting of question regarding their basic demographic details, professional details such as job/position, experience, weekly working hours and health information and the second part will consist of questions to measure the existence of musculoskeletal pain using modified Nordic musculoskeletal questionnaire.
- The 2nd questionnaire was GH-12 to assess the Mental Health. The General Health Questionnaire (GHQ-12) comprises 12 items, each evaluating the severity of mental issues over recent weeks using a 4-point scale (ranging from 0 to 3). Scores from these items are totaled to produce a score ranging from 0 to 36, where higher scores indicate more severe conditions.
- The form was administered through email or WhatsApp to physiotherapist across the city.
- A total of 410 physiotherapists were invited across Gandhinagar and Ahmedabad, among whom 276 responded. These data were analyzed based on eligibility criteria, and a total of 156 physiotherapists participated in the study.

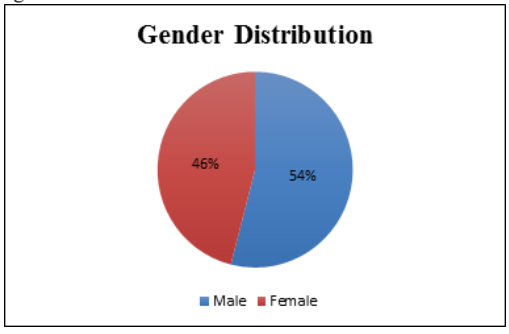
RESULTS

The analysis was done using excel.Total 156 physiotherapists are taken for the study



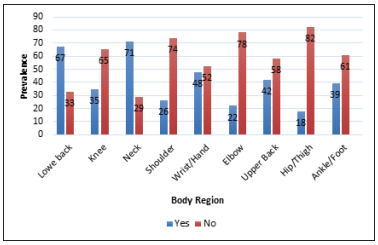
Graph 1

Graph 1 shows the age group of subjects were between 25-55 years and among them 37% were between 25-30 years, 29% were between 31-35 years, 11% were between 36-40 years, 8% were between 41-45 years, 9% were between 46-50 years and 6% were between 51-55 years. Among them 54% were female and 46% were male



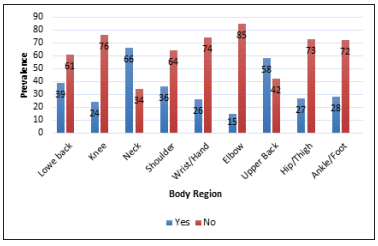
Graph 2

Graph 2 shows the gender distribution of males and females, among them 54% were male and 46% were female.



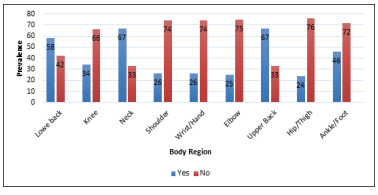
Graph 3

Graph 3 shows the prevalence in 67% suffered from lower back pain, 35% suffered from knee pain, 71% suffered from neck pain, 26% suffered from shoulder pain, 48% suffered from wrist/hand pain, 22% suffered from elbow pain, 42% suffered from upper back pain, 18% suffered from hip/thigh pain and 39% suffered from ankle/foot pain region among Physiotherapists in the last 12 months



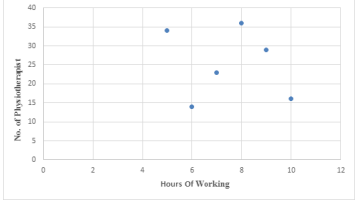
Graph 4

Graph 4 shows the prevalence in 39% suffered from knee pain, 24% suffered from lower back pain, 66% suffered from neck pain, 26% suffered from shoulder pain, 26% suffered from wrist/hand pain, 15% suffered from elbow pain, 58% suffered from upper back pain, 27% suffered from hip/thigh pain and 28% suffered from ankle/foot pain region among physiotherapists which prevented them last 12 months.



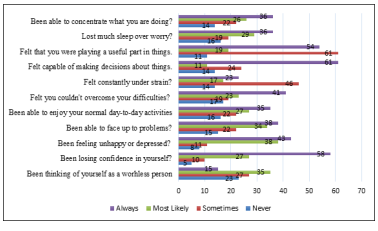
Graph 5

Graph 5 shows the prevalence in 58% are suffered from lower back pain, 34% suffered from knee pain, 67% suffered from neck pain, 26% suffered from shoulder pain, 26% suffered from wrist/hand pain, 25% suffered from elbow pain, 67% suffered from upper back pain, 24% suffered from hip/thigh pain and 46% suffered from ankle/ foot pain region among last 7 days.



Graph 6

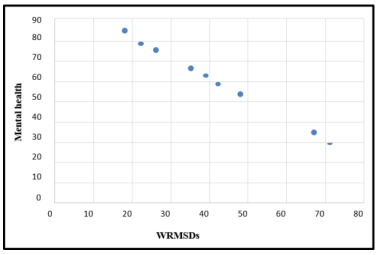
Graph 6 shows that 34 physiotherapist works for 5 hours, 14 works for 6 hours, 23 works for 7 hours, 36 works for 8 hours, 29 works for 9 hours and 16 physiotherapist works for 10 hours per week.



Graph 7

Graph 7 shows the responses of the question asked to the physiotherapist to assess the mental health related to the occupation and workplace with the help of General Health Questionnaire-12 (GH-12)

Graph 8



Graph 8 shows perfect negative correlation of Work-related musculoskeletal disorders and affection of mental health.

DISCUSSION

This study was focused on physiotherapists to investigate the prevalence of Work-related Musculoskeletal Disorders (WRMSDs) and their connection to mental health. It found that many physiotherapists, dealing with patient overload and poor posture, frequently suffer from these disorders, which can also affect their mental well-being. Out of 156 respondents, 102 physiotherapists reported experiencing work-related musculoskeletal issues, resulting in a prevalence rate of 67%. All participants completed standard Nordic Questionnaires and were interviewed about their work hours. Interestingly, despite experiencing WRMSDs, many therapists did not seek treatment, take time off work, or seek evaluation. Most therapists worked 7 hours or more daily, with some making home visits nearby. Female therapists reported more musculoskeletal problems than males, possibly due to their height and leverage issues during manual therapy. The most affected areas were the neck, lower back, and upper back, attributed to handling numerous patients, lifting dependent individuals, and working despite injuries.

The study also examined how these musculoskeletal disorders correlate with mental health, revealing a significant negative impact likely linked to their professional demands. Some therapists had developed coping strategies to manage these challenges. Psychosocial factors were also explored, revealing dissatisfaction with their profession, lack of team cooperation, poor interaction with physicians, and inadequate support from supervisors, although these associations were not statistically strong. Nonetheless, the study confirmed a 67% prevalence of musculoskeletal disorders among physiotherapists. It underscores the importance for physiotherapists to follow ergonomic guidelines, reduce repetitive tasks, or consider alternative treatments to alleviate the effects of WRMSDs.

CONCLUSION

WRMSDs are exacerbated by patient handling and demanding work conditions, not only affect physical health but also impact therapists' mental well-being. Despite the significant prevalence, many therapists do not seek timely treatment or take necessary breaks, potentially exacerbating their conditions. Addressing ergonomic practices, reducing repetitive tasks, and enhancing support systems are crucial steps in mitigating WRMSDs and promoting overall occupational health in the physiotherapy profession.

Limitations

Despite the insightful findings, it is important to acknowledge several limitations in this study Firstly, the relatively small sample size. Other factors not for affection of mental health were not taken into consideration.

ABSTRACT

Background: Achilles tendinopathy (AT) is a clinical condition characterized by pain and swelling in and around the Achilles tendon, mainly arising from overuse. Achilles tendinopathy (AT) or Tendon injury is one of the most common injuries in physical exercise (PE), especially happens to athletes who are always engaged in long-term, continuous and high-intensity competition or training. Even after surgical treatment, AT may still occur repeatedly and the recurrence rate is as high as 44%. It is not easy to be diagnosed in the early stage of disease because of its long incubation period. So, the need of Achilles Tendon injury when participating in Exercise, and on the basis of that we can find out estimated risks of Achilles Tendon injury for different ages, genders, sport events, characteristics of subjects, training years, and regions in Ahmedabad city. **Methodology:** This study included 100 male and female football players with convenient sampling method. Subjects were assessed for Achilles Tendon injury via Royal London test and if positive directed to Victorian Institute of Sports Assessment-Achilles (VISA-A) questionnaire to find out prevalence of Achilles Tendon Injury in football players. **Result And Conclusion:** This study shows that there is Age group of 16-25 having prevalence of 68% and age group of 26-35 having prevalence of 24%.Prevalence of Achilles tendon injury in football players.

Prevalence, Achilles Tendinopathy, Football

INTRODUCTION

The clinical symptoms of pain, swelling, and impaired physical function of Achilles tendon are common in sports and daily life. Traditionally, many terms have been used to describe the disorders, including tendinitis, tendinosis, and paratenonitis. However, recent histopathological studies have found these disorders as a result of a failed healing response, which may cause degenerative changes in the tendon. The failed healing response includes three different and continuous stages (reactive tendinopathy, tendon disrepair, and degenerative tendinopathy) [1][2][3]. However, inflammatory response is not found in the three stages. In 1998, Maffulli et al. suggested to use the term tendinopathy in order to describe these intratendinous disorders [4].

The two main categories of Achilles tendinopathy are classified according to anatomical location and broadly include insertional (at the calcaneus-Achilles tendon junction) and noninsertional (2 to 6 cm proximal to the insertion of the Achilles tendon into the calcaneus) tendinopathy [5].

Achilles tendinopathy is one of the most frequently ankle and foot overuse injuries [6]. This disorder is more likely to be found in the individuals who participate in the physical activities such as running and jumping. It may affect 9% of recreational runners and cause up to 5% of professional athletes to end their careers [7]. In an epidemiologic investigation of 1394 nonathletes, Achilles tendinopathy was found in 5.6% of the subjects (4% insertional, 3.6% noninsertional, and 1.9% both forms) [8]. In another research, Kvist found that 20% to 25% of Achilles tendinopathy patients had insertional disorder, 66% had noninsertional, and 23% had either retrocalcaneal bursitis or insertional tendinopathy [9].

Chronic Achilles tendinopathy is more common in older people than in young people. In Kvist's study, among 470 patients who had Achilles tendinopathy, only 25% of the patients were young athletes and 10% were younger than 14 years [9]. Moreover, insertional tendinopathy tends to occur in more active persons, whereas noninsertional tendon injury tends to occur in older, less active, and overweight persons.

The risk factors of Achilles tendinopathy can be divided into intrinsic and extrinsic factors, either alone or combination. Intrinsic factors include biomechanical abnormalities of the lower extremity such as leg length discrepancy hyperpronation, varus deformity of the forefoot, pes cavus and limited mobility of the subtalar joint[10], and systemic conditions such as increasing age [11][12] , inflammatory arthropathies, corticosteroid use, diabetes, hypertension, obesity, gout, hyperostotic conditions [13][14] [15] [16]lipidaemias, aromatase inhibitors, and quinolone antibiotics[17]. Extrinsic factors include excessive mechanical overload and training errors such as increased interval training, abrupt changes in scheduling, excessive hill training, training on hard or sloping surfaces, increased mileage, increased repetitive loading, poor shock absorption, and wedging from uneven wear.

Sports injuries have been found to inhibit optimal sports' performance and these injuries, which can have both long and short term harmful effects, causes lasting physical damage or disability[1], affect quality of life, thus could result in reduced physical activity participation. Every sport comes with risk of injury that is peculiar. The occurrence of sports injuries and its associated problems are on the increase [2]. In association football, commonly known as soccer, injuries have been identified to result from multiple risk factors and ankle injuries are one of the most common injuries[3].Ankle injuries in soccer may give rise to problems like reduced performance, time away from competition and possibly disability[4]. The bones that make up the ankle joint are a regular site of injury and often times, bending and twisting forces can precipitate these injuries [5], with the most common being ankle sprain, fracture, and tendinopathy.

Achilles tendinopathy is a clinical condition characterized by pain and swelling in and around the Achilles tendon, mainly arising from overuse[6]. It is often a result of increase in training load. The Achilles tendon is the strongest tendon in the body serving both the gastrocnemius and soleus muscles originating near the mid-calf and inserts posteriorly at the calcaneus [7]. Achilles tendinopathy commonly happens in the mid-substance of the tendon or less commonly at its insertion in the calcaneus[8]. Previous observational studies have proved that competitive athletes have a 24% lifetime incidence of Achilles tendinopathy.

Soccer is widely recognized to be the world's most popular sport [14], and is played at different levels, worldwide, national, state, universities and even secondary schools. It is played by players in over 200 countries, making it the world's most popular sport [14]. Soccer involves several crafts that demand complex movements making the athletes susceptible to injuries, and tendinopathy is one of the most recorded overuse sports injuries in modern societies [15].

Participation in soccer is a worldwide event with tremendous health and economic benefits [16], increased self-esteem, peer socialization, general fitness, as well as reducing various diseases risks, crime rate and poverty [17]. A lot of attention has been given to elite soccer players

while in university soccer players, there are higher numbers of participants who began playing early and continue for a longer period. For some of them, their gears are not always suitable for the sport, thereby increasing the threat of tendinopathy [9]. The average university soccer players play soccer at least three (3) times a week, and Achilles tendinopathy occurs as a result of overuse. The increase in the popularity of soccer and expectations from players make meaningful numbers of soccer injuries conceivable. University soccer players also go through rigorous physical training, preparing for inter-club competition, inter- school competition. They are not professionals, so much attention is not given to them, but the trainings and constant field activity also makes them susceptible to sports injuries like Achilles tendinopathy. Also, intrinsic factors inherent in individual's physiology could also influence susceptibility to Achilles tendinopathy [9]

METHODOLOGY

Study Design, Setting And Sampling

Study Design: A Cross-sectional Study

Study Setting: Football academies of Ahmedabad city

Sampling Technique: Convenient Sampling

Population: Football players

Sample Size: 100 subjects, based on following formula:

$N = Z^2 P(1-P) / d^2$

Where, N= Sample size

Z= Level of confidence (95%)

P=Expected Prevalence (Previous researches) d=Precision (Corresponding Effect size)

Selection Criteria

Inclusion Criteria:

- Athletes who are willing to take participate in the survey.
- Age group 16 to 35 years.
- Male and Female football players.
- Playing football more than 2 years.

Exclusion Criteria:

- Athletes who are not willing to take part in survey
- Participants who actively engaged in other sports like basketball, sprinting were excluded because these sports could make them prone to Achilles tendinopathy.
- Any lower extremity trauma or injury in past 5 years.
- Subjects having connective tissue disorder
- Subjects having any neuromuscular disoder

MATERIALS REQUIRED

- Assessment form
- Consent form
- Pen, Pencil and Paper
- Mat and Plinth

METHODOLOGY

Ethical approval was obtained from Institutional Ethical Committee of Venus institute of physiotherapy, Gandhinagar. A letter of introduction from the Department of physiotherapy, Venus institute of physiotherapy, Gandhinagar was given to the coaches of the various teams seeking for permission to carry out the research with their teams. Informed consent was obtained from all participants and assuring them of confidentiality of their information.

The Royal London test, a psychometrically sound instrument, was used for assessing Achilles tendinopathy [18][19]. To start the test, the participant lay prone on the plinth with the feet hanging outside the table. The ankle was in neutral position and the Achilles tendon was palpated for tenderness.

The participant was asked to dorsiflex and the ankle was palpated on dorsiflexion. Results were classified as tenderness present on dorsiflexion or absent. In patients with Achilles tendinopathy, tenderness was felt on palpation with the ankle in neutral position, but on dorsiflexion tenderness was absent or reduced.

Figure 1: Flowchart of the study procedure

OUTCOME MEASURE

VISA–A Scale:

the Victorian Institute of Sports Assessment-Achilles (VISA-A) questionnaire was administered; it is a valid, reliable, and user-friendly index of the severity of Achilles tendinopathy, which contains eight questions that covers the 3 domains of pain (questions 1 to 3), function (questions 4 to 6), and activity (questions 7 and 8). Questions 1 to 7 are scored over 10, and question 8 carries a maximum of 30. Scores are summed to give a total of 100. An asymptomatic person would score 100. For question 8 which has three part (A, B, C), participants must answer only one part; A, B, or C that relates to the person's reality. If the participant experiences pain when performing sport, he or she automatically loses at least 10, and possibly 20, points.

Reliability And Validity of Visa-A:

J M Robinson The VISA-A questionnaire: a valid and reliable index of the clinical severity of Achilles tendinopathy: To develop and test a questionnaire based instrument that would serve as an index

of severity of Achilles tendinopathy. Item generation, item reduction, item scaling, and pretesting were used to develop a questionnaire to assess the severity of Achilles tendinopathy. The final version consisted of eight questions that measured the domains of pain, function in daily living, and sporting activity. Results range from 0 to 100, where 100 represents the perfect score. Its validity and reliability were then tested in a population of non-surgical patients with Achilles tendinopathy (n = 45), presurgical patients with Achilles tendinopathy (n = 14), and two normal control populations (total n = 87). The VISA-A questionnaire had good test-retest (r = 0.93), intrarater (three tests, r = 0.90), and interrater (r = 0.90) reliability as well as good stability when compared one week apart (r = 0.81). The mean (95% confidence interval) VISA-A score in the non-surgical patients was 64 (59-69), in presurgical patients 44 (28-60), and in control subjects it exceeded 96 (94-99). Thus the VISA-A score was higher in non-surgical than presurgical patients (p = 0.02) and higher in control subjects than in both patient populations (p<0.001). The VISA-A questionnaire is reliable and displayed construct validity when means were compared in patients with a range of severity of Achilles tendinopathy and control subjects.

RESULT

All statistical analysis was done using SPSS 25.0 software for windows. Descriptive analysiswas used to obtain mean and standard deviations.

Demographic Data

Age: The research was performed on 100 participants between the age of 16-35. There were 56 patients between the ages of 16 to 25, 44 patients between the age 26 to 35.

Table 1: Age Distribution

TOTAL SCORE (/100) %

DISCUSSION

The overall incidence rate is 1.85 per 1,000 registered persons per year, and for the adult population it is 2.35. There are no other studies on the incidence rates of Achilles tendinopathy in the general population to compare these results with. The prevalence rate was higher than that for another tendinopathy like lateral epicondylitis of 1.3% (men) and 1.1% (women) in 9,696 persons registered at two general practitioners.10 The incidence rates in our study are lower than the incidence of 2.98 found in the military population4 and than the annual incidence 7% and 9% in top-level runners.2 3 While it seems plausible that the incidence rate of Achilles tendon injuries is higher in athletes than within a more general population, only in 35% of the cases in our study was a relationship with sports activity described. Intrinsic risk factors such as body weight and insulin resistance might also play a role.11 Although we could not assess information on body weight, the diagnosis of Diabetes Mellitus (DM) was available from the medical records.

The minor difference between the incidence and prevalence rate suggests that most patients only visit their General Practitioner (GP) once with their Achilles tendon problems. This might be because of a short duration of symptoms or that the patients go to a physiotherapist or sports physician afterwards.

This cross-sectional study has some limitations, due to which the actual incidence of Achilles tendinopathy is probably higher than observed in this study. Firstly, not every person with a certain complaint will visit a healthcare professional. In a cross-sectional population-based study, Picavet et al reported that approximately 50% of the patients with musculoskeletal complaints visited a healthcare professional. However, those with severe or persistent complaints will probably seek healthcare. Second, while most patients in the Dutch healthcare system will visit their GP before being referred to a therapist or specialist, since 2006 patients can visit a physiotherapist or sports physician without referral by a GP. It would be interesting to know the incidence rates of Achilles tendinopathy within the patient population of the Dutch physiotherapists and sports physicians as well, but since the denominators of these populations are unknown, no exact incidence rates could be obtained. Finally, because there is no specific registration code available for Achilles tendinopathy, GPs register this injury using other or more general codes.

In concordance with other studies,13 most cases were encountered in the middle-aged population (age group 41–60 years). At present, the prevalence of Achilles tendon rupture in PE is not clear, a study showed that the incidence of Achilles tendon rupture was higher in sedentary men aged 29–48. It was speculated that the relationship between AT and age may be due to the changes of mechanical properties of Achilles tendon with age. Recently, Sprague et al. found that there was a positive correlation between age and viscosity of uninjured Achilles tendon. Aging was usually associated with reduced cellular structure, increased glycoamine polysaccharide content, and decreased fibrous tissue, all of which can lead to degenerative changes in the Achilles tendon. At the same time, the aging tendon loses elasticity, forcing the muscle to work harder, eventually leading to changes in tendon structure.

Consistent with the previous study, we found that the prevalence of AT in football players was significantly higher than in other sports. This may be related to the high training intensity of football players and the heavy load on Achilles tendon. Some reviews showed that the prevalence of Achilles tendon injury in running and track and field sports is the highest. Ball games generally require athletes to make a rapid judgment according to the competition form in a short time, such as repeated bounce, dribble pass, back and forth quick start and other technical actions with a large load on the Achilles tendon. These technical actions need the support of the Achilles tendon, which also lays a huge hidden danger for its injury.

CONCLUSION

This study was conducted among Football players of Ahmedabad city and it revealed that players those are having long training hours prone to developing tendinopathy. This study shows that there is Age group

of 16-25 having prevalence of 68% and age group of 26-35 having prevalence of 24%.

ABSTRACT

Background: Neck pain commonly seen in back of neck and between the bases of neck to shoulder mainly indicates the involvement of upper trapezius muscle . About two third of people will experience neck pain at some point in their lives. A considerable proportion of patients with upper trapezius spasm had been treated with medical and physical therapy interventions. The study aims to compare the effectiveness of Myofascial Release technique (MFR) versus hot pack in relieving pain, improving cervical ROM and pressure pain threshold in upper trapezius spasm patients. **Methodology:** Total 60 subjects will be assessed which will be divided into 2 groups A and B and then they'll be given MFR and Hot pack treatment respectively to both groups . They'll be assessed and monitored throughout the treatment and their NPRS pain intensity scale will be recorded week by week. **Result:** Out of 60 participants 15 were eliminated because of various conditions which wasn't applicable for the study. 27 were females and 18 were males in them. In this comparison the MFR seems to be slightly more effective than Hot pack in upper trapezius spasm. **Conclusions:** The study shows that although both techniques are effective in depletion of symptoms and associated disability in upper trapezius muscle spasm, Myofascial Release Technique gave better results as compared to Hot pack.

KEYWORDS

NPRS (Numeric Pain Rating Scale), Tenderness Grading Scale, MFR and Hot pack.

INTRODUCTION

The trapezius muscle is a large superficial back muscle that resembles a trapezoid . It extends from the external protuberance of the occipital bone to the lower thoracic vertebrae and laterally to the spine of the scapula . The trapezius has upper , middle , and lower groups of fibers.

The trapezius is a shawl muscle or musculus calculate"(shaped like a monk"s hood) because of its shape and location. The low – level activity of the upper trapezius is frequently found during sitting and standing which is related to head posture and is a common source of tension and neck pain in people who work at a desk and computers or who spend many hours driving (1)

Neck pain is very common in the region of the upper trapezius muscle. About two - thirds of people experience neck pain at some point in their lives . In middle age , Prevalence is highest and women are more affected than men.

Myofascial release is a soft tissue mobilization technique, defined as “the facilitation of mechanical, neural and psychophysiological adaptive potential as interfaced via the myofascial system. (2)

By MFR there is a change in the viscosity of the ground substance to a more fluid state which eliminates the fascia's excessive pressure on the pain – sensitive structure and restores proper alignment. (2)

Only a few studies have looked at the impact of myofascial release (MFR) techniques on the primary metrics of patient outcomes.

Myofascial release is a form of manual therapy that aims to release tension and tightness in the fascia , which is the connective tissue that surrounds and supports muscles and organs . It involves applying sustained pressure to specific points on the body to release tension and improve circulation . Myofascial release has been shown to be effective in reducing pain and improving range of motion in people with a variety of musculoskeletal conditions , including neck and shoulder pain.

Upper trapezius spasm , on the other hand , is a condition that is often treated with stretching and massage of the affected muscle . Stretching and massage can help to relieve tension and reduce pain in the upper trapezius muscle . However , the effectiveness of these treatments may vary depending on the severity of the spasm and the underlying cause of the condition.

In this study , we aim to compare the effectiveness of myofascial release and upper trapezius spasm in reducing pain and Improving range of motion in people with upper trapezius spasm . We will be looking at factors such as pain intensity , range of motion , and functional status to determine which treatment is more effective for this condition .

Previous research has shown that MFR Improves ROM and decreases pain. Furthermore , Kain et al. reported significant improvements in shoulder joint ROM among healthy recipients of either MFR or hot pack therapy (HPT).

The post - treatment effects of MFR intervention have been postulated to parallel those of massage and soft tissue mobilization techniques. These effects include circulatory changes, blood flow changes, capillary dilatation, cutaneous temperature changes, and changes in metabolism. These changes are reflected in increased ROM, improved biomechanics of the joint, increased Extensibility of tissues, improved flexibility, muscle relaxation, reduction of spasm, decreased tone, reduction of edema and analgesia.

The purpose of this study was to compare end results spasm, after MFR techniques and hot pack application. Heat in its various forms has been a popular longstanding modality used to facilitate healing. Transmission of heat, either by conduction, convection, radiation, and / or conversion, comprises the most common methods of heat usage.

Hot packs are designed to deliver moist heat to the affected area, promoting muscle relaxation, increased blood flow, and pain relief. The heat penetrates deep into the muscle tissue, helping to relax tense muscles, decrease muscle spasms, and improve flexibility. Additionally, the increased blood flow to the area can aid in the removal of metabolic waste and promote the delivery of oxygen and nutrients, accelerating the healing process.

The application of a hot pack on the upper trapezius typically involves wrapping the pack in a towel or using a specialized cover to protect the skin from direct heat. The pack is then placed on the affected area for a specific duration , usually around 15-20 minutes. It's important to ensure that the temperature is comfortable and not too hot to avoid burns or skin irritation.

For this study, hot packs were chosen as our comparative modality for a number of reasons :

(1) The simplicity of access to the modality
(2) The ease of application
(3) The accepted usage within the field of rehabilitation
(4) Minimal contraindications
(5) Standardization of application.

Methodology

Study Design and Setting

Study Design: COMPARATIVE STUDY
Study Duration: 4 weeks (5 sessions per week)

Population
 Subjects with upper trapezius spasm between 20 - 40 years of both sexes.

Selection Critaria
Inclusion Critarea
- AGE : 20 - 40 years
- Patient complains of pain in upper trapezius for more than 1 month.
- Subjects are willing to participate .

Exclusion Critarea
- Patients taking 3 or more tablets of 500 mg. paracetamol in a day for pain relief.
- Neurological disorders .
- Any other condition than upper trapezius spasm .
- Any other therapy for trapezius spasm .

Sampling Method and Sample Size
Sampling Method: Simple random sampling
Sample Size: 60

Procedure
A therapist assessed patients at the orthopedic and sports physiotherapy department who had been recommended by an orthopedic physician . The included patients ranged in age from 20 to 40 years old , had neck pain from at least one month , both male and female , displayed the jump sign , which is characterized by patient vocalization or retreat , and had a palpable painful site in the upper trapezius muscle . If they had a history of latent trigger points , healing fractures over the neck and upper back , dermatitis over the upper back , clotting disorders , wounds over the neck region , shoulder pathology , or a degenerative cervical spine , cervical radiculopathy or myelopathy they were eliminated.

The exercises' procedures will be shown, and the subjects will be given instructions on what to do and what not to do .

60 Subjects will be selected according to the selection criteria and the informed consent will be obtained from them . They will be assessed with Neck disability index , NPRS and Tenderness and their respective scores will be documented . The selected subjects will be randomly divided into 2 groups A and B group with nearly same subjects in each group .

All 60 subjects will be randomly assigned to 1 of 2 treatment groups :
- Group - A (n=20) MFR + exercises ,
- Group - B (n=20) Hot pack + exercises ,
- Hot pack : position – Sitting
- Duration – 20 minutes

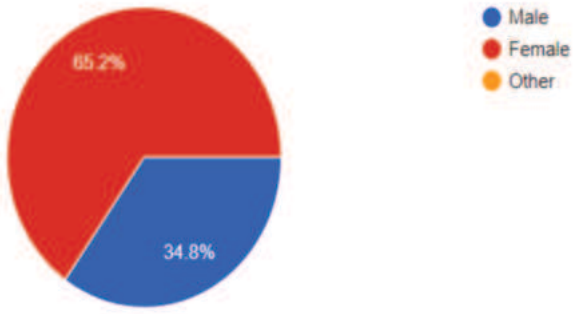
Figure 1 illustrates the screening results , which revealed that 15 people were eliminated , 8 did not give consent , and 2 had cervical radiculopathy and 5 had wounds over the neck region

In this study , 45 participants - 27 females and 18 males – aged 20 to 40 years were enrolled . A consent form was signed by everyone and They were then randomly allocated , using sealed envelopes , into three groups , group B .

Outcome Measures
1. NPRS (NUMERICAL PAIN RATING SCALE): This scale is for assessing the pain score of a patient on different week throughout the treatment.
2. Neck Disability Index.
3. Tenderness Grading.

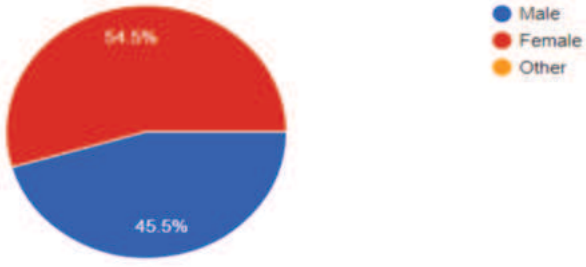
RESULTS
1. Gender Distribution
- There was total 45 participants which was participated in the treatment. They were nearly equally divided in 2 groups A and B.
- 23 patients were in Group A which had MFR in the sessions. 22 patients were in a Group B which had Hot pack therapy.
- Total 27 females and 18 males participated in the treatment.

Group (A) Gender Distribution for MFR



(1.1)

Group (B) Gender Distribution for Hot pack



(1.2)

- Chart 1.1 and 1.2 represents the Gender distribution for both Group A and B respectively.

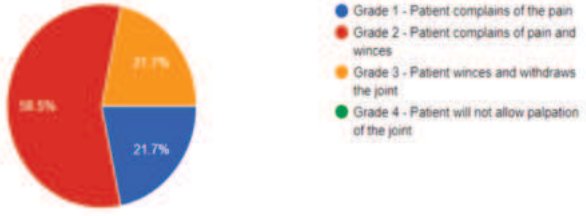
2. Age Distribution
- The mean age of MFR treatment for participants was 30.038 contains 23 people.
- The mean age of Hot pack treatment participants was 31.045 contains 22 people.

(2.1) Age Distribution for both group

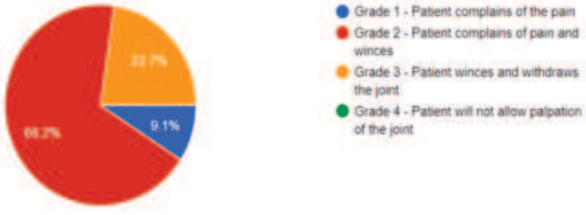
3. Tender Grading Scale Distribution

Measures	Mean
Group A	30.038
Group B	31.045

- Tenderness scale for every patient recorded before pretreatment.



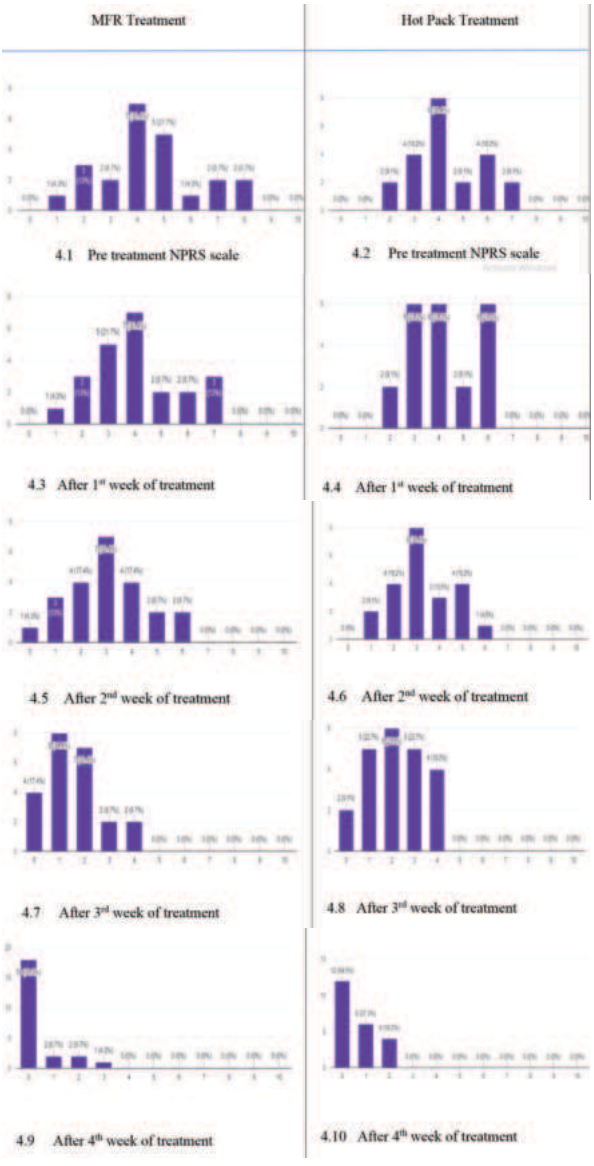
3.1 Group A Tender Grading Scale Distribution



3.2 Group B Tenderness Grading Scale Distribution
- These 2 pie charts 3.1 and 3.2 represents the tenderness grading scale of participants from Group A and Group B respectively.

4. Pain Intensity Comparison
- Numeric pain rating scale measured for pretreatment and then week by week for both treatments.
- Here presenting tables and graphs for NPRS scale.

PRINT ISSN No. 2277 - 8179 | DOI : 10.36106/ijsr



- Graph 4.1 and 4.2 represents the pain intensity of participants before treatment.
- Graph 4.3 and 4.4 represents the pain intensity of participants after 1st week treatment of MFR and Hot pack respectively.
- Graph 4.5 and 4.6 represents the pain intensity of participants after 2nd week treatment of MFR and Hot pack respectively.
- Graph 4.7 and 4.8 represents the pain intensity of participants after 3rd week treatment of MFR and Hot pack respectively.
- Graph 4.9 and 4.10 represents the pain intensity of participants after 4th week treatment of MFR and Hot pack respectively.

Differences Between Pain Intensity Throughout The Different Treatments Accordingly.

Measures	Mean value of Pain	Difference Of pain intensity	
	Pre treatment	Post	
Group A	5.06	0.42	4.64
Group B	4.46	0.65	3.81

(4.11) Mean value difference for both treatment

- This table 4.11 represents the difference between pretreatment pain intensity and post treatment of participants.
- Pretreatment pain intensity in Group A was 5.06 and post treatment value was 0.42 which occurs the difference of 4.46.
- Pretreatment pain intensity in Group B was 4.46 and post treatment value was 0.65 which occurs the difference of 3.81.

DISCUSSION

- His was a comparative study to evaluate the efficacy of hot pack and MFR on trapezius muscle pain due to spasm, the most found musculoskeletal disorder.
- The treatment time duration was 5 sessions per week for 4 weeks for both of Group A and B which had 23 and 22 participants in respective Group.
- After analysis of baseline data and post treatment scores, it reveals significant improvement ($p<0.05$) in group A after 4 weeks treatment session.
- There was significant difference ($p<0.05$) in post treatment comparison between MFR and hot pack group. The findings of this study suggested both MFR and hot pack along with shoulder girdle and cervical exercises were effective in the treatment of upper trapezius.
- The results revealed that both methods of treatment applications provided a similar physiological response on the spasm of trap muscle. The hot pack inducing an increase of blood circulation in the superficial tissue and leading to fluid distribution in the trigger point area and therefore decreasing tissue density.
- Thermal effect further induced blood circulation toward the treated area, resulting in physiological changes and clinical outcomes such as reduced muscle spasm, altered threshold of receptors, minimizing hypoxia, alleviating pain and promoting the healing process.

Whereas, in MFR the stretch is applied to the fascia, which being the superficial structure has the direct effect. Muscle being the deeper structure will have an indirect effect. So, instant effect in terms of relief in the pain and spasm will be seen immediately following treatment, but it may not last for long period. Multiple sessions may be required to have the cumulative effect and sustained relief.

CONCLUSION

As the study shows that although both techniques are effective in depletion of symptoms and associated disability in upper trapezius muscle spasm, Myofascial Release Technique gave better results as compared to Hot pack.

Limitations

- Ergonomical advices and posture correction not employed.
- Limited Age Group , may applicable to larger age group.
- The study had a small sample size.
- No follow up taken after 4 weeks to see the sustained effect of therapy.
- Side specific involvement as per the dominancy was not considered for analysis.
- Short duration of the study.

Future Recomendentions

- It is believed that the conclusion of present study utilizes in the future researches. There is a need for long term studies on efficacy of treatments in reducing symptoms of trap muscle spasm using advanced techniques.
- Thus future studies should use the multidimensional approach regarding the treatments. By this study a good treatment plan can be made for better recovery of patient.
- This study can be further investigated with a large number of samples in relation with lifestyle modification and physiotherapy intervention.

ABSTRACT

Introduction: Chronic neck pain is a prevalent issue among Ola/Uber drivers in Gujarat, adversely impacting their daily functioning and overall well-being. Despite its significance, research focusing on the prevalence and impact of chronic neck pain in this occupational group remains limited. This study aims to address this gap by examining the prevalence, severity, and associated factors of chronic neck pain among Ola/Uber drivers in Gujarat. **Participants:** A total of 300 Ola/Uber drivers from various regions of Gujarat participated in the study, providing valuable insights into the prevalence and impact of chronic neck pain in this population. **Results:** Analysis of the data revealed that a significant proportion of Ola/Uber drivers experienced chronic neck pain, with 66% of the participants reporting some degree of disability according to the Neck Disability Index (NDI). Additionally, varying levels of pain intensity were observed, highlighting the considerable burden of chronic neck pain on the drivers' well-being and work performance. **Conclusion:** The findings underscore the urgent need for targeted interventions and ergonomic improvements to alleviate the burden of chronic neck pain among Ola/Uber drivers in Gujarat. By addressing the underlying factors contributing to neck pain and implementing strategies to improve driver well-being, we can enhance the overall quality of life and safety for Ola/Uber drivers in Gujarat.

INTRODUCTION:

About Anatomy Of Neck

The neck serves as a crucial anatomical region connecting the head to the trunk, housing vital structures responsible for various physiological functions. Understanding the intricate anatomy of the neck is fundamental for medical practitioners across multiple specialties.

The neck comprises several layers, including skin, superficial fascia, platysma muscle, deep cervical fascia, and numerous structures such as blood vessels, nerves, lymph nodes, and viscera. The cervical vertebrae provide structural support while facilitating movement of the head and neck.

Muscles:
Key muscles in the neck include the sternocleidomastoid, scalene, trapezius, and suprahyoid muscles. These muscles play crucial roles in head movement, respiration, swallowing, and speech.1

Blood Supply:
The neck receives arterial blood supply primarily from the common carotid arteries, which bifurcate into internal and external carotid arteries. The vertebral arteries also contribute to cerebral circulation, branching off from the subclavian arteries.

Nerves:
Nerves of the neck include the cervical plexus, brachial plexus, vagus nerve, phrenic nerve, and sympathetic chain. These nerves innervate various structures in the neck and regulate autonomic functions.2

Lymphatics:
The neck contains an extensive network of lymph nodes organized into chains, including the superficial and deep cervical lymph nodes. These nodes play a crucial role in immune surveillance and lymphatic drainage from the head and neck region.

Clinical Significance:
An understanding of neck anatomy is essential for diagnosing and treating various conditions, including neck trauma, infections, tumors, and neurological disorders. Surgical procedures in the neck region require precise knowledge of anatomy to minimize complications. 3951

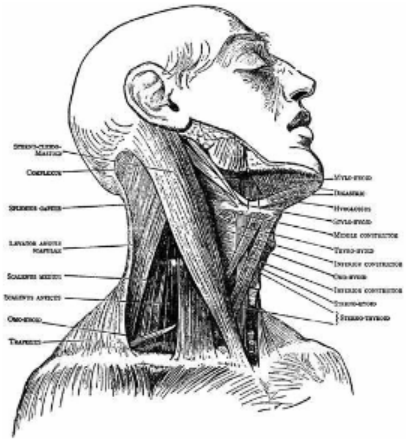

Fig: 1 Anatomy Of Neck

About Neck Pain

Neck pain is a common complaint encountered in clinical practice, affecting individuals of all ages and backgrounds. Understanding the various types of neck pain is essential for accurate diagnosis and appropriate management.

Types of Neck Pain:

1. Mechanical Neck Pain:

- Mechanical neck pain typically results from musculoskeletal causes such as poor posture, muscle strain, or degenerative changes in the cervical spine.
- It is often exacerbated by certain activities or positions and may improve with rest, activity modification, and physical therapy.4

2. Cervical Radiculopathy:

- Cervical radiculopathy occurs when a nerve root in the cervical spine becomes compressed or irritated, leading to pain, weakness, and sensory changes along the distribution of the affected nerve.
- Common causes include herniated discs, spinal stenosis, or foraminal narrowing.

3. Cervical Myelopathy:

- Cervical myelopathy refers to compression or injury to the spinal cord in the cervical region, resulting in motor, sensory, and reflex abnormalities.
- Causes include degenerative disc disease, cervical spondylosis, or spinal cord tumors.

4. Whiplash-Associated Disorder (WAD):
- WAD occurs following sudden acceleration-deceleration forces on the neck, commonly seen in motor vehicle accidents.
- Symptoms may include neck pain, stiffness, headache, and sometimes neurological deficits.5

5. Non-Specific Neck Pain:
- Non-specific neck pain refers to pain in the neck region without a specific identifiable cause.
- It may result from a combination of factors including poor posture, stress, muscle tension, and psychosocial factors.

Clinical Considerations:
- A thorough history and physical examination are essential for evaluating neck pain and determining its underlying cause.
- Diagnostic imaging studies such as X-rays, MRI, or CT scans may be indicated to further evaluate the cervical spine and surrounding structures.
- Treatment options for neck pain vary depending on the underlying cause and may include medications, physical therapy, injections, or surgical intervention in severe 6

Neck Pain Due To Bad Posture And Stress

Neck pain attributed to bad posture and stress is a common complaint encountered in clinical practice, affecting individuals of all ages and occupations. Understanding the underlying mechanisms and management strategies for this type of neck pain is essential for healthcare professionals.

Etiology:

1. Bad Posture:
- Prolonged periods of sitting or standing with poor posture can lead to excessive strain on the muscles, ligaments, and joints of the neck.
- Common postural deviations contributing to neck pain include forward head posture, rounded shoulders, and excessive cervical lordosis.

2. Over Stress:
- Psychological stress and tension can manifest physically as muscle tightness and increased muscle tone in the neck and shoulder region.
- Chronic stress can lead to the development of trigger points, muscle imbalances, and reduced pain threshold, exacerbating neck pain symptoms.

Pathophysiology:
- Poor posture and stress can result in muscular imbalances, leading to altered biomechanics of the cervical spine and surrounding structures.
- Chronic tension and strain on the neck muscles can cause microtrauma, inflammation, and decreased blood flow, contributing to the development of neck pain.7

Neck Disability Index

The Neck Disability Index (NDI) is a validated tool used to assess the impact of neck pain on daily functioning and quality of life. It consists of 10 items covering various aspects of physical and functional impairment related to neck pain. 8

Numeric Pain Rating Scale (NPRS)

The Numeric Pain Rating Scale (NPRS) is a commonly used tool for quantifying pain intensity on a numerical scale from 0 to 10, where 0 represents no pain and 10 represents the worst pain imaginable. It provides a quick and simple method for patients to communicate their pain levels to healthcare providers.9

AIM OF THE STUDY

The aim of this study is to investigate the prevalence and factors associated with chronic neck pain among Ola/Uber drivers in Gujarat, India.

Specifically, the study seeks to:
1. Determine the prevalence of chronic neck pain among Ola/Uber drivers in Gujarat.
2. Identify demographic, occupational, and psychosocial factors contributing to chronic neck pain in this population.
3. Assess the impact of chronic neck pain on the quality of life, work performance, and driving safety of Ola/Uber drivers.
4. Explore potential interventions and preventive strategies to alleviate neck pain and improve the overall well-being of Ola/Uber drivers in Gujarat.

This study aims to provide valuable insights into the burden of chronic neck pain among Ola/Uber drivers and inform the development of targeted interventions to address this occupational health issue.

Need Of The Study

The need for investigating the prevalence of chronic neck pain among Ola/Uber drivers in Gujarat arises from several key factors:
1. Occupational Health Concerns: Ola/Uber drivers spend prolonged periods driving, often in non-ergonomic positions, which may predispose them to musculoskeletal disorders such as chronic neck pain. Understanding the extent of this issue is crucial for addressing their occupational health needs.
2. Lack of Research: Despite the growing reliance on ridesharing services like Ola and Uber, there is limited research focusing on the musculoskeletal health of drivers, particularly regarding chronic neck pain. This study will fill a critical gap in the literature.
3. Impact on Quality of Life: Chronic neck pain can significantly impact the quality of life, work productivity, and overall well-being of individuals. Assessing the prevalence of neck pain among Ola/Uber drivers will shed light on the magnitude of this problem and its implications.
4. Driver Safety: Neck pain can impair mobility and concentration, potentially compromising driver safety and increasing the risk of accidents. Understanding the association between neck pain and driving performance is essential for ensuring road safety.
5. Intervention Development: By identifying the factors contributing to chronic neck pain among Ola/Uber drivers, this study will inform the development of targeted interventions and preventive measures to alleviate pain and improve the health outcomes of drivers.

In summary, there is a pressing need to investigate the prevalence of chronic neck pain among Ola/Uber drivers in Gujarat to address their occupational health concerns, improve their quality of life, ensure driver safety, and inform the development of effective interventions.

Objective Of The Study

The objective of this study is to determine the prevalence of chronic neck pain among Ola/Uber drivers in Gujarat, India, and to explore associated risk factors and impact on drivers' quality of life and work performance. Specifically, the study aims to:
1. Assess the prevalence of chronic neck pain among Ola/Uber drivers in Gujarat through a cross-sectional survey.
2. Identify demographic, occupational, and psychosocial factors associated with chronic neck pain in this population.
3. Evaluate the impact of chronic neck pain on drivers' quality of life, work productivity, and driving safety.
4. Investigate coping strategies and healthcare-seeking behaviors adopted by Ola/Uber drivers in response to chronic neck pain.
5. Provide recommendations for interventions and preventive measures to alleviate neck pain and improve the overall well-being of Ola/Uber drivers in Gujarat.

Study Design And Study Setting

Study Design:

The study will employ a cross-sectional design to investigate the prevalence of chronic neck pain among Ola/Uber drivers in Gujarat.

Study Duration:

The study will be conducted over a period of 6 months, from [10 October, 2023] to [12 March, 2024].

Population:

The target population will consist of Ola and Uber drivers operating in various cities and towns across Gujarat.

Selection Criteria:

a. Inclusion Criteria:
1. Licensed Ola/Uber drivers.
2. Currently active in driving for Ola/Uber services.
3. Willing to participate in the study.
4. Able to understand and respond to the questionnaire in Gujarati or English.

b. Exclusion Criteria:
1. Drivers with a history of traumatic neck injury in the past 6 months.
2. Drivers currently undergoing treatment for neck-related disorders.
3. Drivers with pre-existing chronic conditions affecting the neck, such as cervical spondylosis or rheumatoid arthritis.

Sampling Method:
A convenience sampling method will be employed to recruit participants. Researchers will approach Ola/Uber drivers at various pick-up and drop-off points, rest areas, and driver hubs across different cities in Gujarat.

Sampling Size:
Based on previous studies and considering an estimated prevalence rate of chronic neck pain among Ola/Uber drivers in Gujarat, a sample size of 300 drivers will be targeted to achieve a sufficient level of statistical power and precision in estimating the prevalence rate with a 95% confidence interval and a 5% margin of error.

Outcome Measures:
Numeric Pain Rating Scale (NPRS)
Neck Disability Index (NDI)

METHODOLOGY

Table: 1 Flow Chart Of Procedure

1. Participant Recruitment:
- Identify and approach Ola/Uber drivers at various locations such as taxi stands, transportation hubs, and rest areas across different cities in Gujarat.
- Provide a brief explanation of the study aims, procedures, and benefits to potential participants.
- Obtain informed consent from eligible drivers willing to participate in the study.

2. Demographic Information:
- Collect demographic data including age, gender, educational level, years of driving experience, average daily driving hours, and any previous history of neck pain or related conditions.

3. Numeric Pain Rating Scale (NPRS):
- Explain the NPRS to participants, emphasizing that it is a simple tool used to assess the intensity of their neck pain on a scale from 0 to 10, with 0 representing no pain and 10 representing the worst possible pain.
- Provide a numerical scale to the participants.
- Ask participants to rate their current neck pain intensity by selecting a number on the scale that best represents their level of pain.
- Record the participant's NPRS score.

4. Neck Disability Index (NDI) Scale:
- Introduce the NDI scale to participants, explaining that it is a questionnaire designed to assess the impact of neck pain on their daily activities and functioning.
- Provide a printed or electronic copy of the NDI questionnaire to participants.
- Instruct participants to read each question carefully and select the response that best reflects their current level of disability or limitation due to neck pain.
- Assist participants in completing the questionnaire if necessary, ensuring that they understand each item.
- Collect the completed NDI questionnaire from the participants.

5. Data Collection and Recording:
- Enter the demographic information, NPRS scores, and NDI questionnaire responses into a secure database or electronic spreadsheet.
- Ensure accuracy and consistency in data entry by double-checking entries against the original forms.
- Assign unique identifiers or codes to participants to maintain confidentiality and anonymity of their data.

IMAGE: 2 DATA COLLECTION

IMAGE: 3 DATA COLLECTION

6. Quality Control:
- Periodically review a subset of data entries to identify any errors or inconsistencies.
- Address any discrepancies by verifying the original data sources and making necessary corrections.
- Conduct regular checks to ensure compliance with ethical guidelines and data protection regulations.

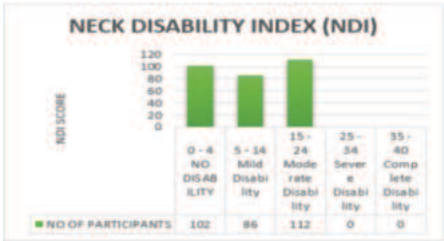
7. Data Analysis:
- Analyze the collected data using appropriate statistical methods to determine the prevalence of chronic neck pain among Ola/Uber drivers in Gujarat.
- Calculate descriptive statistics such as mean NPRS scores, NDI scores, and prevalence rates of neck pain severity and disability.
- Explore potential associations between demographic variables, driving characteristics, and neck pain outcomes using inferential statistics if applicable.

8. Reporting and Dissemination:
- Prepare a comprehensive report summarizing the study findings, methodology, and conclusions

RESULT

1. Neck Disability Index (NDI) Scores:
- No Disability (0-4 score): 102 participants
- Mild Disability (5-14 score): 86 participants
- Moderate Disability (15-24 score): 112 participants
- Severe Disability (25-34 score): 0 participants
- Complete Disability (35-40 score): 0 participants

Table : 2 Neck Disability Score



2. Numeric Pain Rating Scale (NPRS) Scores:
- Score 1: 0 participants
- Score 2: 66 participants
- Score 3: 36 participants
- Score 4: 86 participants
- Score 5: 60 participants
- Score 6: 52 participants
- Score 7, 8, 9, 10: 0 participants

Table: 3 Numeric Pain Rating Scale Score

3. Individuals with Disability:
- Individuals with disability: 198 participants (66%)
- Individuals without disability: 102 participants (34%)
- Total number of participants: 300

Table: 4 Disability Evaluation

The prevalence of chronic neck pain among Ola/Uber drivers in Gujarat is significant, with a total of 198 participants (66%) reporting some level of disability according to the Neck Disability Index (NDI). Among these, the majority exhibit moderate disability, indicating a considerable impact on daily functioning. Numeric Pain Rating Scale (NPRS) scores reveal varying levels of pain intensity, with a notable proportion of participants reporting scores ranging from 2 to 6. These findings underscore the need for targeted interventions and ergonomic improvements to mitigate the burden of chronic neck pain among Ola/Uber drivers in Gujarat and enhance their overall well-being.

DISCUSSION

Chronic neck pain is a complex and multifaceted issue that poses significant challenges for Ola/Uber drivers in Gujarat. This comprehensive discussion will delve into the various facets of chronic neck pain among this occupational group, including its prevalence, impact, contributing factors, and potential avenues for intervention.

Prevalence and Impact of Chronic Neck Pain:

The findings of this study underscore the high prevalence and considerable impact of chronic neck pain among Ola/Uber drivers in Gujarat. **With 66% of participants reporting some degree of disability** according to the Neck Disability Index (NDI), it is evident that chronic neck pain significantly affects the daily functioning of these drivers. Moreover, the distribution of NDI scores highlights the diverse spectrum of disability experienced by drivers, ranging from mild to moderate impairment in performing daily activities. This not only impacts their ability to work effectively but also has implications for their overall quality of life and well-being.

Factors Contributing to Chronic Neck Pain:

Several factors contribute to the development and exacerbation of chronic neck pain among Ola/Uber drivers. Prolonged periods of driving, often in non-ergonomic conditions, can lead to muscle fatigue, tension, and poor posture, all of which are known risk factors for neck pain. Additionally, the repetitive nature of driving, combined with frequent use of mobile devices and navigation systems, can further strain the neck muscles and exacerbate existing pain. Furthermore, psychosocial factors such as stress, anxiety, and job dissatisfaction may also play a role in the development and persistence of chronic neck pain among drivers.

Impact on Work Performance and Well-being:

Chronic neck pain not only affects the physical health of Ola/Uber drivers but also has significant implications for their work performance and overall well-being. The moderate to severe pain intensity reported by a substantial proportion of drivers, as indicated by Numeric Pain Rating Scale (NPRS) scores, can impair their ability to concentrate, make quick decisions, and react to changing road conditions, thereby compromising driving safety. Moreover, the discomfort and disability associated with chronic neck pain may lead to decreased job satisfaction, increased absenteeism, and financial strain, further exacerbating the drivers' overall stress and dissatisfaction.

Potential Avenues for Intervention:

Addressing the burden of chronic neck pain among Ola/Uber drivers requires a multifaceted approach that addresses both individual and systemic factors. Ergonomic improvements in vehicle design, including adjustable seats, lumbar support, and headrests, can help alleviate strain on the neck muscles and promote better posture during driving. Additionally, education and training programs on proper ergonomics, stretching exercises, and relaxation techniques can empower drivers to proactively manage their neck pain and prevent its recurrence. Furthermore, access to timely and affordable healthcare services, including physiotherapy, chiropractic care, and pain management interventions, is essential to address the underlying causes of neck pain and improve the drivers' overall musculoskeletal health

CONCLUSION

In conclusion, the findings of this study shed light on the significant prevalence and impact of chronic neck pain among Ola/Uber drivers in Gujarat. The high percentage of drivers reporting some degree of disability underscores the profound burden of neck pain on their daily functioning and overall quality of life. Moreover, the varying levels of pain intensity reported by drivers further emphasize the complexity of this issue and the urgent need for effective interventions to alleviate their suffering. Addressing the multifaceted factors contributing to chronic neck pain, including ergonomic improvements, education on proper posture and stretching techniques, and access to healthcare services, is paramount to improving the musculoskeletal health and well-being of Ola/Uber drivers in Gujarat.

Moving forward, concerted efforts from policymakers, healthcare professionals, and stakeholders in the transportation industry are essential to implement sustainable solutions that prioritize the health and safety of Ola/Uber drivers. By addressing the root causes of chronic neck pain and promoting proactive measures to mitigate its impact, we can create a supportive environment that empowers drivers to manage their pain effectively and continue their vital role in providing transportation services to the community. Ultimately, by prioritizing the musculoskeletal health of Ola/Uber drivers, we can enhance their overall well-being and contribute to a safer and more sustainable transportation system in Gujarat.

ABSTRACT

Background: Frozen shoulder (FS) is signified by pain and stiffness in the shoulder joint; limited range of motion and pain are the most common symptoms. It is also known as adhesive capsulitis or periarthritis (PA). FS has a prevalence of approximately 2 to 5 % in the general population. The incidence among women is 1.6 to 4-fold higher than in men. Functional impairments caused by FS consist of Limited Reaching, particularly during Overhead or to the side activities. **Methodology:** Patients were analyzed pre and post treatment for frozen shoulder by SPADI and range of motion (ROM) of the shoulder joint by using goniometer. Total 40 Patients were taken and divided in two group. Group A received ultrasound with conventional physiotherapy and Group B received cryotherapy ultrasound with conventional physiotherapy for 6 days a week for 4 weeks. **Result:** The research was performed on 100 participants between the age of 20-40. There were 56 patients between the ages of 20 to 30, 44 patients between the age 31to 40. Moderately negative correlation seen in standing duration and pronation of foot. **Conclusions:** In conclusion the treatment program consisting of Ultrasound with Conventional Physiotherapy is more effective in frozen shoulder to reduce Pain, Functional disability and improve Shoulder range of motion.

Frozen shoulder, Ultrasound therapy, Cryotherapy, Rang of motion, Shoulder Pain And Disability Index

INTRODUCTION

1.1 Shoulder Complex

The shoulder joint, also known as the glenohumeral joint, is a dynamic articulation between the glenoid of the scapula and the proximal humerus, with functions like abduction, adduction, flexion, extension, and rotation. It is supported by the primary four rotator cuff muscles.[1,2] The shoulder joint is one of the most mobile joints in the human body due to its loose capsule and humeral head size. It is commonly dislocated due to its increased mobility. The upper extremity is connected to the axial skeleton via the sternoclavicular joint. The pectoral girdle consists of three joints.[3,4]

"Frozen shoulder" was first introduced by Codman in 1934, a painful shoulder condition with stiffness, difficulty sleeping, and reduced forward elevation and external rotation. This condition was formerly known as 'periarthritis' by Duplay in 1872, and later redefined as 'adhesive capsulitis' by Julius Naviaser in 1945. The disease is distinct from arthritis and preserves the joint.[5,6,7]

1.2 Frozen Shoulder

"Frozen shoulder" was first introduced by Codman in 1934, a painful shoulder condition with stiffness, difficulty sleeping, and reduced forward elevation and external rotation. This condition was formerly known as 'periarthritis' by Duplay in 1872, and later redefined as 'adhesive capsulitis' by Julius Naviaser in 1945. The disease is distinct from arthritis and preserves the joint.[5,6,7]

1.3 Etiology

Frozen shoulder (FS) is often associated with diabetes mellitus, affecting 10-36% of diabetics. Insulin-dependent diabetics are at the highest risk, and the primary cause is unknown, making them 2-4 times more likely to develop the condition.[8,9]

Frozen shoulder is common in thyroid disorders, Parkinson's disease, and cardiac and pulmonary diseases, often triggered by surgical procedures or shoulder injuries.[10,11]

1.4 Epidemiology:

Frozen Shoulder prevalence in general population is 2-5%, with increased rates in diabetics and thyroid gland pathologies, particularly hypothyroidism, up to 10-38%.[12,13]

Type 1 diabetes significantly increases the risk of developing FS, with a lifetime prevalence of 76%, particularly in patients over 45 years old.[14]

1.5 Pathophysiology:

FS is a condition characterized by synovial inflammation and capsular fibrosis, often resulting from cytokines like TNF-alpha and ILs. The cause is unclear, but potential triggers include chronic inflammation, tendon damage, Tendon Fiber rupture, or inflammatory mediators.[15,16,17] Figure 1 Summarizes the pathological event and pathogenesis of FS.[18]

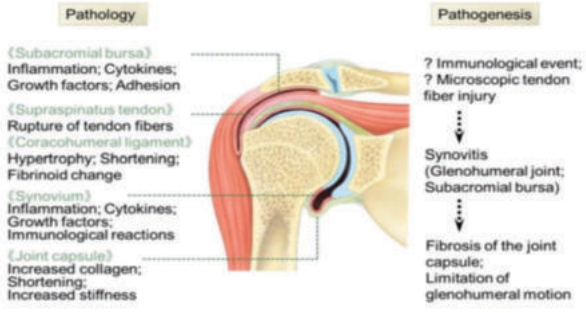

Fig. 1 Pathological event and Pathogenesis of FS

1.6 Stages:

Clinical presentation is typically in three overlapping phases: [19] The clinical presentation of a condition is divided into three phases: Stage 1, which is a gradual onset of pain with movement, Stage 2, which is persistent and intense pain, and Stage 3, which is pain only with movement, significant adhesions, and limited GH motions. Stage 4 of a joint condition, known as Thawing, involves minimal pain, no synovitis, but significant capsular restrictions from adhesions, with gradual motion improvement. The "freezing" stage of treatment for FS should focus on pain control, inflammation reduction, and patient education. Home self-exercise is effective, and daily programs should be given. Other treatments include anesthesia manipulation and surgical procedures.[5,20]

1.7 METHODOLOGY

STUDY DESIGN AND SETTING

Research Design: A COMPARATIVE STUDY

Population: Subjects with Frozen shoulder

Sample Design: Convenient sampling

Sample Size: The study was done on 40 patients. Subjects were divided in to 2 groups.

- Group 1=20 subjects (n=20)
- Group 2= 20 subjects (n=20)

Selection Criteria
Inclusive Criteria:
- Age between 30 to 60 year.
- Painful and limited passive shoulder joint mobility
- FS patients with and without type 2 diabetes mellitus
- More restricted lateral rotation relative to abduction and medial rotation.
- No clear sign (eg. painful arc, positive resistance testing, or loss of power)
- Illness time ranging between 2-15 months
- Stage of frozen shoulder: 1-3 stages

Exclusive Criteria:
- Any previous shoulder surgeries.
- Frozen shoulder Stage 4
- Glenohumeral or Acromioclavicular arthiritis.
- Any condition other than frozen shoulder
- Any Fracture around the shoulder complex
- Patient know to have uncontrolled diabetes mellitus or type 1, orthopedic condition or deformities around shoulder joint and any neuromuscular disorder.

OUTCOME MEASURES:
Shoulder Pain and Disability Index (SPADI) and Shoulder Range of Motion (ROM) Overview

SPADI:
- Self-administered questionnaire with 13 items assessing pain and functional activities.
- Assesses 5 questions on pain severity and 8 questions on difficulty with daily activities.
- High test-retest reliability of 0.92.
- Requires 5-10 minutes of time.

ROM:
- Measured using Universal Goniometer, a highly reliable tool conducted by the same therapist.
- Test-retest reliability of 0.94–0.98.

Patient Positioning and Movement Shoulder Flexibility:
- Patient is supine lying with shoulder and elbow 90º position.
- Axis: Greater tuberosity of the humerus.
- Movable arm placed over the midline of the lateral arm.
- Stable arm placed either perpendicular or parallel to the ground.

Shoulder Extension:
- Patient is prone lying with shoulder and elbow 90º position.
- Axis: One inch below the acromion process of the scapula.
- Movable arm placed over the midline of the anterior arm.
- Stable arm placed perpendicular or parallel to the clavicle.

Shoulder External & Internal Rotation:
- Patient is supine lying with shoulder and elbow 90º position.
- Axis: Olecranon process of the ulna.
- Movable arm placed over the midline of the posterior forearm.

Procedure:
- Approval from Institutional Ethical Committee (IEC) for study.
- Individuals selected based on inclusion/exclusion criteria.
- Informed consent form obtained from willing participants.
- Patients' anamnesis and demographic characteristics recorded.
- SPADI, VAS, and Shoulder joint ROM taken.
- Subjects assigned into two groups:

Group 1(n=20) Ultrasound with Conventional Physiotherapy and Group 2(n=20) Cryotherapy with Conventional Physiotherapy.

Outcome measures taken at baseline, after 2 weeks, and 4 weeks of treatment.

Statistical analysis using SPSS 25.0 software. P value less than 0.05 considered statistically significant.

RESULTS
The study used SPSS 25.0 software for Windows to compare the success of ultrasound and cryotherapy treatment for Frozen shoulder in 40 subjects, with 20 in each group meeting inclusion criteria.

Demographic Data
TABLE 1. Gender distribution

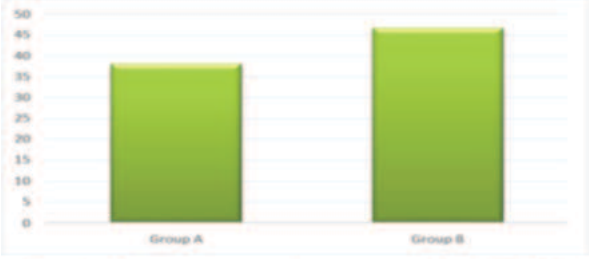
Graph 1: Graph of Gender distribution

Interpretation of Result:
1) Inter Group Analysis:
The table compares shoulder disability in Group A & B using independent T test. At baseline, no significant difference exists, but post-treatment p value of 0.03 suggests significant improvement between groups.

2) Intra Group Analysis:
The table compares shoulder disability in group A and B using paired t-test, showing significant differences in pain scores, indicating effective treatment for both groups.

Graph 2: Intragroup comparison of mean values of SPADI for Group A

Graph 3: Intragroup comparison of mean values of SPADI for Group B

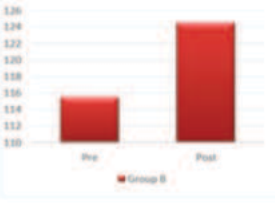


Graph 4: Intergroup comparison of mean values of SPADI

Interpretation of Results:
1) Inter group Analysis:
The study compared shoulder flexion ROM scores between Group A and B using an independent T test, finding no significant difference at baseline but significant improvement post-treatment.

2) Intra group analysis:
The table compares shoulder flexion ROM and pain scores in groups A and B, showing significant differences, indicating effective treatment for both groups.

Graph 5: Intragroup comparison of mean values of Flexion ROM for Group A



Graph 6: Intragroup comparison of mean values of Flexion ROM for Group B

Graph 7: Intergroup comparison of mean values of Flexion ROM

Interpretation of Results:

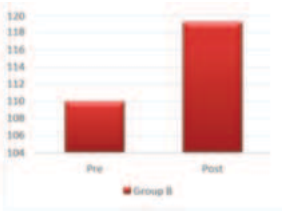
1) Inter group analysis:

The table compares shoulder Abduction ROM scores between Group A and B, showing no significant difference at baseline and a 0.03 post-treatment improvement.

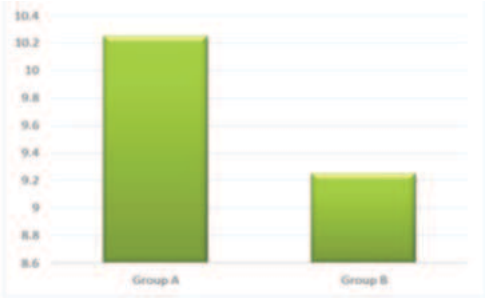
2) Intra group analysis:

The table compares shoulder abduction ROM and pain scores in groups A and B, showing significant differences, indicating effective treatment for both groups.

Graph 8: Intra group comparison of mean values of Abduction ROM for Group A



Graph 9: Intra group comparison of mean values of Abduction ROM for Group B



Graph 10: Intergroup comparison of mean values of Abduction ROM

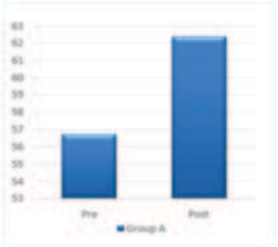
Interpretation of Result:

1) Inter group analysis:

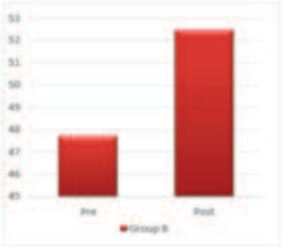
The table compares shoulder External ROM scores between Group A and B, showing no significant difference at baseline and a 0.04 post-treatment improvement.

2) Intra group analysis:

The table compares shoulder external ROM and pain scores in groups A and B, showing significant differences, indicating effective treatment for both groups.



Graph 11: Intragroup comparison of mean values of External rotation ROM for Group A



Graph 12: Intragroup comparison of mean values of External rotation ROM for Group B

Graph 13: Intergroup comparison of mean values of External rotation ROM

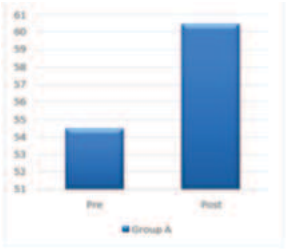
Interpretation of Result:

1) Inter group analysis:

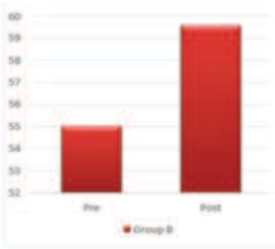
The table compares shoulder Internal ROM scores between Group A and B, showing no significant difference at baseline and a 0.03 post-treatment improvement, suggesting significant improvement between groups.

2) Intra group analysis:

The table compares shoulder Internal ROM and pain scores in group A and B, showing significant differences, indicating effective treatment for both groups.



Graph 14: Intragroup comparison of mean values of Internal Rotation ROM for Group A



Graph 15: Intragroup comparison of mean values of Internal Rotation ROM for Group B

Graph 16: Intergroup comparison of mean values of Internal Rotation ROM

DISCUSSION

The study investigates the effectiveness of ultrasound therapy and cryotherapy in reducing pain, range of motion, and disability in patients with frozen shoulder. Both groups received conventional physiotherapy for 4 weeks. Results showed significant differences in ROM improvement for both groups. However, the group receiving ultrasound therapy showed improvement in flexion extension, internal and external rotation, but not abduction and adduction ROM. The study highlights the self-limiting nature of frozen shoulder symptoms. [21,22] Ultrasound therapy reduces pain, increases blood flow, and aids tissue repair. It's used in rehabilitation for frozen shoulder patients. Connective tissue stretches promote elastic and plastic responses. Crystaltherapy controls pain by altering perception and controlling transmission to higher centers, making it useful for treating shoulder pain. [23] Cold exposure increases norepinephrine, providing calming effects. High-level mobilization improves frozen shoulder treatment in primary patients, while stretching programs relieve symptoms in stage 2 patients. [24,25] The study found that combining cryotherapy with conventional physiotherapy effectively reduced pain, functional disability scores, and improved range of motion in patients with frozen shoulder. Ultrasound therapy, produced using quartz, reduces pain,

increases blood flow, and aids in tissue repair. It's used in rehabilitation for frozen shoulder patients and promotes soft tissue healing. Connective tissue stretches promote elastic and plastic responses.

CONCLUSION

In conclusion the treatment program consisting of Ultrasound with Conventional Physiotherapy is more effective in frozen shoulder to reduce Pain, Functional disability and improve Shoulder range of motion.

Limitations:

✓ Small sample size

✓ No control group was included in the study

Future Recommendation:

✓ The study can be done on a larger number of populations.

✓ The study can be done with control group along with only conventional physiotherapy given in frozen shoulder

ABSTRACT

Background: Increasing rate of musculoskeletal dysfunction due to backpack is matter of concern. Prevalence varies regionally as it depends on many variables. Heavy backpack is one of the important underlying causes. Adolescent spine is in the critical stage of development in the age group of 07-15 years. This study was carried out to decide regional cutoffs of heavy relative weights of backpacks in male and female children. **Methodology:** For this survey, a sample of students from Ahmedabad's New Education School was used. Every student who satisfies the inclusion requirements is welcome to take part in the research. Through the semi-structured questionnaire, the data were collected. The length of the trip, the type of vehicle, and the distance traveled, the posture taken while traveling, and the level of pain were all mentioned in the questionnaires. Every outcome that was measured was obtained at baseline. NDI, SPADI & NPRS. **Result:** In present study we found that from total 60 students 34 students shows highest upper cross syndrome and students with upper cross syndrome were having mean pain score of NPRS 4.52±2.18 and disability as per NDI & SPADI as 50.79 &51.28.overall prevalence of musculoskeletal dysfunction is 55.66%. **Conclusions:** Majority of the School going students are exposed to the risk of adopting poor postures which can lead to musculoskeletal dysfunction. The results of this study suggesting the importance of postural awareness among school going students.

KEYWORDS

Upper Cross Syndrome, Neck Disability Index, Shoulder Pain And Disability Index, Musculoskeletal Disorder.

INTRODUCTION

The World Health Organization states that musculoskeletal disorders—which are primarily linked to Students and cause headaches and chronic neck pain, which are the most common complaints worldwide—are one of the main causes of disability among persons between the ages of 20 and 50. It is acknowledged that disabilities result in severe medical conditions as well as socioeconomic problems; the loss of GDP from absenteeism and low productivity has been estimated to be as high as 2%. Numerous studies found that almost 90% of rehabilitation specialists suffer from musculoskeletal conditions, with 50% of physiotherapists reporting a tendency to develop Work-Related Musculoskeletal Disorders (WMSDs) throughout the course of their five-year careers. This might be because of the nature of their employment, which entails extended periods of sitting, standing, and lifting as well as the use of manual techniques in academic or clinical settings. The high prevalence (66%) in lower limb, particularly in the low back and neck region (61%), may be related to their line of work, which involves extended standing, sitting, lifting, or using manual procedures in clinical or academic settings[1].

Upper Cross Syndrome (UCS), also known as cervical cross syndrome, is defined as a pattern of alternative tightness and weakness of the neck's Serratus Anterior, Pectorals Major, Levator Scapulae, Rhomboids, and Deep Flexors, especially the Scalene muscles. This pattern is thought to be caused by improper body ergonomics, poor work habits, or low self-esteem. Rather than only affecting one muscle, Upper Cross Syndrome is typified by an imbalance in the activation and inhibition of skeletal muscles. Muscular insufficiencies arise from any inability of the tonic and phasic muscles to activate coherently. Thus, the most common symptom of UCS is neck and upper back pain, which is typically diagnosed as Cervicogenic Vertigo with shoulder pathology in a number of patients. This bad posture causes hypnosis, forward head posture, loss of cervical lordosis, and some postural patterning of the front shoulders[2]. The upper portion of the body experiences general pattern changes as a result of these anomalies.

This pattern alteration results in strain to the shoulder blade and muscle attachments of the shoulder, giving the impression of a rounded shoulder. While extended use of this position does not always result in pain, people frequently report upper back and neck pain various factors including musculoskeletal structures, body changes regarding age, cultural customs, motor performances and occupation affects the head position of the person while sitting. The patients may develop forward head posture because of this poor sitting posture along with rounded shoulder which occurs due to the increased hypnosis in thoracic region[2].

When seated, the forward head position causes the upper cervical region to extend, the lower cervical region to flex, and the shoulders to round. This reduces the length of muscle fibers on average, which causes extensor torque around the upper cervical region's joints. This aberrant state leads to a number of musculoskeletal problems, such as increased internal rotation, anterior tilt, and decreased scapular upward rotation. It makes it even harder to keep an erect posture[3].

Upper crossed syndrome is what occurs when rounded shoulders and forward head posture occur at the same time. Students enrolled in college typically adopt a range of positions throughout class and exams. Therefore, it is necessary to determine if these aberrant postures are learned or inherited. It is also necessary to ascertain whether any of the elements of a muscle imbalance are present at this point and to identify the reason for the change in upper back posture[4].

Work related segments, for instance, postponed static muscle load and dismal work might be a hotspot for hurt headway. Physical activity and masculinity are two further characteristics that may be linked to musculoskeletal pain. Issues with posture, vision, or mental health might also bring about musculoskeletal issue, particularly affecting the cervical and thoracic locale. As demonstrated by Janda's farsighted clarification of muscle ponderousness, significant cervical flexors and lower scapular stabilizers get the opportunity to be subdued in a foreseen illustration (upper crossed disorder)[5].

Proximal or shoulder support crossed confusion is another term used to describe Upper-Crossed Syndrome (UCS). Coziness of the levator scapula and upper trapezius on the dorsal side of the UCS intersects with coziness of the genuine and minor pectoralis muscles. Significant cervical flexor weakness ventrally crosses with insufficient middle and lower trapezius; this unevenness causes joint fractures, especially at the glen humeral joint, atlantooccipital joint, C4-5 area, cervicothoracic joint, and T4-T5[6].

Janda observed a discrepancy between these concentrated areas of discomfort inside the spine and the transitional zones where the morphology of the adjoining vertebrae changes. This study aimed to identify the key factors that contribute to students' upper-crossed issues changing. Certain particular postural motions are observed in upper cross problem, such as forward head carriage, thoracic hypnosis and extended cervical lordosis, elevated and developed shoulders, and

scapular winging and discontent. Due to Serratus front weakness, which causes the scapulae to grasp, turn, and wing, these postural movements decrease glen humeral quality by allowing the glenoid fosse to become more vertical[7].

Purpose Of the study to find Prevalence Musculoskeletal Dysfunction Due to backpacks in students with upper cross syndrome.

METHODOLOGY

Study Design: Observational study

Duration of Study: 6 months to 1 year.

Sample Size: 60 students (both male and female)

Selection Criteria

Inclusion criteria:

- Age of students (07 to 15) Years.
- Students suffering from Upper Cross Syndrome.
- Subject willing participate.

Exclusion criteria:

- Developmental disorders,
- Neurological disorders,
- Surgical interventions and previous spinal fractures

For this survey, a sample of students from Ahmedabad's New Education School was used.

Every student who satisfies the inclusion requirements is welcome to take part in the research. Through the semi-structured questionnaire, the data were collected. The student's posture, the weight of the bag, and the level of pain were all noted. Every outcome that was measured was obtained at baseline.

- SPADI
- NDI
- NPRS

RESULT:

Descriptive analysis for Windows was used for all statistical studies. The mean and standard deviations were obtained using descriptive analysis. Demographic Data

AGE:

The research was performed on 60 participants between the age of 7-15 years. There were 36 participants between the ages of 7 to 10, 24 participants between the age 11 to 15.

Table1: Age Distribution

Age Distribution	
7-10 years	11-15 years

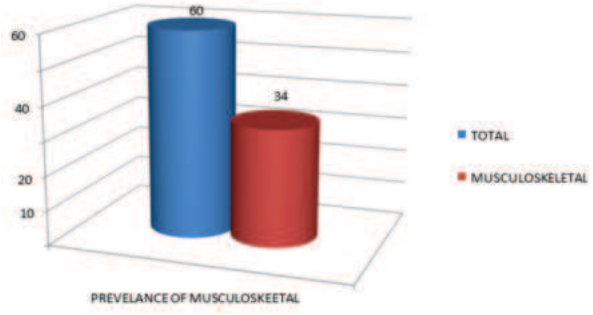
	Mean + SD
Age	9.6+4.46 years
NPRS	4.51+2.18
NDI	50.79 + 19.98
SPADI	51.28 ± 17.84



Graph 2: Prevelence Of Musculoskeletal Dysfunction

DISCUSSION:

The goal of the current study was to determine how common upper crossed syndrome is among school-age children. We had classified two diagonal muscles—the neck flexors and scapular retractors being weak, or the neck extensors and pectoralis minor being tight—as weak or tight for the purpose of the prevalence analysis. The cervical spine and shoulder girdle biomechanics may change as a result of a muscle imbalance in any one of the two diagonal muscles.

Present study conducted on 60 school going students with age of 07 to 15 years among that 34 students showed positive impact of musculoskeletal dysfunction with mean pain score 4.51±2.18, NDI mean & sd 50.79 ± 19.98 & SPADI 51.28 ± 17.84 Overall prevalence of musculoskeletal dysfunction is 55.66%.

A study on Neck, Shoulder, and Back Pain Associated with Carrying Heavy Backpacks among Spirit School Children in Lahore was undertaken by Rubina Khan et al. They came to the conclusion that children's back, shoulder, and neck pain was significantly correlated

with the weight of their school bags. Less symptoms were displayed by students who carried their bags over both shoulders and used twin straps[8].

Mayank Mohan et al done An experimental study on the Effect of backpack loading on cervical and shoulder posture in Indian school children and examining the effects of backpack loading on posture[9].

Sheir-Neiss, et al conducted study on The Association of Backpack Use and Back Pain in Adolescents and concluded that The use of backpacks during the school day and backpack weights are independently associated with back pain[10].

Mubeen et al done investigate on primary indicators of upper cross syndrome, which include forward head position, rounded shoulders, and neck stiffness and pain. The results of the study showed that 36.07% of students had neck pain when studying or using any kind of electronic device. Additionally, it was shown that 76.39% of students believed that when using a device or studying, they needed to support their head and upper back. However, 23.60% of the pupils felt otherwise.In their investigation on the prevalence of upper cross syndrome results showed that 52.1% of pupils found it challenging and 48.7% of students felt neck pain[11].

Clare Haselgrove et al had done study on Perceived school bag load, duration of carriage, and method of transport to school are associated with spinal pain in adolescents: an observational study and concluded that Neck pain is as common as back pain amongst adolescents. Perceived school bag load, duration of carriage and method of transport to school are associated with back and neck pain. Physical activity in the form of walking or riding to school may offset the potentially provocative effects of prolonged bag carriage and warrants further investigation.[12].

Therefore, it is imperative that people of all ages, especially students, take some action to improve their postural awareness.

CONCLUSION

Majority of the School going student are exposed to the risk of adopting poor postures which can lead to musculoskeletal dysfunctions. The results of this study suggesting the importance of postural awareness among school going students.

ABSTRACT

Background: This research focuses on assessing work-related musculoskeletal disorder among recreational cricket players using modified Nordic musculoskeletal questionnaire. Using MNMQs, the aim is to gather detailed information on the prevalence, severity and location of musculoskeletal problems experienced by recreational cricket players during their participation in the sport. **Methods:** A Cross sectional study was carried out on 105 recreational cricket players using Modified Nordic Musculoskeletal Questionnaire to find the prevalence of work-related Musculoskeletal disorder among recreational cricket players. **Results:** Out of 105 cricket players 73 (69.5%) players experienced work-related musculoskeletal problem in last 12 months. Shoulder, low back and Hips/thighs were the most common areas of problem in last 12 months. Hips/thighs, low back were the most common areas of problem in last 12 months in Batsmen. Shoulder and Ankles/feet were the most common areas of problem in last 12 months in bowlers. Low back, shoulders were the most common area of problem in last 12 months in All-rounders. Sprain (38%) and Strain (33%) were the most common type of injury among recreational cricket players. **Conclusion:** This study concludes that the work-related musculoskeletal disorder in recreational cricket players were more. Shoulders and Lower back were the most common injured body parts followed by Hips/thighs, Ankles/Feet and Knees. According to role of cricket, Bowlers were more affected than Batsmen and All-rounder. The study conclude that Hips/thighs and low back are the common site of injury in batsmen. Shoulder and Ankles/feet are the common site of injury in bowlers and Low back and shoulder were the most common site of injury in All-rounders. The study also concludes that due to the Low back Injury or pain players had affected from doing their daily activity of living in last 12 months. This research findings indicate that sprain and strains rank as the predominant injuries experienced by cricket players.

KEYWORDS

Work-related musculoskeletal disorder, Modified Nordic Musculoskeletal Questionnaire, recreational cricket players.

INTRODUCTION

Work-related injuries pose a significant burden on individuals, organizations, and society at large, with musculoskeletal disorders (MSDs) being one of the primary causes and contributors to workers' compensation claims. The lack of specific data on work-related musculoskeletal diseases in developing nations complicates efforts to identify prevalent issues and occupations at high risk, though occupations requiring heavy physical exertion, such as construction, stone work, mining, and cleaning, are likely the most vulnerable. Additionally, musculoskeletal disorders (MSDs) are defined as soft tissue disorders not resulting from sudden events, and are deemed work-related when the work environment significantly contributes to their development. [1]

Cricket is a major international sport played in more than 60 countries. The laws of cricket were drawn up by the London Club in 1944 formalizing a game that had been played for a hundred of years ago.[2] Cricket is regarded as a leisurely, gentlemen's game.[3] In cricket, bowlers deliver a hard ball at a high speed directly to the batsman.[4] Now cricket is played in more than sixty countries and regarded as major international team sport. Cricket also played in many commonwealth countries as popular sport. Cricket is the most popular team sport in Indian subcontinent that consists India, Pakistan, Afghanistan, Bangladesh, Sri Lanka. The popularity for cricket in India was started after its success in 1983 world cup in which it was the champion; this led to a greater number of people participating in cricket. There are various clubs and centres with skilful coaches to train them. Injuries are inevitable when one player is training and compete. There are numerous studies available at international level, but in India there is a lack of research in cricket.[5]

The ICC Trophies Won by India:

India's cricket legacy began with the 1983 ICC Cricket World Cup victory, where Kapil Dev's team triumphed against the odds, defeating Clive Lloyd's West Indies, marking India's first ICC trophy. Until then, the Indian cricket team held little significance in the sporting world, but this underdog victory transformed the perception of cricket in India. The 2002 Champions Trophy stands as a unique event in ICC history, being the solitary tournament where a definitive champion wasn't determined, resulting in Sri Lanka and India being declared joint winners. This marked a significant milestone, breaking a nearly two-decade drought for India in ICC trophy victories. Sri Lanka, considered pre-tournament favourites, secured their spot in the final through dominant performances in the group stage, culminating in a convincing seven-wicket win over Ricky Ponting's formidable Australian team. Conversely, India, fielding a relatively youthful squad, earned their place in the final after a hard-fought 10-run victory against South Africa. However, unforeseen rain disruptions plagued the finals, forcing two washouts and ultimately leading to both Asian cricket powerhouses sharing the trophy. The inaugural ICC T20 World Cup introduced both a new competition and a fresh captain, sparking apprehension over India's performance. With MS Dhoni, then 26 years old, assuming leadership, following Rahul Dravid, Sourav Ganguly, and Sachin Tendulkar's self-exclusion from T20I cricket's premier event in 2007, the team faced the challenge with a predominantly inexperienced roster. As a result, the burden fell on Dhoni, hailing from Ranchi, to orchestrate a remarkable feat. India's 28-year wait for another ICC Cricket World Cup ended in 2011, with MS Dhoni's iconic six in the final against Sri Lanka, while Yuvraj Singh's stellar performance anchored the victorious campaign, marking a fitting farewell for cricket legends Sachin Tendulkar and Virender Sehwag. The 2013 edition of the ICC Champions Trophy, India beat England in finals and MS Dhoni becomes only captain in world cricket to will all three ICC trophies. Currently the men's Indian cricket team is ranked 1st in test cricket, 1st in one-day international and 1st in T20 (as of 26/03/2024 - ICC rankings). There is a lot of crazes for cricket in India. Many children here like or even play cricket. There is a big cricket player in every street here. People love cricket a lot. Cricket is not just a sport but an emotion for the children of India. There is no shortage of talent in India, there is a dangerous player in every street regarding cricket. Every child here dreams of becoming a successful cricketer and playing for his country.[6]

Cricket, characterized by its dynamism, encompasses a plethora of abstract skills and movements. To refine these intricacies, many players prioritize maintaining peak physical fitness and strength. The game's three distinct facets (bowling, batting, and fielding) each pose unique injury risks. [7,8,9] Musculoskeletal discomfort may manifest in diverse scenarios during cricket matches, including impacts from balls or bats, swift rotational actions, sliding and diving maneuvers, collisions with fellow players, and the cumulative effects of overuse. [10,11,12,13]

Running is a common thing in cricket, whether it is batting or bowling or fielding, running has to be done by all, hence lower limb is more

affected in cricket. After that, the second task is to throw the ball because all the players do field and hence upper limb injuries also occur. After that, injuries to the upper and lower trunk occur, due to twisting or overstretch of the trunk.

The stance of a batsman while batting is somewhat like this, it can be differed from batsmen to batsmen. This is a normal stance of the batsman, after that the bowler bowls the ball and the batsman hits the stroke according to the ball. The posture of batsmen is different in every stroke, sometimes extra force is applied on the body or if the body gets twisted too much than the injury can occur. And also, when the batsmen take run, he will run fast so the batsmen have chances to get injured while running. That's why batsmen suffer more injuries to their back and hips.

The ideal bowling action of the player. While bowling, a bowler runs, then makes a jump, rotates his arm in a circular motion and delivers the ball. And experts believe that while delivering the ball, 7 to 8 times more force is applied to the bowler's ankles/feet and the repetitive movement of the shoulder is happens while bowling. That's why bowlers suffer more ankle/feet and shoulder injuries.

Fielding is another role in cricket. So, while doing this, a player gives extra efforts to save runs for the team. During this, his chances of getting injured are increased because he runs, slides, dives, throws and catches the ball and players even collide with each other. Therefore, fielders are at greater risk of hip/thigh injuries, knee injuries, low back and shoulder injuries.

According to Sathya et al., 61% of players encountered musculoskeletal issues linked to cricket. Stretch et al.'s findings indicated that South African cricketers predominantly suffered lower limb injuries (50%), followed by upper limb (23%) and back/trunk injuries (23%). [14] Musculoskeletal pain (Injury) is defined as 'A sensation of agony that inhibits the individual from participating in cricket or practice for a minimum of 24 hours'[15]

There are many studies available at domestic and international level on injuries faced by cricket players. Thus, the purpose of the study is to find the work-related musculoskeletal disorder among recreational cricket players.

Methodology

Study Place

Tanman Cricket Ground, Galaxy Cricket Ground, Samarpan Cricket Ground, Norada 108 Cricket Ground.

Sampling Design

Convenience sampling

Study Design

A cross-sectional survey studies.

Duration of Study

6 months

Sample Size: 105

Inclusion Criteria

- Male cricket players of age 19-27 years
- Playing experience of minimum 3-4 years with regular practices

Exclusion Criteria

- Recent fracture or injury.
- Any recent cardiovascular surgery.
- Any Neurological condition.
- Alter mental illness.
- Players who do not play regularly

Materials Required

- Consent form
- Assessment form
- Modified Nordic Musculoskeletal Questionnaire (MNMQ)
- Pen

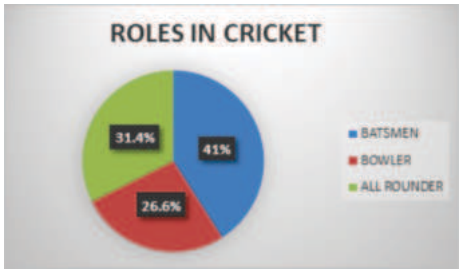
Method

- A sample of cricket players was taken in this survey from various cricket ground located in Ahmedabad.
- All players who meet the inclusion criteria were eligible to participate in the study.
- The data collection was done involving the questionnaire is based on MNMQs.
- Firstly, players were made aware about the purpose of the study. Each component of Modified Nordic Musculoskeletal Questionnaire was explained to each and every player. And consent of each player was taken.
- Then, General demographic data was taken Name, age, gender, occupation, role they play in cricket from the player and asked them to recall their injuries from last one year from April 2023 to March 2024.
- Afterward, the questionnaire content six component.
- The questionnaire content binary questions and player have to fill the answers respectively.
- Then data was collected from 105 player and analyzed in simple percentage and graphs.

RESULTS

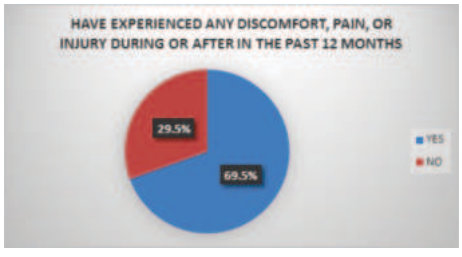
- The analysis was done using excel.
- Total 105 player are taken for the study

A. The above graph shows, out of 105 players 43(41%) were batsmen, 28(26.6%) were bowler, 34(31.4%) were all-rounder.



Graph 1

B. The above graph shows, out of 105 players, 73(69.5%) players had experienced any discomfort, pain, or injury during or after cricket activities in the past 12 months.

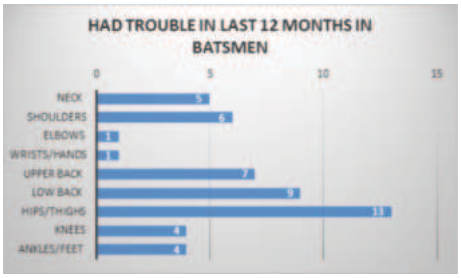


Graph 2

C. The above Graph show the trouble held to cricket players during the last 12 months according to anatomical site. The commonest site for pain or injury among the players is Shoulder and low back (41%) followed by Upper back and Hips/thighs (35%), Ankles/feet (31%), Neck (23%), Wrists/hands (16%), Knees (15%), Elbows (11%).

Graph 3

D. The above graph shows the trouble held to Batsmen during last 12 months according to anatomical site. Out of 43 batsmen 24 (55%) experienced pain or discomfort during or after cricket in last 12 months. The commonest site for batsmen is Hips/Thighs (54%), followed by low back (37%), upper back (29%), shoulder (25%), Neck (20%), Knees and Ankles/Feet (16%), Elbow and Wrists/Hands (4%).



Graph 4

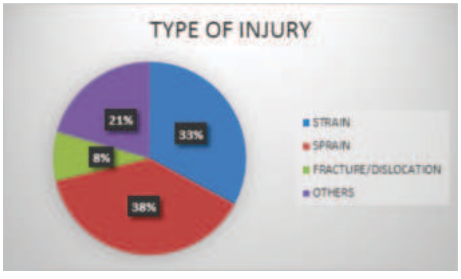
E. The above graph shows the trouble held to Bowler during last 12 months according to anatomical site. Out of 28 bowlers 23 (82%) experienced pain or discomfort during or after cricket in last 12 months. The commonest site for bowler is Shoulders and Ankles/Feet (60%) followed by Wrists/Hand (30%), Hips/Thighs (26%), Neck (21%), Elbows and Kness (17%), Low back (13%), Upper back (8%)

Graph 5

F. The above graph shows the trouble held to All-rounder during last 12 months according to anatomical site. Out of 34 all-rounder 25 (73%) experienced pain or discomfort during or after cricket in last 12 months. The commonest site for all-rounder is Low back (72%), followed by Shoulder (48%), Upper back (36%), Neck and Hips/Thighs (28%), Ankles/feet (20%), Wrists/Hands (16%), Elbows (12%), Knees (8%).

Graph 6

G. The above graph shows types of injuries in cricket players. Out of 105 players investigated 73 (69.5%) experienced work-related musculoskeletal problem within last 12 months. Out of 73 players 28 (38%) had Sprain, 24 (33%) had strain, 15 (21%) had other injuries and 6 (8%) had fracture/dislocation.



Graph 7

DISCUSSION

The study was done on 105 recreational cricket players (males) of age group of 19-27 years with minimum experience of 3-4 years. The Aim and objective of the study was to find work-related musculoskeletal disorder among recreational cricket player. Modified Nordic Musculoskeletal Questionnaire was used to find the work-related musculoskeletal problem in recreational cricket players in last one year. Out of 105 players 73 (69.5%) experienced work -related musculoskeletal problem. According to Graph -3, the most common site of injury or pain is in shoulders and low back (41%), followed by Ankles/feet, upper back, hips/thighs. Because of repetitive movement of shoulder and trunk. Fielder throws the ball, bowler runs and deliver the ball with maximum effort so the movement of shoulder is much more that's why the risk of shoulder injuries is more on other hand repetitive hyperextension, rotation of trunk while batting or deliver the ball by bowlers.

The Graph-4 shows the prevalence of work-related musculoskeletal problem in last 12 months in Batsmen. Out of 43 batsmen 24 (55%) experienced musculoskeletal problem. Hips/thighs, low back, upper back these 4 sites are most commonly affected in batsmen because more use of trunk and lower extremities is there. That's why trunk and lower limb is most commonly affected. The Graph-5 shows the prevalence of work-related musculoskeletal problem in last 12 months in Bowler. Out of 28 bowler 23 (82%) experienced musculoskeletal problem. Shoulder, Ankles/Feet these 3 sites are most commonly affected in bowler because of repetitive movement of shoulder for delivering the ball and also when the bowler delivers the ball, the whole weight of the body came to ankles/feet. Hence shoulder, ankles/feet are most commonly affected. The Graph-6 shows the prevalence of work-related musculoskeletal problem in last 12 months in All-rounder. Out of 34 All-rounder 25 (73%) experienced musculoskeletal problem. Low back, Shoulder, Upper back, Hips/thighs these 4 are the most common site of injury or pain in all-rounder because they have to play all the roles in cricket (Batting, Bowling and Fielding).

Player who prevented from doing normal work in the last 12 months due to work-related musculoskeletal problem: The most common site for preventing from doing normal work during last 12 months are Low back and Upper back followed by Shoulder. Player who had trouble at any time during last 7 days: The most common site causing trouble in last 7 days are Hips/Thighs followed by Upper back and Low back. Out of 105 players only 18 (17%) players had ever hurt themselves body part in an accident. Shoulder and Ankle/feet are hurt more in an accident followed by Hips/thighs and Knees. When the players were asked about the total length of time that had trouble during the last 12 months. The most common answered was 1-7 days followed by 8-30 days and very few were for more than 30 days. The last component of the MNMQs was about the type of the Injury. As the Graph 7 shows, 28 players were affected with Sprain, 24 Players were affected with Strain and 21 players were affected with Other and Fracture/dislocation.

Chandrasekhar Bodanki et al. conducted a study on Prevalence of cricket-related musculoskeletal pain among Indian junior club cricketers and finds that CIPP should be implemented and strictly followed from the early stages of sports life. Pre-training warm-up and post-training cool-down sessions into their regular training regimen is essential. It's crucial to steer clear of overuse, such as prolonged play beyond scheduled times, and to refrain from disregarding any pain experienced during practice or matches. A supervised training and regular screening of players by orthopaedician or sports physician will keep them fit to play with full potential.[16]

P. Sathya et al. conducted a study on Prevalence of Musculoskeletal Problems in Cricket Players and finds that the findings revealed a 61% prevalence of musculoskeletal problems among cricket players. The lower back emerged as the most frequently affected area, followed by ankles/feet, knees, and hips/thighs. Musculoskeletal problems were more prevalent among all-rounders than batsmen and bowlers. Specifically, ankles/feet were frequently affected in all-rounders, while bowlers and batsmen commonly experienced issues in the low back area, alongside other regions. Furthermore, strain and sprain were identified as the predominant types of injuries among cricket players, regardless of their specific role in the game. [14]

Sumit Kumar et al. conducted a study on One year prevalence of musculoskeletal disorder among cricket Players in Haryana: A retrospective study: - Injury data was gathered using a modified Nordic Musculoskeletal Injury Questionnaire. Frequency of musculoskeletal injuries is more among cricket players. Conditioning by coaches and early rehabilitation by physiotherapists are essential to reduce the

injury rate in this population. [5]

Present study was conducted on 105 recreational cricket player and the prevalence of Musculoskeletal problem was 69.5% and shoulder and Low back (41%) were the most commonly injured body part followed by Ankles/feet, upper back, hips/thighs.

CONCLUSION

This study concludes that the work-related musculoskeletal disorder in recreational cricket players were more. Shoulders and Lower back were the most common injured body parts followed by Hips/thighs, Ankles/Feet and Knees. According to role of cricket, Bowlers were more affected than Batsmen and All-rounder. The study conclude that Hips/thighs and low back are the common site of injury in batsmen. Shoulder and Ankles/feet are the common site of injury in bowlers and Low back and shoulder were the most common site of injury in All-rounders. The study also concludes that due to the Low back Injury or pain players had affected from doing their daily activity of living in last 12 months. This research findings indicate that sprain and strains rank as the predominant injuries experienced by cricket players.

Limitations

- Collecting accurate data in recreational cricket player is difficult due to factors such as player recall bias on injuries and the absence of official records or statistics.
- This study is only conducted on male cricket players.

Future Recommendation

- Future studies can be done with a larger sample size to get the more appropriate result.
- The study should be conduct specially for professional cricket players.
- Explore the use of technology, such as mobile applications, to collect real-time data on recreational cricket gameplay.
- The study can be done on another sports like football, volley ball, Tennis, etc.
- The study can be conducted on Female cricket players.

ABSTRACT

Background: Achilles tendinopathy (AT) is a clinical condition characterized by pain and swelling in and around the Achilles tendon, mainly arising from overuse. Achilles tendinopathy (AT) or Tendon injury is one of the most common injuries in physical exercise (PE), especially happens to athletes who are always engaged in long-term, continuous and high-intensity competition or training. Even after surgical treatment, AT may still occur repeatedly and the recurrence rate is as high as 44%. It is not easy to be diagnosed in the early stage of disease because of its long incubation period. So, the need of Achilles Tendon injury when participating in Exercise, and on the basis of that we can find out estimated risks of Achilles Tendon injury for different ages, genders, sport events, characteristics of subjects, training years, and regions in Ahmedabad city. **Methodology:** This study included 100 male and female football players with convenient sampling method. Subjects were assessed for Achilles Tendon injury via Royal London test and if positive directed to Victorian Institute of Sports Assessment-Achilles (VISA-A) questionnaire to find out prevalence of Achilles Tendon Injury in football players. **Result And Conclusion:** This study shows that there is Age group of 16-25 having prevalence of 68% and age group of 26-35 having prevalence of 24%.Prevalence of Achilles tendon injury in football players.

Prevalence, Achilles Tendinopathy, Football

INTRODUCTION

The clinical symptoms of pain, swelling, and impaired physical function of Achilles tendon are common in sports and daily life. Traditionally, many terms have been used to describe the disorders, including tendinitis, tendinosis, and paratenonitis. However, recent histopathological studies have found these disorders as a result of a failed healing response, which may cause degenerative changes in the tendon. The failed healing response includes three different and continuous stages (reactive tendinopathy, tendon disrepair, and degenerative tendinopathy) [1][2][3]. However, inflammatory response is not found in the three stages. In 1998, Maffulli et al. suggested to use the term tendinopathy in order to describe these intratendinous disorders [4].

The two main categories of Achilles tendinopathy are classified according to anatomical location and broadly include insertional (at the calcaneus-Achilles tendon junction) and noninsertional (2 to 6 cm proximal to the insertion of the Achilles tendon into the calcaneus) tendinopathy [5].

Achilles tendinopathy is one of the most frequently ankle and foot overuse injuries [6]. This disorder is more likely to be found in the individuals who participate in the physical activities such as running and jumping. It may affect 9% of recreational runners and cause up to 5% of professional athletes to end their careers [7]. In an epidemiologic investigation of 1394 nonathletes, Achilles tendinopathy was found in 5.6% of the subjects (4% insertional, 3.6% noninsertional, and 1.9% both forms) [8]. In another research, Kvist found that 20% to 25% of Achilles tendinopathy patients had insertional disorder, 66% had noninsertional, and 23% had either retrocalcaneal bursitis or insertional tendinopathy [9].

Chronic Achilles tendinopathy is more common in older people than in young people. In Kvist's study, among 470 patients who had Achilles tendinopathy, only 25% of the patients were young athletes and 10% were younger than 14 years [9]. Moreover, insertional tendinopathy tends to occur in more active persons, whereas noninsertional tendon injury tends to occur in older, less active, and overweight persons.

The risk factors of Achilles tendinopathy can be divided into intrinsic and extrinsic factors, either alone or combination. Intrinsic factors include biomechanical abnormalities of the lower extremity such as leg length discrepancy hyperpronation, varus deformity of the forefoot, pes cavus and limited mobility of the subtalar joint[10], and systemic conditions such as increasing age [11][12] , inflammatory arthropathies, corticosteroid use, diabetes, hypertension, obesity, gout, hyperostotic conditions [13][14] [15] [16]lipidaemias, aromatase inhibitors, and quinolone antibiotics[17]. Extrinsic factors include excessive mechanical overload and training errors such as increased interval training, abrupt changes in scheduling, excessive hill training, training on hard or sloping surfaces, increased mileage, increased repetitive loading, poor shock absorption, and wedging from uneven wear.

Sports injuries have been found to inhibit optimal sports' performance and these injuries, which can have both long and short term harmful effects, causes lasting physical damage or disability[1], affect quality of life, thus could result in reduced physical activity participation. Every sport comes with risk of injury that is peculiar. The occurrence of sports injuries and its associated problems are on the increase [2]. In association football, commonly known as soccer, injuries have been identified to result from multiple risk factors and ankle injuries are one of the most common injuries[3].Ankle injuries in soccer may give rise to problems like reduced performance, time away from competition and possibly disability[4]. The bones that make up the ankle joint are a regular site of injury and often times, bending and twisting forces can precipitate these injuries [5], with the most common being ankle sprain, fracture, and tendinopathy.

Achilles tendinopathy is a clinical condition characterized by pain and swelling in and around the Achilles tendon, mainly arising from overuse[6]. It is often a result of increase in training load. The Achilles tendon is the strongest tendon in the body serving both the gastrocnemius and soleus muscles originating near the mid-calf and inserts posteriorly at the calcaneus [7]. Achilles tendinopathy commonly happens in the mid-substance of the tendon or less commonly at its insertion in the calcaneus[8]. Previous observational studies have proved that competitive athletes have a 24% lifetime incidence of Achilles tendinopathy.

Soccer is widely recognized to be the world's most popular sport [14], and is played at different levels, worldwide, national, state, universities and even secondary schools. It is played by players in over 200 countries, making it the world's most popular sport [14]. Soccer involves several crafts that demand complex movements making the athletes susceptible to injuries, and tendinopathy is one of the most recorded overuse sports injuries in modern societies [15].

Participation in soccer is a worldwide event with tremendous health and economic benefits [16], increased self-esteem, peer socialization, general fitness, as well as reducing various diseases risks, crime rate and poverty [17]. A lot of attention has been given to elite soccer players

while in university soccer players, there are higher numbers of participants who began playing early and continue for a longer period. For some of them, their gears are not always suitable for the sport, thereby increasing the threat of tendinopathy [9]. The average university soccer players play soccer at least three (3) times a week, and Achilles tendinopathy occurs as a result of overuse. The increase in the popularity of soccer and expectations from players make meaningful numbers of soccer injuries conceivable. University soccer players also go through rigorous physical training, preparing for inter-club competition, inter- school competition. They are not professionals, so much attention is not given to them, but the trainings and constant field activity also makes them susceptible to sports injuries like Achilles tendinopathy. Also, intrinsic factors inherent in individual's physiology could also influence susceptibility to Achilles tendinopathy [9]

METHODOLOGY

Study Design, Setting And Sampling

Study Design: A Cross-sectional Study

Study Setting: Football academies of Ahmedabad city

Sampling Technique: Convenient Sampling

Population: Football players

Sample Size: 100 subjects, based on following formula:

$N = Z^2 P(1-P) / d^2$

Where, N= Sample size

Z= Level of confidence (95%)

P=Expected Prevalence (Previous researches) d=Precision (Corresponding Effect size)

Selection Criteria

Inclusion Criteria:

- Athletes who are willing to take participate in the survey.
- Age group 16 to 35 years.
- Male and Female football players.
- Playing football more than 2 years.

Exclusion Criteria:

- Athletes who are not willing to take part in survey
- Participants who actively engaged in other sports like basketball, sprinting were excluded because these sports could make them prone to Achilles tendinopathy.
- Any lower extremity trauma or injury in past 5 years.
- Subjects having connective tissue disorder
- Subjects having any neuromuscular disoder

MATERIALS REQUIRED

- Assessment form
- Consent form
- Pen, Pencil and Paper
- Mat and Plinth

METHODOLOGY

Ethical approval was obtained from Institutional Ethical Committee of Venus institute of physiotherapy, Gandhinagar. A letter of introduction from the Department of physiotherapy, Venus institute of physiotherapy, Gandhinagar was given to the coaches of the various teams seeking for permission to carry out the research with their teams. Informed consent was obtained from all participants and assuring them of confidentiality of their information.

The Royal London test, a psychometrically sound instrument, was used for assessing Achilles tendinopathy [18][19]. To start the test, the participant lay prone on the plinth with the feet hanging outside the table. The ankle was in neutral position and the Achilles tendon was palpated for tenderness.

The participant was asked to dorsiflex and the ankle was palpated on dorsiflexion. Results were classified as tenderness present on dorsiflexion or absent. In patients with Achilles tendinopathy, tenderness was felt on palpation with the ankle in neutral position, but on dorsiflexion tenderness was absent or reduced.

Figure 1: Flowchart of the study procedure

OUTCOME MEASURE

VISA–A Scale:

the Victorian Institute of Sports Assessment-Achilles (VISA-A) questionnaire was administered; it is a valid, reliable, and user-friendly index of the severity of Achilles tendinopathy, which contains eight questions that covers the 3 domains of pain (questions 1 to 3), function (questions 4 to 6), and activity (questions 7 and 8). Questions 1 to 7 are scored over 10, and question 8 carries a maximum of 30. Scores are summed to give a total of 100. An asymptomatic person would score 100. For question 8 which has three part (A, B, C), participants must answer only one part; A, B, or C that relates to the person's reality. If the participant experiences pain when performing sport, he or she automatically loses at least 10, and possibly 20, points.

Reliability And Validity of Visa-A:

J M Robinson The VISA-A questionnaire: a valid and reliable index of the clinical severity of Achilles tendinopathy: To develop and test a questionnaire based instrument that would serve as an index

of severity of Achilles tendinopathy. Item generation, item reduction, item scaling, and pretesting were used to develop a questionnaire to assess the severity of Achilles tendinopathy. The final version consisted of eight questions that measured the domains of pain, function in daily living, and sporting activity. Results range from 0 to 100, where 100 represents the perfect score. Its validity and reliability were then tested in a population of non-surgical patients with Achilles tendinopathy (n = 45), presurgical patients with Achilles tendinopathy (n = 14), and two normal control populations (total n = 87). The VISA-A questionnaire had good test-retest (r = 0.93), intrarater (three tests, r = 0.90), and interrater (r = 0.90) reliability as well as good stability when compared one week apart (r = 0.81). The mean (95% confidence interval) VISA-A score in the non-surgical patients was 64 (59-69), in presurgical patients 44 (28-60), and in control subjects it exceeded 96 (94-99). Thus the VISA-A score was higher in non-surgical than presurgical patients (p = 0.02) and higher in control subjects than in both patient populations (p<0.001). The VISA-A questionnaire is reliable and displayed construct validity when means were compared in patients with a range of severity of Achilles tendinopathy and control subjects.

RESULT

All statistical analysis was done using SPSS 25.0 software for windows. Descriptive analysiswas used to obtain mean and standard deviations.

Demographic Data

Age: The research was performed on 100 participants between the age of 16-35. There were 56 patients between the ages of 16 to 25, 44 patients between the age 26 to 35.

Table 1: Age Distribution

Age Distribution	
16-25 years	26-35 years

TOTAL SCORE (/100) %

DISCUSSION

The overall incidence rate is 1.85 per 1,000 registered persons per year, and for the adult population it is 2.35. There are no other studies on the incidence rates of Achilles tendinopathy in the general population to compare these results with. The prevalence rate was higher than that for another tendinopathy like lateral epicondylitis of 1.3% (men) and 1.1% (women) in 9,696 persons registered at two general practitioners.10 The incidence rates in our study are lower than the incidence of 2.98 found in the military population4 and than the annual incidence 7% and 9% in top-level runners.2 3 While it seems plausible that the incidence rate of Achilles tendon injuries is higher in athletes than within a more general population, only in 35% of the cases in our study was a relationship with sports activity described. Intrinsic risk factors such as body weight and insulin resistance might also play a role.11 Although we could not assess information on body weight, the diagnosis of Diabetes Mellitus (DM) was available from the medical records.

The minor difference between the incidence and prevalence rate suggests that most patients only visit their General Practitioner (GP) once with their Achilles tendon problems. This might be because of a short duration of symptoms or that the patients go to a physiotherapist or sports physician afterwards.

This cross-sectional study has some limitations, due to which the actual incidence of Achilles tendinopathy is probably higher than observed in this study. Firstly, not every person with a certain complaint will visit a healthcare professional. In a cross-sectional population-based study, Picavet et al reported that approximately 50% of the patients with musculoskeletal complaints visited a healthcare professional. However, those with severe or persistent complaints will probably seek healthcare. Second, while most patients in the Dutch healthcare system will visit their GP before being referred to a therapist or specialist, since 2006 patients can visit a physiotherapist or sports physician without referral by a GP. It would be interesting to know the incidence rates of Achilles tendinopathy within the patient population of the Dutch physiotherapists and sports physicians as well, but since the denominators of these populations are unknown, no exact incidence rates could be obtained. Finally, because there is no specific registration code available for Achilles tendinopathy, GPs register this injury using other or more general codes.

In concordance with other studies,13 most cases were encountered in the middle-aged population (age group 41–60 years). At present, the prevalence of Achilles tendon rupture in PE is not clear, a study showed that the incidence of Achilles tendon rupture was higher in sedentary men aged 29–48. It was speculated that the relationship between AT and age may be due to the changes of mechanical properties of Achilles tendon with age. Recently, Sprague et al. found that there was a positive correlation between age and viscosity of uninjured Achilles tendon. Aging was usually associated with reduced cellular structure, increased glycoamine polysaccharide content, and decreased fibrous tissue, all of which can lead to degenerative changes in the Achilles tendon. At the same time, the aging tendon loses elasticity, forcing the muscle to work harder, eventually leading to changes in tendon structure.

Consistent with the previous study, we found that the prevalence of AT in football players was significantly higher than in other sports. This may be related to the high training intensity of football players and the heavy load on Achilles tendon. Some reviews showed that the prevalence of Achilles tendon injury in running and track and field sports is the highest. Ball games generally require athletes to make a rapid judgment according to the competition form in a short time, such as repeated bounce, dribble pass, back and forth quick start and other technical actions with a large load on the Achilles tendon. These technical actions need the support of the Achilles tendon, which also lays a huge hidden danger for its injury.

CONCLUSION

This study was conducted among Football players of Ahmedabad city and it revealed that players those are having long training hours prone to developing tendinopathy. This study shows that there is Age group

of 16-25 having prevalence of 68% and age group of 26-35 having prevalence of 24%.
