Abstract Hydrocarbon pollution is a perennial problem not only in India but throughout the globe. A plethora of microorganisms have been reported to be efficient degraders of these recalcitrant pollutants. In the present study the Basidiomycetous a fungal isolate *Agaricomycetes sp.* AGAT was isolated from wood bark collected from Anand, Gujarat India. The isolate was screened for production of ligninolytic enzyme by primary and secondary screening. The isolate *Agaricomycetes sp.* AGAT is also able to degrade the polycyclic aromatic hydrocarbons (PAHs) present in the contaminated soil. The basidiomycetous fungal *Agaricomycetes sp.* AGAT was able to grow on 100 ppm Pyrene, Phenanthrene, Fluorene and Fluoranthene as a sole source of carbon in minimal medium. Maximum degradation of 78.53%, 85.05%, 20.5% and 70.49% of Phenanthrene, Pyrene, Fluoranthene and Fluorene respectively. The depletion in the residual PAHs in the culture medium was determined by HPLC. By GC-MS analysis metabolites were identified as 1-hydroxypyrene and phthalic acid from Pyrene, 9H- Fluoren-9-ol from Fluorene, Fluorene, 4-[1,2-dihydroxethyl] from Fluoranthene and 9,10-dihydro-9,10-dihydroxyphenanthrene from Phenanthrene. Further effect of surfactants, mediator were also studied. Phytotoxicity study of degraded metabolite was also studied.

Keywords: *Agaricomycetes sp. AGAT, polycyclic aromatic hydrocarbons (PAHs), phytotoxicity*

Cite This Article: Archana Pandey, and Akshaya Gupte, "Polycyclic Aromatic Hydrocarbons (PAHs) Metabolism by White Rot Fungi *Agaricomycetes sp* AGAT and Its Microcosm Study." *International Journal of Environmental Bioremediation & Biodegradation*, vol. 6, no. 2 (2018): 36-56. doi: 10.12691/ijebb-6-2-1.

1. Introduction

Basidiomycetes group are regarded as most interesting group of fungi with their ability to grow under detrimental environment condition constantly acting as natural degraders of lignocellulose [1]. They are further classified into brown rot fungi and white rot fungi according to the way they degrade wood. Brown rot fungi have ability to degrade wood polysaccharides while white rot fungi have ability to decompose all wood polymers including lignin. White rot fungi are known for actively degrading lignin because of presence of extracellular enzyme complex containing lignin peroxidase (LiP, E.C. 1.11.1.14), manganese peroxidase (MnP, E.C. 1.11.1.13) and laccase (Lac, E.C.1.10.3.2). These enzymes are involved in oxidation of lignin present in wood and in oxidation of xenobiotic compounds including synthetic dyes and polycyclic aromatic hydrocarbons (PAHs).

Contamination of environment by aromatic compounds has become one of the global problem. Polycyclic aromatic hydrocarbons (PAHs) contamination is serious and increasing problem for human and ecosystem because of spill in soil, water and other natural resources. Polycyclic aromatic hydrocarbons (PAHs) are a group of organic compound having two or more fused benzene ring which have been identified as persistent organic pollutants and are of great concern due to the characteristics of toxicity, mutagenicity and carcinogenicity. The US Environmental Protection Agency (US EPA) has listed 16 PAHs as priority pollutants [2,3]. PAHs are formed due to incomplete pyrolysis of organic materials such as petroleum, coal and wood.

Various potential techniques are being developed now-a-days to overcome these problems. Microbiological process of degradation of organic pollutants is considered as a promising method for environmental problem. Use of microbial resources for remediation of PAH contaminant has been important 'green solution' [4,5,6]. Bioremediation is the technique using microbes (bacteria, fungi and algae) which degrade or transform and mineralize contaminants to carbon di oxide and water. Bioremediation is simple process that is economical, versatile, ecofriendly and efficient as compared to chemical technique that produce toxic intermediate and have lower bioavailability for contaminants. The extracellular ligninolytic enzymes secreted by white rot fungi oxidize PAHs via a non-specific, radical-based reaction with corresponding quinones [7]. Catalysis reaction by laccase depends on the monoelectronic oxidation transforming the substrate to reactive radicals with the help of mediator [8]. Use of various mediators (ABTS, HBT and Phenol) for enhancement of PAH degradation have being reported by [9,10,11]. PAHs bioavailability can be enhanced by

addition of surfactants which increase its surface tension and increase its solubilization through formation of micelles in solution. This phenomena is observed at its critical micellar condition (CMC) [12].

The main objective of the present work was to study degradation of Pyrene, Phenanthrene, Fluoranthene and Fluorene by white rot fungi *Agaricomycetes sp* AGAT. Attempts were made for enhancing the degradation of PAHs by addition of surfactants and mediators to the medium. The potential isolate *Agaricomycetes sp* AGAT was explored for its interaction with indigenous microflora present in the soil through microcosm study. Degraded metabolites were analyzed using HPLC and GC-MS analysis.

2. Materials and Method

2.1. Microorganisms and Culture Conditions

Agaricomycetes sp AGAT (Genbank accession no. KT153994) was grown on 2% Malt extract agar (MEA). MEA contained (g/l) Malt Extract 30.0, Peptone 5.0, and Agar 25.0 (pH: 5.4) at 30℃.

2.2. Chemicals

ABTS (2, 2-Azino-bis (3-ethylbenzthiozoline-6-sulphonic acid), Phenol and HBT (1-hydroxybenzotriazole) was purchased from Sigma Aldrich (Sigma St. Louis, MO, USA). Malt Extract Agar (MEA), glucose, sodium acetate, KH_2PO_4, H_3BO_3, $NaNoO_4$, Alk $(SO_4)_2$, yeast extract, sodium dedecyl sulphate (SDS), sodium sulphate, thiamine were purchased from Hi-Media Labs (Mumbai, India). Ammonium tartrate, copper (II) sulphate pentahydrate, manganese (II) sulphate monohydrate, magnesium sulphate heptahydrate, calcium chloride dihydrate, zinc sulfate were procured from S D Fine chemicals (Mumbai, India). Tween 80, Triton X-100, Ethyl acetate, Acetone, Acetonitrile, HCl and HPLC grade water were purchased from Merck (Mumbai, India).

Polycyclic aromatic hydrocarbon (PAHs) Pyrene, Phenanthrene, Fluorene and Fluoranthene were procured from Sigma Aldrich (Sigma St. Louis, MO, USA).

2.3. Enzyme Assays

Laccase (E.C.1.1.03.2) activity was determined by measuring the oxidation of 2, 2'-azino-bis 3-ethylbenzothiazoline-6-sulphoric acid (ABTS) as increase in absorbance for 3 minutes was measured spectrophotometrically at 420nm ($\varepsilon = 36000 cm^{-1} M^{-1}$) [13]. The reaction mixture contained 100µl of 50 mM ABTS and 800 µl of 20 mM Sodium Acetate buffer (pH 4.5) and 100 µl of appropriately diluted enzyme extract. One unit of enzyme activity was defined as the amount of enzyme that oxidized 1 µM of corresponding substrate per min.

2.4. Isolation, Screening and Identification of Isolated Fungal Strain

Various mushroom samples, decayed wood and barks of trees were collected from the nearby regions of Vadodara (22°19'18.64" N 73°09'19.19" E) and Anand (22°33'08.87" N 72°55'38.68" E) Districts, Gujarat, India. Samples collected were screened for the presence of ligninolytic enzymes. Surface sterilization of collected samples was performed by suspending in 0.01 %(v/v) mercuric chloride solution for 2-3 minutes followed by washing. The samples were placed on 2% (w/v) malt extract agar (MEA) plates containing streptomycin (25µg/ml) and the plates were further incubated at 28℃ for 8-10 days. Isolated cultures were repeatedly sub cultured to obtain a pure culture. Microscopic studies were performed to study the characteristic of white rot fungi. Further samples were screened for the phenol oxidase activity. The presence of laccase enzyme (primary screening) was studied using various chromogenic substrates like ortho-dianisidine; guaiacol and gallic acid at a concentration of 0.01% (w/v) supplemented in 2% (w/v) malt extract agar plates. The actively grown culture (agar plugs) were placed on the plates and incubated at 28℃ for 10 days. Fungal isolate showing positive Bevandamm's reactions were further explored for the quantitative detection of ligninolytic enzymes. Cultures were maintained on MEA plates at 30℃ and stored at 4℃.

Quantitative detection (secondary screening) of ligninolytic enzyme was performed using 5.0 gm of wheat bran as a solid substrate with Asther's medium as a moistening agent under solid state fermentation.

The molecular identification of the new isolate AGAT was done by using ITS4 (TCCTCCGCTTGATATGC) and ITS5 (GGAAGTAAAAGTCGTAACAAGG) gene sequencing by Agarkhar Research Institute (ARI) Pune, India.

2.5. PAHs Degradation

Degradation studies were conducted in 250ml Erlenmeyer flasks containing 100 ml of degradation medium prepared according to Tien & Kirk [14] containing (g/l) glucose 10, ammonium Tartrate 0.2, sodium acetate 3.28, thiamine 2, KH_2PO_4 2; $MgSO_4.7\ H_2O$, 0.53; $CaCl_2$, 0.1; $CuSO_4$, 0.001, $MnSO_4$, 0.005; H_3BO_3, 0.001; $NaMoO_4.\ 2H_2O$, 0.0001; $ZnSO_4.\ 7H_2O$, 0.0001; $AlK\ (SO_4)_2.\ 12H_2O$, 0.0001; and yeast extract 0.5. The pH of the medium was adjusted to 5.0 with 2N HCl. Flasks were sterilized at 121℃ for 20 min. Thiamine was separately filter sterilized and added thereafter. All the flasks were inoculated with fungal agar disc of 9 mm diameter from the edge of the actively growing culture. All the flasks were incubated at 28℃ at 100 rpm for 6 days. Stock solution of PAHs were prepared in acetone, filter sterilized with help of 0.2 µm filter and added to 6 day old culture at a final concentration of 100 ppm. All the flasks were re-incubated at 28℃ at 100 rpm for 25 days.

2.5.1. Effect of Surfactants on PAHs Degradation

Surfactants plays an important role in degradation of PAHs in order to study the effect of surfactant the degradation medium was seeded with surfactants like SDS, Triton X-100 and Tween 80 at a concentration of 0.1,1 and 2mM. Control flask was without surfactant.

2.5.2. Effect of mediator on PAHs degradation

Mediator plays an important role in degradation of PAHs in order to study the effect of mediator the degradation medium was seeded with mediator like ABTS,

Phenol and HBT at a concentration of 0.1,1 and 2mM. Control flask was without mediator.

2.6. Extraction of Residual PAHs

The entire content of the flask (100ml) were extracted for determination of residual PAHs.

After addition of PAHs to six day old culture extraction was done on 5th, 10th, 15th, 20th and 25th day of incubation. The mycelia was filtered using Whatman filter paper No1. The liquid was extracted in double volume of ethyl acetate, kept at 30℃ at 150 rpm for 30 mins. The mixture was separated using separating funnel. The organic phase was collected and saved.

The extract obtained was dried using anhydrous sodium sulphate to remove aqueous phase.

2.7. Calculations for PAHs Degradation Rate

Degradation rate of PAHs was calculated by subtracting the amount of PAH extracted from the abiotic control from the other samples. The rate of degradation was calculated as:

PAH degradation rate (%) = Abiotic control extraction (100%) - Sample extraction

Sample extraction means filtrate obtained.

2.8. Microcosm Study

Microcosm preparation was planned in four different sets of soil model systems were prepared as:

- (Set A)-Sterile soil containing PAH which served as abiotic control
- (Set B)-Sterile soil supplemented with PAH (100ppm) was inoculated by *Agaricomycetes sp* AGAT to determine the PAH degradation efficiency by *Agaricomycetes sp* AGAT in absence of indigenous organisms
- (Set C)-Non sterile Soil with native or indigenous organisms and PAH, to evaluate the intrinsic ability of soil to degrade PAH
- (Set D)-Non sterile soil supplemented with PAH and inoculated with *Agaricomycetes sp* AGAT to check the degradation rate by *Agaricomycetes sp* AGAT in presence of indigenous flora.

2.9. Analytical Procedures

2.9.1. Determination of residual PAHs:

The residual PAHs were analyzed by reverse-phase HPLC (Shimadzu, Japan) equipped with Nuclosil 100-5 Column (C-18 PAH Column, 250mm X 4.6mm) series 200 pump. Detection was done using D2 detector set at 254 nm. Dried samples were re-extracted in 1 ml of mobile phase (Acetonitrile: Water, 70:30), filtered through 0.2µM filter and 20µl was injected to HPLC Column.

2.9.2. Detection of Metabolites

The residual metabolite was extracted from the sample with equal volume of ethyl acetate. Further 2ml of sample was transferred to GC vial for GC-MS analysis carried out by using Shimadzu Gas Chromatograph Mass Spectrophotometer GC-MS (Shimadzu). The total sample injected was 2µl.

2.9.3. Phytotoxicity Analysis

The method of testing of Phytotoxicity of PAHs and its metabolites was performed according to Kalme *et al.*, [15]. The test was carried out for standard and the extracted metabolites on the seeds of *Triticum aestivum*, common Indian agricultural crops. Ten seeds were supplied daily with 10ml of standard and extracted metabolites dissolved in water for 7-10 days in small pots, maintaining light and temperature (30℃) in a controlled environment. Toxicity effect was measured in terms of percent germination, lengths of root and shoot of the plant after 7-10 days.

2.9.4. Data Analysis

The data in subsequent sections represent arithmetic mean values of three experimental repetitions (each one was made in duplicate).

3. Results

3.1. Isolation and Primary Screening

Table 1. Response of different fungal isolates on MEA plates containing different chromogenic substrates

Strain No	Isolate code	Primary screening Chromogenic substrates (0.01%w/v) ODA	Guaiacol	Gallic Acid	Secondary screening Laccase (U/gm)
1	AGAT	++++	++++	++++	117653.8
2	AGAT - 1	+++	+++	+++	60166.6
3	AGAT - 2	ND	ND	ND	ND
4	AGAT - 3	+	+	+	10077
5	AGAT - 4	++	++	++	52250.7
6	AGAT - 5	ND	ND	ND	ND
7	AGAT - 6	ND	ND	ND	ND
8	AGAT - 7	ND	ND	ND	ND
9	AGAT - 8	+	+	+	5145.8
10	AGAT - 9	++	++	++	20250.6
11	AGAT - 10	ND	ND	ND	ND
12	AGAT - 11	ND	ND	ND	ND
13	AGAT - 12	++	++	++	28520
14	AGAT - 13	+	+	+	2053
15	AGAT - 14	ND	ND	ND	ND

++++ - Excellent producer, +++ - Good producer, ++ - Moderate producer, + - poor producer, ND- No detection of colored zone on MEA plates containing chromogenic substrates

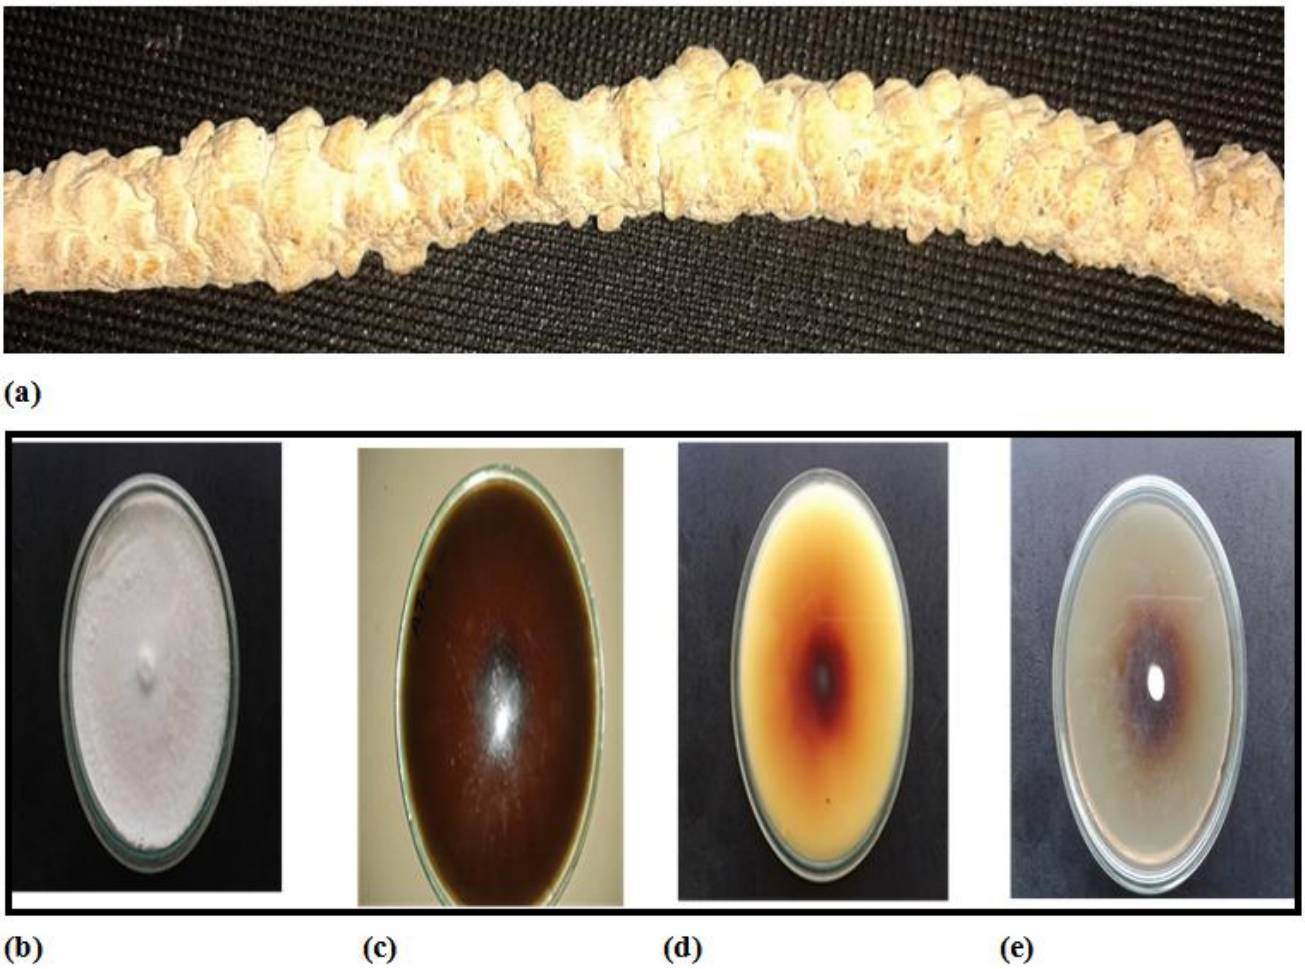

Figure 1. (a) Fruiting Body of AGAT. (b) Growth pattern of AGAT on 2%MEA, (c) - (e) Plate assay for Laccase on MEA plate containing different chromogenic substrates viz. orth-dianisidine, Guaiacol and Gallic acid

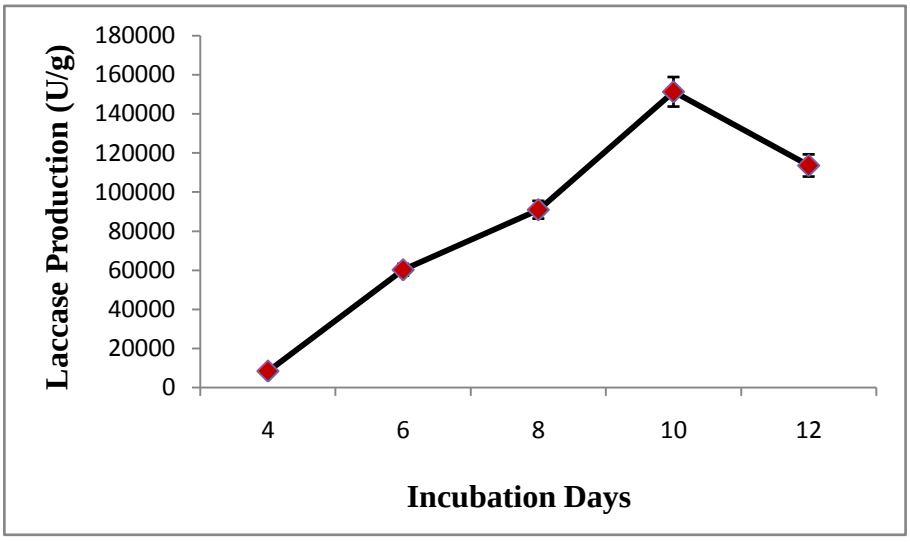

Figure 2. Secondary screening for laccase production

In the present study out of 15 isolates only 8 isolates were potential to produce ligninolytic enzyme by plate assay method. Dark brown zone surrounding the growth of mycelial disc on MEA plate containing o-dianisidine and gallic acid. Reddish brown colour zone was observed with plate containing guaiacol at concentration of 0.01% w/v (Figure 1). This is a characteristic of phenol oxidase which indicates of positive bevandamm's reaction for laccase activity. Further the isolate were classified as poor, moderate, good and excellent producer of laccase (Table 1).

Secondary screening of laccase was done using wheat bran as solid substrate and Asther's medium as moistening agent under solid state fermentation (SSF) (Figure 2). Maximum production of 1.65 X 10^5 U/g of dry substrate was obtained on 10^{th} day of incubation for wheat bran. Hence, on the basis of primary and secondary screening isolate AGAT was selected and explored for PAHs degradation.

3.2. Identification of the Fungal Isolate

3.2.1. Macroscopic Characteristics

Isolate AGAT fruiting body was found to be grown on bark of wood of mulberry tree with fleshy white mat like growth. Strain grew well on MEA covering the entire plate in 8-10 days incubated at 28℃.

3.2.2. Microscopic Characteristics

Microscopic examination of fruiting body revealed the presence of Basidiospores and gleopleros hyphae and binding hyphae as shown in Fig 3.sp Spore observed were size of around 12.56 X 7.75 µm. The molecular identification of the new isolate AGAT was confirmed by isolation of genomic DNA followed by amplification of ITS region of rDNA using universal fungal primers ITS4 and ITS5 (Agharkar Research Institute, Pune). Similarity of the DNA sequence in Genbank Database was found to be same with *Agaricomycetes sp.* with 99% similarity. The isolate was identified as *Agaricomycetes sp.* AGAT with Genbank Accession No KT153994 (Figure 4).

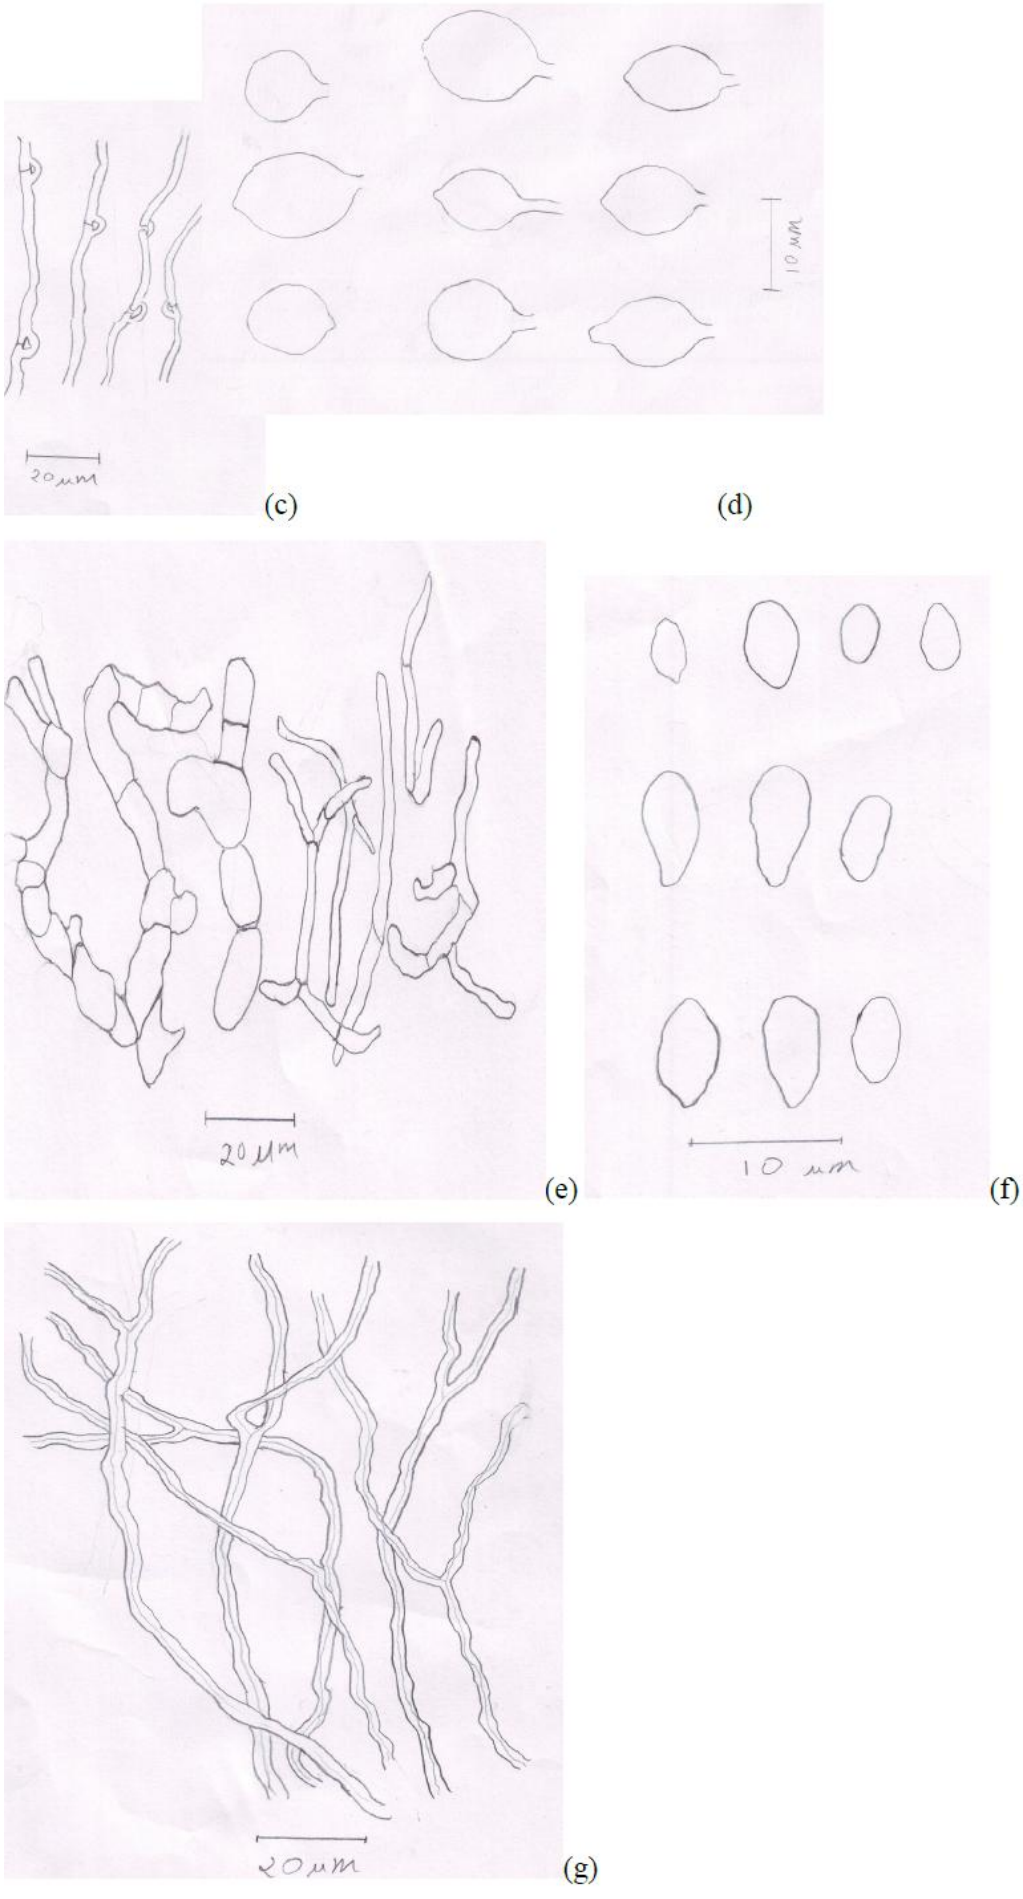

Figure 3. (e) Gloeopleros hyphae (f) Basidiospores observed in fruiting body (g) Binding hyphae.

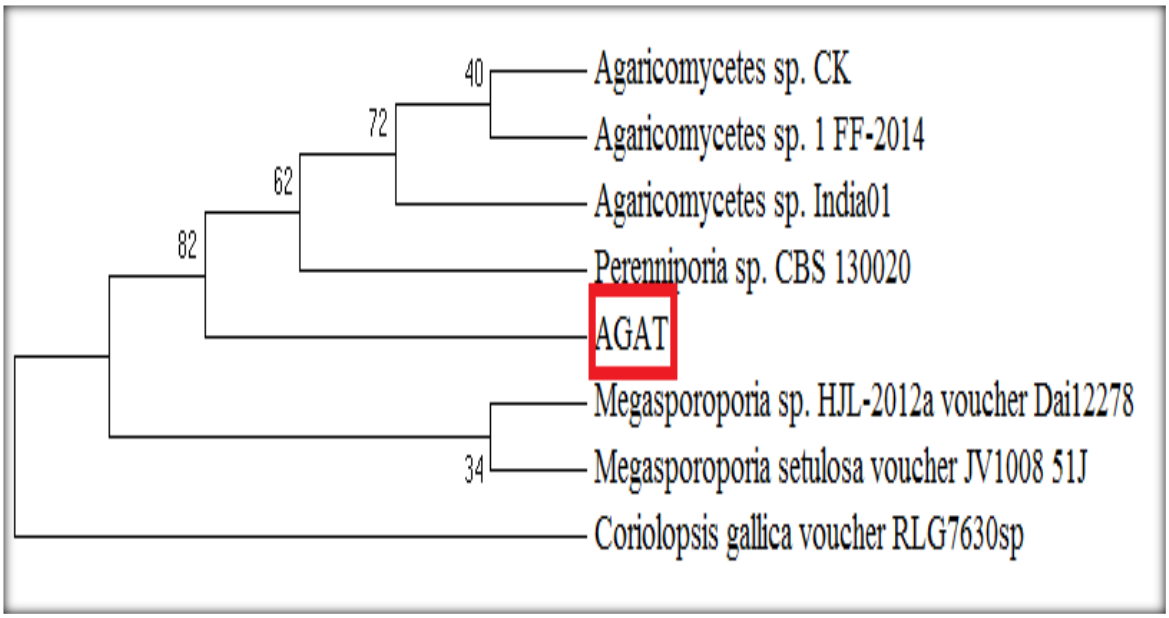

Figure 4. The bootstrapped unrooted tree of AGAT by NJ analysis

3.3. Growth of Fungal Culture *Agaricomycetes sp* AGAT on PAHs

The isolate *Agaricomycetes sp.* AGAT was grown on MEA plate containing 100 ppm of each PAH (Benzo (a) Anthracene, Fluorene, Pyrene, Acenaphthene, Anthracene and Phenanthrene).the isolate *Agaricomycetes sp.* AGAT was able to grow and utilize PAH as a sole source of carbon and energy as shown in Figure 5. Table 2 shows the growth in terms of zone of proliferation of isolate *Agaricomycetes sp.* AGAT on 8th day of incubation.

3.4. Degradation of PAHs by *Agaricomycetes sp* AGAT

The isolate *Agaricomycetes sp.* AGAT was grown in degradation medium (Minimal Salt medium) by spiking with different PAHs as sole source of carbon and energy. Degradation study using LMW PAH like Phenanthrene and Fluorene while HMW PAH like Pyrene and Fluoranthene was done. *Agaricomycetes sp.* AGAT was able to degrade 30.5% Phenanthrene in 20 days with 1250 U/ml of enzyme activity. Degradation of PAHs was dome more efficiently in presence of co-substrate such as glucose (Figure 6).

Table 2. Growth of Fungal Culture on MEA Plate with different PAHs (100 ppm) on 8th day of incubation period

PAHs	Diameter (cms)
Malt Extract (Control)	9.0
Pyrene	8.25
Anthracene	8.5
Fluorene	7.25
Fluoranthene	9.0
Phenanthrene	3.9
Acenaphthene	4.0

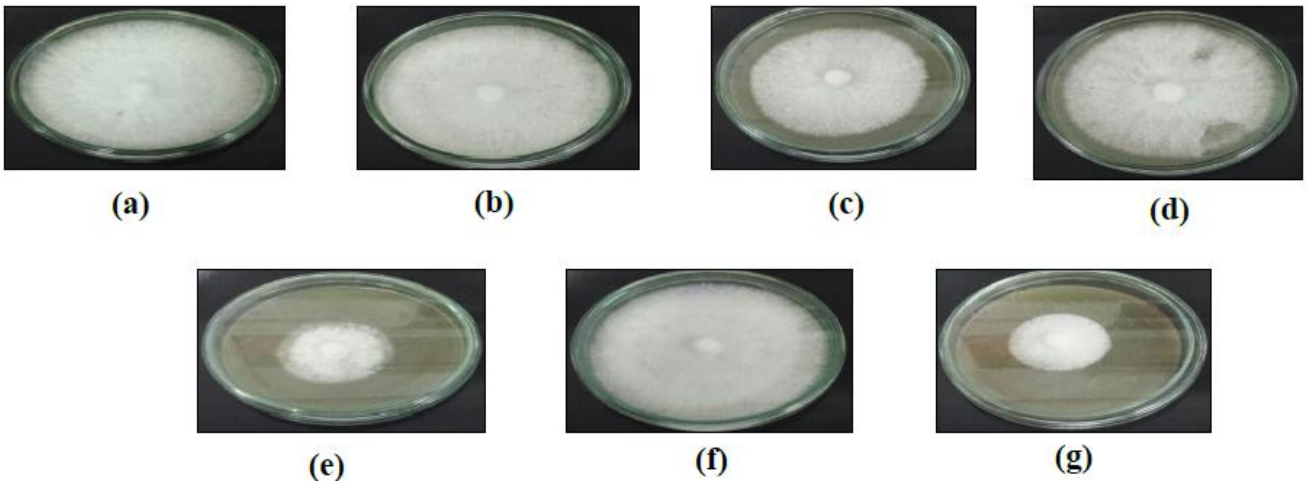

Figure 5. Fungal culture grown on different PAH used as sole source of carbon: (a). Control (b) Benzo(a) Fluoranthene (c) Fluorene (d) Pyrene (e) Acenaphthene(f) Anthracene (g) Phenanthrene

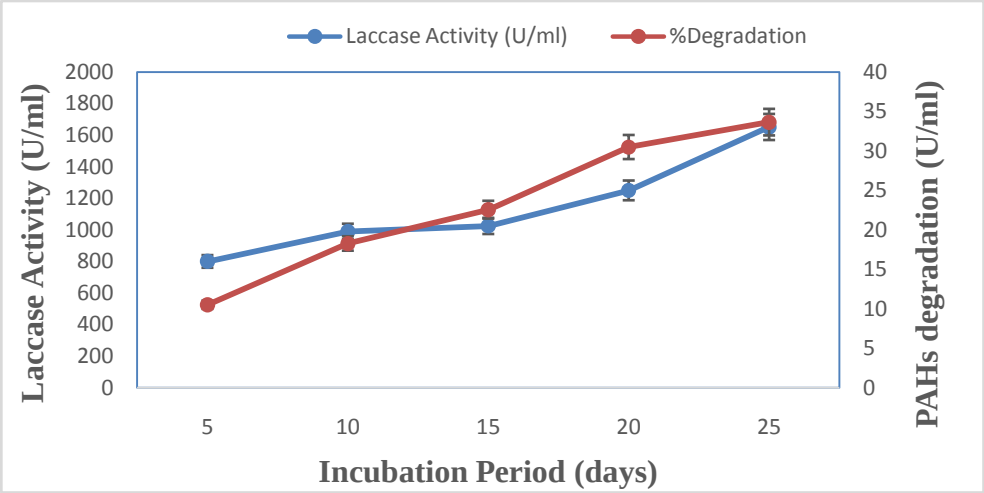

Figure 6. Phenanthrene degradation by *Agaricomycetes sp* AGAT as a sole source of carbon and energy

With addition of glucose as co-substrate in degradation medium the degradation of Phenanthrene increased to 78.53% with 3394.16U/ml on 20th day of incubation. Amongst the various co-substrates glucose was found to be best. Therefore, glucose was used in our further studies for the degradation of PAHs (Figure 7).

The degradation profile of various PAHs were studied with respect to laccase activity, incubation period and % degradation. In the present study 100 ppm of different PAHs were used for degradation study by fungal culture *Agaricomycetes sp* AGAT. Pyrene showed maximum degradation of 85.05% on 15th day of incubation with 2650.2 U/ml of enzyme activity and Fluoranthene reported 20.5% degradation on 25th day of incubation with 3580.2 U/ml enzyme activity (Figure 8 - Figure 11).

No further significant PAHs degradation was observed. The growth of fungus in liquid medium with PAHs can be observed by comparing it with control flask (Figure 12).

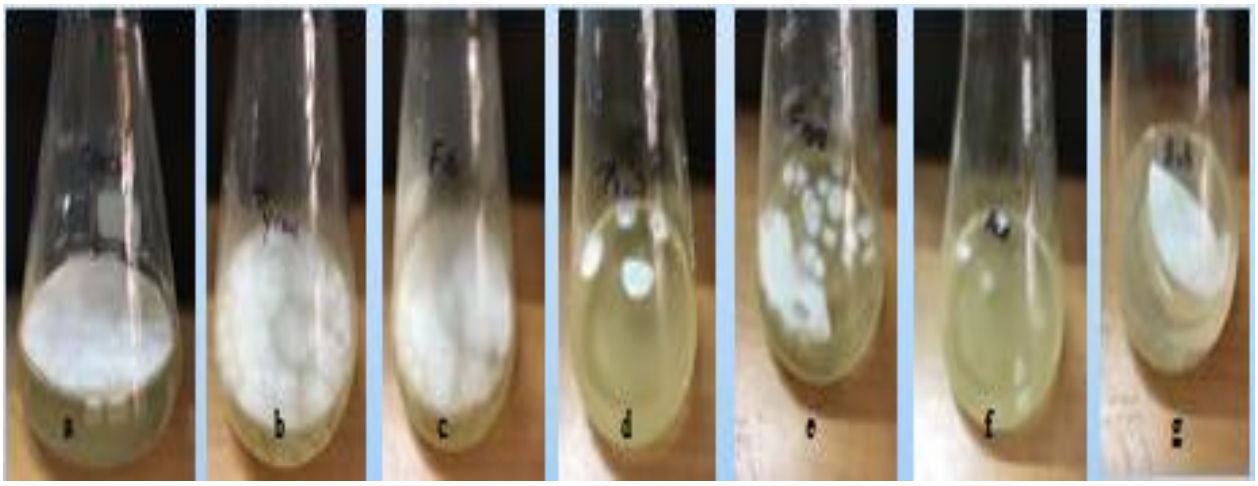

Figure 12. Growth of *Agaricomycetes sp.* on different PAHs. (100ppm): (a) Control (b) Pyrene (c) Fluoranthene (d) Phenanthrene (e) Fluorene (f) Acenaphthene (g) Anthracene

3.5. Effect of Different Surfactants on Degradation of PAHs

All the surfactants (SDS, Tween 80 and Triton X-100) were incorporated in medium. At concentration of 1mM were found to enhance the degradation of PAH as compared to control and other two concentration i.e. 0.1mM and 2 mM. When the surfactants used at different concentration then considerable difference in degradation was observed (Figure 13 - Figure 15).

Whereas Figure 13 shows a significant increase in degradation of Fluoranthene from 20.35% to 88.09%. Further increase in concentration of Tween 80 reduced the degradation as high concentration of surfactant may affect the growth of fungi in medium.

Similarly SDS was also found to be effective in increasing PAHs degradation as Tween 80. Maximum degradation of around 99% of Pyrene, Fluoranthene, Phenanthrene and Fluorene at concentration of 0.1mM, 1mM and 2mM was obtained.

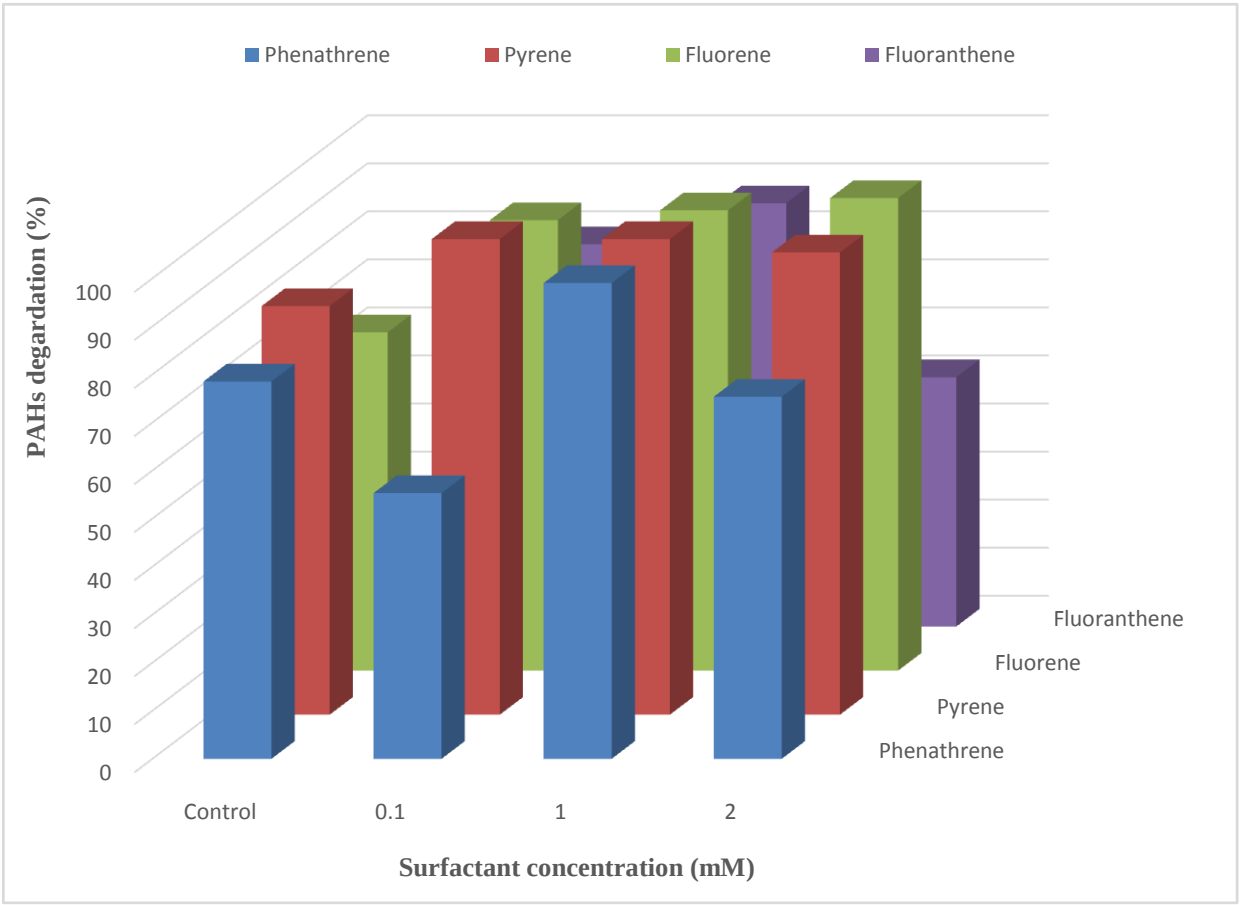

Figure 13. Degradation of PAHs in the presence of different concentrations of Tween 80 on 15th day of Pyrene, 20th day of Phenanthrene and Fluorene and 25th day of Fluoranthene

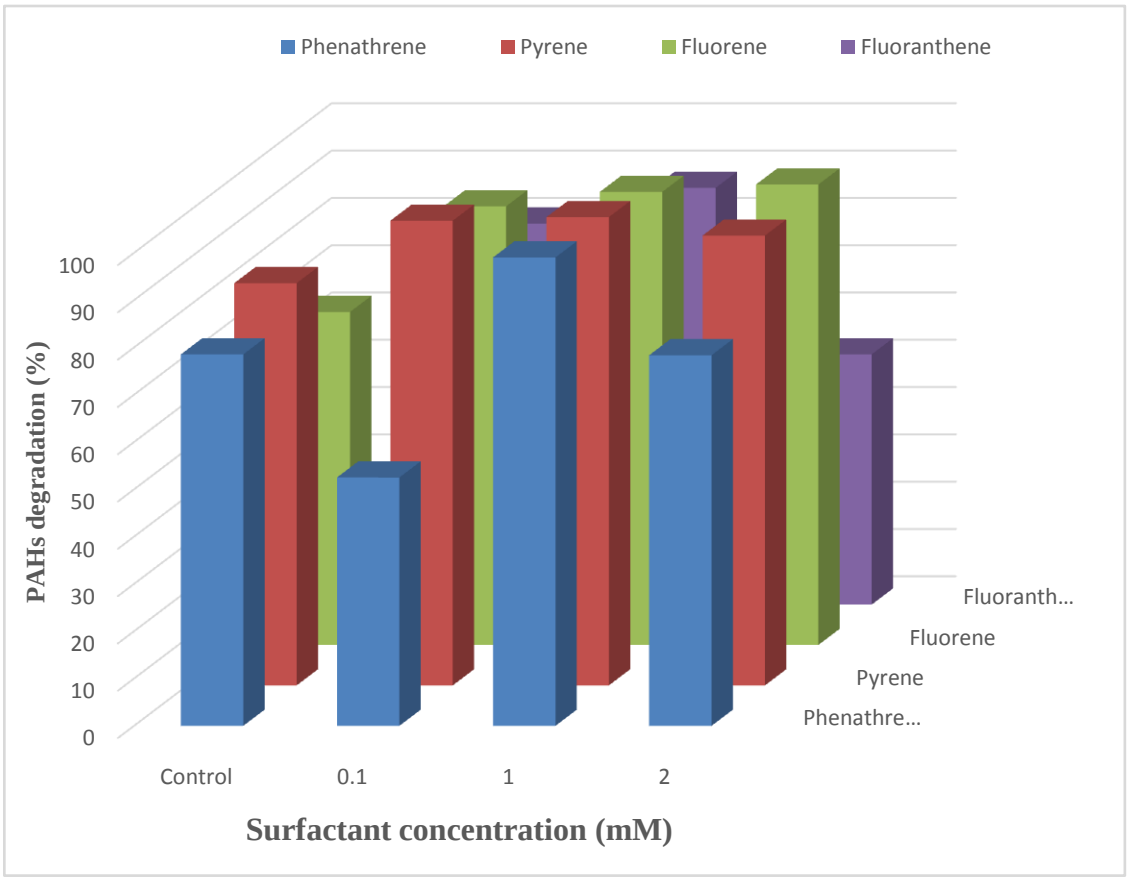

Figure 14. Degradation of PAHs in the presence of different concentrations of SDS on 15th day of Pyrene, 20th day of Phenanthrene and Fluorene and 25th day of Fluoranthene

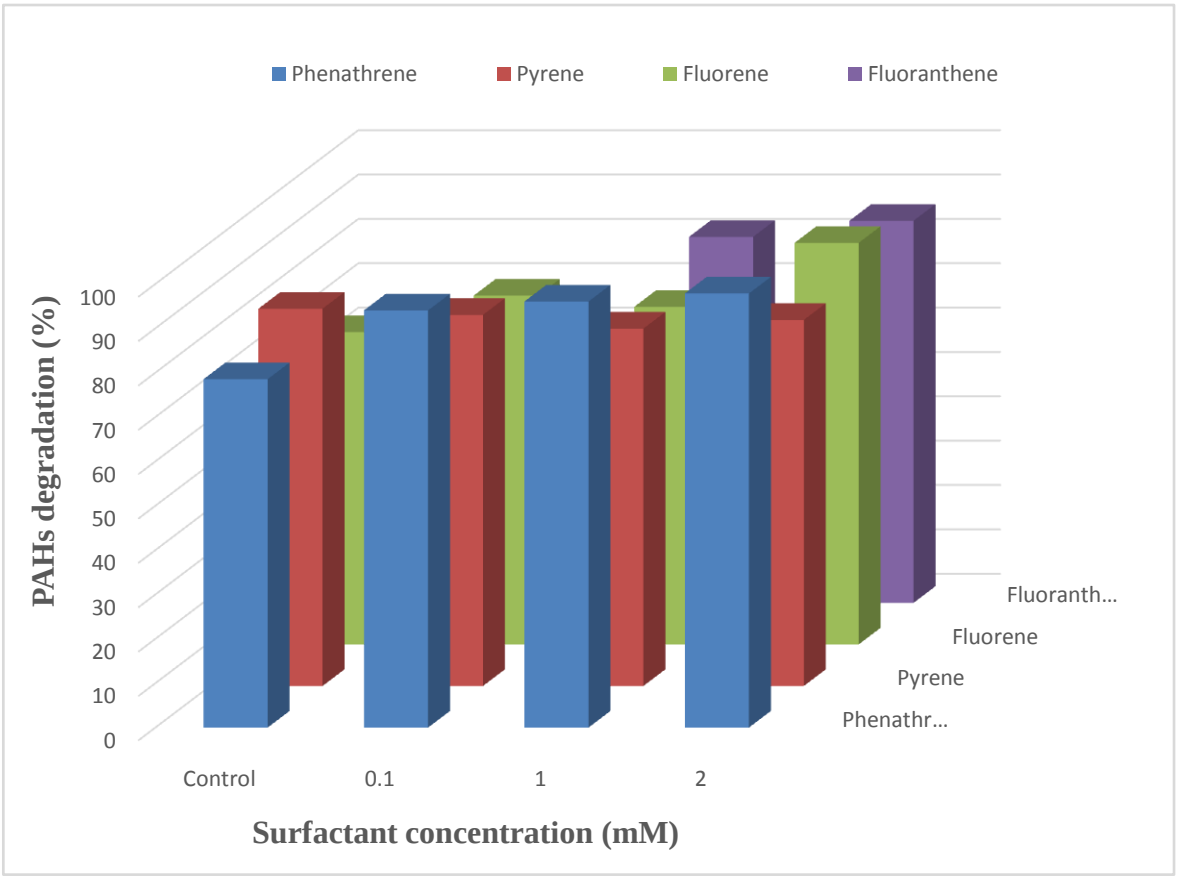

Figure 15. Degradation of PAHs in the presence of different concentrations of Triton X-100 on 15th day of Pyrene, 20th day of Phenanthrene and Fluorene and 25th day of Fluoranthene.

3.6. Effect of Different Mediator Compounds on Degradation of PAHs

In the present study 3 mediator used were ABTS, HBT and Phenol at concentration of 0.1mM, 1mM and 2mM. Amongst all HBT was found to be best and powerful mediator in PAH degradation. Around 99.1% of Pyrene removal was observed on 15th day of incubation. HBT showed 95.25%, 94.74% and 75.25% removal of Phenanthrene, Fluorene and Fluoranthene on 20th and 25th day of incubation respectively at 2mM concentration. Even at low concentration of 0.1mM HBT showed effective enhancement in PAH degradation (Fig 16).ABTS showed 98% elimination of Pyrene and Phenanthrene at concentration of 2mM. Around 90.21% degradation of Fluorene and 86.98% degradation of Fluoranthene were obtained at 2mM concentration of ABTS (Figure 17). Phenol also used mediator showed almost 90% removal of all PAHs in system at concentration of 2mM (Figure 18).

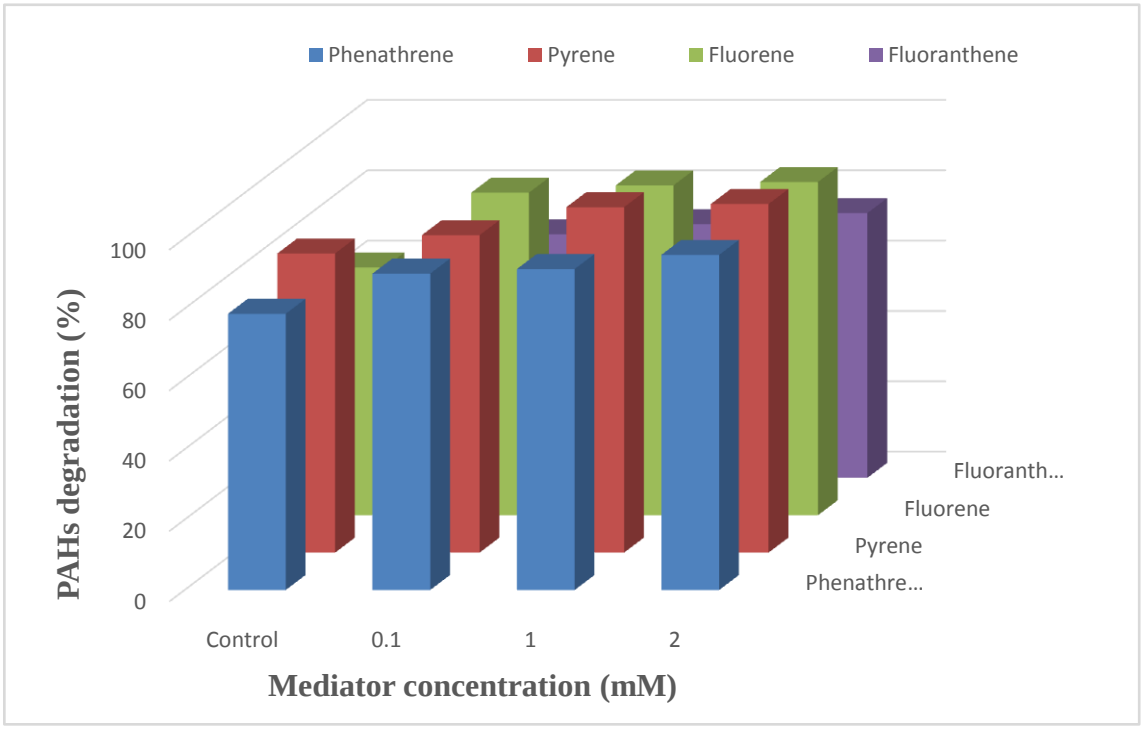

Figure 16. Effect of different concentrations of mediator compound HBT on degradation of PAHs

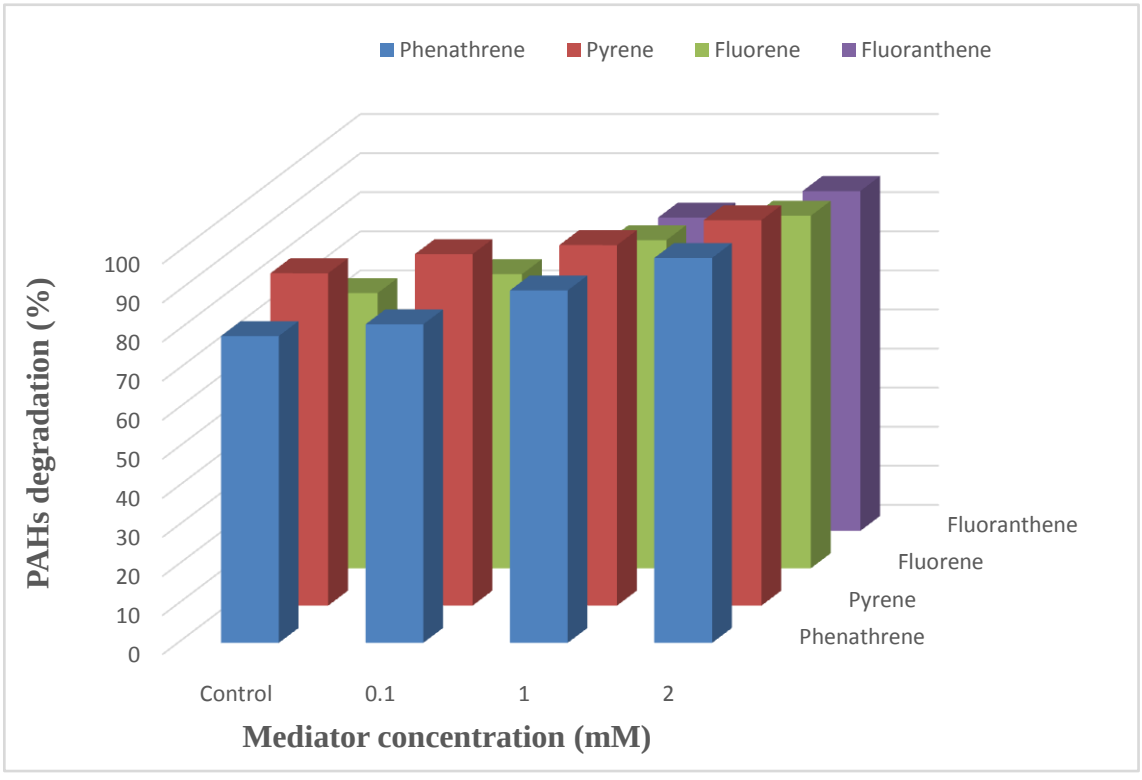

Figure 17. Effect of different concentrations of mediator compound ABTS on degradation of PAHs

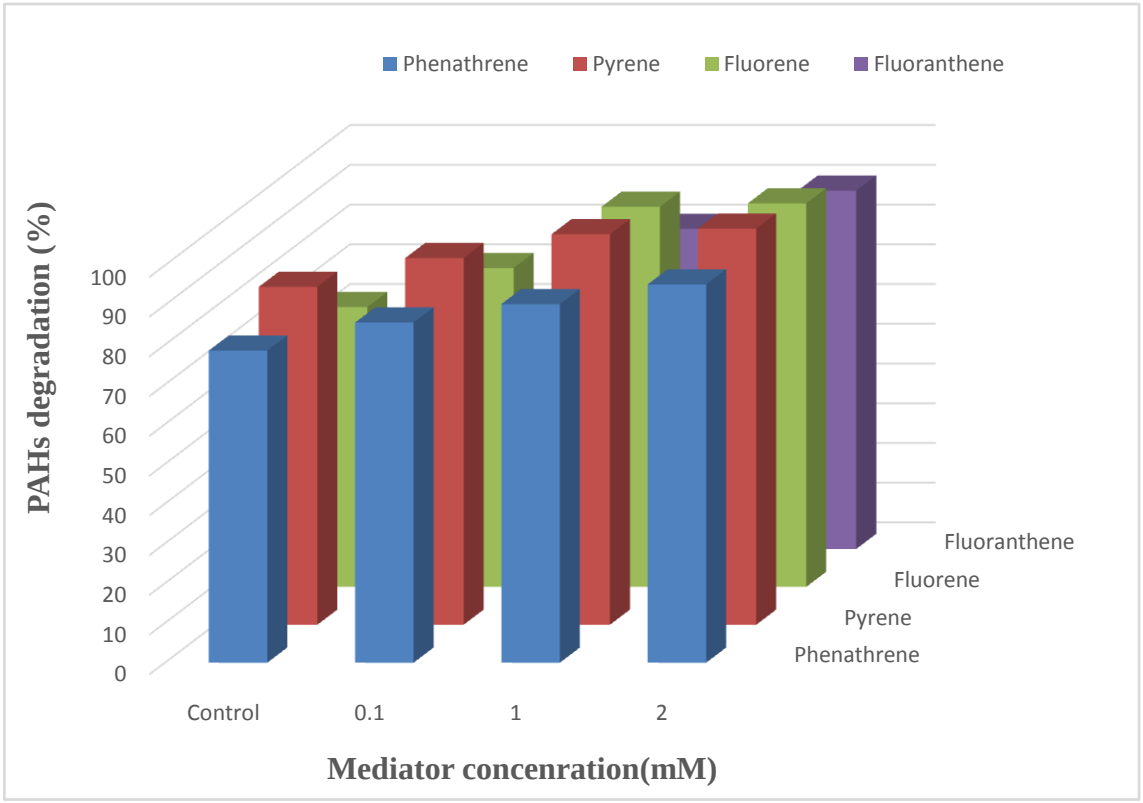

Figure 18. Effect of different concentrations of mediator compound Phenol on degradation of PAHs

3.7. Microcosm Study to Explore the Bioremediation Potential of *Agaricomycetes sp* AGAT

Microcosm study of PAHs such as Phenanthrene, Fluoranthene, Fluorene and Pyrene at concentration of 100 ppm using different sets of experiments were studied. The study shows the abiotic loss of Phenanthrene i.e. set A without microorganisms was about 25% i.e. control set (Set A). In set B 76.63% Phenanthrene degradation was observed by *Agaricomycetes sp* AGAT without the presence of indigenous flora. Presence of microbes in soil showed 45.50% (set c) degradation while set D showed maximum degradation of 96.66% with presence of both micro-flora and isolate AGAT (Figure 19). Present study showed that the maximum degradation in presence of Fluorene (93.88%) was achieved in set B i.e. having only presence of isolate *Agaricomycetes sp* AGAT as compared to set D which showed 46.20% degradation in presence of both indigenous flora along with isolate *Agaricomycetes sp* AGAT as shown in Figure 20. Pyrene and Fluoranthene also showed maximum degradation of 90.25% and 35.74% by *Agaricomycetes sp* AGAT present in sterile soil i.e. Set D. (Figure 21- Figure 22).

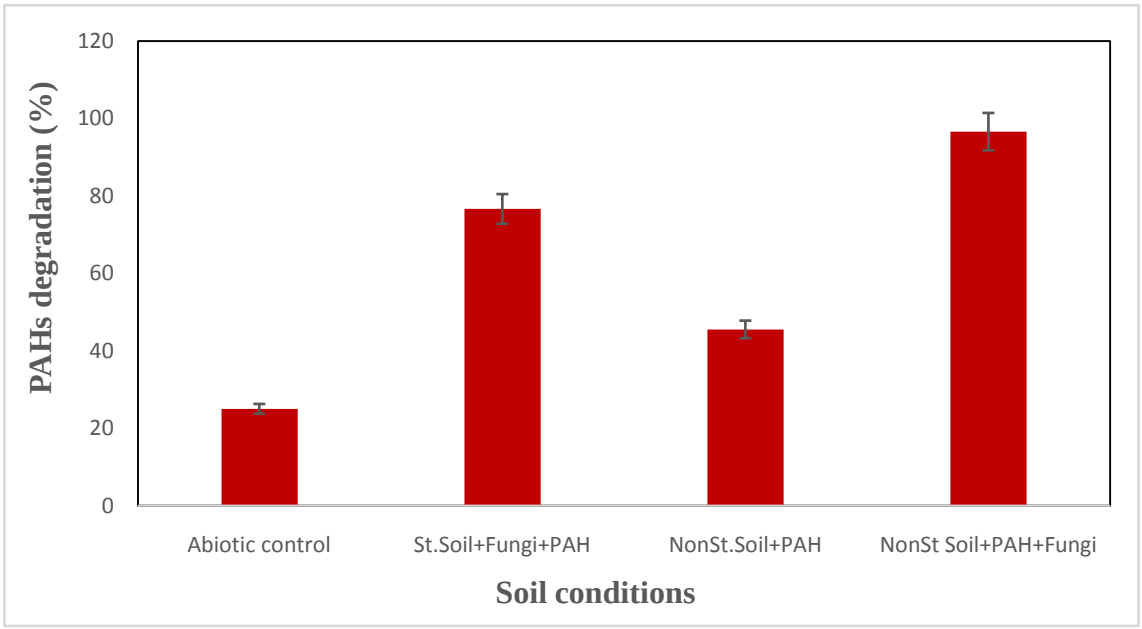

Figure 19. Microcosm study for Phenanthrene degradation

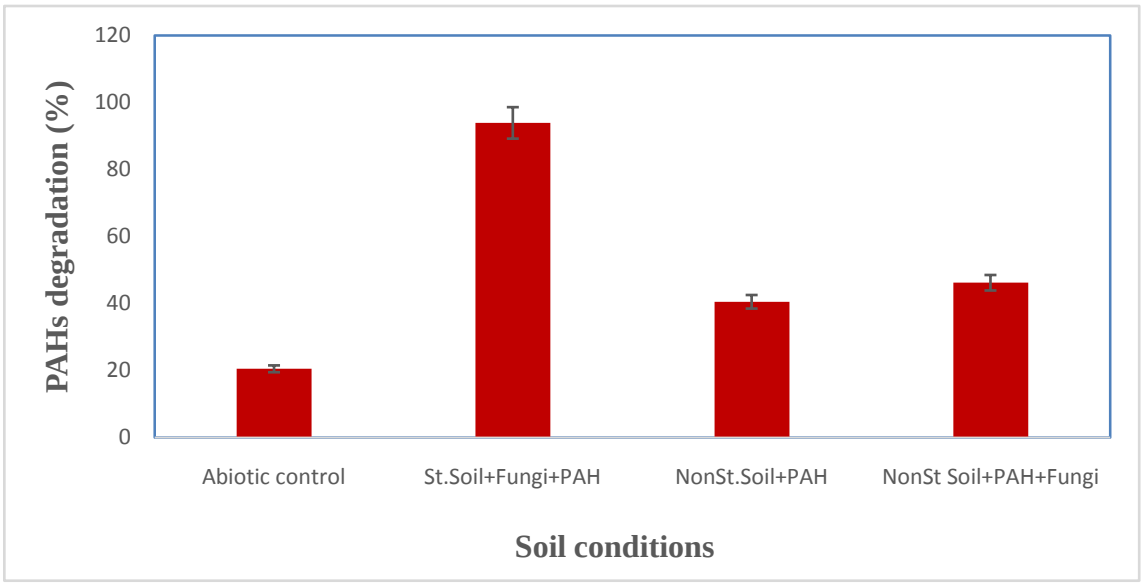

Figure 20. Microcosm study for Fluorene degradation

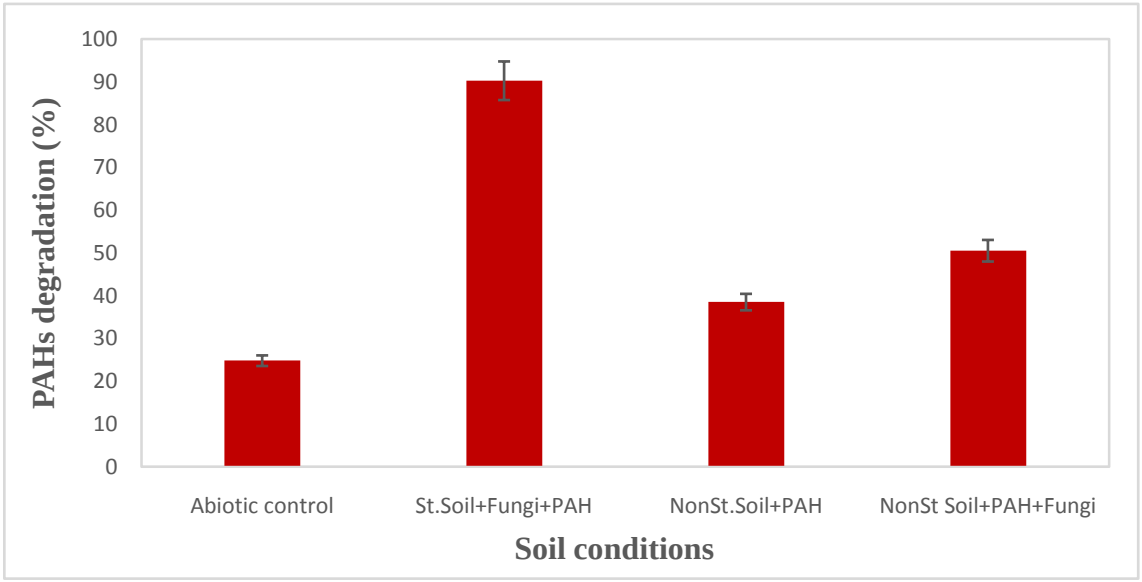

Figure 21. Microcosm study for Pyrene degradation

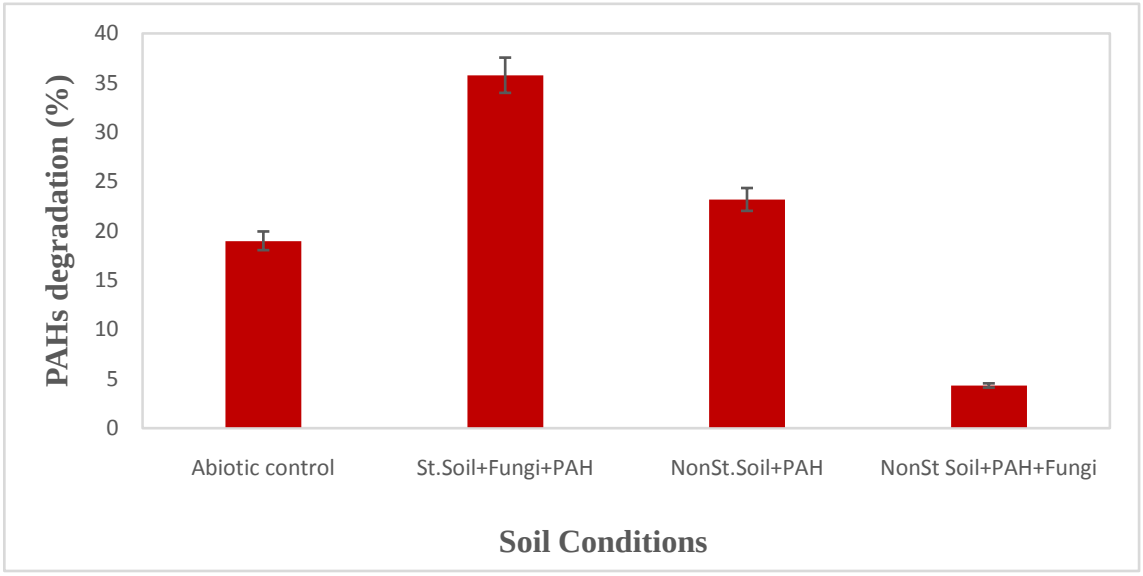

Figure 22. Microcosm study for Fluoranthene degradation

3.8. Detection of PAH Degradation Metabolites

For detection of degraded metabolite GC-MS analysis was performed. GC-MS analysis showed one peak as compared to control sample which was identified as 1-hydroxypyrene and phthalic acid with 218.5 m/z and 166.3m/z ratio respectively (Figure 23). Proposed pathway is shown in Figure 24.

GC-MS spectra of Phenanthrene showed presence of one peak as compared to control as shown in Figure 25. Peak corresponds to formation of 9,10-dihydroxy Phenanthrene it's an intermediate compound formed due to ring cleavage of cytochrome P-450 and epoxide hydrolase enzyme. Proposed pathway for degradation of Phenanthrene is shown as in Figure 26.

GC-MS analysis of Fluorene was Fluoren-9-ol as intermediate product after degradation on 20th day of incubation (Figure 27 - Figure 28). Fluorene 4- [1,2-dihydroethyl] is the intermediate detected by mass spectra of Fluoranthene (Figure 29 - Figure 30).

3.9. Phytotoxicity Study of Degraded Metabolite

The results of phytotoxicity studies using PAHs and its degraded metabolite on *Triticum aestivum* are shown in Table 3. Length of plumule and root length (in cms) of germinated seeds were recorded after 10 days. Maximum shoot length observed in degradation metabolite of Pyrene (21 cms) Figure 31.

% germination of seeds was affected after addition of PAH at concentration of 100 ppm to pot as compared to degraded metabolite as shown in Table 3. It is observed that Fluorene is most toxic for seed germination as compared to other PAHs.

4. Discussion

By plate assay method isolate were screened for ligninolytic enzyme production using o-dianisidine, guaiacol and gallic acid. Positive Bevandamm's reaction observed for laccase activity. Chhaya and Gupte [16] reported the similar results with litter dwelling fungi for screening of laccase producers using ABTS and guaiacol as a substrate. Gao *et al.,* [17], Patel *et al.,* [18] and Agrawal *et al.,* [19] reported the similar results for the screening of presence of laccase enzyme in the fungi by plate assay. Primary screening method is a very rapid for detection of the presence of the laccase enzyme by comparing the intensity of color and time required for development of colour due to oxidation of chromogens.

Solid state fermentation is one of the best process which have been used for ligninolytic enzyme production using agro-industrial residues. As agro-industrial residues are produced world-wide in abundance as a waste/ by product of crop cultivation and food processing industry. Secondary screening of laccase production was carried out using wheat bran as a solid substrate and Asther medium as a moistening agent under solid state fermentation. The Asther's medium [20] was used as a moistening agent to maintain the moisture level of the substrates. Maximum laccase production of 1.65 X 10^5 U/g of dry substrate for wheat bran was reported on 10^{th} day of incubation. Vares *et al.,* [21] and Gupte *et al.,* [22] reported higher laccase production with *Phlebia radiata* and *Pleurotus ostreatus* respectively under SSF using wheat straw as substrate. Kapoor *et al.,* [23] also reported maximum laccase production with *Lentinus edodes* from peanut meal supplemented wheat straw. On the basis of primary and secondary screening the isolate *Agaricomycetes sp.* AGAT was selected for further studies as it was considered as an excellent producer of laccase.

PAHs are considered to be environmental pollutants which having the ability to affect plants, animals and humans. PAH are mainly degraded by biological transformations thus the use of microbes represents the potential route for the removal of PAH from the environment. White rot fungi are the choice of organisms used widely in bioremediation. They are known to actively degrade wide range of recalcitrant and xenobiotic compounds. It has been assumed by many researchers that the degradation of these compounds is catalyzed by the enzymatic machinery of these fungi [24,25,26]. Fungi like Pleurotus *eryngii* [27], *Pleurotus pulmonaris F043* [25], *Scopulariopsis brevicaulis [28], Pycnoporus sanguineus H1* [2] and Phanerochaete chrysosporium [29] has been used for PAHs degradation.

The isolate *Agaricomycetes sp* AGAT showed degradation in degradation medium. The % degradation was enhanced in presence of co-substrate glucose present in medium. Mao and Guan [28] reported enhanced degradation of PAH by *Scopulariopsis brevicaulis.* using glucose as co-substrate. Hwang *et al*., [30] and Tekere *et al*., [31] also reported using other co-substrates enhanced the degradation. It has been reported by Wang *et al*., [32]; Swamy and Ramsay [33]; that the degradation of organic pollutants is faster when glucose is used as a co-substrate for growth.100% removal of Fluorene within 23 days was reported by Hadibarata and Kristanti [27] at a concentration of 10 ppm by fungal isolate *Pleurotus eryngii* F032 while 100% Fluoranthene was eliminated in 30 days at 10ppm concentration by *Pleurotus pulmonarius* F043 [25]. Mao and Guan [28] using *Scopulariopsis brevicaulis* reported removal of Pyrene (64.3%), Fluoranthene (61.9%) and Phenanthrene (60%) after 30 days. The decline in PAHs removal probably occurs in nitrogen limiting conditions. This can attributed as ligninolytic enzymes are also produced in nitrogen-limiting condition which decrease the PAHs available in the system. The present study shows the involvement of laccase in the degradation process.

Bioavailability for PAH degradation was enhanced by addition of surfactant to the medium. Surfactants have been known to increase surface area of the PAHs and the subsequent flux in an aqueous medium [34]. The solubility of the PAHs studied were as Phenanthrene 1.3mg/l; Fluoranthene 0.26 mg/l; Pyrene 0.14mg/l and Fluorene 1.992 mg/l [35]. The rate of degradation depends on the mass transfer rate of PAHs from solid phase to water phase [36]. Surfactants become intermediate between immiscible phases because of their hydrophobic and hydrophilic moieties. By addition of surfactants it increases the concentration of hydrophobic compounds in water phase by solubilization or emulsification. Solubilization occurs only above a specific threshold concentration, critical micellar concentration (CMC) after which surfactants molecules will aggregate to micelles. 72% degradation could be achieved by Hadibarata and Tachibana [37] with Tween 80 as surfactants after 30 days of incubation. Tween 80 enhance both uptake and release of compounds from the cells through modification of cell membrane permeability. Zhao *et al*., [38] found that Tween 80 is best for the degradation of Phenanthrene. Rate of degradation increased from 68.8% to 87.4% in the presence of AOT with Tween 80 within 10 days by *Pleurotus ostreatus* D1 [11]. Higher concentration of SDS may inhibit the growth of fungi. It may be attributed due to change in physico-chemical interactions between fungus and surfactants or limited bioavailability of micellar PAH due to low exit rates from the micelles [39]. Degradation of PAHs has been investigated by using Triton X-100 and SDS with *P.chrysogenum, M.racemosus, L.theobromae* [40]..

In the present study *in vivo* system is used where whole of fungal culture is used for degradation of PAHs. The PAHs selected for the present study is LMW-PAH and HMW -PAH with two or more benzene rings. The reaction catalyzed by laccase depends on monoelectric oxidation which transforms substrates to corresponding reactive radicals. The small molecule which act as single electron donor and activator of enzymes known as mediators enhances the rate of oxidation of the enzyme. The synthetic mediators like ABTS and HBT are mainly used in degradation studies. In our study three mediator used were ABTS, HBT and phenol at varying concentration of 0.1mM, 1mM and 2mM. ABTS when used as a mediator in a system the rate of degradation of Pyrene increased to 92% by *Pyconoporus sanguineus* H1 [2]. HBT has been used widely as mediator because of its high redox potential and its ability to stimulate PAHs oxidation by laccase [41]. Higher concentration resulted in complete removal of PAH due to production of coupling

products with oxidized mediators in a nonstoichiometric production of the quinone [42].

Bioaugmentation technique has been proposed as a strategy for enhancement of the bioremediation of contaminated soils. For *in-situ* bioremediation of the contaminated sites, addition of microorganisms has been a valuable tool in order to increase the rate and extent of biodegradation of organic pollutants. Various physico-chemical parameters affect the efficiency of organisms as compared to native microbial population present in contaminated sites. The use of organism depends on survival and performance in natural ecosystem. Therefore, to ensure the organism need to be studied for its survival and degradation efficiency in soil and also in the presence of the ingenious microbial populations [43,44]. Microcosm study provides an insight towards the competition between culture and indigenous microflora present in the environment. Bioaugmentation by *Paracoccus sp* increased Phenanthrene degradation as reported by Teng *et al*., [45]. Jain and Bajpai [46]; Singh and Ward [47] reported that in natural environment various processes have been studied in order to understand the role of microorganisms and microbial communities in bioremediation. The degradation of Fluorene, Fluoranthene and Pyrene in soil was 0, 6.2% and 7.5% respectively within 10 days [8]. Degradation of PAHs Fluorene, Fluoranthene, Phenanthrene and Pyrene was increased from 98 to 100%, 73 to 98%, 99 to 100% and 26 to 94% by inoculation of *P.velutina* to soil sample which shows that the degradation rate enhanced together by *P.velutina* together with indigenous microbes [48]. *Anthracophyllum discolor* degraded Phenanthrene (62%), Fluoranthene (54%) and Pyrene (60%) from soil sample after 60 days of incubation [49].

For detection of degraded metabolite GC-MS analysis were performed of all PAHs. 1-hydroxypyrene and phthalic acid with 218.5 m/z and 166.3 m/z ratio respectively were reported from degradation of Pyrene. Bezalel *et al*., [50] reported that initially pyrene was metabolized at the 4, 5 bond (K region) which forms an epoxide, which was hydrated to form pyrene trans-4, 5-dihydrodiol using *Pleurotus ostreatus.* Sack *et al*., [51] reported 1-pyrenol as degraded metabolite using wood decaying fungi.

It has been reported by various researchers that the ring metabolite 2, 2'-diphenic acid is from Phenanthrene via Phenanthrene trans9,10-dihydrol or Phenanthrene 9,10-quinone. This dead end product formed 2, 2'-diphenic acid is produced due to activity of ligninolytic enzymes from various white rot fungi [26,50,51,52].

Further decarboxylation reaction leads to formation of dead end product phthalic acid which leads to central metabolism pathway. The GC-MS of all four PAHs compound showed the presence of phthalic acid as an intermediate compound. Phthalic acid formation is one of the ring fission products formed after degradation of PAHs by white rot fungi, further derivatization of phthalic acid to carbon-di-oxide and highly polar metabolites takes place [53].

The toxicity of the degraded product can be defined as phytotoxicity assay. The PAH and its degraded metabolite were used for phytotoxicity study using *Triticum asetivum* seeds. The rate of germination can be used as an indicator for pollutant contamination because this process is very sensitive to various kinds of pollutants [54]. The toxic effects of PAHs depends on various factors. Chemical structure and chemical properties of the pollutants are main reason for affecting PAH toxicity. Phytotoxicity study of various PAHs has been reported by Somtrakoon and Chouychai [55] on economic crops.

In conclusion, large number of isolate were screened for ligninolytic enzyme production by plate assay method. The isolate showing positive Bevandamm's reactions by oxidation of phenolic compounds were screened for secondary screening. The isolate AGAT was identified as *Agaricomycetes sp AGAT* by ITS4 & ITS5 sequencing and further explored for PAHs degradation study. In present study a varied rate of degradation of various PAHs (Pyrene, Fluorene, Fluoranthene and Phenanthrene) were observed using *Agaricomycetes sp* AGAT. Rate of degradation depends upon their molecular weight and structure. There is correlation observed between ligninolytic enzyme and PAHs degradation. *In-situ* bioremediation techniques i.e. microcosm study has been performed which showed the importance of the indigenous flora present by increasing the degradation of PAH. Phytotoxicity study was performed on *Triticum asetivum* to check the effect of degraded metabolites obtained after degradation. GC-MS analysis was performed for identification of metabolites formed. A proposed pathways for PAHs degradation has been given depending upon the intermediate obtained in our study.

Abstract

The purpose of this study is to explore the soil of the Gujarat, Kachchh region to identify amylase-producing bacteria and characterize them using molecular methods. The unique ecological characteristics of the Kachchh region may facilitate the isolation of these bacteria. Samples were collected from multiple locations within the Kachchh District, including Gandhidham, Rapar, Bhuj, Nakhatrana, Mandvi, and Mundra Talukas. These samples were then screened to isolate amylase-producing bacteria. A total of 27 different types of colonies were identified, out of which 16 exhibited amylase production (M1-M16). Out of 27 colonies identified, 16 showed amylase production. Strains M2, M7, and M13 exhibited high amylase activity, with M2 showing a consistent increase over 72 hours, making it a strong candidate for amylase production. Further identification of M2 stain identified M2 as a Gram-positive, spore-forming, capsulated, and motile bacillus, specifically *Bacillus licheniformis*. This was confirmed through DNA sequencing and analysis in the NCBI database, which showed a 99.15% similarity with *Bacillus licheniformis*. The study concludes that Soil in Kachchh is rich with microorganisms that produce amylase, an enzyme with diverse industrial applications. These organisms are valuable for sectors like food, textiles, paper, detergents, pharmaceuticals, and biofuel production.

INTRODUCTION

Alpha-amylase, an enzyme that breaks down starch into simple sugar components, plays a pivotal role in various industries such as starch processing, brewing, sugar manufacturing, textiles, and detergents. In 1894 amylase enzyme produced from a fungal source, was used as a pharmaceutical aid for digestive diseases. Alpha-amylases are among the most critical enzymes, contributing to approximately 30% of the global enzyme production.[1]

These enzymes are ubiquitous, found in animals, plants, and bacteria. Microorganisms, including bacteria, fungi, and yeast, are known sources of amylase, and their properties have been extensively studied. Among these, Bacillus strains are noteworthy for their ability to produce significant amounts of amylase, accounting for about 60% of commercially available enzymes. Specifically, *Bacillus subtilis* and *Bacillus mesentericus* produce the most widely used thermostable amylase in the starch industry.[2]

Amylase is a key player in the carbon biogeochemical cycle and finds extensive applications in biotechnological food, detergent, and pharmaceutical industries. It can break down glycosidic bonds in polysaccharides. Interestingly, amylase is present in human saliva and initiates the chemical process of digestion in starchy foods like rice and potatoes. This enzymatic conversion of starch into sugar imparts a mildly sweet taste when these foods are consumed. The pancreas also produces alpha-amylase, which hydrolyzes dietary starch into disaccharides and trisaccharides, which are subsequently converted into glucose by other enzymes.[3]

The use of alpha-amylase extends to various industrial processes, including those in the food, fermentation, and pharmaceutical industries. The selection of the appropriate organism is crucial to ensure a high yield of useful enzymes. The development of new microbial strains for industrial enzyme synthesis using low-cost carbon and nitrogen sources is a constant endeavor. In microorganisms, two primary types of amylases have been identified: alpha-amylase and glucoamylase.[4,5]

The commercial applications of alpha-amylase have expanded to several domains, including clinical, pharmaceutical, and analytical chemistry, among other extracellular enzymes. Industries such as food, textile, fermentation, and paper heavily rely on starch-degrading bacteria. In the realm of biotechnology, the isolation and manipulation of pure cultures of starch-degrading microorganisms from soil are crucial. The extraction and manipulation of pure culture from various waste materials are vital for several biotechnology sectors.[6,7]

Significant amylase-producing microbes include *Bacillus subtilis, Bacillus licheniformis, Bacillus amyloliquefaciens, Bacillus cereus,* and *Bacillus megaterium,* as well as fungi such as *Aspergillus niger, Penicillium, Rhizopus, Cephalosporium,* and *Neurospora*. Microbial alpha-amylases have been demonstrated to be a viable alternative to chemical hydrolysis, although the enzyme's low yield has always been a challenge in commercial amylase production.[8]

Amylase-producing bacteria can be found in soil, and exploring various regions can be helpful in finding potent amylase-producing bacteria. The unique nature of the soil may harbor a more diverse range of bacteria. The Kachch soil could be checked for amylase production.

MATERIALS AND METHODS

Sampling

The research initiative collected soil samples from six distinct Talukas (namely Gandhidham, Rapar, Bhuj, Nakhatrana, Mandvi, and Mundra) in the Kachchh District of Gujarat, India, (GPS coordinates of 23° 44' 1.4352'' N and 69° 51' 35.0676'' E) targeting a diverse range of soil characteristics and microbial ecosystems (Figure 1). The extraction process focused on the subsurface strata at depths of 3 to 4 centimetres, using aseptic techniques to prevent contamination and preserve the indigenous microbial populations. The samples were sealed in sterile plastic bags and transported under strict aseptic conditions to the Mayur Laboratory in Adipur, Kachchh, where they were stored at 4 degrees Celsius to maintain microbial viability. The primary focus was to identify and isolate amylase-producing microorganisms.[9]

Primary screening

A 10 g soil sample was prepared for amylase isolation, suspended in 90 ml of sterile saline solution containing 0.85% sodium chloride. This isotonic environment maintains the physiological conditions of the microorganisms and prevents osmotic shock. Serial dilutions (10^{-1} to 10^{-10}) were prepared from the sample and 100 µL suspensions from each dilution were spread on starch agar plates.[10,11]

The inoculated plates were incubated at a constant 37°C for 72 hours, allowing bacterial colonies to proliferate and express amylase activity. Post incubation, the plates were visually examined for bacterial growth. The presence of amylase activity was confirmed using the Gram's iodine test. This involved flooding the agar plates with a solution of Gram's iodine, leading to a blue-black complex formation in the presence of residual starch. This served as an indirect indicator of starch hydrolysis by amylase-producing bacteria.[11,12]

Secondary screening

After the initial screening identified bacteria capable of producing amylase, the focus shifted to isolating the strain with the highest amylase activity. The transition from primary screening to selecting the most potent strain aims to maximize amylase production efficiency. This involves a thorough evaluation of the amylase's enzymatic properties and cultivation aspects, paving the way for advancements in industrial and biotechnological applications. The secondary screening selected the isolate with the highest enzyme activity for further applications.[13,14]

Post-incubation, the crude enzyme was purified by adding 50 ml of a phosphate buffer (50 mM, pH 7.4) to the media. The resulting slurry was strained using a damp cheesecloth and then centrifuged at 11648 RCF for 15 minutes in a cooling centrifuge. This process separated cells, small particles, and spores. As amylase is an exoenzyme, the cell-free supernatant was used as the enzyme. This purification process is crucial for obtaining a clean sample of the enzyme for further analysis.[15]

Amylase activity was assessed using the 3,5-dinitrosalicylic acid (DNSA) method,[16,17] which measures reducing sugars produced during the enzyme-substrate reaction. The amylase assay was conducted with a reaction mixture containing 1% soluble starch in a 50 mM phosphate buffer at pH 7.2. The mixture was incubated for 10 minutes at 37°C, and the reaction was terminated by adding 2 ml of DNSA reagent.

The reaction mixture was then heat-treated at 100°C for 10 minutes and cooled to stop the enzymatic reaction and stabilize the products. The optical density of each sample was measured at 540 nm using a spectrophotometer, allowing for the quantification of the colored reaction product, and providing a direct measurement of amylase activity. Enzyme activity was quantified in units, where 1 unit/ml represents the amount of enzyme that releases 1 µl mole of glucose under the specified assay conditions. This comprehensive methodology reliably assesses the amylase-producing capabilities of bacterial strains.

Identification of amylase producing bacterial strains

The identification of the most potent amylase-producing bacteria involved key steps: Colony Morphology characterization, Microscopic characterization, Biochemical characterization and Molecular characterization.[18]

Figure 1. Sampling and Isolation of Amylase producing bacteria

Colony morphological characterization

Colony Morphology Analysis provided a comprehensive characterization of bacterial isolates, examining color, shape, size, colony nature, and pigmentation. These parameters offered insights into the bacteria's nature, growth patterns, structural characteristics, physiological attributes, and environmental adaptations.[19]

Microscopic characterization

Microscopic Observation revealed specific structural features of the bacterial cells. Techniques such as Gram staining, capsule staining, endospore staining, and the motility test provided a detailed view of the structural and functional attributes of the bacterial isolates. These methods collectively contributed to a nuanced understanding of the isolates, laying the groundwork for further investigations into their physiological and ecological characteristics. This systematic approach was crucial in identifying the most potent amylase-producing bacteria.[20]

Biochemical characterization

Biochemical characterization of bacterial isolates was performed both manually and using the VITEK system. The VITEK system, with its comprehensive library of biochemical profiles, facilitated a thorough analysis of the isolates' unique biochemical traits.

The process involved preparing bacterial isolates for testing, setting up the VITEK system, and conducting various biochemical tests. The VITEK system automated the analysis of the biochemical reactions, comparing the observed reactions with the patterns stored in its database. This resulted in outputs based on the unique biochemical characteristics of each isolate, aiding in the classification, and understanding of the microbial community. The extensive biochemical library ensured a high level of accuracy and precision in the identification process. The VITEK system covered a broad spectrum of biochemical reactions, providing a comprehensive analysis of the isolates' metabolic and enzymatic activities. This contributed to a more detailed understanding of the bacterial community.[21]

Molecular characterization

Molecular identification by DNA sequencing is the most precise tool for identifying microbial strains. The DNA sequencing of the isolated strain was carried out in several steps[20,22]

DNA Purification: A ready-to-use kit was used to purify DNA from bacterial cells. The purification process involved a spin column-based nucleic acid purification method, utilizing solid-phase extraction to rapidly purify nucleic acids. The method consisted of four main stages: lysing, binding, washing, and eluting.

DNA amplification

PCR primers were used for the amplification of DNA. The primers used were 16S rRNA FP: 5'-AGAGTTTGATCCTGGCTCAG-3' and 16S rRNA RP: 5'-ACGGCTACCTTGTTACGACTT-3'.

Quality test of PCR product

After the completion of the PCR reaction, the resulting products were visualized through 2.5% agarose gel electrophoresis under ultraviolet (UV) light.

DNA sequencing

The procedure for DNA sequencing was done by Sanger sequencing. The sequencing was performed using a Thermo Fisher DNA sequencer (Model No: 3730xl DNA Analyzer).

DNA sequencing data analysis

Data obtained from DNA sequencing were analysed in the NCBI database. The BLAST Web Interface was accessed as per the procedure. This comprehensive approach allowed for the identification of the most potent amylase-producing bacteria.

RESULT AND DISCUSSION

Isolation of amylase producing bacteria

Primary screening

Post-incubation, different colonies were counted from six sampling sites: Gandhidham, Nakhtrana, Bhachou, Mundra, Mandavi, and Rapar. A total of 27 different types of colonies were identified. For instance, Gandhidham yielded

8 bacterial isolates, Nakhtrana had 4, Bhachou had 5, Mundra had 3, Mandavi had 1, and Rapar had 6 (Figure 2).

The Gram's iodine test was applied to each plate for primary screening of amylase-producing bacteria. Out of the 27 colonies, 16 showed a clear zone around them, indicating amylase production. For example, out of the 8 bacteria isolated in Gandhidham, 5 exhibited amylase production. Similarly, Nakhtrana yielded 2 amylase-producing isolates out of 4. A similar pattern was observed for Bhachou, Mundra, Mandavi, and Rapar. This systematic approach was crucial in identifying the most potent amylase-producing bacteria.

The colony characteristics of the 16 amylase-producing strains were analysed across multiple parameters, including size, shape, colour, elevation, texture, margin, and optical properties. Each strain exhibited unique features, contributing to a nuanced understanding of their visual attributes.

The primary screening for amylase production involved measuring the clear zones formed after the application of iodine on starch agar plates. These clear zones indicate the extent to which the 16 isolated strains, labelled as M1 to M16, are capable of hydrolysing starch. A larger clear zone generally suggests higher amylase activity and more potent amylase production.

The clear zone measurements exhibited notable variability among the strains, ranging from 0.4 mm (M9) to 3.5 mm (M2). This diversity suggests differences in the amylase-producing capabilities of the isolates. Strains M2, M6, M7,

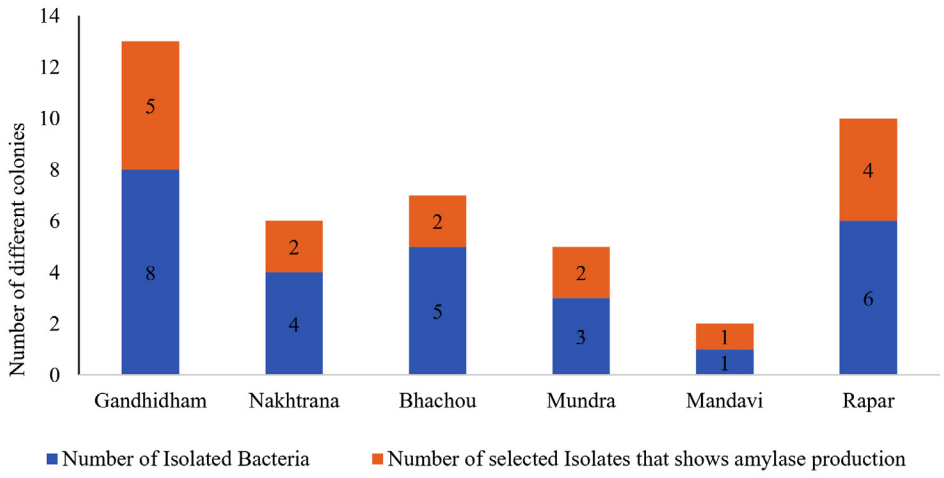

Figure 2. Results of Isolation and primary screening of amylase producing bacteria

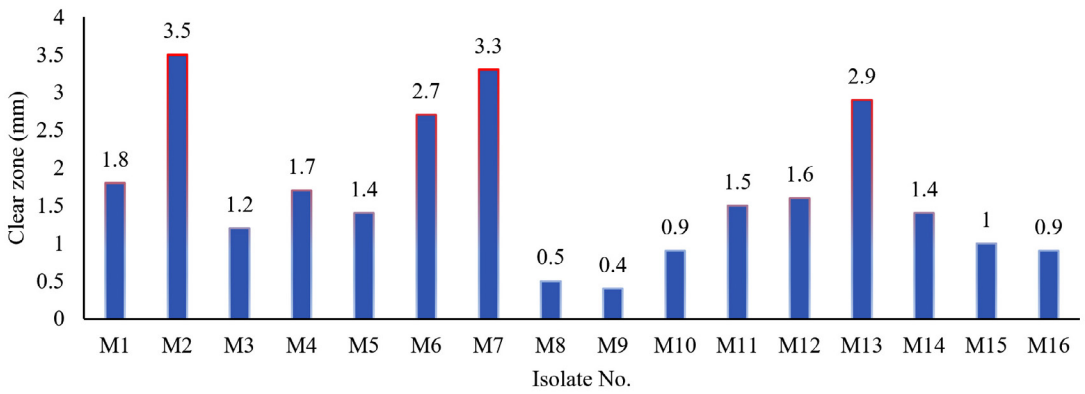

Figure 3. Results of Starch hydrolyzing zone of amylase producing bacteria

and M13 stood out as potentially potent amylase producers, showcasing clear zones of 3.5 mm, 2.7 mm, 3.3 mm, and 2.9 mm, respectively (Figure 3).

The distinct clear zone sizes for each strain indicate that amylase production is not uniform across the microbial isolates. This information is crucial for selecting specific strains with desirable amylase-producing capabilities.

Secondary screening

Following the initial screening, 16 amylase-producing bacterial strains underwent a secondary screening to evaluate their specific amylase activity across different time intervals (24 hours, 48 hours, and 72 hours). The results provided comprehensive insights into the temporal dynamics of amylase production.

Notably, strains M2, M7, and M13 consistently demonstrated elevated amylase activity, suggesting their potential as robust amylase producers. However, M2 at 48 hours and M7 at 72 hours recorded unusually low amylase activity values, indicating biological variability within these strains.

An ascending trend in amylase activity was observed from 24 hours to 72 hours across many strains, with particularly pronounced time-dependent increases in M2, M6, M7, M11, M13, and M14. Conversely, strains M8 and M9 consistently exhibited relatively low amylase activity across all time points (Figure 4).

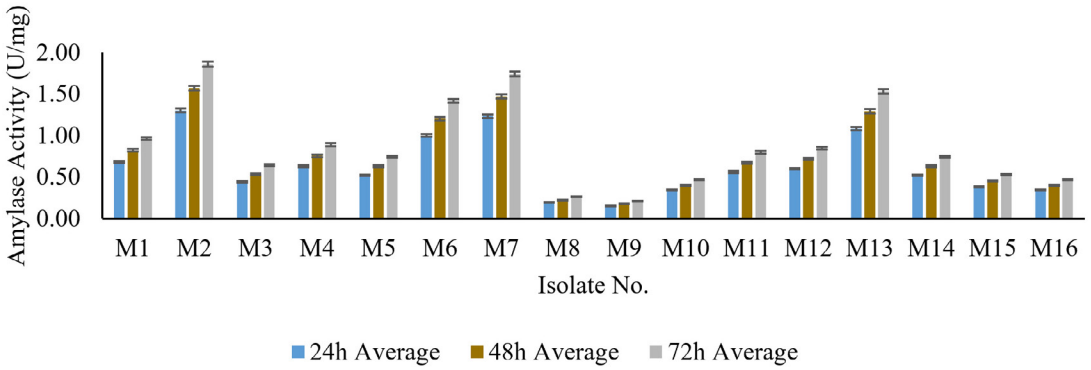

Figure 4. Amylase activity of produced amylase from amylase producing bacteria at different time interval

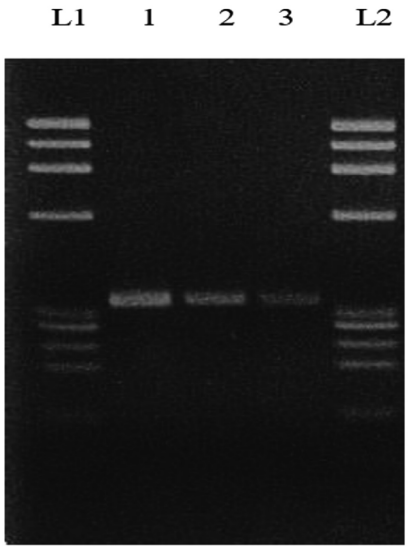

Figure 5. Electrophoresis of DNA (4th sample)
L1: Leader 1, 1: Replicate 1, 2: Replicate 2, 3: Replicate 3, L2: Leader 2

Upon closer examination, certain strains, notably M2, showed an incremental trend in amylase activity over the 72-hour period, positioning M2 as a robust and persistent amylase producer. These findings aid in identifying promising bacterial strains for further exploration or potential industrial applications. Strains demonstrating both elevated overall amylase activity and temporal stability, such as M2, merit careful consideration for their suitability in practical applications. Following the secondary screening process, the M2 strain was specifically chosen for subsequent phases of identification.

Identification of amylase producing bacterial strains

The M2 strain, identified as the most potent amylase-producing bacteria, was characterized by several distinctive features.

Colony morphology

The colony of the M2 strain is medium-sized, irregular, and powdery in nature. It displays a spectrum of colours, ranging from white to beige and cream. The colony is flat or slightly convex in terms of elevation, and its texture is described as powdery. The margin of the colony is irregular and undulate, exhibiting a wavy pattern. Notably, no specific optical properties were identified for the M2 colony.

Microscopic observation

The M2 strain, based on microscopic examinations, is identified as a Gram-positive bacillus capable of forming endospores and capsules. Furthermore, the rod-shaped bacteria occur in chain formations, indicating a particular structural arrangement. The motility test confirmed the ability of the M2 strain to exhibit movement. These detailed observations provide valuable insights into the morphological diversity of the isolates, aiding in the identification of the most potent amylase-producing bacteria.

The M2 strain underwent a comprehensive biochemical characterization, performed both manually and using the VITEK system (Table).

Manual biochemical tests

The results provided valuable information about the biochemical profile of the organism. The organism exhibited a negative response for the Indole test, indicating the absence of indole production. Conversely, it demonstrated positive reactions for various tests, including Methyl Red, Citrate Utilization, Sugar Fermentation (both glucose and sucrose), Catalase, Oxidase, Starch Hydrolysis, Nitrate Reduction, and Glucose Fermentation. These positive reactions suggest the organism's ability to metabolize certain substrates or produce specific enzymes.

Biochemical test with VITEK analysis

The VITEK analysis of the M2 strain yielded a wealth of biochemical results, providing a detailed overview of its metabolic capabilities. Key observations from the VITEK analysis include positive results for tests such as Beta-Xylosidase, Phenylalanine Arylamidase, Beta-Galactosidase, L-Pyrrolydonyl-Arylamidase, Alpha-Galactosidase, Tyrosine Arylamidase, Cycloheximide utilization, Glycogen, Myo-Inositol, Methyl-α-D-glucopyranoside, Ellman reduction, Maltotriose, D-Mannitol, D-Mannose, N-Acetyl-D-Glucosamine, Palatinose, Beta-Glucosidase,

Table. Microscopic observation of amylase producing bacteria

Gram staining		Gram-positive bacilli
Endospore staining		Spore forming bacilli
Capsule staining		Capsulated bacilli
Motility		Motile

Alpha-Glucosidase, D-Tagatose, D-Trehalose, Inulin, D-Glucose, D-Ribose, Growth in 6.5% NaCl, Kanamycin resistance, Oleandomycin resistance, Esculin hydrolysis, Tetrazolium red, and Polymyxin B resistance. The results also indicate negative outcomes for tests such as L-Lysine-Arylamidase, L-Aspartate Arylamidase, Leucine Arylamidase, L-Proline Arylamidase, Alanine Arylamidase, Beta-N-Acetyl-Glucosaminidase, Ala-Phe-Pro Arylamidase, Methyl-D-Xyloside, Alpha-Mannosidase, Glycine Arylamidase, D-Melezitose, L-rhamnose, Beta-Mannosidase, Phosphoryl Choline, Pyruvate, and Putrescine assimilation.

The culmination of these comprehensive biochemical tests and the VITEK 2 data analysis confidently identified the M2 strain as *Bacillus licheniformis*. This taxonomic classification provides essential information for understanding the strain's physiological and biochemical characteristics. The positive outcomes in various enzymatic assays suggest the strain's potential utility in industrial applications, particularly in enzyme production. These findings contribute not only to the taxonomic knowledge of the M2 strain but also have implications for potential biotechnological and industrial applications in areas such as enzyme production and microbial processes.

Molecular characterization

The M2 strain was further confirmed by a molecular method, specifically DNA sequencing. After the purification of DNA from the isolate, it was multiplied using the PCR method to increase the quantity. The purification and amplification of DNA were confirmed by electrophoresis (Figure 5).

The DNA sequencing results were analysed in the NCBI database to identify the most suitable microorganisms through BLAST. The results showed that *Bacillus licheniformis* had a 99.15% similarity with the test microorganisms. Specifically, the *Bacillus licheniformis* strain DLSB-13 16S ribosomal RNA gene partial sequence (Accession: MK795391.1) scored 2124, with a 100% query cover and an E-value of 0.0. This confirms the identification of the M2 strain as *Bacillus licheniformis*, providing essential information for understanding the strain's physiological and biochemical characteristics. These findings have implications for potential biotechnological and industrial applications in areas such as enzyme production and microbial processes.

Study's revelation of the rich microbial diversity within the soil samples from the Kachchh region is a significant contribution to our understanding of the area's ecological dynamics. The identification of amylase-producing microorganisms as a prominent group within this diversity underscores their potential role in the region's biogeochemical cycles and industrial applications.

Our findings are in harmony with the research conducted by Joshi and Trivedi, which also highlighted the microbial richness of Kachchh soil. Their work, which isolated 48 bacterial types with 36 identified as amylase producers, provides a broader context for our study. It suggests that the Kachchh region may be a hotspot for microbial diversity, particularly for strains capable of producing industrially relevant enzymes like α-amylase.[23] It also emphasizes the need for further research into the specific conditions that foster such high levels of microbial diversity and enzyme production. Understanding these factors could lead to more efficient exploitation of these resources for industrial purposes, such as in the production of biofuels, bioplastics, and other value-added products.

Another study conducted in the unexplored Nasinuan Forest of Thailand has led to the discovery of 13 bacterial isolates capable of producing the amylase enzyme. These isolates were identified using 16S rRNA sequencing on 1% starch agar, revealing a diverse group of bacteria with amylase-producing potential.[24]

The study's findings are noteworthy as they mirror our research where the M2 strain was identified as *Bacillus licheniformis* through DNA sequencing and 16S rRNA gene analysis. This consistency in results underscores the reliability of these molecular techniques in identifying bacterial strains with specific enzymatic activities.

The implications of such discoveries are significant, particularly for industries that rely on amylase enzymes, such as food and agriculture.[1] The ability to harness these enzymes from natural sources can lead to more sustainable and cost-effective production methods.[6]

The study conducted in Sudan, which focused on the isolation and characterization of α-amylase producing microorganisms, has yielded results that are noteworthy for their implications in both scientific research and industrial applications. The identification of Bacillus cereus and *Bacillus licheniformis* as starch hydrolyzing bacteria with amylase activity is particularly significant. This finding is consistent with our current study, where *B. licheniformis* was observed to produce a clear zone indicative of amylase activity.[20]

The presence of these bacteria in Sudanese soil samples suggests a potential for harnessing their enzymatic capabilities for various biotechnological processes. The ability of *B. licheniformis* to produce amylase is not only crucial for the natural degradation of starch but also holds promise for industrial applications such as the production of bioethanol, where amylase plays a key role in breaking down starch into fermentable sugars.[14]

Moreover, the similarity between the findings of the Sudanese study and our own underscores the global nature of microbial diversity and its potential for enzyme production. It highlights the importance of cross-regional studies in identifying and utilizing microbial resources for sustainable development.[17]

CONCLUSION

In conclusion, our study has isolated and identified *Bacillus licheniformis* from Kachch soil as a potent amylase producer. The comprehensive morphological, microscopic, and biochemical characterization of the strain, coupled with DNA sequencing confirmation, has provided a robust identification of this microorganism.

The amylase activity of *Bacillus licheniformis* holds significant promise for industrial applications, particularly in the field of enzyme production. This discovery not only enriches the existing knowledge base but also opens new avenues for research into the sustainable exploitation of microbial resources in the Kachchh region.

Future research should focus on exploring the genetic and environmental factors that contribute to the prevalence of amylase-producing bacteria in this ecosystem. Such studies could lead to optimized conditions for enzyme production and contribute to the development of sustainable biotechnological processes. The potential of Kachchh soil as a reservoir for industrially relevant microorganisms is immense, and continued investigation will undoubtedly yield further valuable insights.

ABSTRACT

This study presents a comprehensive investigation into the production of amylase, a crucial enzyme with wide-ranging industrial applications, using locally sourced substrates from Kachchh, Gujarat. The research employed the *Bacillus licheniformis* strain and substrates such as coconut, rice husk, wheat bran, paddy straw, and maize straw. The study found paddy straw to be the most promising substrate for amylase production. The research also systematically optimized various process parameters for amylase production in Solid-State Fermentation (SSF) using the One Variable at a Time (OVAT) method. These parameters included incubation period, temperature, inoculum level, additional carbon sources, starch concentrations, additional nitrogen sources, initial pH, different mineral salt ions, initial moisture level, and surfactants. The results showed that the optimal conditions for maximum amylase yield were an incubation period of 48 hours, an incubation temperature of 35°C, an inoculum level of 10%, starch as the additional carbon source, a starch concentration of 2.5%, yeast extract as the additional nitrogen source, an initial pH of 7, NaCl as the mineral salt, an initial moisture level of 75%, and Tween 80 as the surfactant. This research provides a reliable and sustainable approach to enzyme production, offering valuable insights for the optimization of the solid-state fermentation process for maximum amylase production.

INTRODUCTION

Enzymes play a pivotal role in numerous industrial applications, catalyzing biochemical reactions with remarkable specificity and efficiency. Among these enzymes, amylase holds a significant position due to its wide-ranging applications in various industries, including food, textiles, and biofuel production. Solid-state fermentation (SSF) has emerged as an environmentally friendly and economically viable approach for amylase production, using agricultural waste as a substrate (Souza & Magalhaes 2010).

Amylase, an enzyme that hydrolyzes starch into simpler sugars, is crucial for many industrial processes. Traditionally, amylase has been produced using submerged fermentation; however, SSF offers distinct advantages, such as reduced water consumption, higher enzyme stability, and the use of solid substrates, particularly agricultural waste. This shift towards SSF aligns with the global efforts to develop sustainable and eco-friendly processes in the biotechnological industry (Saxena & Singh 2011).

Agricultural waste, a substantial byproduct of farming activities, poses environmental challenges when not effectively managed. The utilization of these agricultural residues as substrates for SSF not only addresses the issue of waste disposal but also transforms these residues into valuable resources for enzyme production. The incorporation of agricultural waste into the SSF process adds an extra layer of sustainability to the bioprocess, contributing to the concept of a circular economy (Sadh et al. 2018).

In this context, this research paper aims to investigate the production of amylase through solid-state fermentation, using agricultural waste as a cost-effective and sustainable substrate. The study focuses on optimizing the fermentation conditions to enhance amylase yield and activity, thereby contributing to the development of efficient and environmentally friendly enzymatic processes. The utilization of agricultural waste not only aligns with the principles of sustainable biotechnology but also addresses the dual challenges of enzyme production and waste management in the agricultural sector.

Through a comprehensive exploration of the potential of solid-state fermentation using agricultural waste, this research looks to provide insights into the optimization of amylase production, offering a sustainable alternative to traditional enzyme production methods. The findings

of this study could have far-reaching implications for the biotechnological industry, fostering a greener and more efficient approach to enzyme production.

MATERIALS AND METHODS

Selection of Microbial Culture

The research initiative involved the meticulous collection of soil specimens from six distinct Talukas, namely Gandhidham, Rapar, Bhuj, Nakhatrana, Mandvi, and Mundra, situated within the Kachchh District of Gujarat, India. For isolation and screening purposes designated 24-72-h incubation period on the starch agar plates was subjected to meticulous visual examination for growth.

Selection of Substrate

This study used locally sourced substrates like coconut, rice husk, wheat bran, paddy straw, and maize straw from Kachchh, Gujarat, for amylase production. Their abundant availability ensures a steady supply for enzyme production. Using these agricultural residues promotes sustainability by repurposing waste and economically utilizing local resources.

Pretreatment of Substrate

The substrate was pretreated through several steps. It was washed with tap water and distilled water, treated with 1% NaOH to remove impurities, and dried at 80°C for two days. After being ground into fine particles, it was autoclaved at 121.6°C for 20 min (Mushtaq et al. 2023).

Preparation of Bacterial Inoculum

A 500 mL flask was filled with 250 mL of nutrient broth and autoclaved at 121.6°C for 20 min. After cooling, 1 mL of a 24-h-old broth was added and incubated at 37°C with 150 rpm agitation. Post -24hour incubation, 1 mL of the broth culture was added to the dry substrate for enzyme production (Saxena & Singh 2011).

Effect of Various Substrates on Enzyme Production

Four substrates-coconut, rice husk, wheat bran, paddy straw, and maize straw-were selected based on their starch content. After preparing the substrates, each underwent Solid-State Fermentation as per the below procedure.

Solid-state Fermentation (SSF)

SSF was conducted in 500 mL flasks, each containing 5 g of substrate. The moisture content was kept at 50%. After autoclaving at 121.6°C for 20 min and cooling, 1 mL of bacterial inoculum was added. The setup was then incubated for 48 h at 37°C (Cerda et al. 2016).

Purification of Crude Enzyme

Post-incubation, 50 mL of pH 7.4 phosphate buffer was added for crude enzyme extraction. The slurry was strained using a damp cheesecloth and centrifuged at 10000 rpm for 15 min to separate cells and particles. The cell-free supernatant, having the exoenzyme amylase, was used as the crude enzyme (Ramapriya et al. 2018).

Amylase Activity

Amylase activity was assessed using the 3,5-dinitrosalicylic acid (DNSA) method (Elyasi Far et al. 2020), which measures reducing sugars produced in the enzyme-substrate reaction. This systematic approach, from determining amylase activity to purifying the crude enzyme and conducting detailed assays, provided a reliable method for evaluating the amylase production of bacterial strains.

The amylase assay was conducted using a reaction mixture with 1% soluble starch in a 50 mM phosphate buffer at pH 7.2. The mixture was incubated for 10 minutes at 37°C, and the reaction was stopped by adding 2 mL of DNSA reagent. The mixture was then heat-treated at 100°C for 10 min and cooled. The optical density of each sample was measured at 540 nm using a spectrophotometer. Enzyme activity was quantified in units, with 1 unit.mL^{-1} represents the enzyme amount that releases 1 µ mole of glucose under the assay conditions. The substrate with the highest amylase production was identified for further study.

Optimization of Amylase Production Using the One Variable at A Time (OVAT) Method

This study systematically optimized various process parameters for amylase production in solid-state fermentation (SSF) (Table 1). Physicochemical parameters like fermentation period, initial pH, moisture level, and inoculum concentration were adjusted to study their effects on α-amylase production. Nutritional parameters like carbon and nitrogen sources, surfactants, and metal ions were also fine-tuned. The goal was to maximize enzyme production in SSF, enhancing the efficiency and yield of α-amylase, which is crucial for practical applications of SSF processes (Dike et al. 2022).

RESULTS AND DISCUSSION

Selection of Microbial Culture

Among various pure cultures, the *Bacillus licheniformis* was utilized for the production of amylase enzyme. *Bacillus licheniformis* was screened out as a potent one and identified (16 S rRNA) from a soil sample.

This publication is licensed under a Creative Commons Attribution 4.0 International License

Effect of Various Substrates on Enzyme Production

Four substrates-coconut, rice husk, wheat bran, paddy straw, and maize straw-were evaluated for amylase production. Paddy straw showed the highest enzyme activity at 1.002 IU.g^{-1}, making it a promising substrate for amylase production. Wheat bran also showed good results with an activity of 0.812 IU.g^{-1}. Coconut substrates and rice husk had lower activities at 0.513 IU.g^{-1} and 0.612 IU.g^{-1}, respectively, while maize straw had a moderate activity of 0.849 IU.g^{-1}. (Fig. 1).

Optimization of Amylase Production Using The One Variable at A Time (OVAT) Method

Effect of incubation period on enzyme production: The effect of the incubation period on enzyme production was investigated by varying the duration of fermentation at 24, 48, 72, and 96 h. The enzyme production, measured in IU.g^{-1}, varied at different incubation times, as outlined in Fig. 2.

The results show that amylase production varies across different incubation periods. The highest yield was observed at the 48-h mark, reaching 1.40 IU.g^{-1}, indicating that this is the optimal duration for enzyme production in this process. The lower yield at 24 hours (0.07 IU.g^{-1}) suggests that the fermentation process might not have reached peak efficiency in this short duration. The decline in enzyme production at 72 h (0.36 IU.g^{-1}) and 96 h (0.10 IU.g^{-1}) could be due to factors like substrate depletion, accumulation of by-products, or other inhibitory factors. Dike et al. (2022) also found a similar kind of pattern during the production of amylase enzyme.

Effect of incubation temperature on enzyme production: The study found that incubation temperature significantly affects amylase production. The highest yield was observed at 35°C, with an enzyme production of 0.20 IU.g^{-1}, suggesting this is the optimal temperature for this process. At 30°C and 40°C, the production was relatively high (0.18 IU.g^{-1} and 0.15 IU.g^{-1}, respectively), indicating these temperatures are also favorable for amylase synthesis. However, a decrease in enzyme production was noted at 45°C (0.10 IU.g^{-1}) and

Table 1: Optimization parameters for amylase production.

Parameter	Levels
Incubation Period	24, 48, 72, 96 h
Incubation Temperature	30, 35, 40, 45, 50, 55°C
Inoculum Level *(Bacillus licheniformis)*	5%, 10%, 15%, 30%
Additional Carbon Sources [1%]	Starch, lactose, glucose, and fructose
Starch Concentrations	0.5, 1, 1.5, 2, and 2.5%
Additional Nitrogen Sources [1%]	NH_4Cl, $(NH_4)_2SO_4$, NH_4NO_3, Yeast extract, and peptone
Initial pH	4, 5, 6, 7, and 8
Different Mineral Salts Ions [100 µM]	NaCl, KH_2PO_4, $FeCl_2$, $CaCl_2$, and $MgSO_4$
Initial Moisture Level	25%, 50%, 75%, and 100%
Surfactants	Tween 20, Tween 80, SDS, and PEG

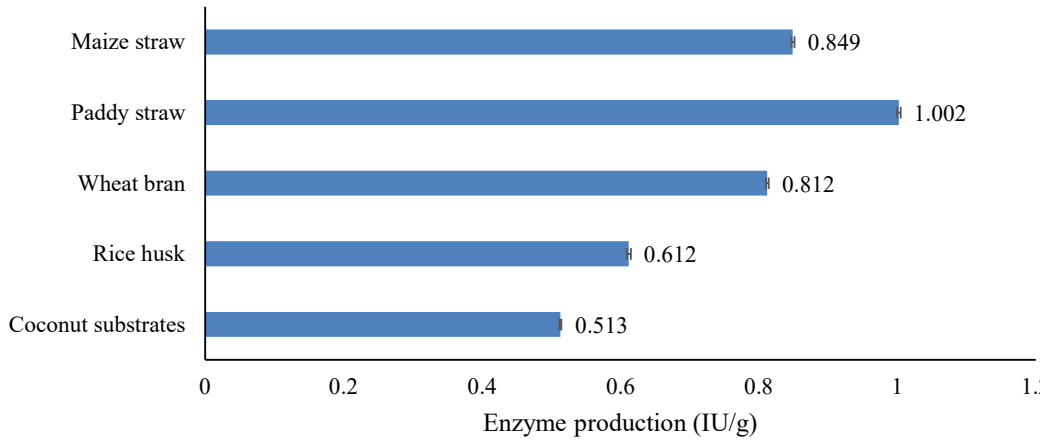

Fig. 1: Amylase production with different substrates.

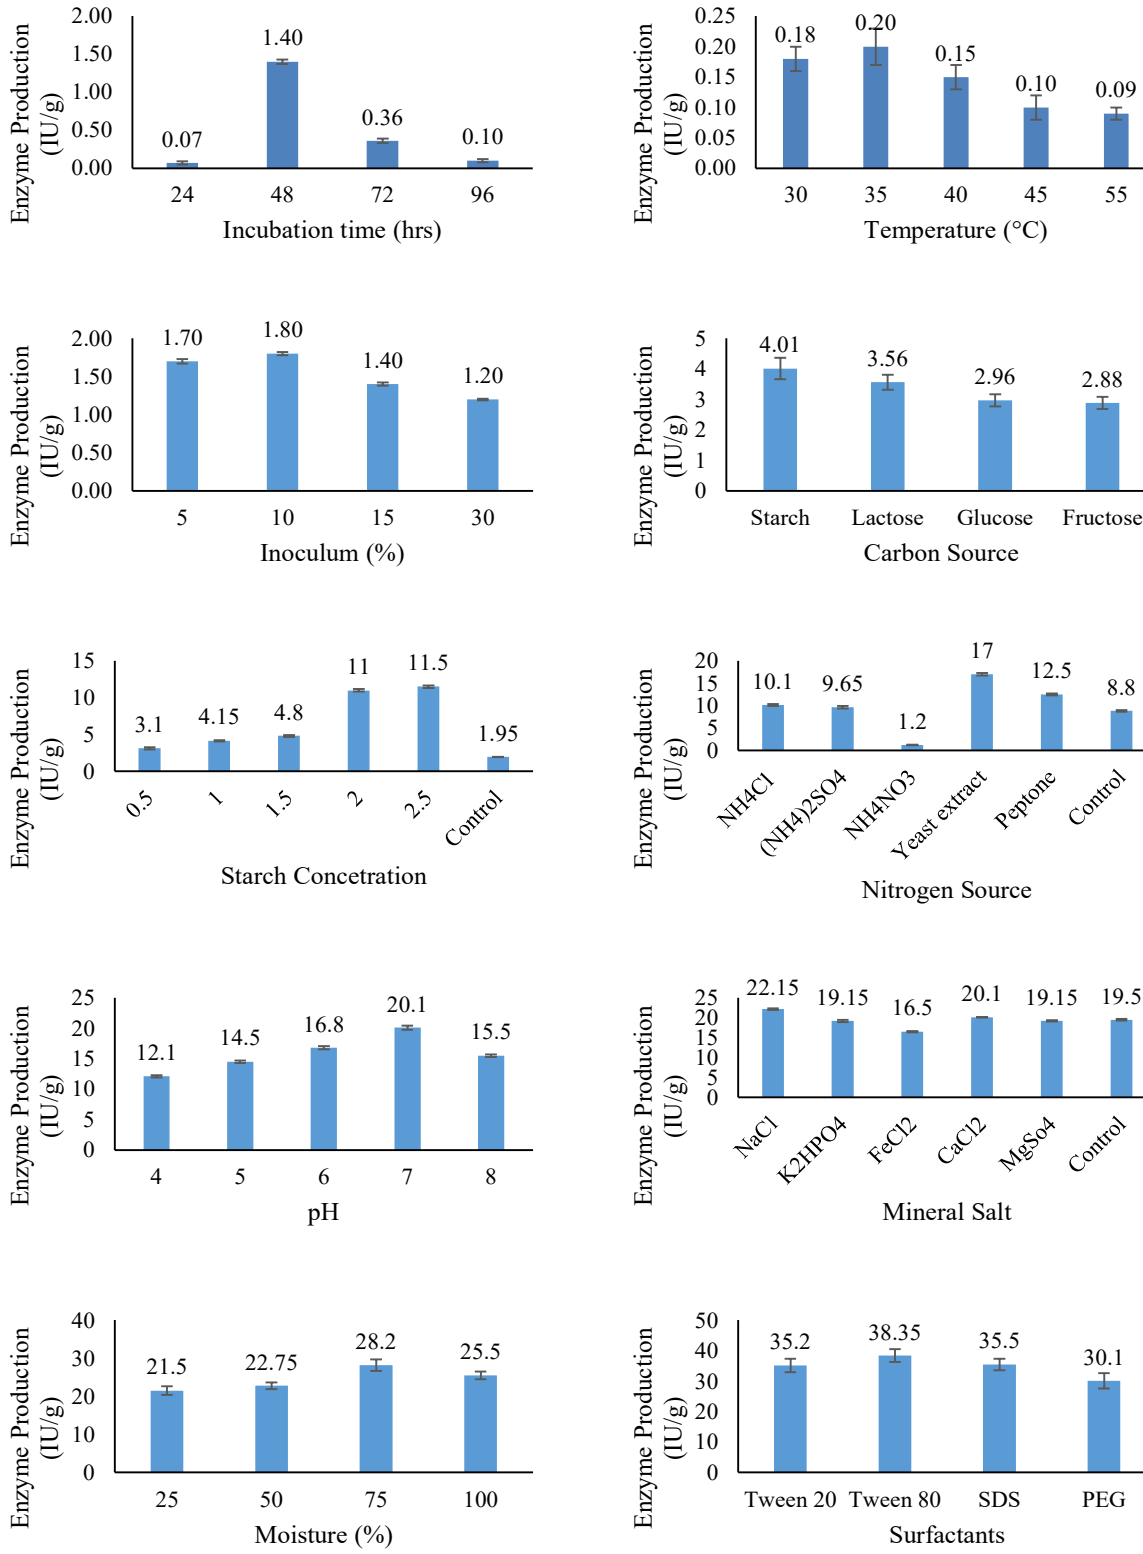

Fig. 2: Results of optimized parameters for amylase production.

This publication is licensed under a Creative Commons Attribution 4.0 International License

55°C (0.09 IU.g^{-1}), implying reduced enzymatic activity at higher temperatures. Notably, at 50°C, no measurable amylase production was observed, indicating a temperature beyond the optimal range for enzymatic activity under these conditions (Fig. 2).

In a study on amylase production by *Bacillus subtilis*, it was found that the optimal activity temperature was 40°C. However, the enzyme yield dropped down more quickly with the increase in incubation period at 50°C (Salman et al. 2016). It is important to note that the optimal incubation temperature can vary depending on the specific strain of microorganisms used, the substrate, and the specific conditions of the fermentation process.

Effect of inoculum level on enzyme production: The study found that the inoculum level of isolated *Bacillus licheniformis* significantly impacts amylase production. The highest yield was observed with a 10% inoculum, reaching 1.80 IU.g^{-1}, suggesting this is the optimal level for this process. At lower inoculum levels of 5% and 15%, the production remained relatively high (1.70 IU.g^{-1} and 1.40 IU.g^{-1}, respectively), indicating these levels are also favorable for amylase synthesis. However, a slight decrease in enzyme production was noted at a higher inoculum level of 30% (1.20 IU.g^{-1}), implying that an excessively high inoculum may not be conducive to maximum amylase yield (Fig. 2).

Amylase is an enzyme that hydrolyses starch to glucose units. The production of amylase is influenced by several factors, including the inoculum level (Ozdemir et al. 2012).

In a study on amylase production by Aspergillus awamori under solid-state fermentation, an inoculum level of 10% (volume per mass) was found to be optimum for α-amylase production (Kalaiarasi & Parvatham 2015).

Effect of additional carbon sources on enzyme production: The investigation into the effect of additional carbon sources on amylase production revealed varying outcomes based on different carbon supplements (Starch, lactose, glucose, and fructose) with paddy straw. The enzyme production, measured in IU.g^{-1}, in the presence of different carbon sources, is summarized in Fig. 2.

The study found that the type of carbon source significantly impacts amylase production. Starch was the most effective, yielding the highest enzyme production at 4.01 IU.g^{-1}, suggesting that it, along with paddy straw, creates an optimal environment for amylase synthesis. Lactose also showed substantial effectiveness, yielding 3.56 IU.g^{-1} of amylase, indicating its potential as a supplementary carbon source. However, glucose and fructose resulted in lower amylase production (2.96 IU.g^{-1} and 2.88 IU.g^{-1}, respectively), suggesting they might not be as conducive to amylase synthesis as starch and lactose under these experimental conditions.

In a study on amylase production by *Trichoderma viride*, it was found that the different commercial carbon substrates significantly affected the concomitant syntheses of amylase (Juwon & Emmanuel 2012).

Effect of different starch concentrations on enzyme production: The exploration of different starch concentrations for amylase production revealed varying outcomes, emphasizing the importance of starch concentration in optimizing enzyme yield. The enzyme production, measured in IU.g^{-1} at different starch concentrations, is presented in Fig. 2.

The study found a clear concentration-dependent effect on amylase production. As the starch concentration increased, so did the enzyme yield. Specifically, at starch concentrations of 2% and 2.5%, amylase production significantly increased, reaching 11 IU.g^{-1} and 11.5 IU.g^{-1}, respectively, suggesting that higher starch concentrations are favorable for maximizing amylase synthesis.

At lower concentrations (0.5%, 1%, and 1.5%), a progressive increase in enzyme production was also observed, indicating a positive correlation between starch concentration and amylase yield. However, the most substantial enhancement was observed at higher concentrations.

The control experiment with a starch concentration of 0% yielded an amylase production of 1.95 IU.g^{-1}, serving as a baseline for comparison. This reinforces the notion that starch is a critical substrate for amylase production and its absence results in significantly lower enzyme yields.

A study on amylase production by *Bacillus licheniformis* ZB-05 under solid-state fermentation found that as additional carbon sources, 2% soluble starch enhanced α-amylase production (Karatas et al. 2013).

Effect of additional nitrogen sources on enzyme production: The investigation into the effect of additional nitrogen sources on amylase production revealed distinct outcomes, highlighting the influence of different inorganic nitrogen sources. The enzyme production, measured in IU.g^{-1}, with various nitrogen sources at a 1% concentration, is summarized in Fig. 2.

The study found that nitrogen sources significantly impact amylase production. Yeast extract was the most effective, yielding the highest enzyme production at 17 IU.g^{-1}, suggesting it provides optimal conditions for amylase synthesis. Peptone also showed substantial effectiveness, producing 12.5 IU.g^{-1} of amylase.

This publication is licensed under a Creative Commons Attribution 4.0 International License

Ammonium chloride and ammonium sulfate resulted in moderate amylase production (10.1 IU.g^{-1} and 9.65 IU.g^{-1}, respectively), indicating their suitability as nitrogen sources, albeit with a lower impact compared to yeast extract and peptone.

However, ammonium nitrate led to lower amylase production (1.2 IU.g^{-1}), suggesting it might be less conducive to amylase synthesis under these experimental conditions.

The control experiment with no added nitrogen yielded an amylase production of 8.8 IU.g^{-1}, serving as a baseline for comparison. This reinforces the notion that the presence of specific nitrogen sources positively influences amylase production.

In a study on amylase production by *Brevibacillus borstelensis* R1, it was found that the addition of different nitrogen sources greatly affected the production of amylase (Suribabu et al. 2014).

Effect of Initial pH on Enzyme Production

The investigation into the effect of initial pH on amylase production revealed distinct outcomes, emphasizing the significance of pH in optimizing enzyme yield. The enzyme production, measured in IU.g^{-1} at different pH levels, is summarized in Fig. 2.

The study found that the initial pH significantly impacts amylase production. The optimal pH was found to be 7, yielding the highest enzyme production at 20.1 IU.g^{-1}, suggesting a slightly acidic to neutral pH environment is conducive for maximum amylase synthesis.

At pH 6 and 8, substantial amylase production was observed (16.8 IU.g^{-1} and 15.5 IU.g^{-1}, respectively), indicating that the enzyme is still active and efficient at these pH levels.

However, lowering the pH to 5 and 4 resulted in decreased amylase production (14.5 IU.g^{-1} and 12.1 IU.g^{-1}, respectively), suggesting that excessively acidic conditions may adversely affect amylase synthesis.

A published study emphasized the of pH influence the production of alpha-amylase (Kalaiarasi & Parvatham 2015, Suribabu et al. 2014)

Effect of different mineral salt ions on enzyme production: The investigation into the effect of different mineral salts on amylase production provided insights into the influence of specific metal ions on enzyme yield. The enzyme production, measured in IU.g^{-1}, with various mineral salts at a concentration of 100 μM is summarized in Fig. 2.

The study found that the addition of specific mineral salts significantly impacts amylase production. Here are the results:

- NaCl (Sodium Chloride): The presence of NaCl resulted in the highest yield at 22.15 IU.g^{-1}, suggesting that sodium ions play a positive role in promoting amylase synthesis.
- K_2HPO_4 (Potassium Hydrogen Phosphate): The addition of K_2HPO_4 yielded 19.15 IU.g^{-1}, indicating that potassium ions contribute to the enhancement of amylase synthesis.
- $FeCl_2$ (Iron (II) Chloride): Iron ions resulted in an α-amylase production of 16.5 IU.g^{-1}, demonstrating a positive impact on amylase synthesis.
- $CaCl_2$ (Calcium Chloride): Calcium ions positively influenced α-amylase production, yielding 20.1 IU.g^{-1}, suggesting that calcium plays a role in enhancing amylase synthesis.
- $MgSO_4$ (Magnesium Sulphate): Magnesium ions resulted in an α-amylase production of 19.15 IU.g^{-1}, indicating that, like potassium and calcium, magnesium ions contribute to the positive regulation of amylase synthesis.

The control experiment, without the addition of specific mineral salts, produced α-amylase at 19.5 IU.g^{-1}, serving as a baseline for comparison. A Published study shows a significant effect on the production of amylase enzyme (Saxena & Singh 2011).

Effect of initial moisture level on enzyme production: The investigation into the effect of different levels of initial moisture on amylase production elucidated the impact of varying substrate moisture content on enzyme yield. The enzyme production, measured in IU.g^{-1} at different moisture levels, is summarized in Fig. 2.

The study found that the initial moisture level of the substrate significantly impacts amylase production. Here are the results:

- 25% Moisture: A moisture level of 25% resulted in an amylase production of 21.5 IU.g^{-1}, suggesting that lower moisture levels still support significant amylase synthesis.
- 50% Moisture: Increasing the moisture level to 50% positively impacted amylase production, yielding 22.75 IU.g^{-1}, indicating that a moderate increase in substrate moisture enhances enzyme yield.
- 75% Moisture: The highest amylase production was observed at a moisture level of 75%, reaching 28.2 IU.g^{-1}, suggesting that the fermentation process

This publication is licensed under a Creative Commons Attribution 4.0 International License

is particularly efficient when the substrate has a higher moisture content.

- 100% Moisture: A further increase to 100% moisture resulted in a slight reduction in amylase production to 25.5 IU.g^{-1}, indicating that excessively high moisture levels may not be optimal for enzyme synthesis.

This information is crucial for optimizing the solid-state fermentation process for maximum amylase production. It shows the importance of carefully controlling the moisture level of the substrate to achieve the best results (Gangadharan et al. 2007).

Effect of various surfactants on enzyme production: The investigation into the effect of various surfactants on amylase production provided insights into the impact of different surface-active agents on enzyme yield. The enzyme production, measured in IU.g^{-1}, with various surfactants is summarized in Fig. 2.

The study found that different surfactants significantly impact amylase production. Here are the results:

- Tween 20: The addition of Tween 20 enhanced amylase production, yielding 35.2 IU.g^{-1}, suggesting it positively influences amylase synthesis.
- Tween 80: Tween 80 was the most effective, yielding the highest enzyme production at 38.35 IU.g^{-1}, indicating it's particularly effective in promoting amylase production.
- SDS (Sodium Dodecyl Sulphate): The addition of SDS also positively influenced amylase production, yielding 35.5 IU.g^{-1}, suggesting it contributes to the enhancement of amylase synthesis.
- PEG (Polyethylene Glycol): PEG resulted in slightly lower amylase production at 30.1 IU.g^{-1} compared to the other surfactants, indicating its impact on amylase synthesis is less pronounced under these experimental conditions.

This information is crucial for optimizing the solid-state fermentation process for maximum amylase production. It shows the importance of carefully selecting the surfactants to achieve the best results (Singh & Kumar Brahman 2013).

CONCLUSION

The comprehensive study we conducted aimed to optimize amylase production through a systematic exploration of a range of factors and conditions. The final set of media identified to maximize enzyme yield includes:

- Substrate Composition: Paddy straw (5 g) and Starch (3%).
- Mineral Salt and Additives: NaCl (100 µM), Tween-80 (1%), and Yeast Extract (1%).
- Moisture Content: Initial Moisture (75%).
- Incubation Conditions: Incubation Time (48 hours), Temperature (35°C), and pH (7).

This optimal combination ensures significant enzymatic activity and provides insights for process scalability and industrial applications. The established parameters serve as a valuable foundation for further studies and applications in the field of enzyme production. This research offers a systematic and tailored approach to maximize amylase yield, contributing to the advancement of biotechnological processes and applications.

Zones of Singapore river planning area:-Total 3kms long

Robertson Quay- Waterfront Residential living Art related Facilities

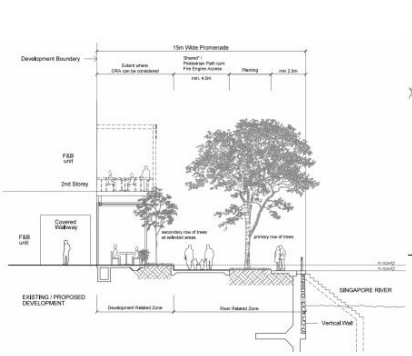
Clarke Quay -Conserved Mixed used Building ,Commercial, Residential & Hotel

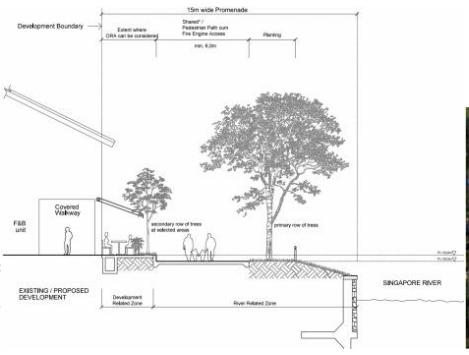
Boat Quay-Conserved 100 shop buildings ,Commercial activities

AGU

To create vibrant precincts attractive, pedestrian-friendly streets, AGU (Activity generating uses) like retail,food& beverages at

- Riverfront promenade,
- pedestrian malls,
- block links,
- key streets &
- public spaces.





ORA

Outdoor Refreshment Area are allowed at:

- Along riverfront promenade
- Public areas or open spaces
- ORA defined by different floor finishes or planters etc.
- Structures (scale & design) compliment the adjacent developments.

Robertson Quay

- Abutting within the boundary
- Maximum height -4mts related to 1st storey of development/adjacent covered walkway to a maximum height of 4mts.
- Market styled umbrellas ,not anchored to the promenade.

Clark Quay

Standalone ORA structures near river related zones

- Light weight & not exceed 4m height.

Form & Massing

- Scale form & architectural expression of the surrounding buildings.
- Buildings should be designed to contribute skyline profile of city & pedestrian experience along the riverfront promenade.
- Design of building form & massing with architectural treatment depends upon how it is viewed form different places.

1. Major approaches/landmarks
2. Promenades
3. Pedestrian malls.

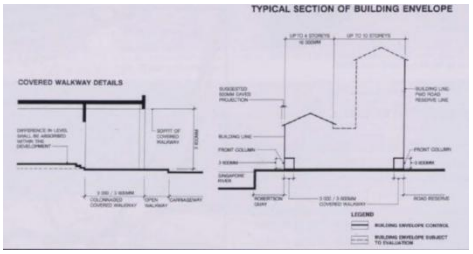
- Robertson Quay blocks were of former warehouse styles lined the river to be retained.
- Existing Buildings
- Roof profiles & solid & void expressions.

Location- Front to next to F & B Unit.(as shown in section above)

The riverfront promenade, pedestrian malls and public spaces (covered walkways,courtyards,within the setbacks).

Boat Quay

- Umbrellas are allowed.
- Tent structures allowed.
- Existing trees are not pruned.
- Tree aeration and plantation are kept open.



Building Height

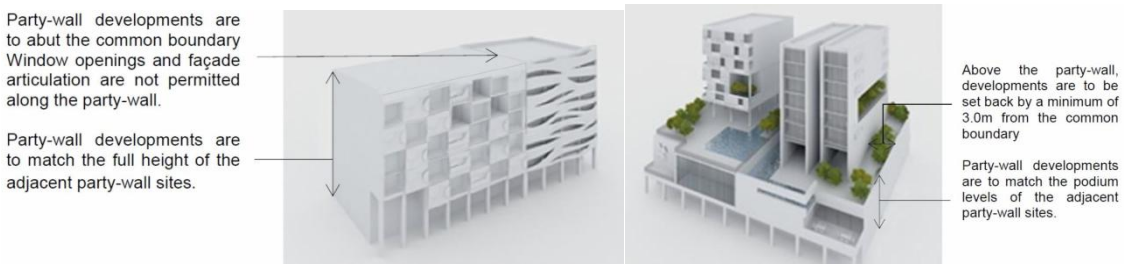
- Specified to create 3 dimensional skyline profile.
- Lower Height for pedestrian friendly scale :

1. River front promenade.
2. Low rise conserved buildings.

- Higher building heights in non-river fronting portion.
- Higher building heights assigned for focal points & variety in built environment
- Robertson Quay & Clarke Quay has 2.8 plot ratio.
- Boat Quay has 4.2 Plot Ratio.

Building Edge

- Creative distinctive well defined streets.
- 40% per building frontage, between the corners of development for bu;ding form articulation.
- Create distinctive well defined streets developments built to the lines of road reserves /promenade reserves to a minimum of 2 storeys.



https://www.ura.gov.sg/Corporate/Guidelines/Urban-Design/-/media/2E4EBF3B00E044E7B33F1B79C34AE172.ashx

Party Wall

- Party wall developments -to abut the common boundary with the Lower Height for pedestrian friendly scale :

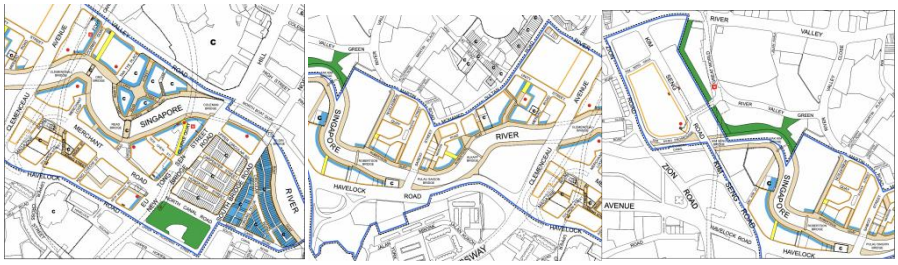
1. River front promenade.

2. Low rise conserved buildings.

- Higher building heights in non-river fronting portion.

Building Edge

- Creative distinctive well defined streets.
- 40% per building frontage, between the corners of development for building form articulation.
- Create distinctive well defined streets developments built to the lines of road reserves /promenade reserves to a minimum of 2 storeys.



https://www.ura.gov.sg/Corporate/Guidelines/Urban-Design/-/media/19E6D4E9144F45CE814CB24AD8853F87.ashx

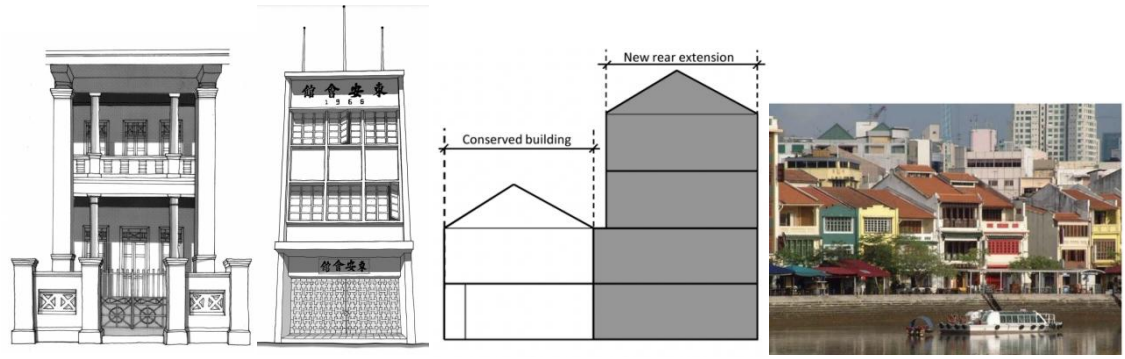
Public Spaces

- Developments fronting the riverfront promenade or pedestrian malls or nodes-provision of public open spaces within the site.
- Landscaping in these open spaces for visual and physical porosity.
- Well connected to river promenade open and covered walkways and accessible from underground and elevated 2nd storey.

Roofscape

- Roofs of both high rise and low rise parts of developments are to be considered which contributes the distinctive and coherent character of Singapore river.
- Relating to the conserved buildings,development at Robertson Quay have terracotta clay tiled pitched roofs as the predominant roof form.

Conservation Development Urban Design Guidelines



Art Deco Modern Shop house

Boat Quay Historic Districts Shop-houses conservation guidelines:

A new Jack roof .Skylight at the rear slope of main roof & on rear secondary roofs.

A cover over the air well.A cover over the rear court.New windows on rear facade & gable end wall.

Addition of secondary doors & windows.

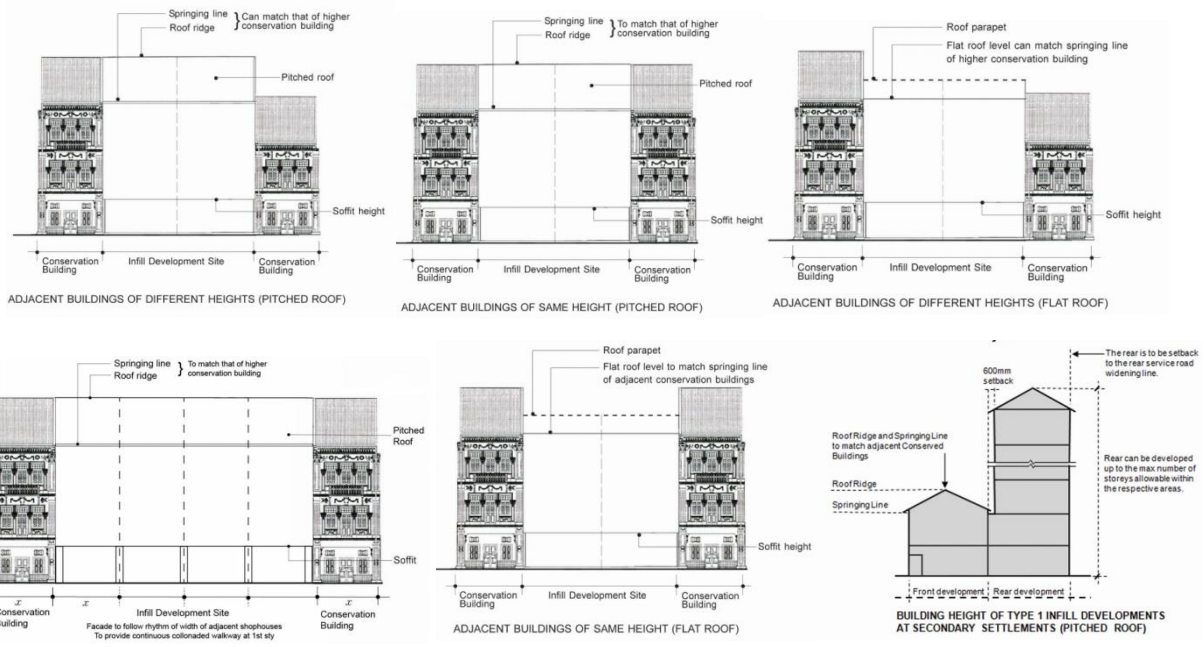
Art Deco

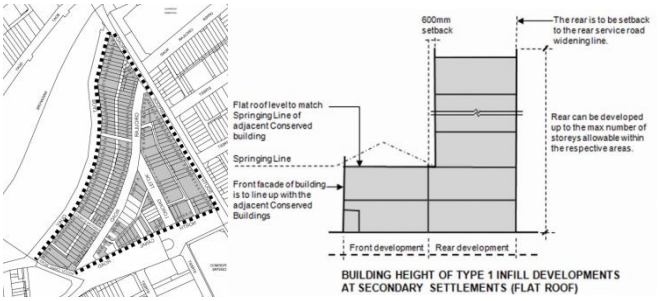
Streamlining columns,arches, orders, keystones & pediments, into geometric design. No clay tiles .

Proportional beauty & elevation composition.

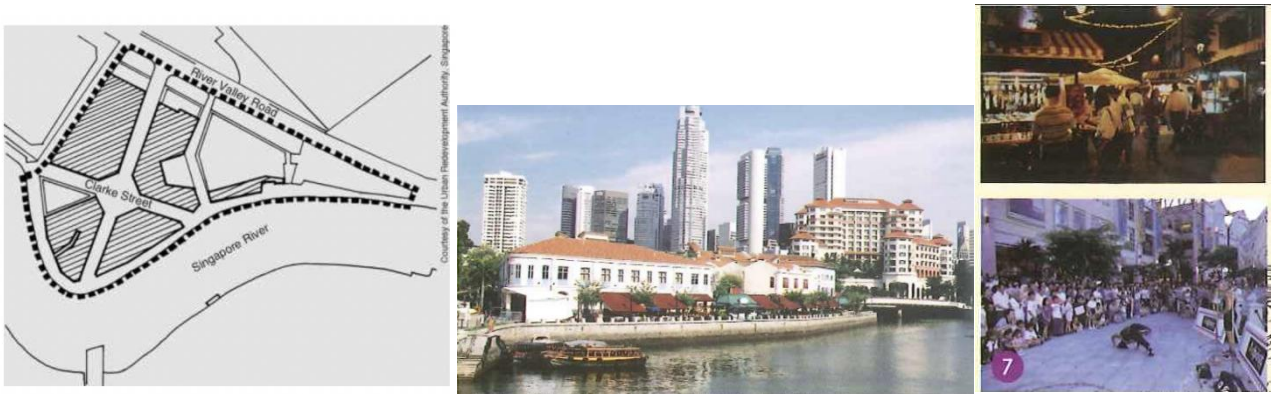
Modern Shop house

Thin air fins & air vents which are functional & decorative. Well proportioned windows to compliment with geometric design. Functionalism moving towards modernism approach. Representation of Post war economic situation



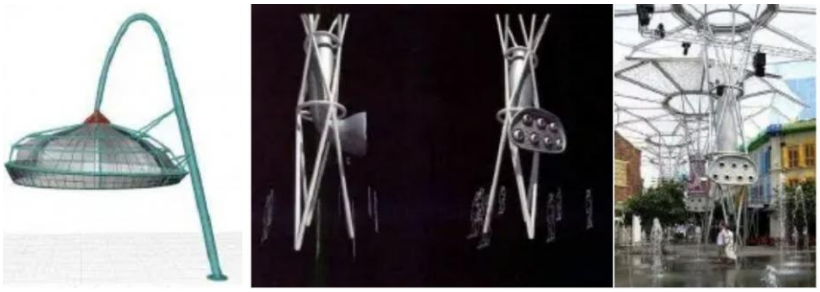


Clarke Quay conserved ware houses (Mixed use developments) guidelines:



60 go-downs at Clarke quay converted into 200 & more shops, restaurant,bars,etc.

60 go-downs at Clarke quay converted into 200 & more shops, restaurant,bars,etc.



Blue bells figures showing Clarke quay revival plans.

The Clarke quay after revival in 2003 created a promenade with chairs,kiosks, trees & steps along the bank . However, the new installations of lilypads& bluebells in 2003 weakened the visibility of the river while narrowed the pedestrian space. The facade of the whole area also changed.

Facade Transformation of Clarke Quay

Facade Transformation of Clarke Quay

Regeneration of shop houses made the Clarke quay increase the economy of people

Heritage precinct is continuously reinventing itself from family oriented festival market to retail centre& warehouses into night clubs. Heritage structures modifications done many times.

Conclusion:

The riverfront was developed in a way to attract more people to it.

Appropriate relations between the government & private companies lead to the development of the

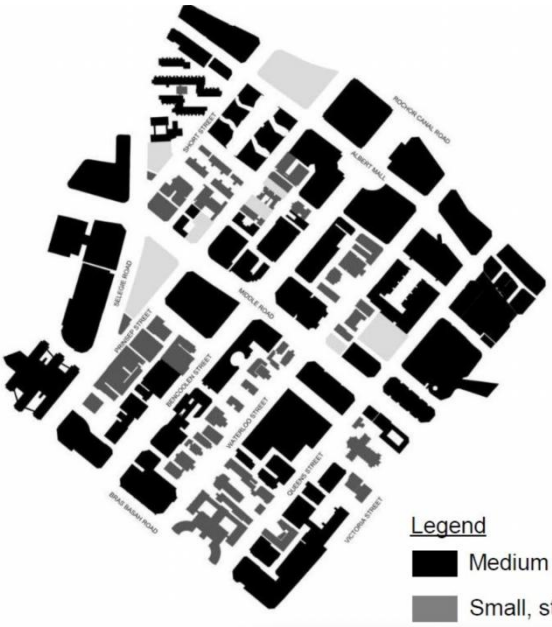
riverfront to be the centre of tourist attractions.

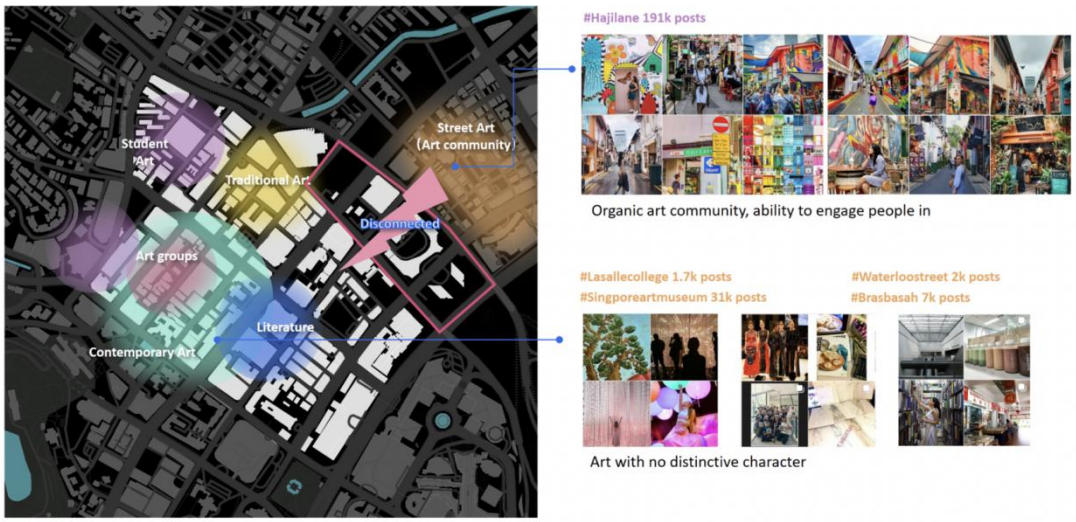
The efficiency of links between spaces,encourages pedestrian movement & makes all places adjoining the river easily accessible.

The movement along the river is development such that each pocket of area has a different experience to offer with its environment, along with buffer spaces in between, allowing users to gain better clarity of the space.

Urban Design Guidelines

Rapid development in 1980s improved the quality of life in Singapore but changes also led to a loss of vibrancy to formerly bustling districts. To inject life back into the Bras Basah Bugis precinct, the URA embarked on a 20 yr plan, with a focus on encouraging walking, to being back life to the streets.





Rochor Planning Urban Design guidelines-

Land Use

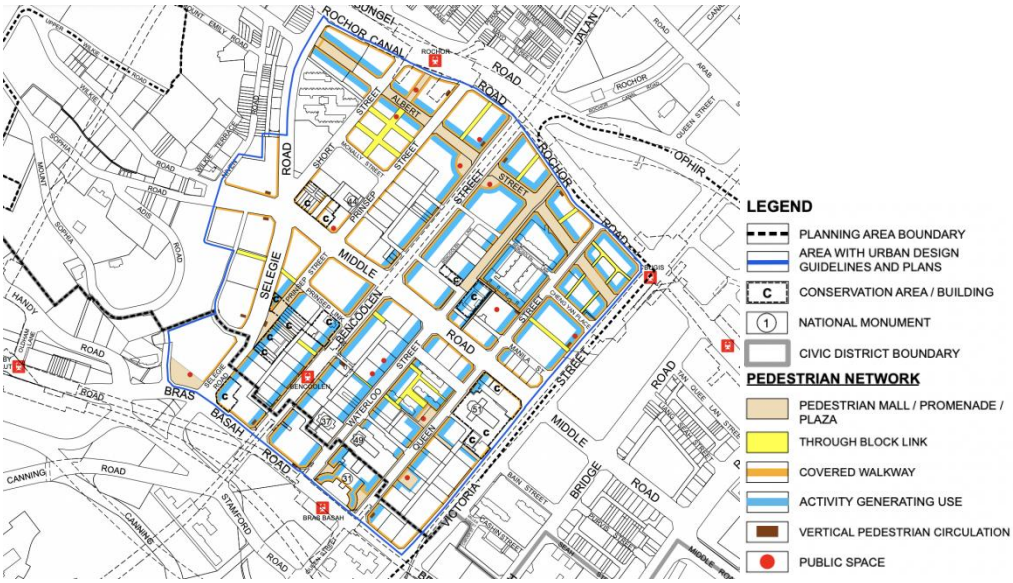
- The Bras Basah Bugis (BBB) Museums, shopping belt, Learning and heritage enclave.
- Guidelines ensures the individual development contributes to strengthen the planning vision for the area, while retaining BBB'S eclectic character.
- Standalone religious buildings, schools, medium to large scale commercial buildings and public housing.

Differentiated urban design guidelines for different streets wrt the character of each street.

Varied Street scapes Innovative & varied building forms & scale, as well as shop fronts with high level of transparency enhances the street experience.Pedestrian Friendly District

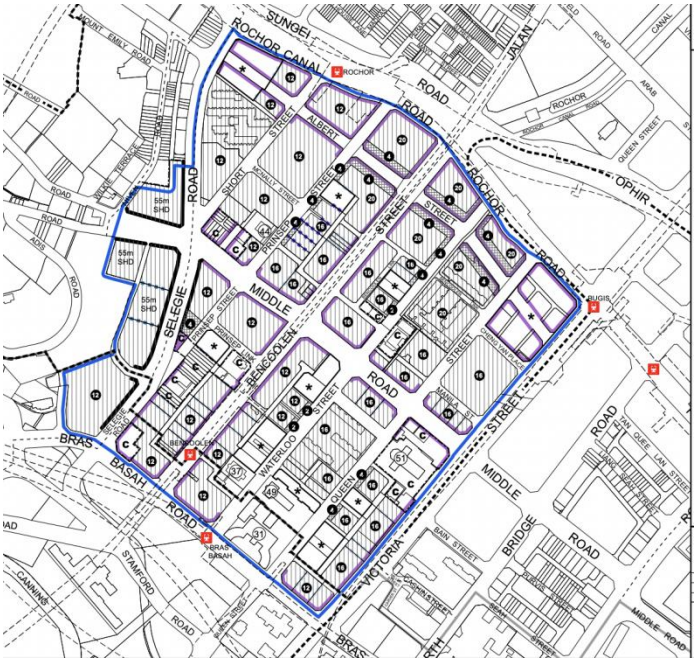
Connectivity between developments via a comprehensive network of pedestrian malls,covered walkways & laneways in between buildings will make the area more walk-able. For large scale development permeability in ground level is important to allow pedestrians to walk through the buildings.Active Vibrant streets Many public spaces are connected by pedestrian malls & walkways are safeguarded for the public enjoyment & for organized events & spontaneous activities.

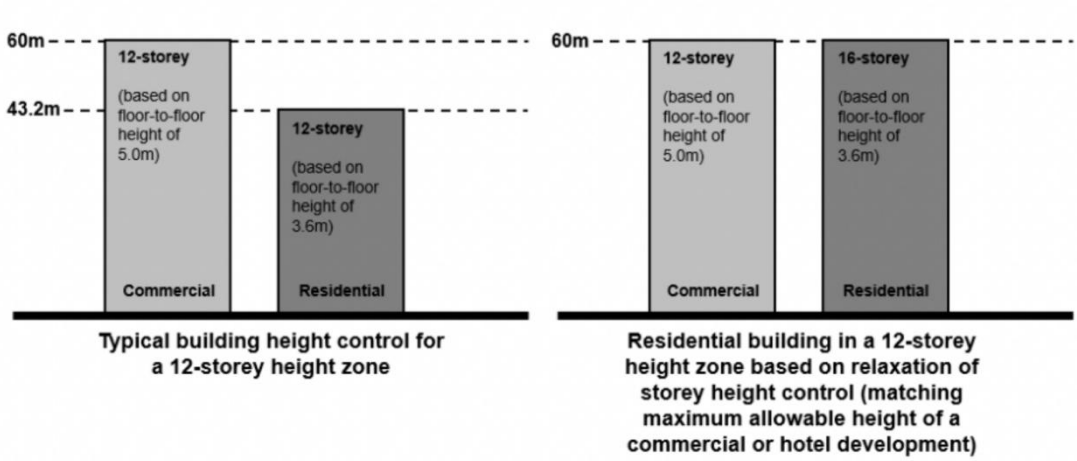
ORA



- ORA & ODA (Outdoor Display Area) can be allowed in selected locations.
- GFA for ORAs are to be computed as part of maximum GFA for the development & subject to the prevailing Development Control Guidelines.

Building Form & Massing





Typical building height control for a 12-storey height zone

Residential building in a 12-storey height zone based on relaxation of storey height control (matching maximum allowable height of a commercial or hotel development)

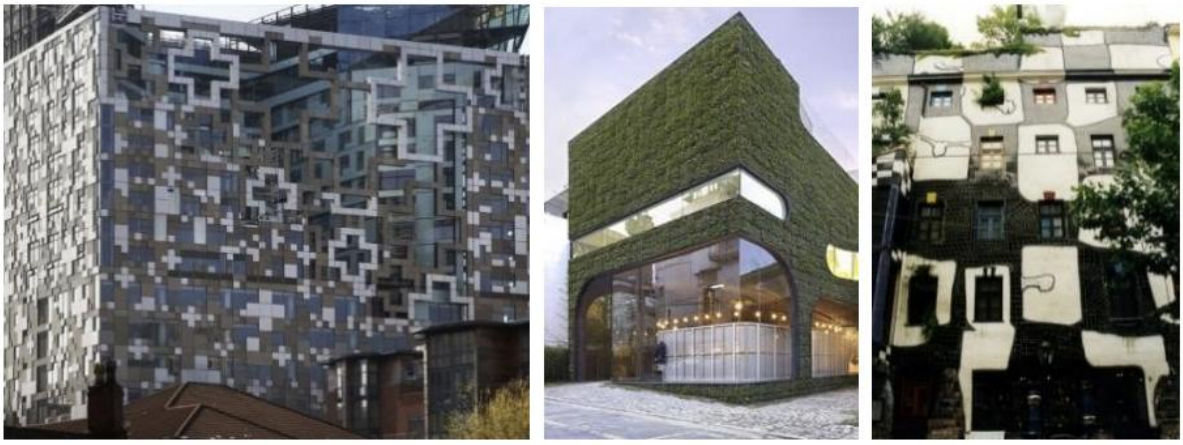
- Looking at scale form & architectural expressing of the surrounding buildings, to enhance the varied character of the different streets in BBB.
- Building heights are specified to respond to the site context and to reinforce the character of the district.
- Lower height near Mount Sophia to retain lower-rise character around the hill.
- Residential development with BBB an equivalent building height to the maximum allowable height for a commercial building can be considered to give greater design flexibility.

Building Edge

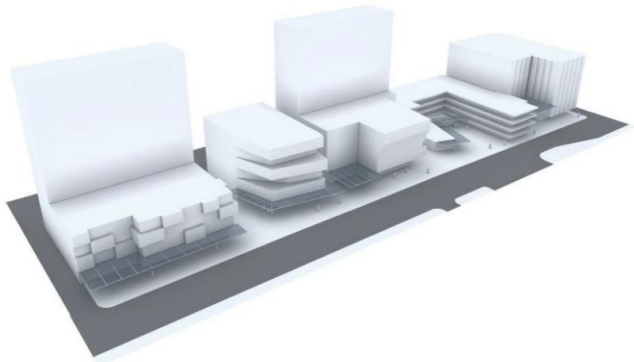
- Building edge of developments helps to define the streetscape & urban spaces within the city.
- Creative expression of the overall building form & architectural treatment is highly encouraged, with a variety of building materials & textures.
- Integrated facade lighting & landscaping, to provide interest & variety to the street scape.

- A high level of transparency & porosity is also encouraged at the street level.

Examples of Variety of Building Edge treatment.



Different architectural expressions on facade are encouraged to prevent uniform quality of evelopments. Give variety to the building edge &streets-cape. The development along other streets-should not to be built up to the Road Reserve.Developments having setbacks from the Road Reserve, the area fronting the developments is to be landscaped as attractive & accessible public spaces. Open car parks, as well as gates & boundary walls that obstruct public access will not be allowed withinbuilding setback.

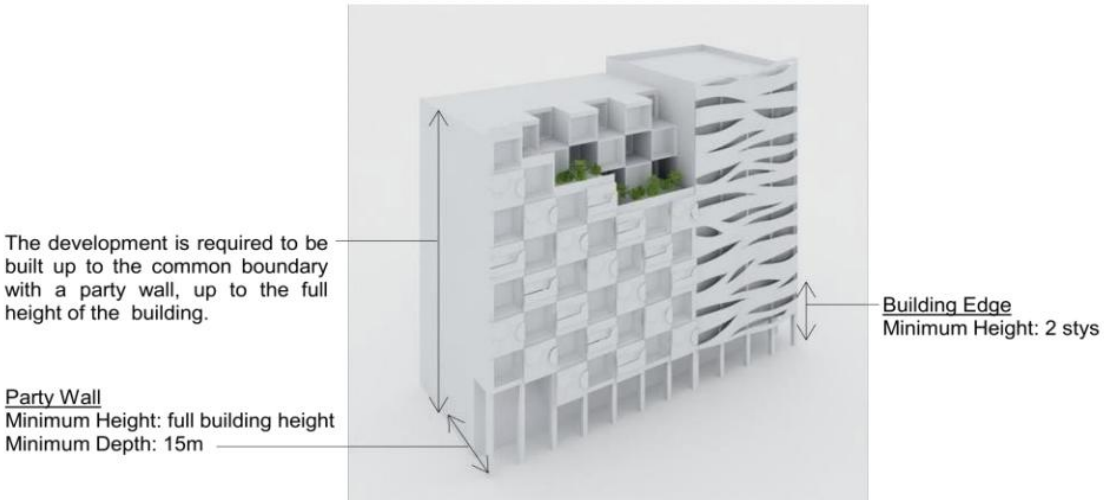


Mix of buildings of different typologies. Ranging from traditional shop-houses to small & medium scale modern developments.Buildings that are set back from the line of Road Reserve to provide public spaces

in front of the developments.Existing are built up to the common boundary with the adjacent developments with a party-wall. This maximize building footprint & creates a continuous pedestrian walkway between developments. Developments within these street-blocks are to be built up to the common boundaries as party wall developments. No windows are allowed along party walls, as these will be constructed by the future adjacent party wall development.Standalone buildings are with setback of 3m (minimum) from the common boundary.

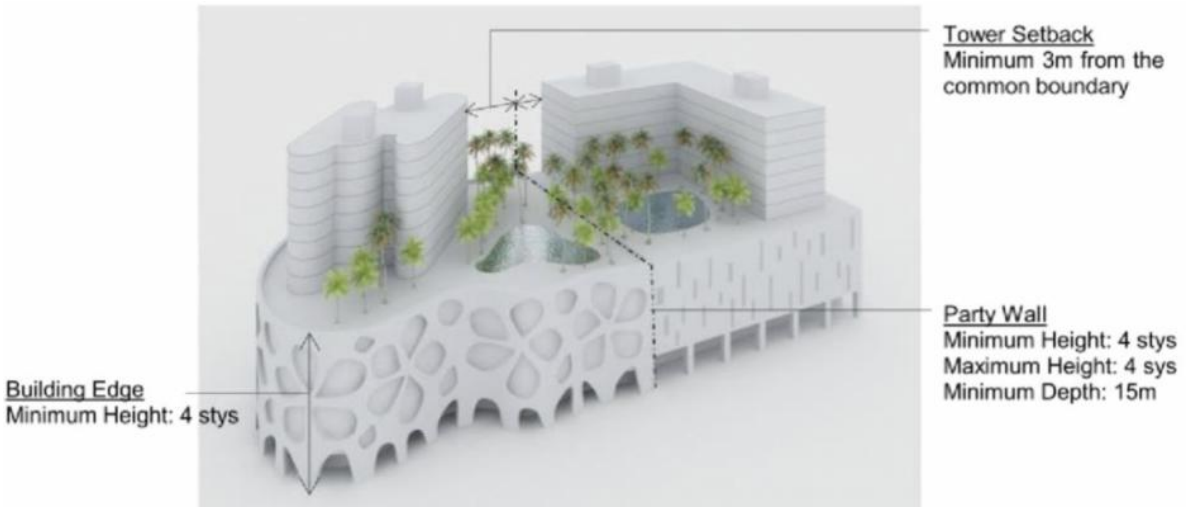
Guidelines for commercial street blocks

Party wall with full height of the building with common boundary.



Guidelines for Residential street blocks

Party-wall developments are to be built up to a minimum 2 storeys& not exceeding 4 storeys. Beyond the height of 4 storeys, the building is to be set back minimally 3m from the common boundary, & 7.5 m from the Road Reserve. This allows openings in the residential development



Guidelines for Mixed use development.

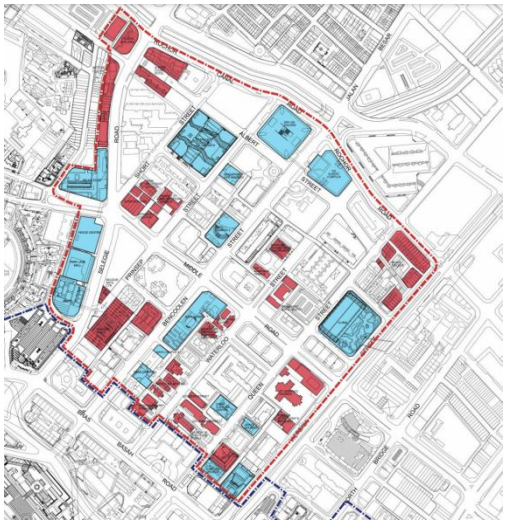
The mixed-use developments along Seleige Road are to be built up to the common boundary upto 4 storeys. In view of the relatively large building footprint, the tower blocks above the podium are to be set back 3m (minimum) from the common boundary. This prevents wall-like developments &provide opportunities for more window openings within the mixed-use development.

Public Spaces

It is important to provide spaces within private developments for users to enjoy. Selected developments fronting key pedestrian malls or nodes are required to provide public open spaces within the development site. Public spaces are well connected pedestrian mall, adjacent open & covered walkways, thru block links & where applicable, are encouraged to be linked & designed to be well integrated and easily accessible from the underground & elevated 2ndstorey pedestrian networks within the development.
https://www.ura.gov.sg/-/media/User-Defined/URA-Online/circulars/2013/nov/dc13-16/dc13-16-Annex-A.pdf

Greenery Replacement & Landscaping

To create a green & sustainable city, all new developments will be required to incorporate landscaping in the form of sky terraces & roof gardens according to Landscape Replacement Area.

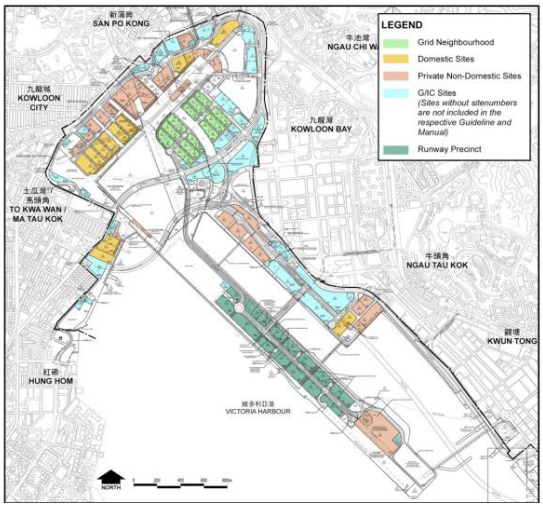


Night Lighting

Various arts,culture& heritage developments, as well as key commercial buildings are to provide night lighting to enhance the district character at night.Buildings with unique & attractive luminous facades will enhance vibrant street life & can be allowed for Contemporary buildings that suit the context of their locations. Luminiuos facades are not allowed for Classic Buildings.

https://development.asia/case-study/enhancing-urban-spaces-pedestrian-friendly-mixed-use-development

Urban Design Guidelines for Grid Neighborhood of Kai Tak Hong Kong.



Kait tak urban design guidelines for Grid Neighborhood

Overall Urban Design Framework for Kai Tak

Following are Key Urban Design & Landscape principles:-

- Connecting Neighborhoods
- Creating Nodes
- Activating the Harbour-front
- Creating a Pedestrian Friendly Environment.
- Creating Dynamic Skyline
- Celebrating Views.
- Celebrating Gateways.
- Creating "A Green Web for Sustainable Development.

Principal Function is to achieve coherent overall design of high quality.

Parameters that are specifically applicable are:-

- Relating to Proposed residential Low blocks.
- High Blocks
- A retail belt from the Station Square.

Introduction

To create Visual identity.Adistinguished,vibrant, attractive and people oriented community.increase of Visual permeability across site by Southeast & Northwest axis.

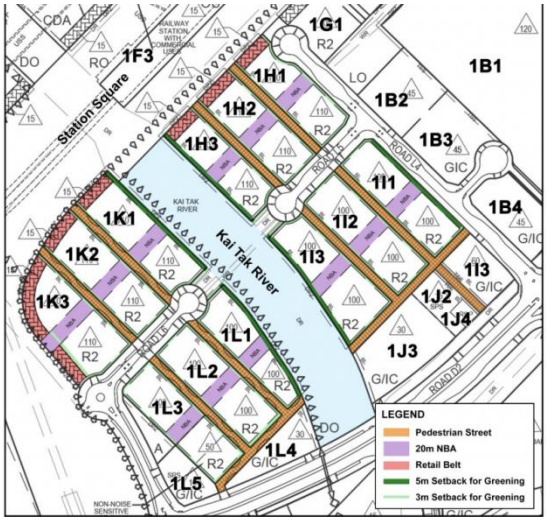
Public Creative framework

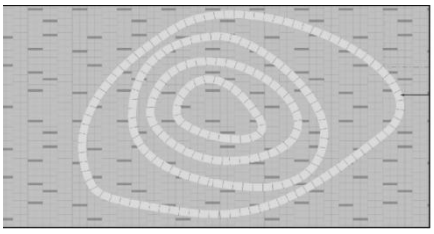
Color scheme- features 8 main color and 6 highlight color. Colors- core values of Kai Tak-Connecting, Natural, Healthy, Future Driven,Strong

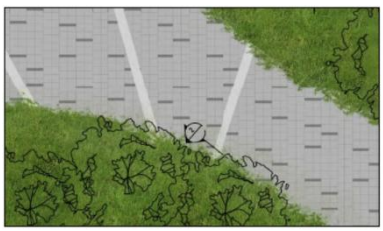
Colors are in harmony with society and Urban structures (architectural constructions,park and leisure environment, and business areas etc)

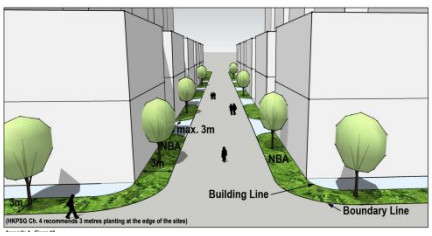
Ambient Tone and Color

Defines building or an area. Applied in building facade, furniture,street pavements. Sense of place, improves visual quality of neighborhood, soften visual impact of buildings.Visually appealing pedestrian circulation.Connection with public realm.









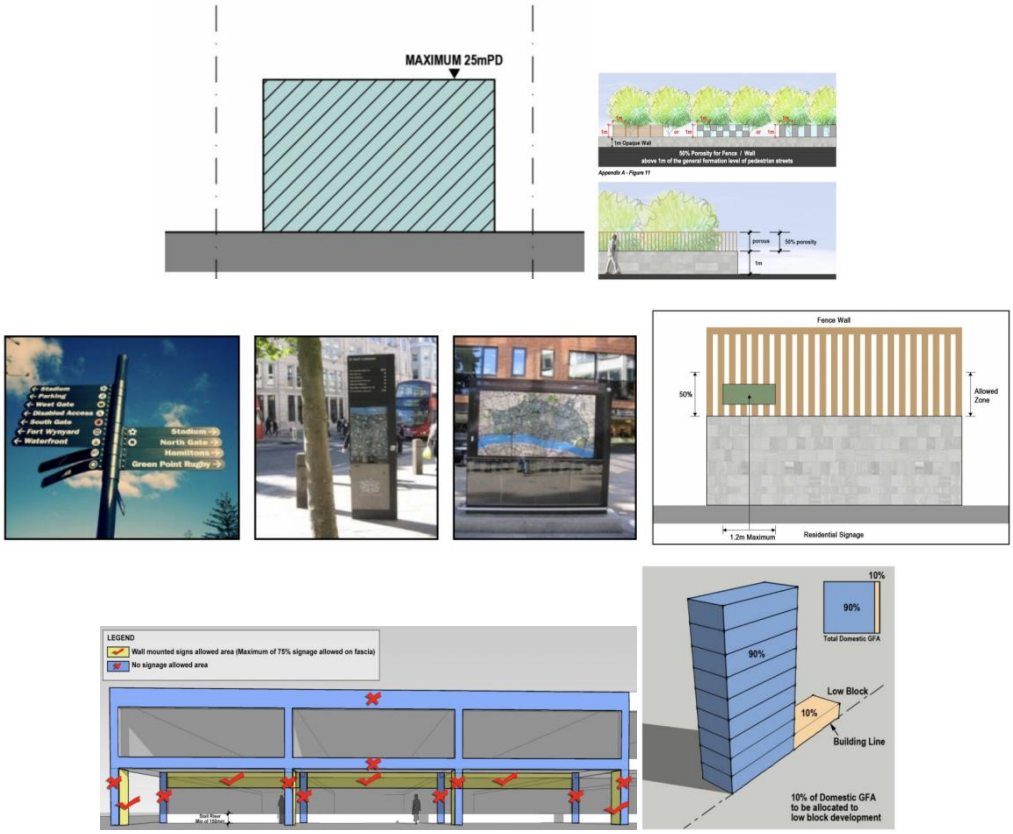
Streets-cape Design:

Historic Street Pattern: Efficient, effective design and pedestrian movement.Increase of Visual permeability across site by Southeast and Northwest axis. Riverine edge- 5 mts setback forgreening.3mts wide NBA (non building area)10 mts wide Pedestrian streets.20mts wide Visual corridor with organized trees , plants .For points and routes of access and circulation to define spaces character and function with visual order.Enhance legibility there should be change of paving material at

the junction of pedestrian street and visual corridor.

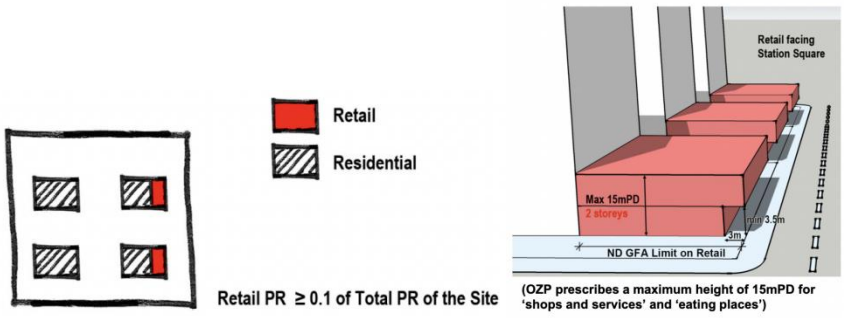
Residential Facade Treatment

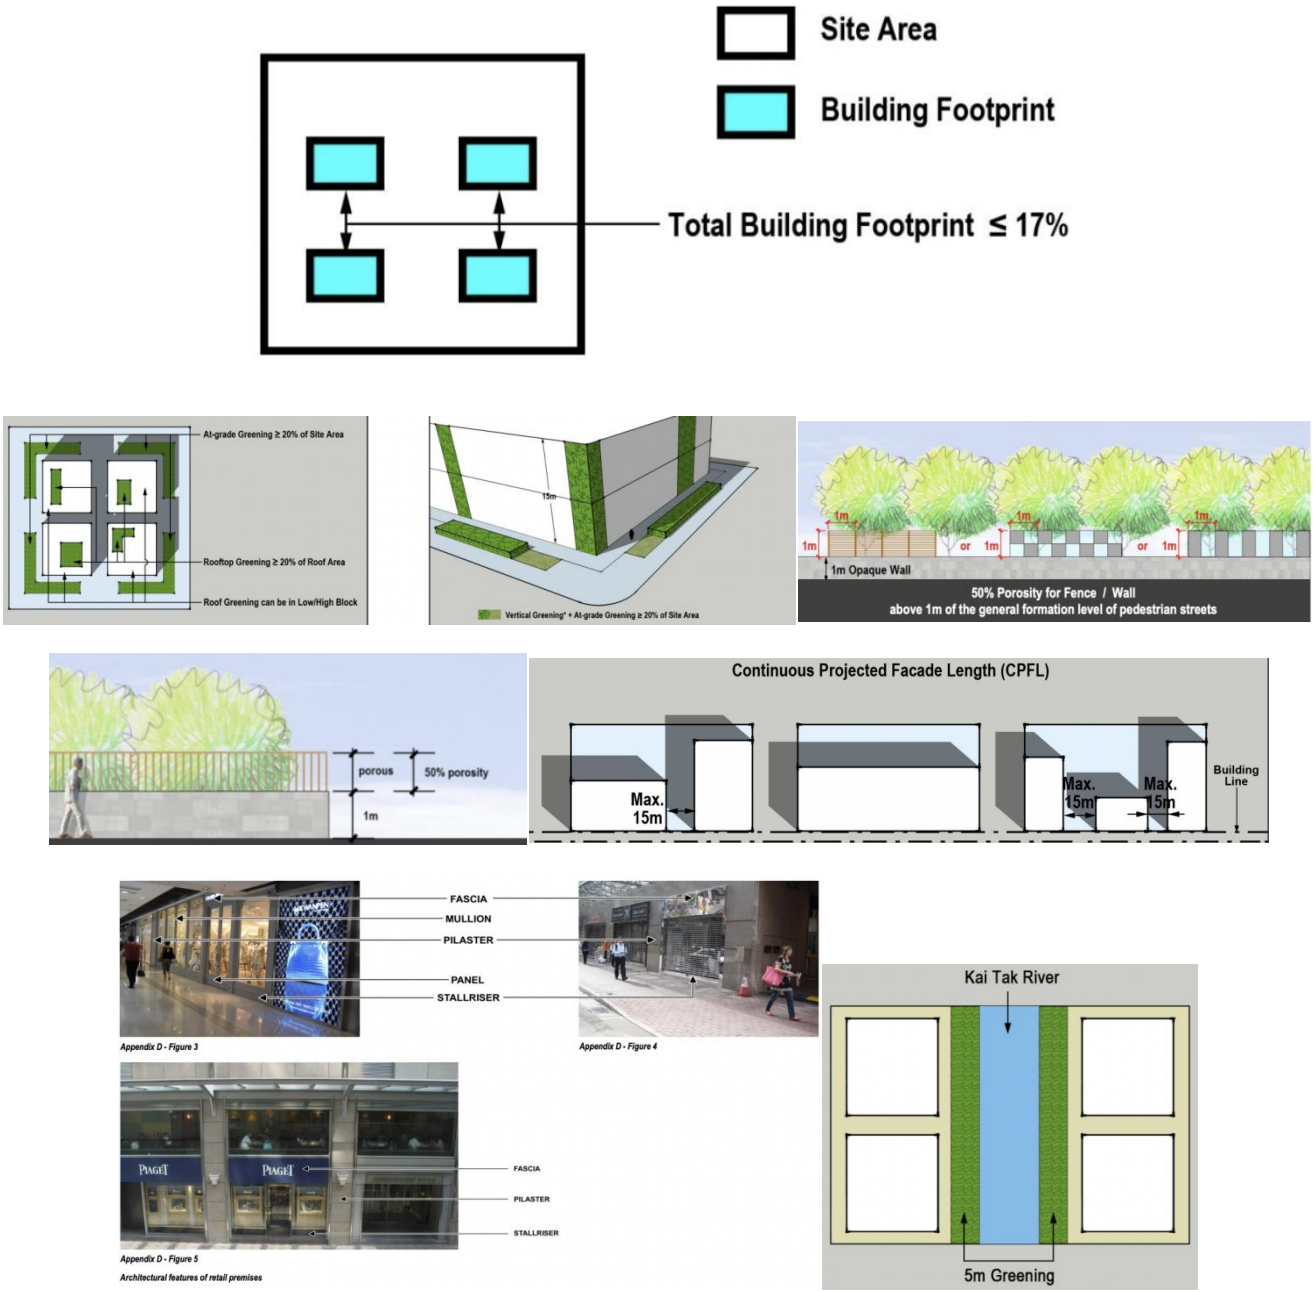
Continuity of facade treatments at ground level. Building frontages with balconies, bay windows, clearly defined windows &windows.Quality edge in the neighborhood, and interest in public realm created by the texture and exterior detailing which is related to human scale.Also foster a sense of lightness and subtlety in the development.Soft materials like recycled wood/natural materials to be used.Wood and glass - express the character, architecture and form of the buildings with enhancing the quality of built environment.Modern low maintenance material brick and stone soften the visual appearance of the buildings.Excessive long facade should also be avoided.Windows,doors and balconies located in street face of building help to add visual variety and depth to a building.



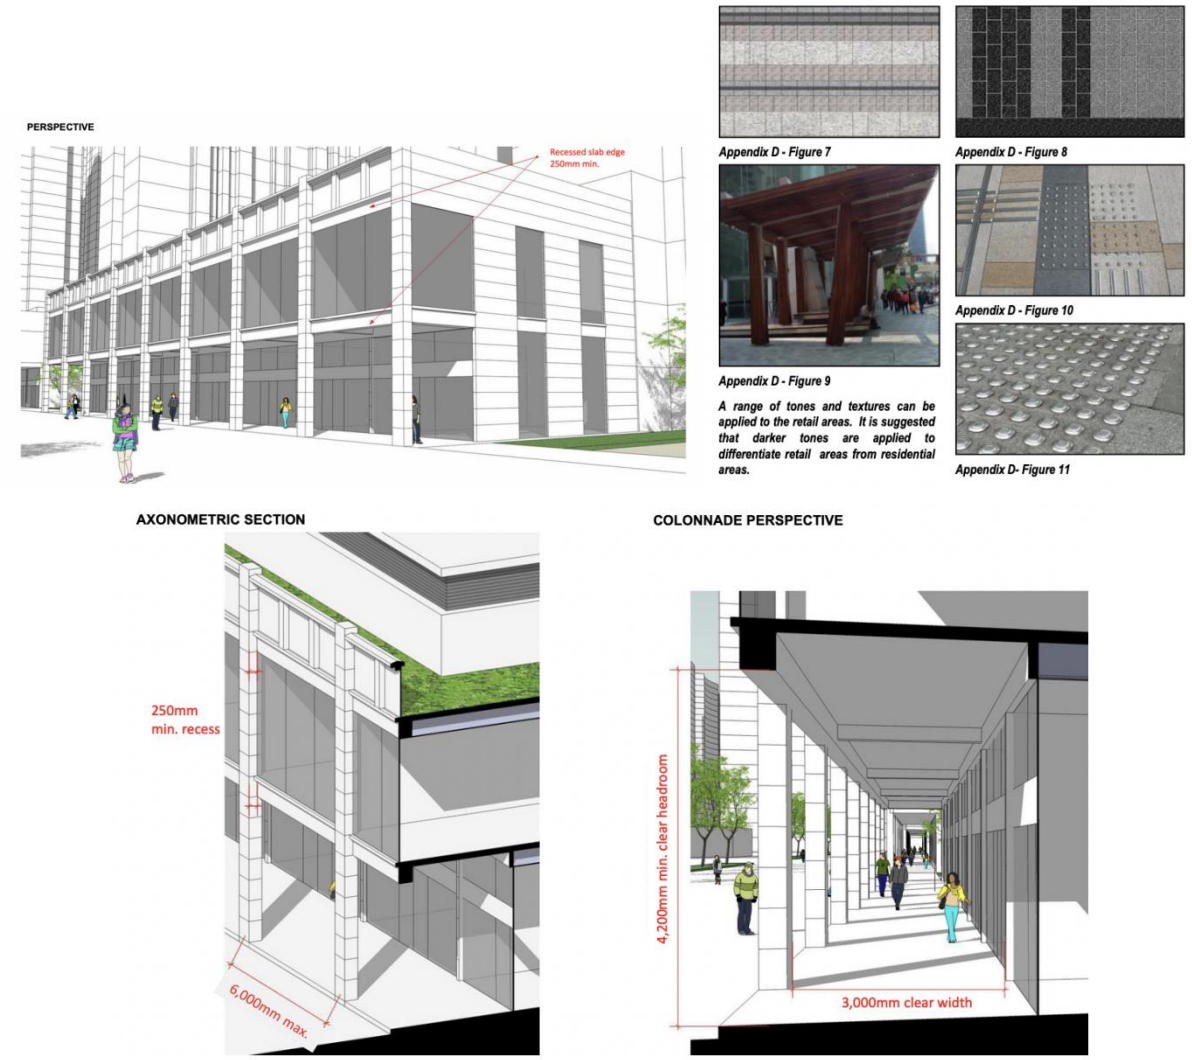
Greater permeability of fence walls to enhance interaction between neighborhood and pedestrian street.Use of polished metal surfaces incorporated into building design.Highly reflective to be avoided as they produce glare.Directional signage, retail signage, street name signage & residential name signage with regard to certain building and dimension constraints.Residential signage locations.

Low rise resiential blocks-BH 25m pd.A minimum of 10% of GFA -Low rise Residential block.





Facade length dot exceeds 40m.Retail development should not be more than 15 mts.Overall greening ratio-30%.Pedestrian greening ratio-20% Roof area greening ratio-20%.



Form Based Code at Chandigarh

Form based Code are used to create visual identity and maintaining the desired character of a building by :-

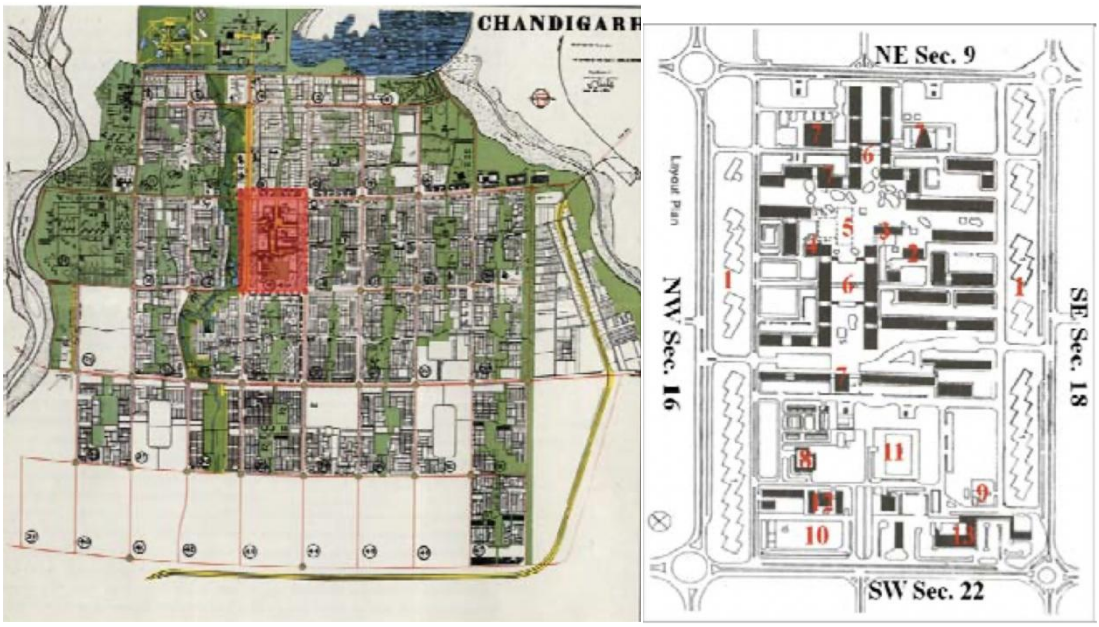
Building Height & bulk.

Facade treatment.

Location of Parking.

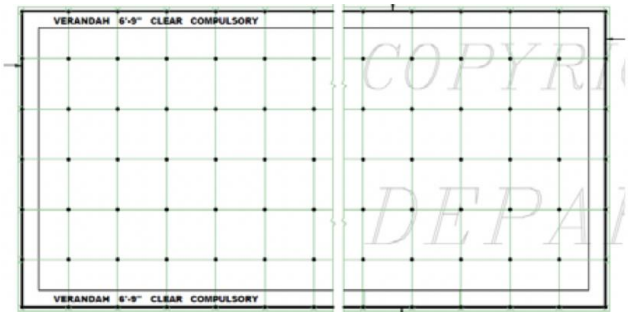
Location of building.

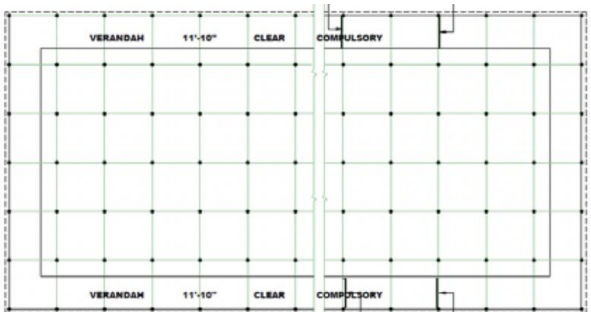
Appearance and Quality of Public Realm.

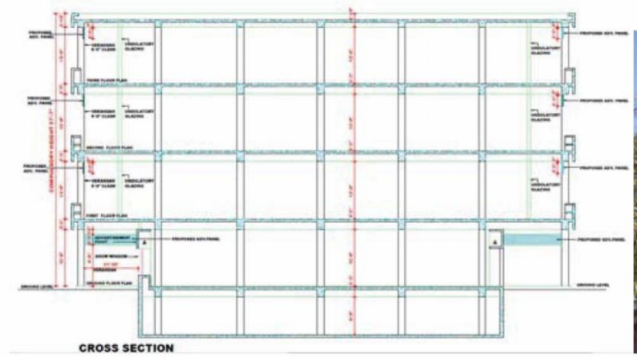


Form Based Code in Sector 17 is a Commercial activity Hub.

These Codes are specified for 4 storeyed, 5 storeyed R.C.C Building blocks, Brick faced building blocks, peripheral blocks, cinemas and petrol pumps.4-storeyed Shop cum Office buildings:

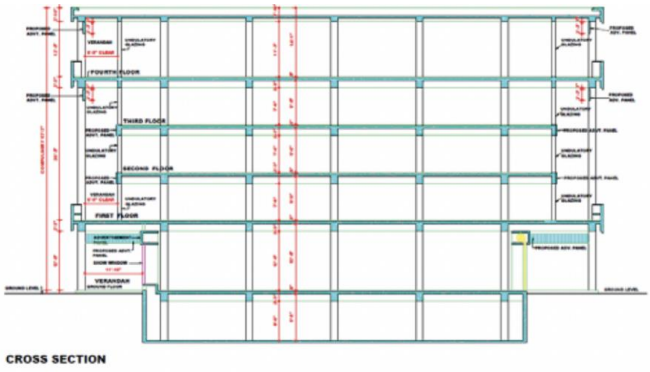






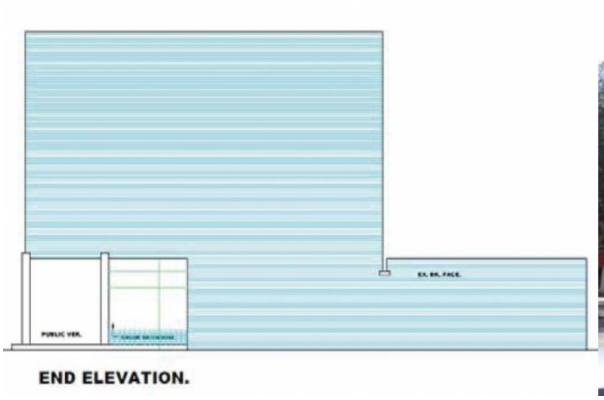
Architectural Controls:

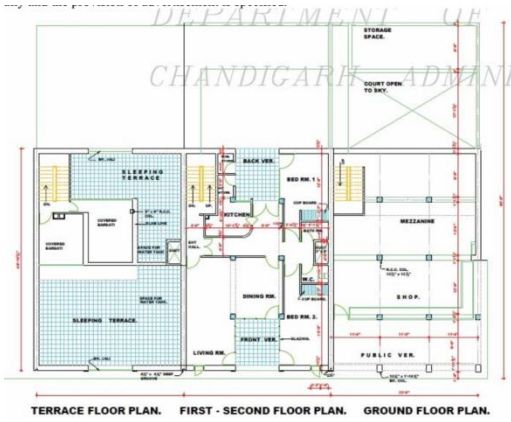
Verandah in ground floor 11’ wide, first,second and third floor 6’ wide.Height restricted to 57’7”.Space for Advertisement Panels as shown in the figure Basement -services like machine rooms, store rooms, cycle rooms, strong rooms for banks etc.In a commercial complex -Main door entry of the shop for an extra entry size of door is same as the existing door, that to at the rear side.Party wall should be till the ceiling height.



5 storeyed Shop and Office Building:-

Height remains the same 57'7" internal heights of floors changed.





Shops cum Office (Brick faced)

Height remains 48'9". Upper floors with recessed balconies or windows for play of solid and void. No basement, provision of Mezzanines.1/2" of groove to separate the shops visually.Peripheral blocks are designed for a better view from the main road.

Cinemas having almost similar character.

Facade violation

Texture on concrete, paint on concrete and colour on exposed brick facade.

New cinema block with glass facade, and old on the right side. The city center is governed by architectural controls of "System of Construction and Architectural Treatment of Exterior Controls". http://ijiet.com/wp-content/up loads/2016/08/10.pdf

Are The Urban Design Guidelines Similar To Form Based Codes.

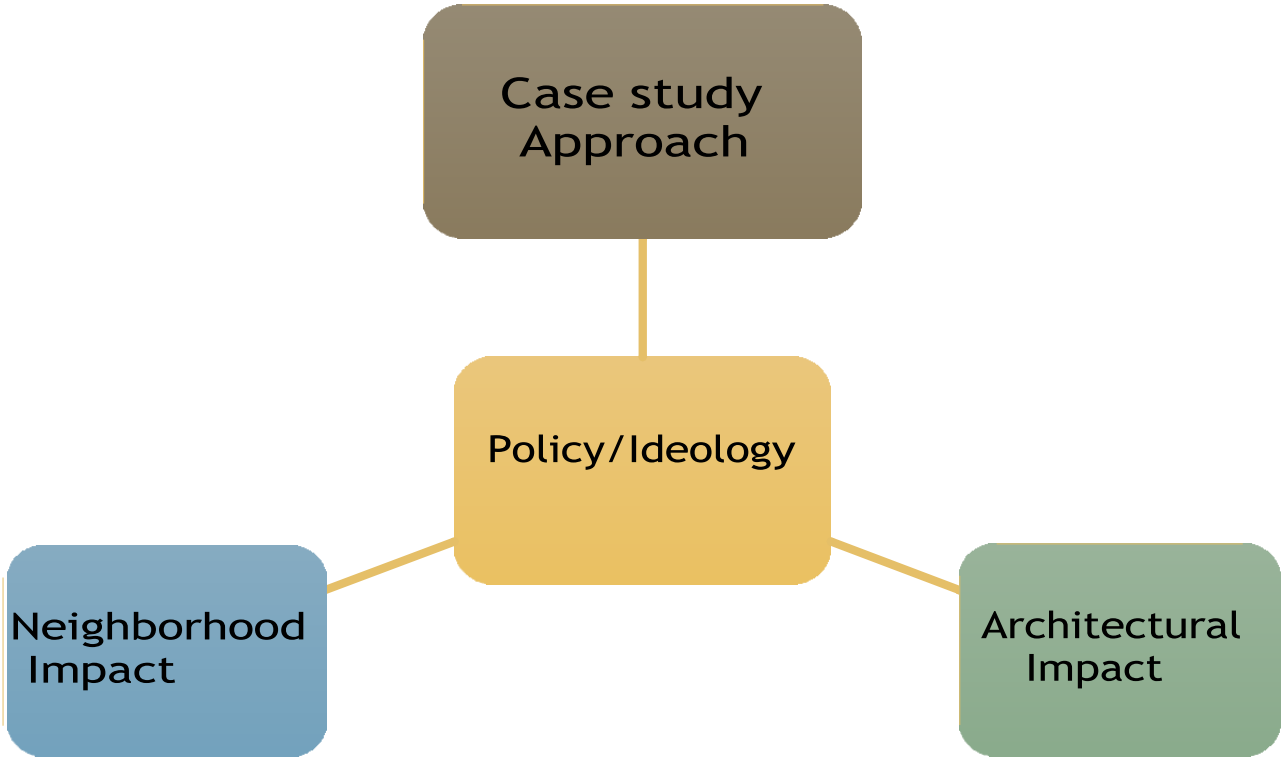
An Ideal Place

Many countries have started to take initiative in planning and designing places that are livable sustainable and forms identity of that place.
Many planners and philosophers have tried to achieve that vision of an ideal place for over decades now. In the last century Conventional planning or use based planning or we can also call it as Euclidean zoning have been the most common one.
Factors comprising to make a place ideal Source : Shweta Kapoor 2023

Approach:



New Urbanism

'New Urbanism is a planning and development approach based on the principles of how cities and towns had been built for the last several centuries: walkable blocks and streets, housing and shopping in close proximity, and accessible public spaces. In other words: New Urbanism focuses on human-scaled urban design'. According to the Congress of the New Urbanism,[CITATION CNU22 \l 16393]

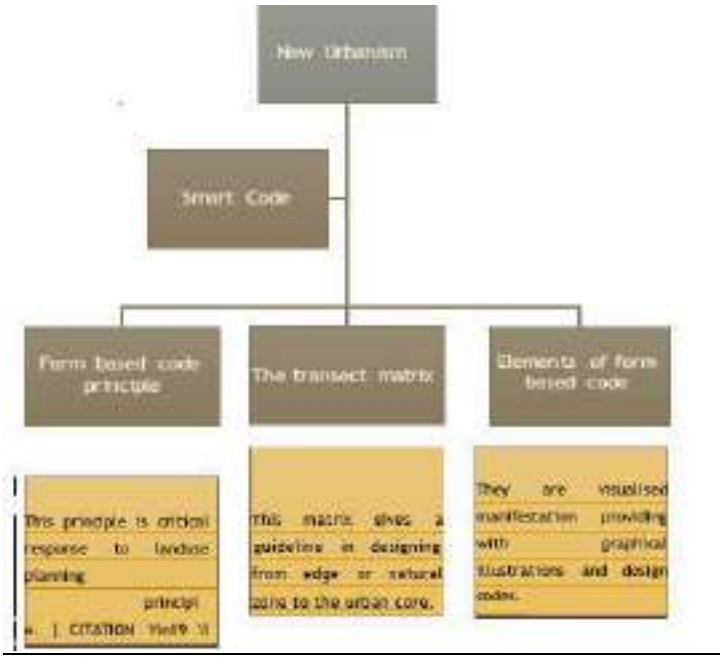


Table 1- New Urbanism Heirerchy Source : 2023

Form - Based Code

What is form based Code?

According to [CITATION For16 \l 16393] 'A form-based code is a land development regulation that fosters predictable built results and a high-quality public realm by using physical form (rather than separation of uses) as the organizing principle for the code. A form-based code is a regulation, not a mere guideline, adopted into city, town, or county law.'

Conventional zoning

- *In conventional zoning the city or town is divided in different landuse typessuch as residential, commercial, industrial, recreational, etc.[CITATION Pla \l 16393].*
- *Conventional zoning also known as Euclidean zoning was formulated keeping public health in mind, by separating residential and industrial zones.*
- *This planning guideline gained popularity in early 20th century and was practiced far and wide.*
- *But rapid urbanisation gave rise to urban sprawl and due to division of landuse dependency on automobile increased manifold times. [CITATION Yin19 \l 16393]. Thus, there was a need of a new planning methodology to replace this traditional zoning.*

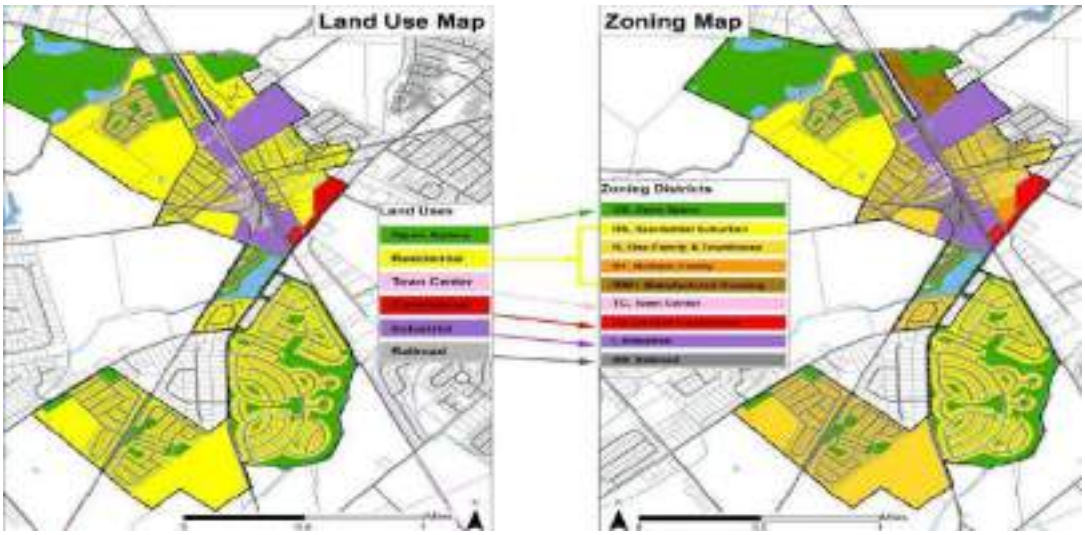

***Figure 1** - Land use map vs zoning map*

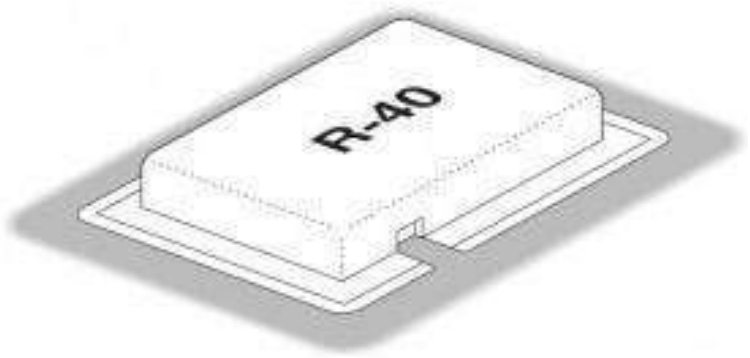
Source [CITATION Lan \l 16393 CITATION Lan \l 16393] : [CITATION Lan \l 16393 CITATION Lan \l 16393]

Form Based Code Principle

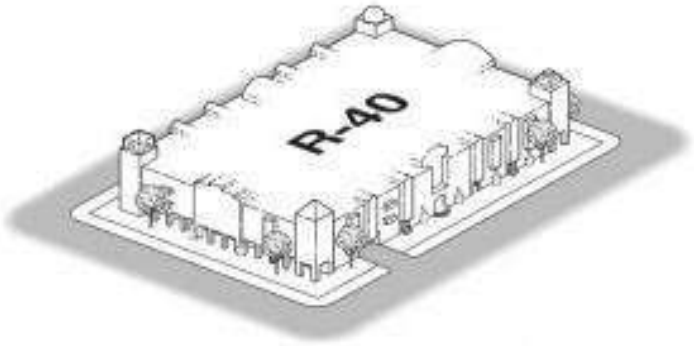
How conventional zoning designs a block or area?

- Density Use
- FAR (Floor Area Ratio)
- Building setbacks
- Parking requirements
- Maximum building heights



How Zoning design guidelines, define a block?

- Density Use
- FAR (Floor Area Ratio)
- Building setbacks
- Parking requirements
- Maximum building heights
- Frequency of Openings
- Surface Articulation



How Form- based code, defines a block

Street and building types

- Build-to lines
- Number of floors
- Percentage of built site frontage specified
- .

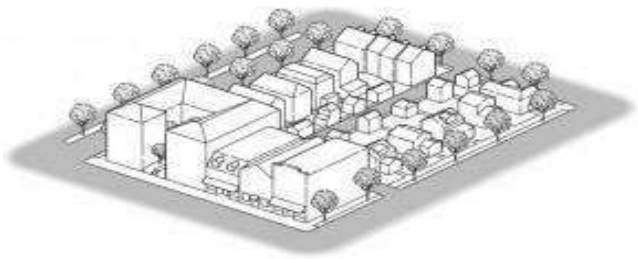


Figure 2 - Comparison between convention zoning, zoning design guildelines and form-based code

Difference between conventional/ Euclidean zoning and Form based code

	Euclidean Zoning	Form based code (FBC)
1	Giving an area or landmass certain Land use is a primary factor in Euclidean zoning.	Understanding the Physical form and the contextual need of the place are primary factors in Form based code planning.
2	District plan	Neighbourhood plan
3	Dependency on automobiles increased for eg. local business were placed outside residential zone.	Self sustaining neighbourhood led to increased walkability and reducing dependency on automobiles.
4	Landuse specific planning principle.	Mixed land use planning principle including walkability, easy access and compact plan.
5	Housing discrimination and racial segregation increased. [CITATION Pla \l 16393]	Mixed landuse planning decreased housing discrimination.[CITATION Pla \l 16393]
6	Plot ratio, density is taken into consideration in terms of the landuse whose outcomes can be quite unpredicatable for different plot. [CITATION Yin19 \l 16393]	While setting standards and parameters such as frontage, building line, etc. the form is taken into consideration rather than generalised landuse rules. [CITATION Yin19 \l 16393]

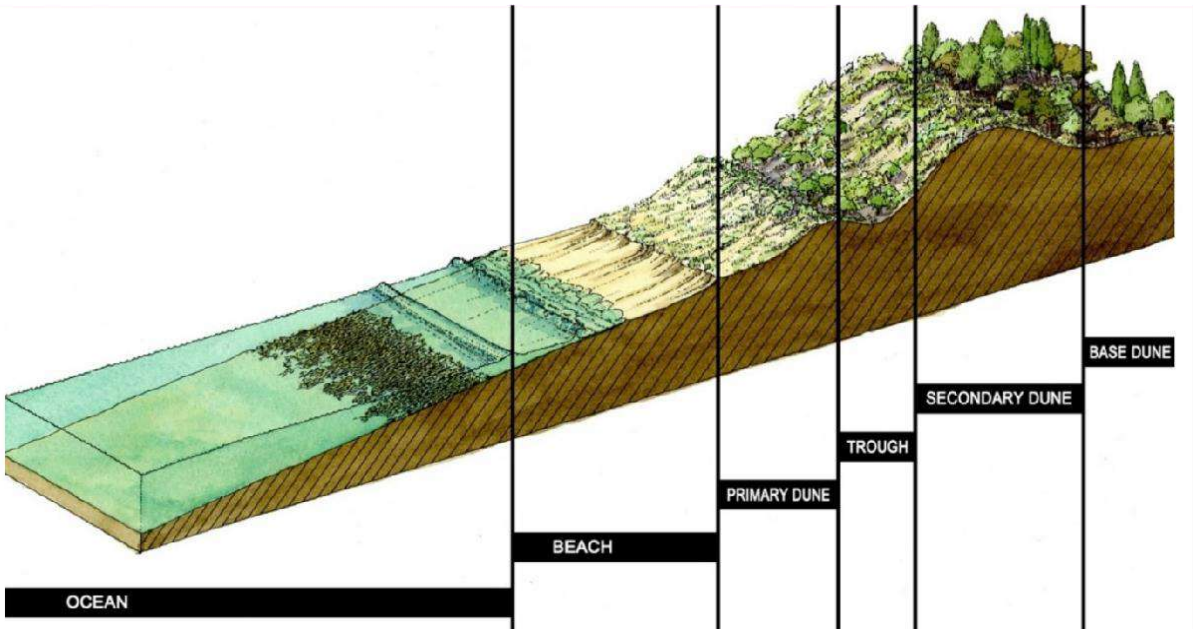
Conventional zoning model vs Form based zone model

Figure 3 3 - Conventional Zoning Source : [CITATION Yin19 \l 16393]

Figure 4 4 - Form-based code Source : [CITATION Yin19 \l 16393]

The Transect Matrix

According to ecologists, the transition of ecosystem from one habitat to another depending on the characteristics of that ecosystem can be described as



Transect [CITATION Ste09 \l 16393].

Figure 5 - Transect from ocean to dune in ecosystem Source :[CITATION The \l 16393]

Similarly, there is a transition from rural – to - urban settlement patterns. This transect gives rise to different zone types depending on the urban characteristics and hierarchical development of that zone [CITATION The \l 16393]. Thus, in 2003, Duany Plater Zyberk & Company, wrote standards for Transect based matrix which further formed the framework for Form based code.

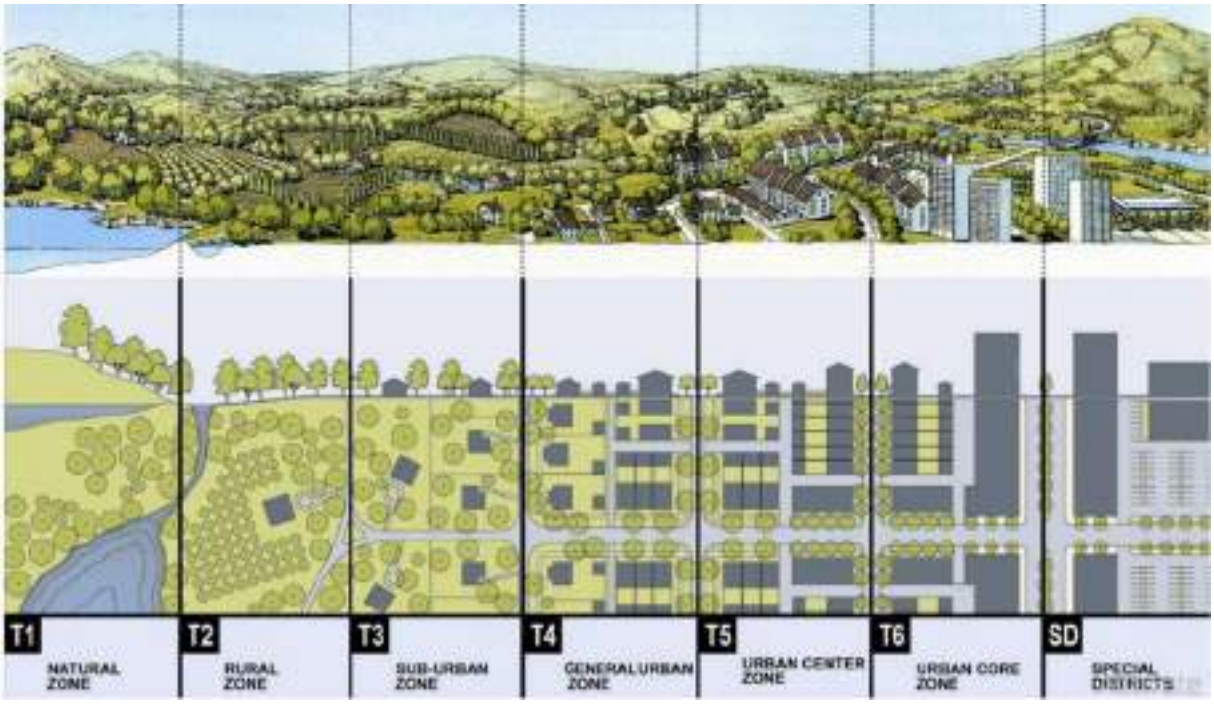


Figure 6 - Standard Transect Matrix of Form based code Source : [CITATION Yin19 \l 16393]

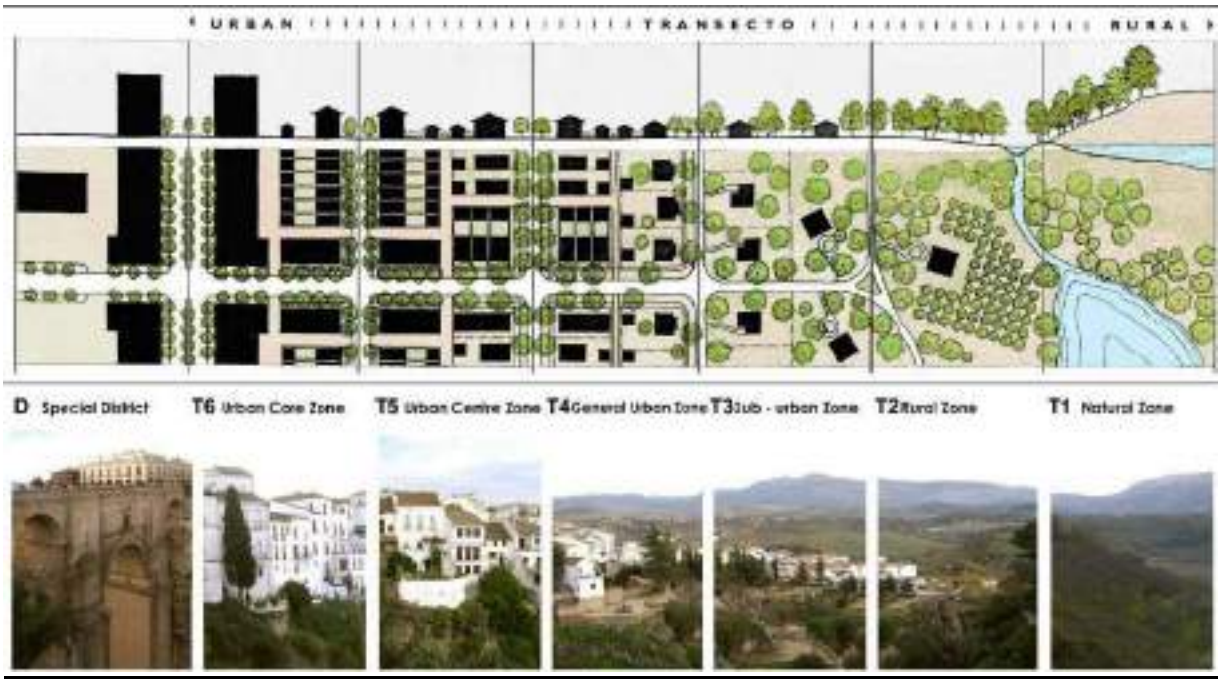
Transect Matrix zone application in Europe



Ronda Spain

Figure 7 - Transect matrix zone of Ronda, Spain Source : [CITATION Cen \l 16393]

Pienza Italy

The figure below shows a gradual transect section of Pienza, Italy. The left side shows a gradual transition from T-2 zone to T-5 zone. But on the right side there is a drastic transition from T-5 zone to T-2 zone which at the city wall. Such transitions are quite intriguing and are very much similar to the central park in New York city. [CITATION Cen \l 16393]

Figure 8 - Transect section of Pienza Italy Source : [CITATION Cen \l 16393]

Hammonton, New Jersey

The figure below shows the Plan of Hammonton in New Jersey adopting form based code where they used transect matrix zoning, but changed the nomenclature of T- zones to district zones according to the city's need. Their transect zones are as follows.

- Gateway Crossroads (G3),
- Gateway Boulevard (G2),
- Gateway Avenue (G1),
- Near Town (D1),
- In Town Railway (D2),
- In Town (D3), and
- Main Street (D4),

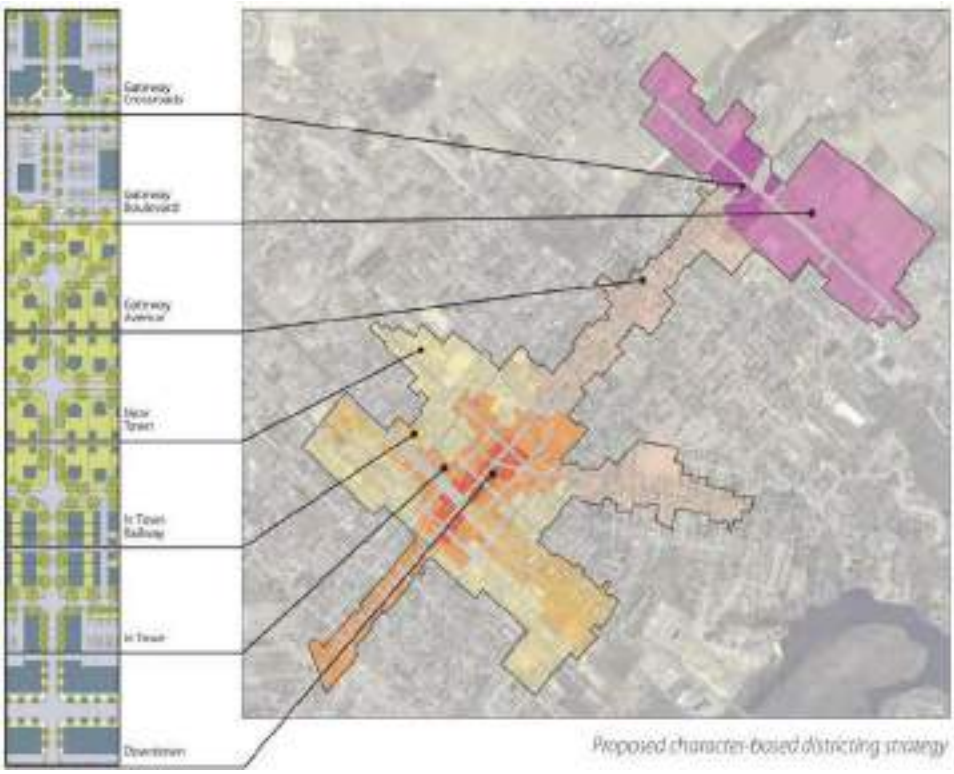


Figure 9 - *Form based code, Regulating plan of Hammonton Source : [CITATION Sli12 \l 16393]*

Elements of form based Code

Conventional zoning included standards mostly in text format on contrary to form based code which emphasizes more on graphical and pictorial representation while setting regulations & standards.

1. *Regulating Plan*

   'A regulating plan is essentially a fine – grained zoning map combined with a street plan, keyed to a set of standards….Each street, block, or parcel must comply with illustrated standards in the FBC.' [CITATION Mar14 \l 16393]

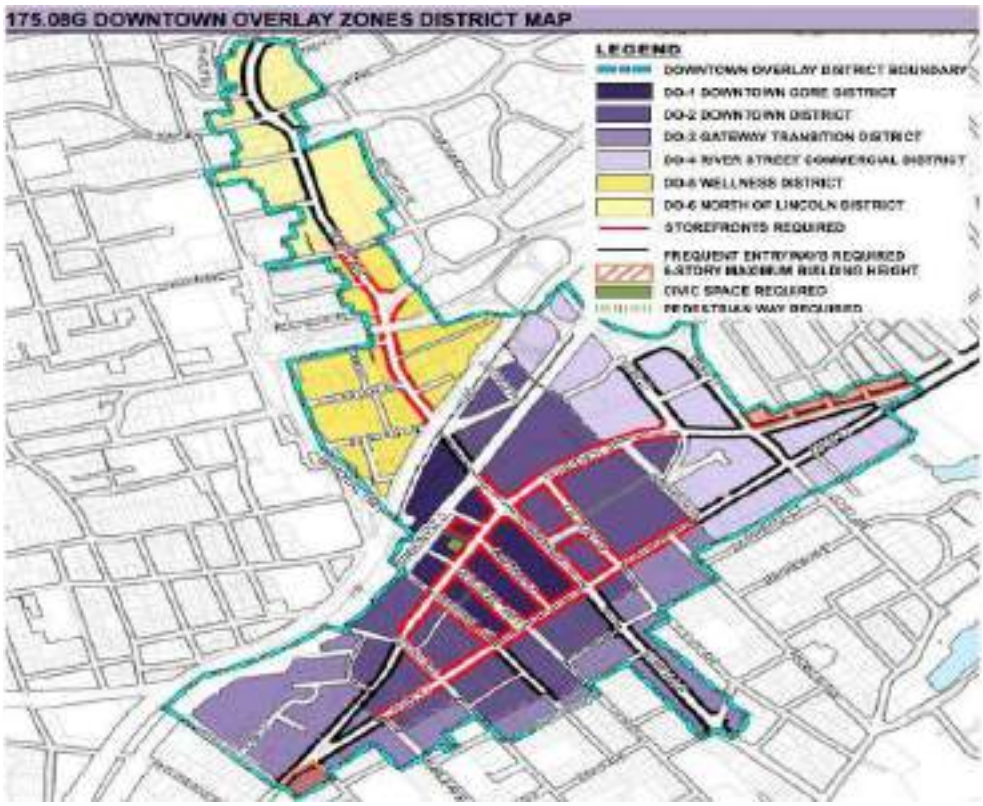

Figure 10 - *Regulating Plan of City of Rochelle as a form based code, Source : [CITATION For20 \l 16393]*

1. **Public Standards**

Public standards are generally applied to the designated regulating plan that encompasses everything that comes in public realm. The codes are generally applied to sidewalks, travel lanes, on-street parking, street trees, and street furniture. [CITATION For16 \l 16393]

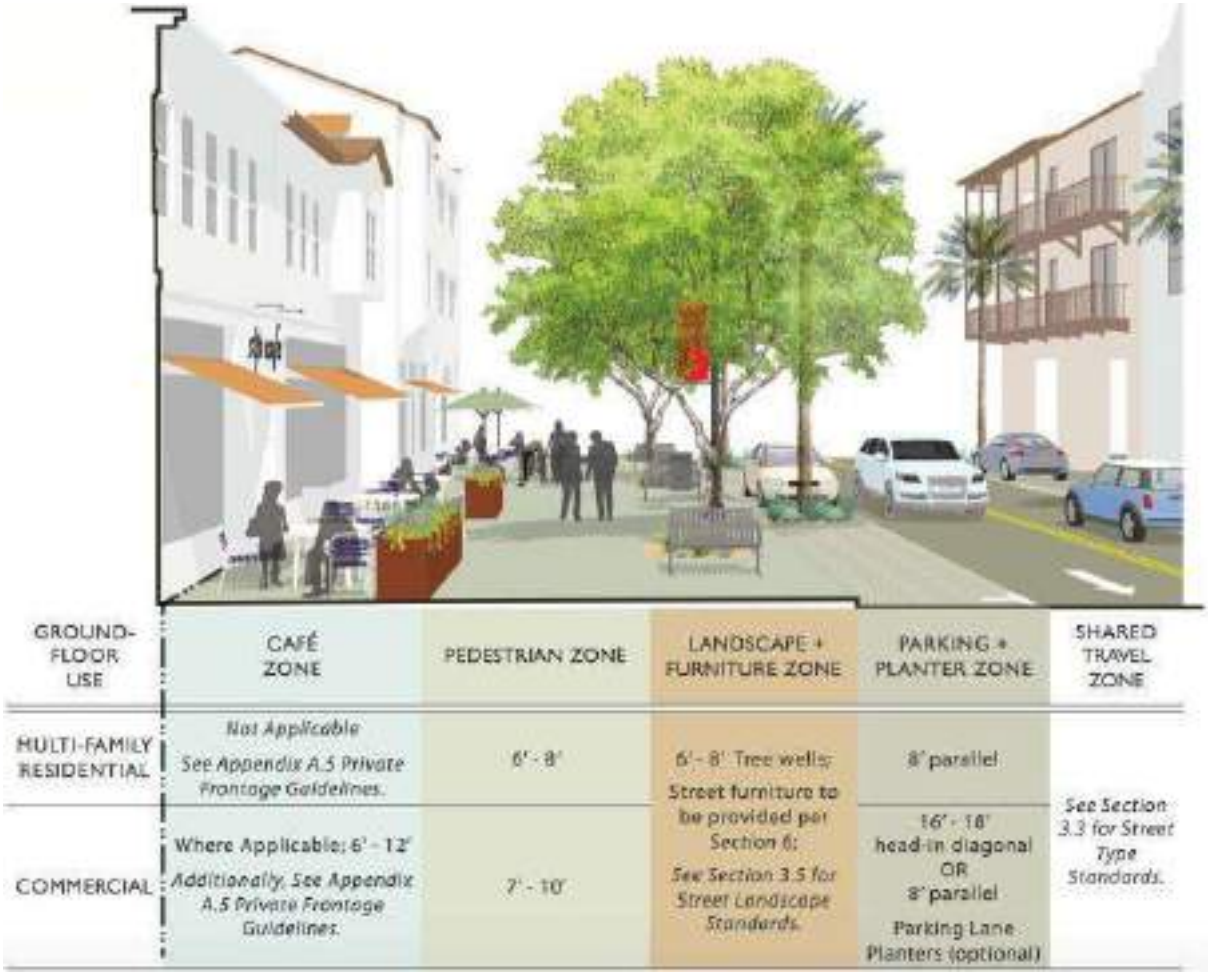

Figure 11 - Public standards in form based code,

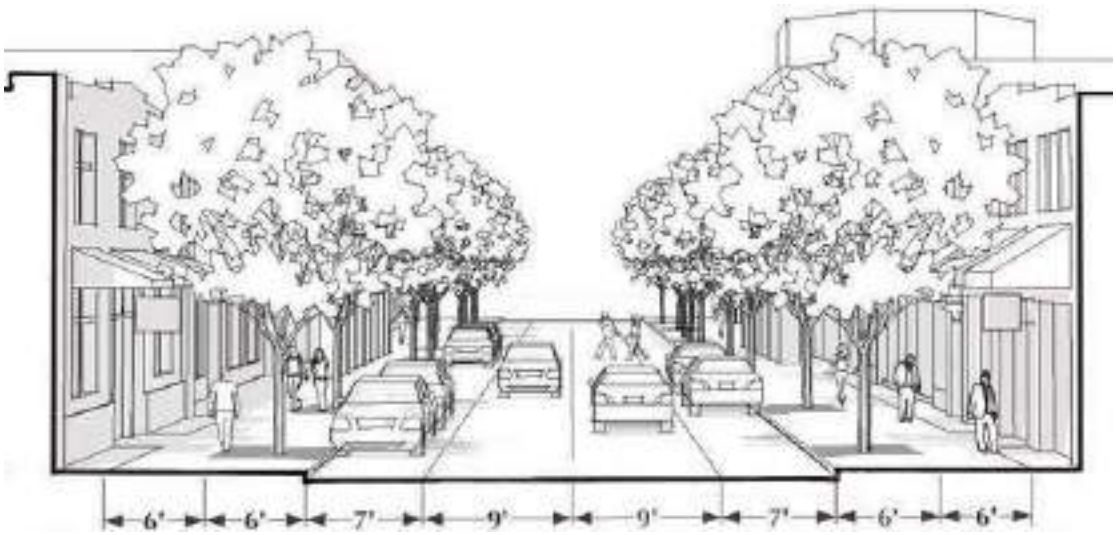
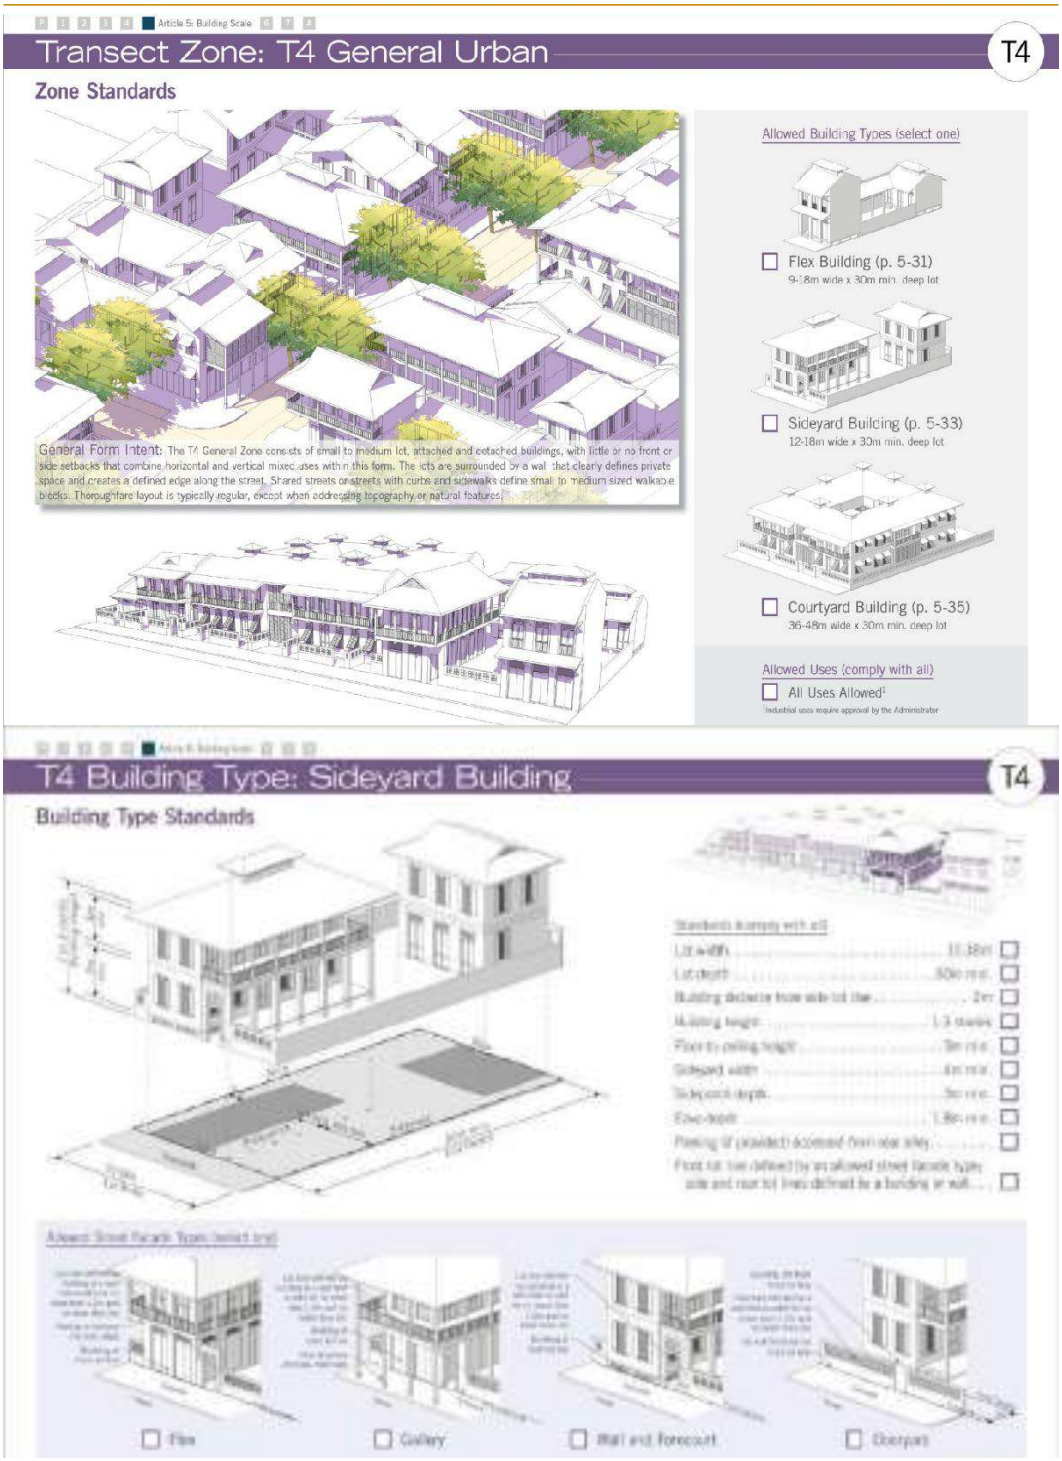


Source : [CITATION Sma19 \l 16393]

Figure 12 - Schematic cross section of a mixed landuse street in florida, Source : [CITATION Mar14 \l 16393]

2. **Building Standards**



[CITATION Yin19 \l 16393]

Figure 135 - Building Standards forAkanda Source :[CITATION Opt21 \l 16393]

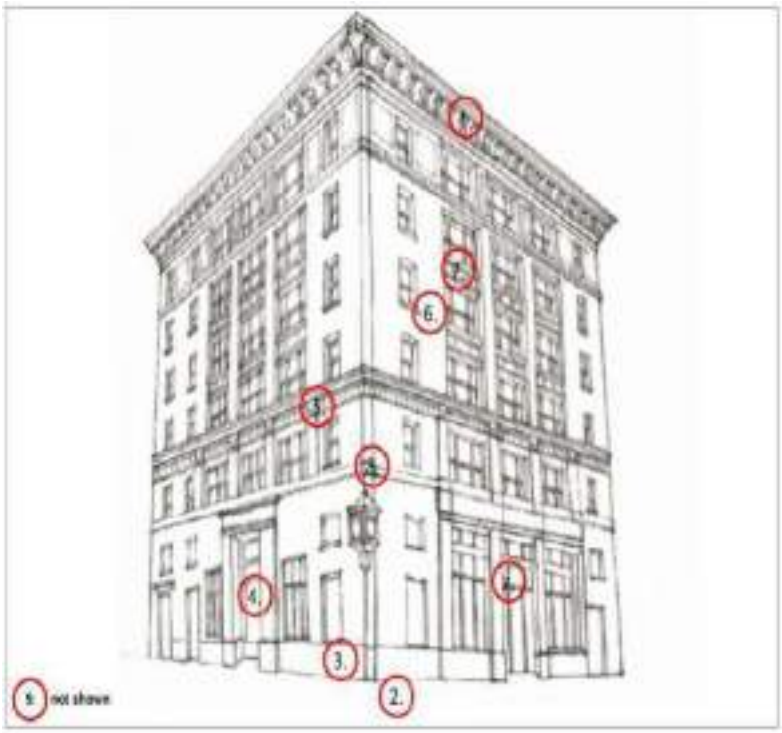
The standards set for the form and configuration of the building is regulated in building standards. These standards may also include parking standards and their placements, allowed encroachments as well as building typologies too.

3. Administration
   Administration outlines clearly defined application, project reviews and spells out how the process will occur.[
4. Definitions
   The glossary consists of definitions of all technical terms contained in the code. [CITATION For16 \l 16393]

5. Other optional Cases

- Architecture

Architectural standards include guidelines drawn for exterior of a building where material and designs are provided as well. They can be applicable to most heritage towns, but they are not compulsory. Mostly architectural standards depends on the scope of the project as well as objectives laid by the community.



Key Characteristics

1. **Roof** - flat roof with projecting cornice or parapet.
2. **Floor Plan/Elevation** - simple, rectangular plans with L-shaped or U-shaped variations.
3. **Base** - articulated base by change in material, change in plane, or both.
4. **Shading** - recessed arcades & entries, balconies, or fabric awnings.
5. **Form/Massing** - 1 to multiple stories, with base, middle, and top. Vertically proportioned with corner towers common.
6. **Walls** - flat planes of stone, brick, or plaster, punctuated by deep openings.
7. **Openings** - large storefront openings at ground, vertically proportioned, with transoms arranged in rhythmic pattern. Upper floors include combinations of small and large openings relating to ground level openings. Serial or symmetrical composition are typical.
8. **Articulation** - base, middle and top of facade are clearly defined by changes in material and horizontal banding. Ground floor and/or build-to/scaled base receive most detailed attention. Other details include cornices, balconies, awnings.
9. **Colors** - public buildings are more reserved, with muted colors. Otherwise, the palette is open to interpretation.

- ***Landscape***

'Some form-based codes include requirements to control the character and quality of the landscape within private spaces as it affects the public realm and the public good, such as requiring native species to address water usage, as well as screening parking lots from the street, buffering more or less intensive uses, and greening parking lots.'[CITATION Chi12 \l 16393]

Case study 1 – Miami 21 Code

Project details:

- Project size/area – 35,514 acres
- Client – City of Miami
- Date of Design – 2004
- Location – Florida, U.S.A.

Figure 15 *- Location of Miami,Florida Source : (2023)*

Figure 6 *- Fisher Island, Miami Source :[CITATION ADE19 \l 16393]*

'Miami was the first large American city to adopt SmartCode' [CITATION THE10 \l 16393].
Who wrote the Code?
Transect/Form based code was prepared by Duany Plater – Zyberk for the entire city of Miami which includes 37 square miles of land area. The document prepared for SmartCode provides both regulatory guidelines as well as solves liveability concerns which were difficult to achieve by old Euclidean zoning. [CITATION DPZ20 \l 16393]
How was the Code Adopted?
Miami adopted the Code in 2010 with a vision of smart growth and new urbanism. The city staf f and code prepares held more over 100s of public hearings and review meeting before replacing the Ordinance 11000. [CITATION Yin19 \l 16393]
Why was the Code prepared?

- *The code was in response to rapid urbanisation and clash between development along corridors and preservation of low to moderate intensity or single family housing.*
- *This lack of planning provision resulted in physically incompatible, out of scale developments with no provision for reinvestment. [CITATION DPZ20 \l 16393]*
- *There was a need of transition in approach as the city started to lose its identity.*

Transect Matrix Plan of Miami 21 Code
Transect Planning within Form-Based Code

The transect matrix of Miami contains more zones due to its high density morphology. Designers have further sub divided T6 zone into T6-8,T6-12,T624, etc. The customised Transect matrix also specifies landuse. But unlike Euclidean these are workplace, Industrial & waterfront industrial.

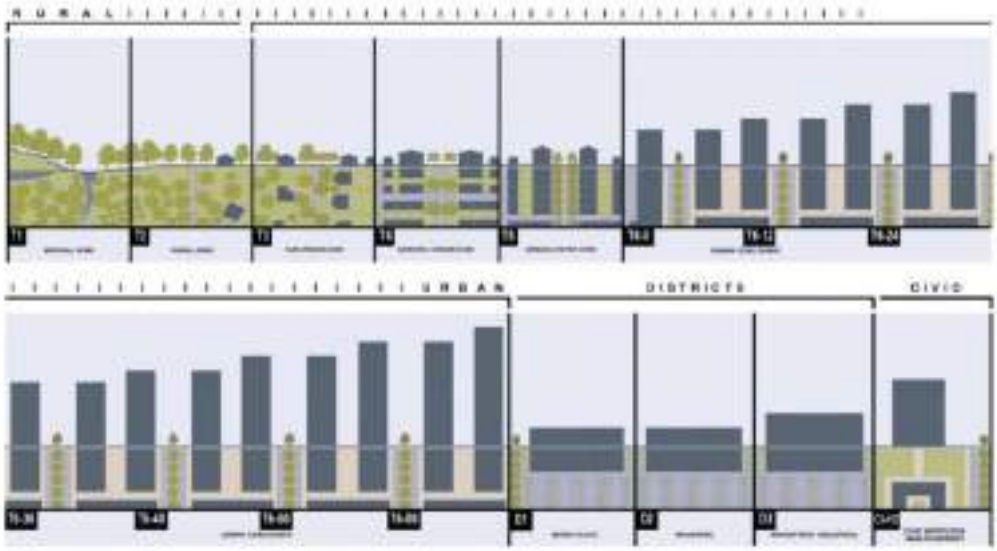


Figure 7 - *Transect zone plan of Miami, Source : [CITATION The10 \l 16393]*

Building Standards

[CITATION The10 \l 16393] has provided with a detailed standards guide with respect to its transect zone. Below is the example of guidelines provided in T6-24 zone

ILLUSTRATION 5.6 URBAN CORE TRANSECT ZONES (T6-24)

BUILDING DISPOSITION		BUILDING PLACEMENT
LOT OCCUPATION		a. Lot Area	5,000 s.f. min.; 100,000 s.f. max.	
b. Lot Width	50 ft min.	
c. Lot Coverage		
- 1-8 Stories	80% max.	
- Above 8th Story	15,000 sf. max. Floorplate for Residential & Lodging 30,000 sf. max. Floorplate for Office & Commercial	
d. Floor Lot Ratio (FLR)	T6-24a: 7 / 30% additional Public Benefit T6-24b: 16 / 40% additional Public Benefit	
e. Frontage at front Setback	70% min.	
f. Open Space	10% Lot Area min.	
g. Density	150 du/ac max.*	
BUILDING CONFIGURATION		**BUILDING HEIGHT**
FRONTAGE		a. Common Lawn	prohibited	
b. Porch & Fence	prohibited	
c. Terrace or LC	prohibited	
d. Forecourt	permitted	
e. Stoop	permitted	
f. Shopfront	permitted (T6-24-L and T6-24-O only)	
g. Gallery	permitted by Special Area Plan	
h. Arcade	permitted by Special Area Plan	
BUILDING HEIGHT		
a. Min. Height	2 Stories	
b. Max. Height	24 Stories	
c. Max. Benefit Height	24 Stories Abutting all Transects Zones except T3

Public Standards

	SECTION LOT PRIVATE Frontage | R.O.W. ◄ PUBLIC Frontage	PLAN LOT PRIVATE Frontage | R.O.W. ◄ PUBLIC Frontage
a. Common Lawn Frontage wherein the Façade is set back substantially from the Frontage Line. The front yard created remains unfenced and is visually continuous with adjacent yards, supporting a common landscape. The Setback can be densely landscaped to buffer from higher speed Thoroughfares.		b. Porch & Fence Frontage wherein the Façade is set back from the Frontage Line with an attached Porch permitted to encroach. A fence at the Frontage Line maintains the demarcation of the yard while not blocking view into the front yard.		c. Terrace or Light Court Frontage wherein the Façade is set back from the Frontage Line by an elevated terrace or a sunken light court. This type buffers residential use from urban sidewalks and removes the private yard from public encroachment. The raised terrace is suitable for outdoor cafes.		
d. Forecourt Frontage wherein a portion of the Façade is close to the Frontage Line with a portion set back. The forecourt with a large tree offers visual and environmental variety to the urban Streetscape. The

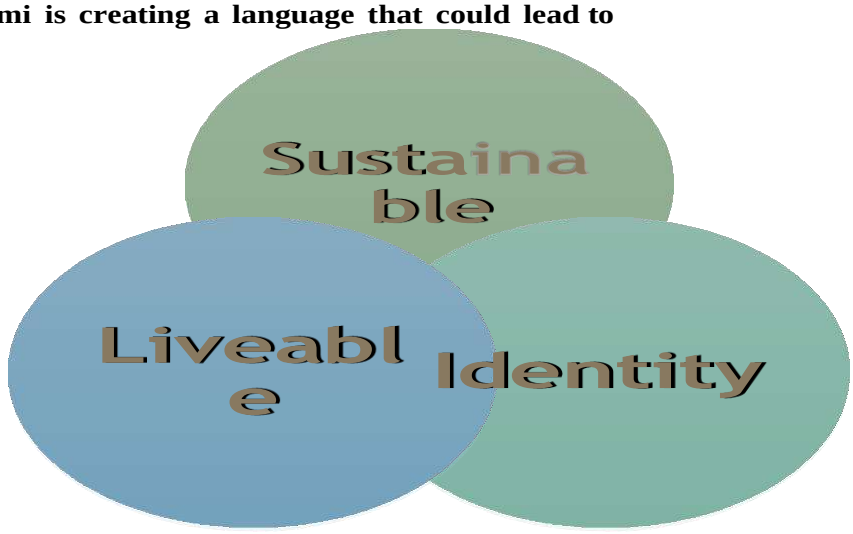
How Form-Based Code in Miami is creating a language that could lead to



Sustainability –

- Incorporation of LEED building standards for buildings that are 50,000 square feet and above
- Energy substitutes and initiatives like Green Corridor Property Assessed Clean Energy (PACE) program and renewable energy resources have been incorporated for areas that are already developed.
- Miami Green Lab is an inititive started by the council under FBC ordinance where it serves as a green building resource center for community, it also imparts education on energy conservation, urban agriculture and green buildings.
- The FBCs also have made a code of ordinances where the city has adopted Tree masterplan to increase the overall health of trees, that set a goal of achieving 30% tree canopy.

Livability –

- Due to incorporation of FBCs the standard of living has been increased manifold times. Rick Bernhardt the former executive director mentioned that after adopting FBCs the economy of the place have also increaseddue to development and mixed use planning.
- Car dependency increases due to Form based code planning and zoning as it keeps the community convenience in mind.
- Sustainable cities also increases the livability of a place. And Miami has recently earned LEED Gold certification.

Identity –

Transect matrix planning helps to retain the character of the place and gives experiential identity to a place.

Before

Figure 9 - Transforming Blank wall (Before) Source : [CITATION The10 \l 16393]

Transforming Blank Wall

Figure 10 - Transforming Blank wall

(After) Source : [CITATION The10 \l16393]
Figure 7 shows how the blank walls and open parking areas which were abutting to the main roads have been completely transformed into a residential area. FBCs also promotes reconstruction of area that has a potential in transforming a neighbourhood.

Urban Infill Redevelopment

Figure 11 - Urban Infill Redevelopment, Source : [CITATION The10 \l 16393]

Figure 12 - Urban Infill Redevelopment, Source :[CITATION The10 \l 16393]

Green Corridors and urban infrastructural development helps in increasing the livability of the place.

Turning Development Outward

Figure 13 *- Turning Development Outward, Source : [CITATION The10 \l 16393]*

Figure 14 *-- Turning Development Outward, Source : [CITATION The10 \l 16393]*

The ordinances also mentions of designing a commercial place that is more welcoming and not leaving any place between road and the property. There are different by-laws that helps understand the frontages of lots and buildings.

Mixed-Use Corridors with Transit

Case Study 2 – Downtown Code for Nashville

Project details:

- ***Project size/area – 388 acres***
- ***Client – City of Nashville***
- ***Date of Design – 2010***
- ***Location – Tennessee, U.S.A.***

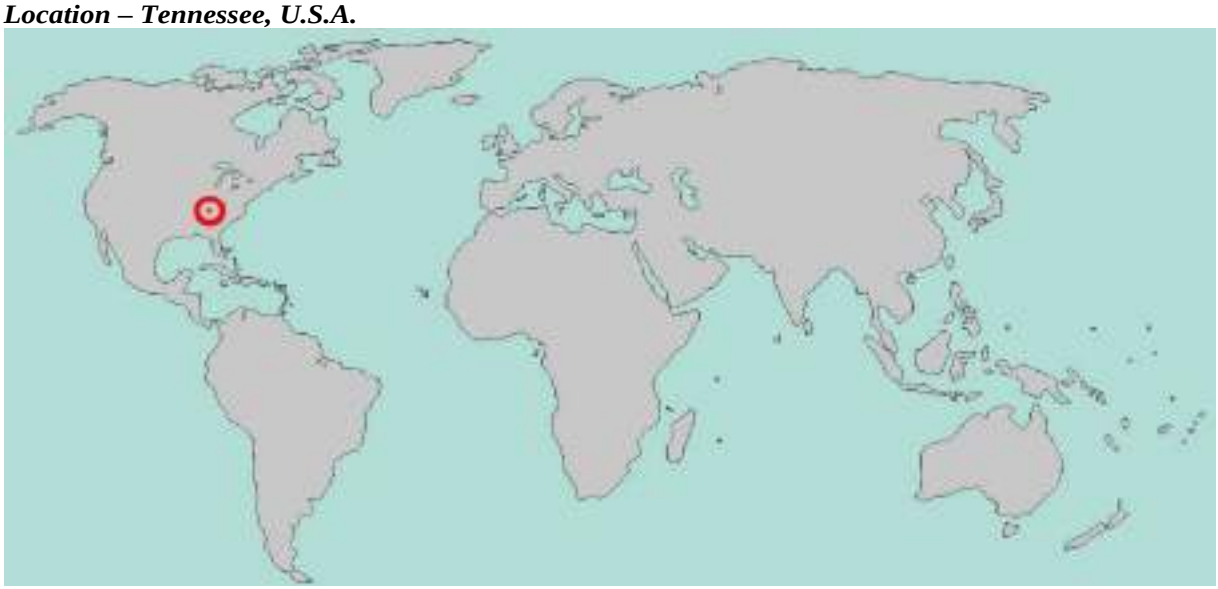

Figure 33 - Location of downtown Nashville, U.S.A. *Source : (2023)*

Why this case study?

case study is done to give an example on how a form based code can be applied only to a small part or the Regulating Plan**.**

Figure 34 - Downtown Nashville, U.S.A. Source: [CITATION Cve00 \l 16393]

Who wrote the Code?

Rick Bernhardt, former executive director, Planning Department, Metropolitan Nashville and Davidson County. He is also one of the board members of Form –ased Code institute as well as he was a chair member of planners force task for the Congress of New Urbanism.[CITATION Ros181 \l 16393].

How was the Code Adopted?
The Code was adopted in 2010, by means of community involvement and making them as key stakeholders and the city planning department. [CITATION Met \l 16393]

Why was the Code prepared?
- The cities wheel – to – spoke planning pattern led to create a good connectivity to the the neighbouring cities.
- This pattern also led to increased dependency on vehicles.
- Nashville being one of the oldest music town it always faced the issue of urbanisation which led to sprawl development and the traditional zoning was being incompetent to the growing needs of the city.

Transect Matrix of Nashville

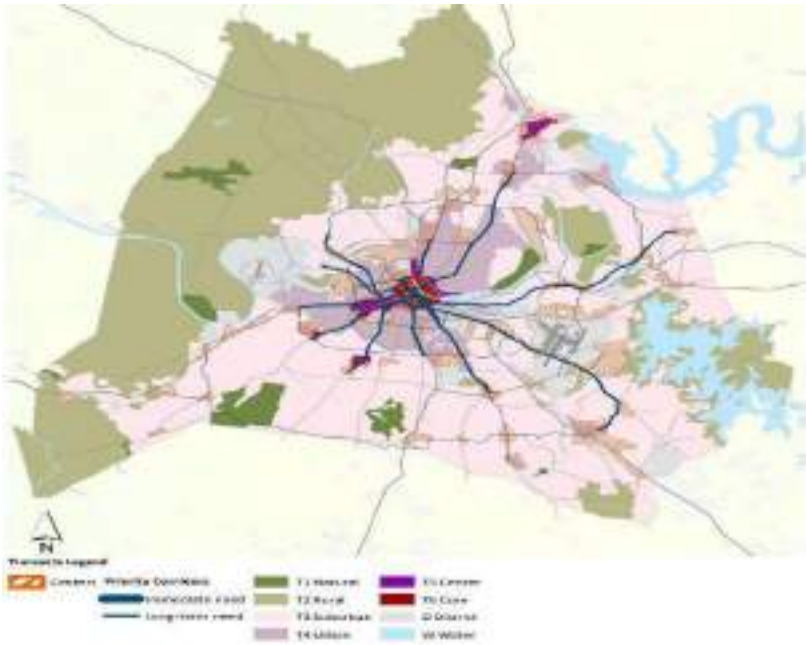

Figure 35 - Transect plan for Nashville Source : [CITATION Met \l 16393]

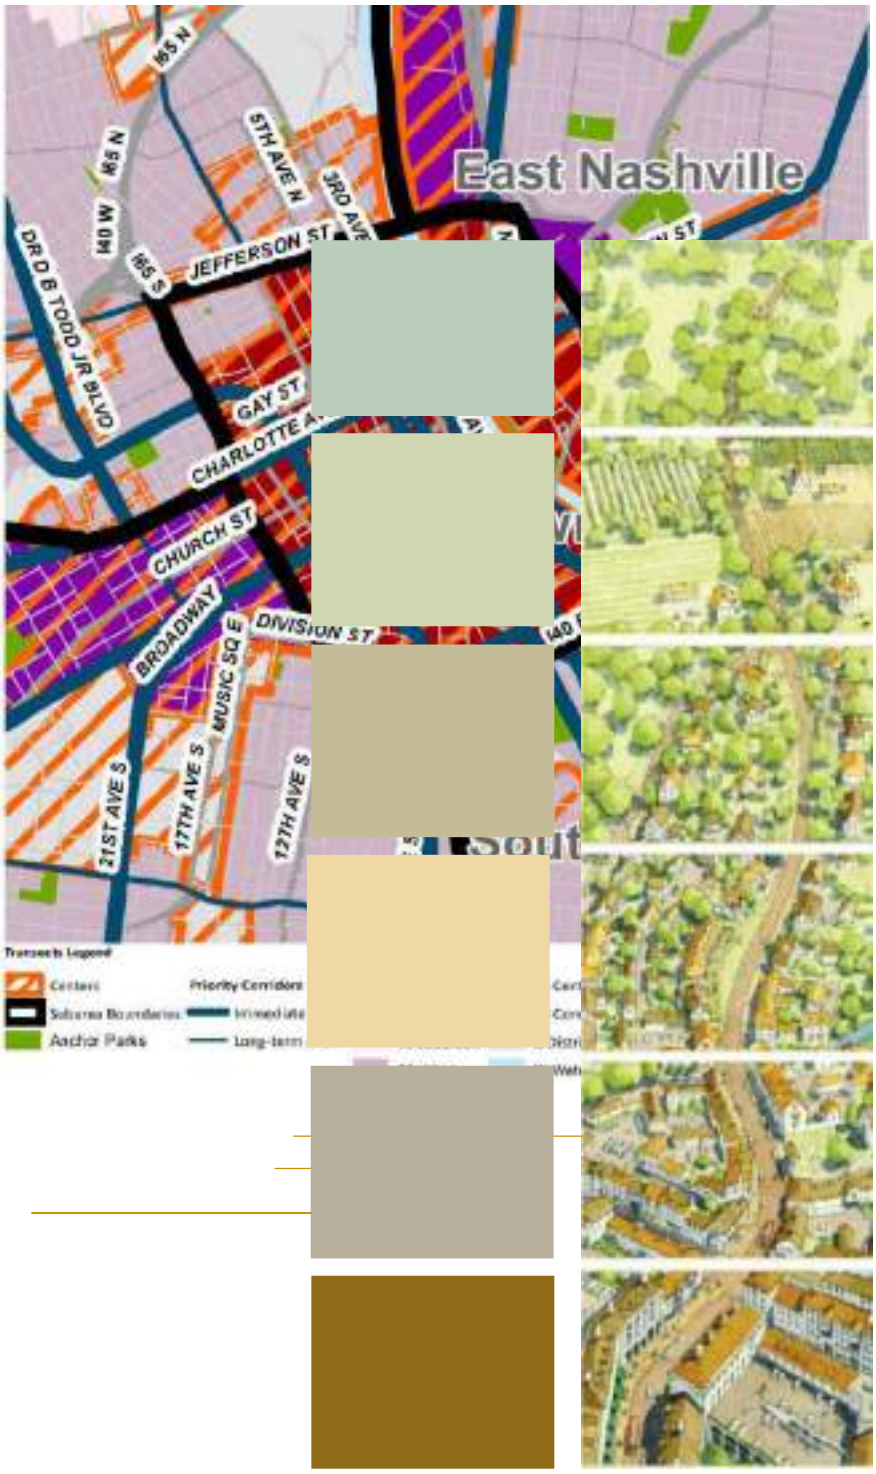
The transect plan was adopted only for the core downtown area as shown below in Figure 36 - Transect Matrix for Downtown Nashville

Figure 36 - Transect Matrix for Downtowndraw guidelines and code Source : [CITATION Met22 \l 16393



.

T6 – Downtown Encompasses all the downtown region.

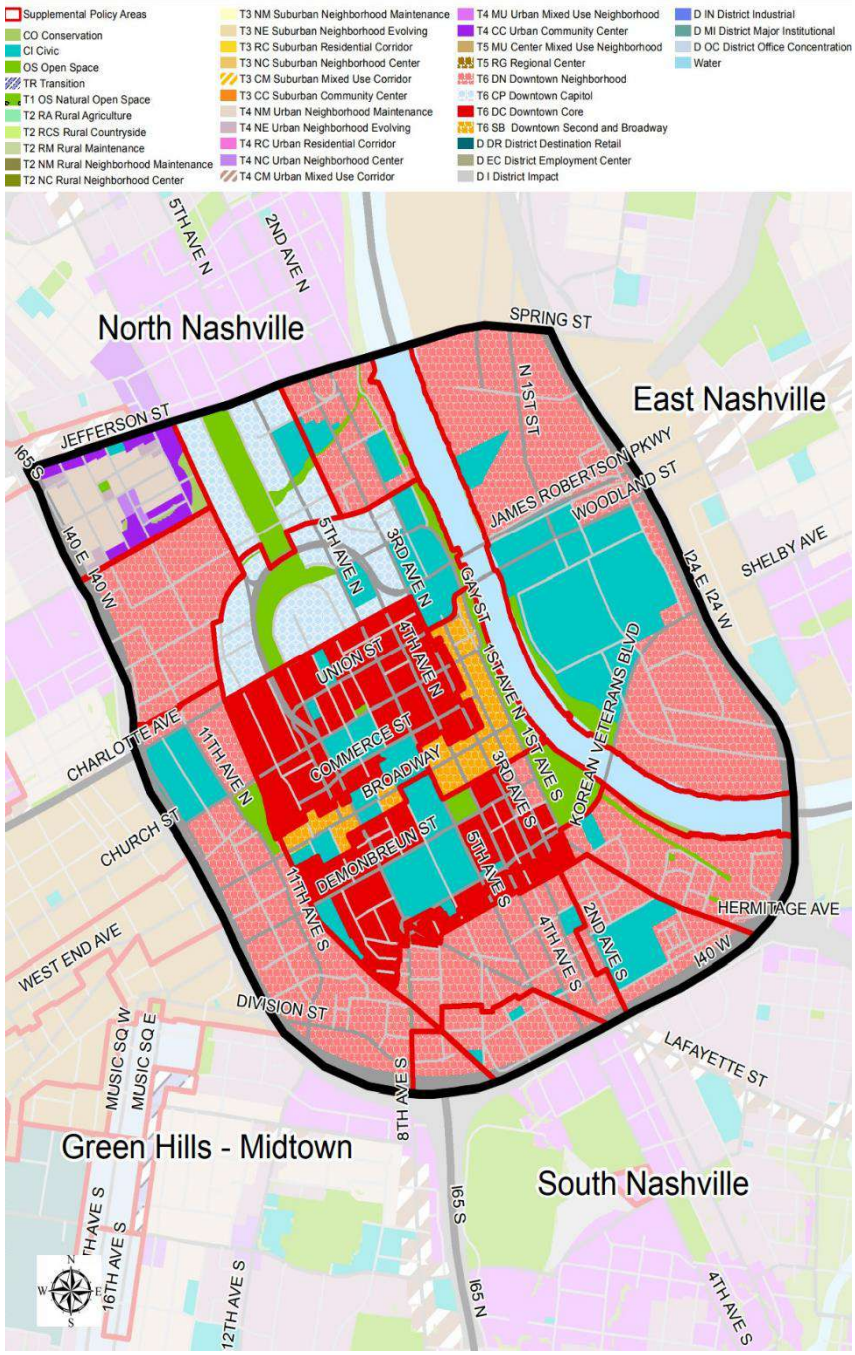


Figure 38 *– Regulating Plan of Subdistrict Boundaries Source : [CITATION Nas17 \l 16393]*

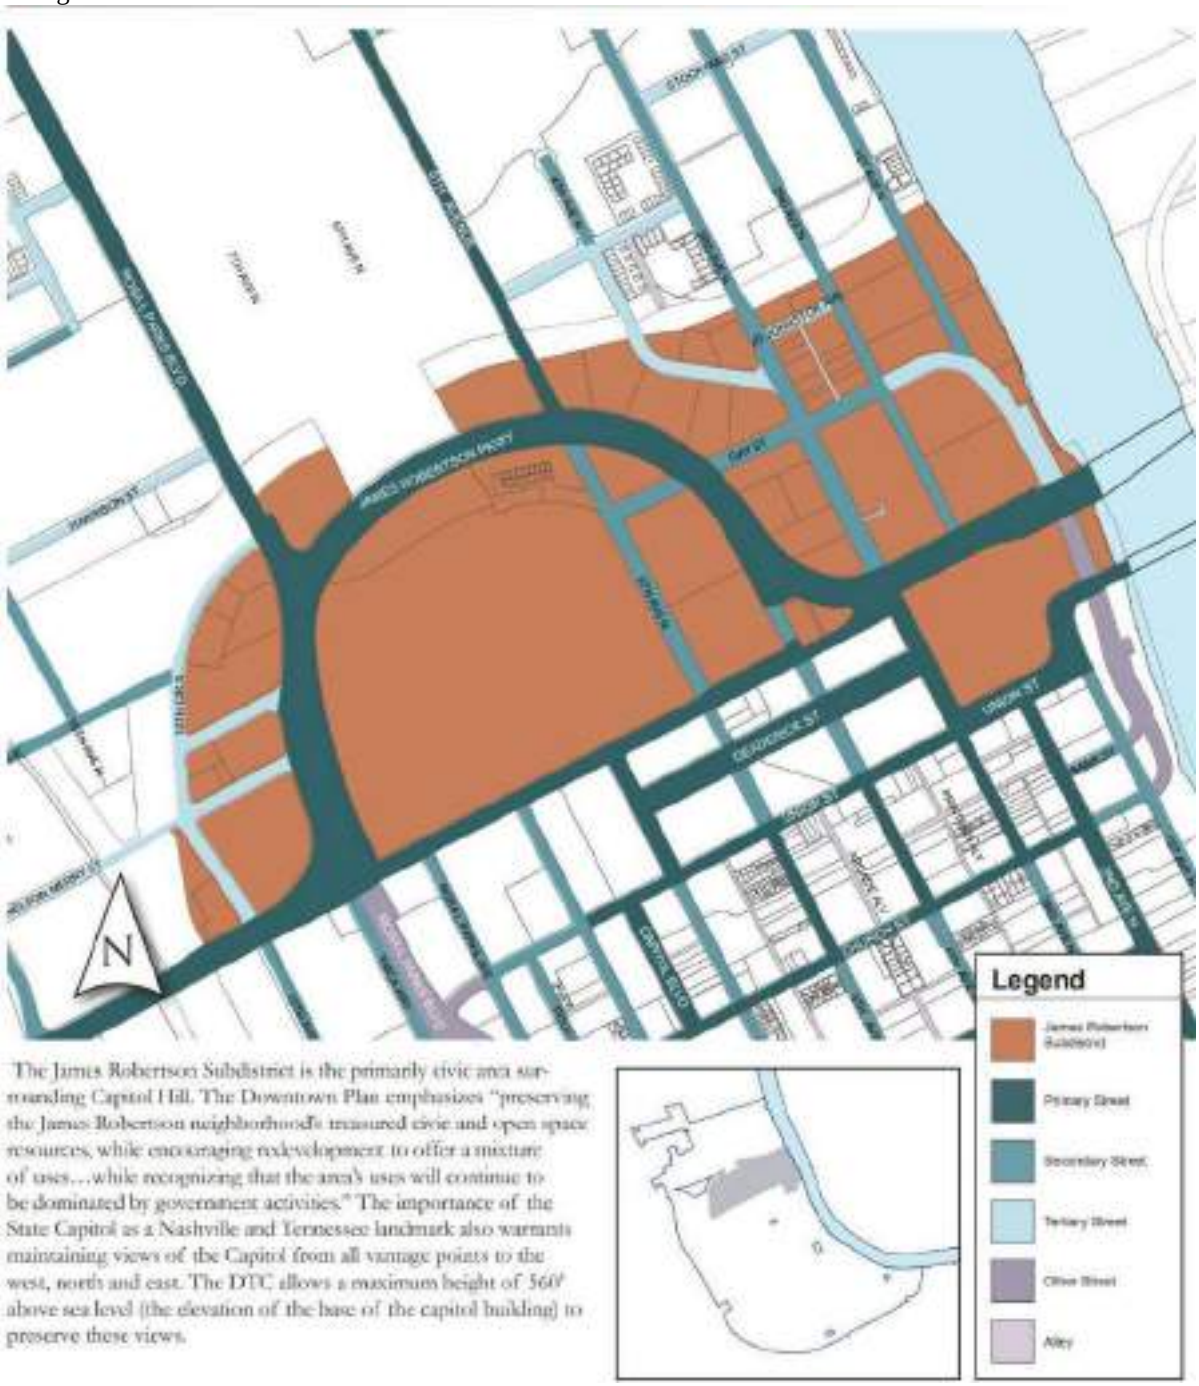
Regulating Plan – James Robertson Subdistrict



The James Robertson Subdistrict is the primarily civic area surrounding Capitol Hill. The Downtown Plan emphasizes "preserving the James Robertson neighborhood's treasured civic and open space resources, while encouraging redevelopment to offer a mixture of uses…while recognizing that the area's uses will continue to be dominated by government activities." The importance of the State Capitol as a Nashville and Tennessee landmark also warrants maintaining views of the Capitol from all vantage points to the west, north and east. The DTC allows a maximum height of 560' above sea level (the elevation of the base of the capitol building) to preserve these views.

Figure 39 - *James Robertson Subdistrict Regulating Plan*

Building Standards

Frontage

A Allowed Frontage Types with Required Build-to Zone

Primary Street
- Storefront Frontage
  - James Robertson Boulevard
    - West of 3rd Ave 20'-30'
    - East of 3rd Ave 0'-10'
  - Charlotte Avenue 0'-10'
- Stoop Frontage
  - James Robertson Boulevard
    - West of 3rd Ave 20'-30'
    - East of 3rd Ave 5'-10'
  - Charlotte Avenue 5'-10'

Secondary Street
- Storefront Frontage 0'-10'
- Stoop Frontage 5'-10'

Tertiary Street
- Storefront Frontage 0'-10'
- Stoop Frontage 5'-10'

B Facade width

Primary Street	80% of lot frontage min.
Secondary Street	60% of lot frontage min.
Tertiary Street	60% of lot frontage min.

Remaining lot frontage may be used for pedestrian amenities and shall not be used for parking.

C Min. building depth 15' from building facade

A building liner is required surrounding parking structures on the all floors facing James Robertson Blvd.

Height

D Max. elevation of 560'

Step-back *

Step-back required for all buildings 8 stories or greater on all public streets and Open Space

E Step-back between 4th and 8th stories

F Min. step-back depth 15'

* see page 61 for full description

Sidewalk & Planting

Improvements to the sidewalk corridor according to the General Standards and the Major and Collector Street Plan.

"IMPACT OF AWARENESS PROGRAM ON KNOWLEDGE REGARDING COMMON BOTTLE-FEEDING PROBLEMS IN INFANTS AMONG MOTHERS"

[1]Dr Amit Vyas
[1]Principal
[1]Aarihant Institute of Nursing, Swarrnim Startup Innovation University, Gandhi Nagar, Gujrat, India,

ABSTRACT
The current study has been undertaken to assess knowledge score regarding common bottle-feeding problems among mothers by awareness program in selected community area of Gandhi Nagar, Gujrat. The research design used for the study was pre-experimental in nature. The tool for study was self-structured knowledge questionnaire which consists of 2 parts- PART- I consisted of questions related to Socio-demographic data; PART-II consisted of self -structured knowledge questionnaire to assess knowledge score regarding common bottle-feeding problems among Mothers. The data was analyzed by using descriptive & inferential statistical methods. The most significant finding was that 25.0% of Mothers were having average knowledge regarding common bottle-feeding problems whereas 75.0% had good knowledge after post-test. It was suggested that nurses must educate mothers regarding common bottle-feeding problems.
Keyword- Awareness program, common bottle-feeding problem, mothers.

Introduction

Most often mothers find problems when bottle feeding their infants. Some of these problems are minor and can be rectified easily and with not much fuss and hassle. However, for major and health problems, your doctor should be the first one to be contacted. It is good to get educated before you start bottle feeding your child and this should be from a reliable and good source.

Do not forget that although breast feeding is said to be natural and good since many years, it lacks some important ingredients for the right growth of mind and body of the infant. These are added to the formula feed as they are prepared scientifically and contain measured ingredients. **Common types of bottle-feeding problems**

- Turning away from the bottle.
- Gagging or fussing as the bottle's nipple nears their mouth.
- Being unable to latch/compress the bottle's nipple and express milk.
- Chewing on the bottle's nipple.

Sputtering or coughing while feeding.

Objective of the study

1. To assess the pre-test & post-test Knowledge score regarding common bottle-feeding problems among Mothers.
2. To assess impact of awareness program on knowledge regarding common bottle-feeding problems among Mothers.
3. To find out association between pre-test knowledge score regarding common bottle-feeding problems among Mothers with their selected demographic variables

Hypotheses:

RH_0: There will be no significant difference between pretest & post-test knowledge score on common bottle-feeding problems among Mothers.

RH_1: There will be significant difference between pretest & post-test knowledge score on common bottle-feeding problems among Mothers.

RH_2: There will be significant association between pre-test score on common bottle-feeding problems among Mothers with their selected demographic variables.

Assumption

1. Mothers may have deficit knowledge regarding common bottle-feeding problems.
2. Awareness program will enhance knowledge of Mothers regarding common bottle-feeding problems.

Methodology

An evaluative approach was used and pre-experimental one group pre-test post-test research design was used for the study. The samples consisted of 44 Mothers selected by Non probability convenient sampling technique. The setting for the study was selected community area of Gandhi Nagar, Gujrat. Data was gathered with help of demographic variables & administering a self-structured knowledge questionnaire by analyst prior & after awareness program. Post-test was done after seven days of pre-test. Data were analysis using descriptive & inferential statistics.

Analysis and interpretation

SECTION-I Table -1 Frequency & percentage distribution of samples according to their demographic variables.

n = 44

S. No	Demographic Variables	Frequency	Percentage
1	**Age in Years**		
a.	18-22	11	25.0
b.	23-27	26	59.1
c.	28-32	6	13.6
d.	More than 32	1	2.3
2	**Educational Status**		
a.	No formal education	5	11.4
b.	Primary	6	13.6
c.	Secondary	15	34.1
d.	Higher secondary	17	38.6
e.	UG & PG	1	2.3
3	**Family income**		
a.	10000-15000	12	27.3
b.	150001-20000	19	43.2
c.	Above 20000	13	29.5
4	**Type of family**		
a.	Nuclear	29	65.9
b.	**Joint**	10	22.7
c.	Extended	5	11.4
5	**Previous knowledge related to common bottle-feeding problems**		
a.	Yes	37	84.1
b.	No	7	15.9

SECTION-II- Table- 2.1.1- Frequency and percentage distribution of Pre-test scores of studied subjects:

Category and test Score	Frequency (N=44)	Frequency Percentage (%)
POOR (1-10)	37	84.1
AVERAGE (11-20)	7	15.9
GOOD (21-30)	0	0.0
TOTAL	44	100.0

The present table 2.1.1 concerned with the existing knowledge regarding common bottle-feeding problems among Mothers were shown by pre-test score and it is observed that most of the mothers 37 (84.1%) were poor (01-10) knowledge & some Mothers have 7 (15.9%) were from average category.

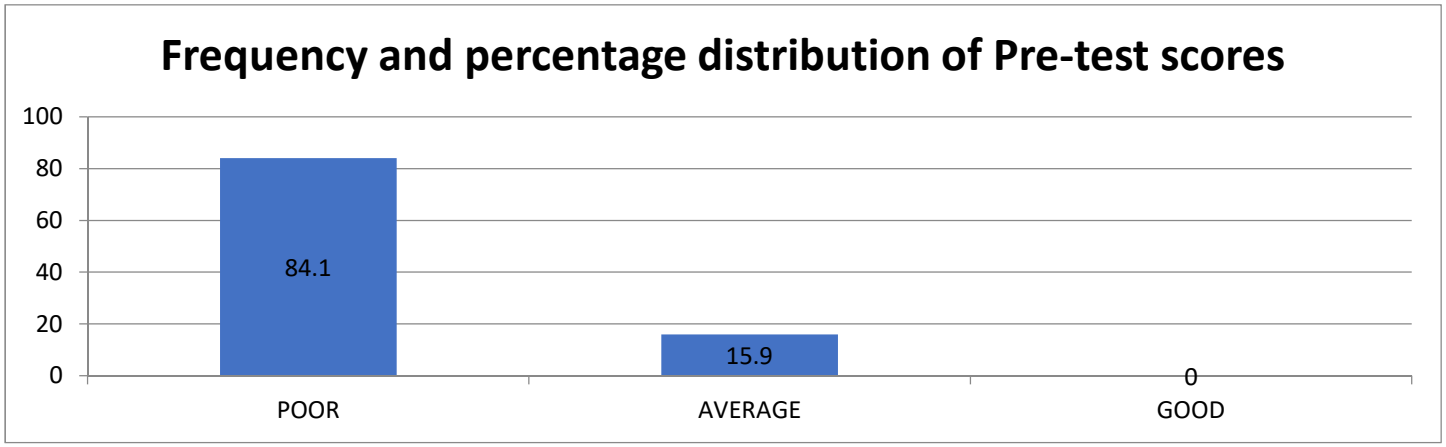

FIG.-2.1.1- Frequency and percentage distribution of Pre-test scores of studied subjects

Table-2.1.2. - Mean ($\overline{X}$) and standard Deviation (s) of knowledge scores:

Knowledge Pre –test	Mean ($\overline{X}$)	Std Dev (S)
Pre-test score	**8.09**	**2.90**

The information regarding mean, percentage of mean and standard deviation of test scores in shown in table 2.1.2 knowledge in mean pre-test score was 8.09± 2.90 while in knowledge regarding common bottle-feeding problems among Mothers in in selected community area of Gandhi Nagar, Gujrat.

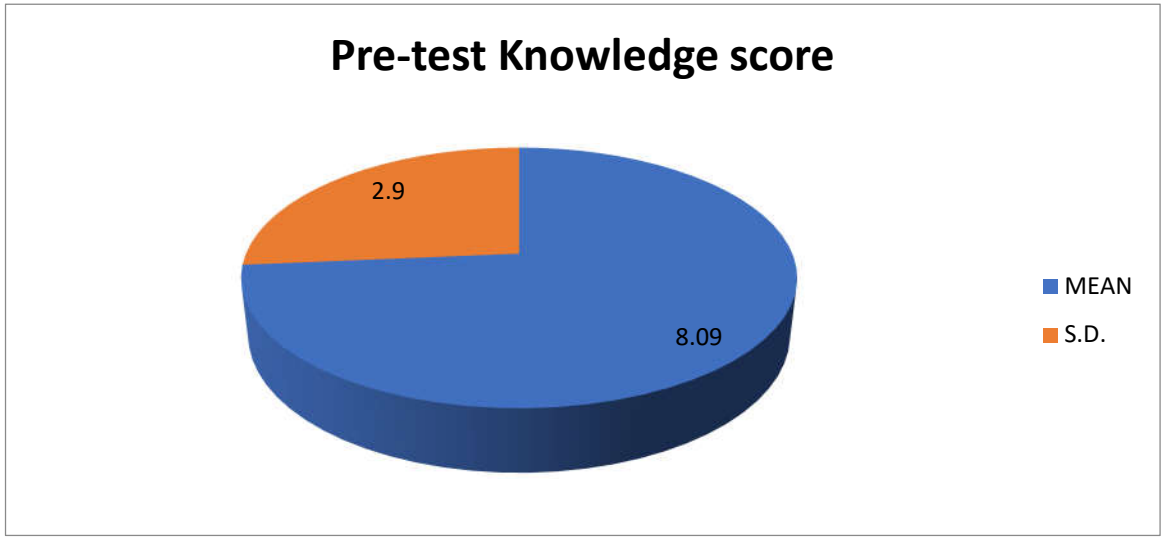

FIG.-2.1.1. - **Mean ($\overline{X}$) and standard Deviation (s) of knowledge scores**

Table-2.2.1- Frequency and percentage distribution of Post test scores of studied subjects:

Category and post-test Score	**Frequency (N=40)**	**Frequency Percentage (%)**
POOR (01-10)	0	0.0
AVERAGE (11-20)	11	25.0
GOOD (21-30)	33	75.5
TOTAL	44	100%

The present table 2.2.1 concerned with the existing knowledge regarding common bottle-feeding problems among Mothers was shown by post test score and it is observed that most of the mothers 33 (75.0%) were **GOOD** (21-30) knowledge & other Mothers have 11 (25.0%) category which are **AVERAGE** (11-20) posttest knowledge score in present study.

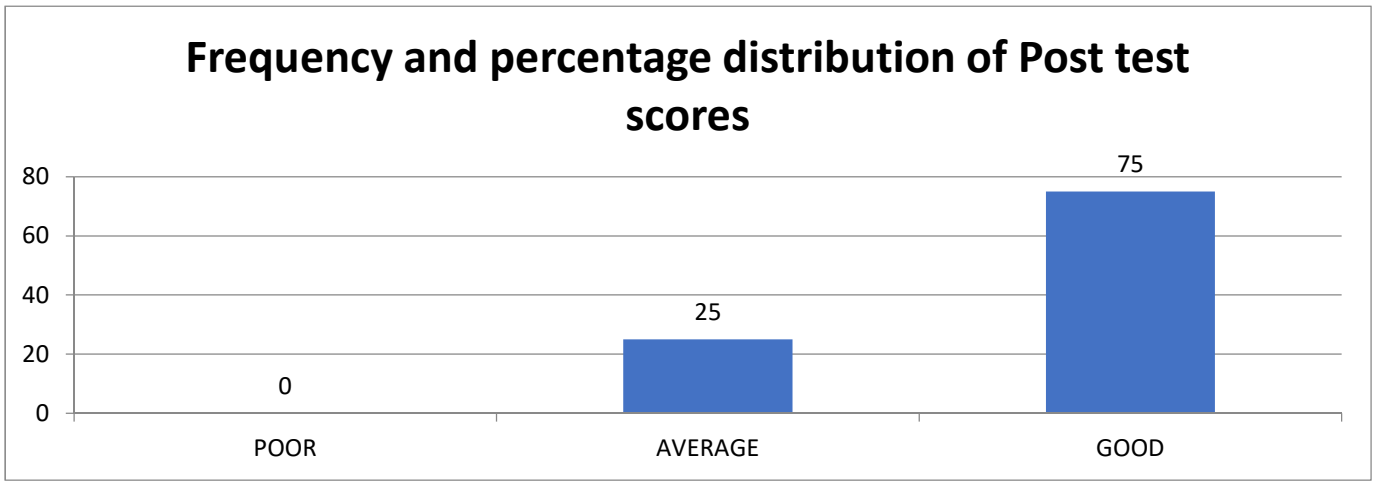

FIG.-2.2.1- Frequency and percentage distribution of Post test scores of studied subjects

Table-2.2.2. - Mean ($\overline{X}$) and standard Deviation (s) of knowledge scores:

Knowledge Test	**Mean ($\overline{X}$)**	**Std Dev (S)**
Post-test score	**21.50**	**3.75**

The information regarding mean, percentage of mean and SD of post test scores in shown in table 2.2.2 knowledge in mean post test score was 21.50 ± 3.75 while in knowledge regarding common bottle-feeding problems among Mothers in in selected community area of Gandhi Nagar, Gujrat.

Hence, it is confirmed from the tables of section-II that there is a significant difference in mean of test scores which partially fulfill 2nd objective of the present study.

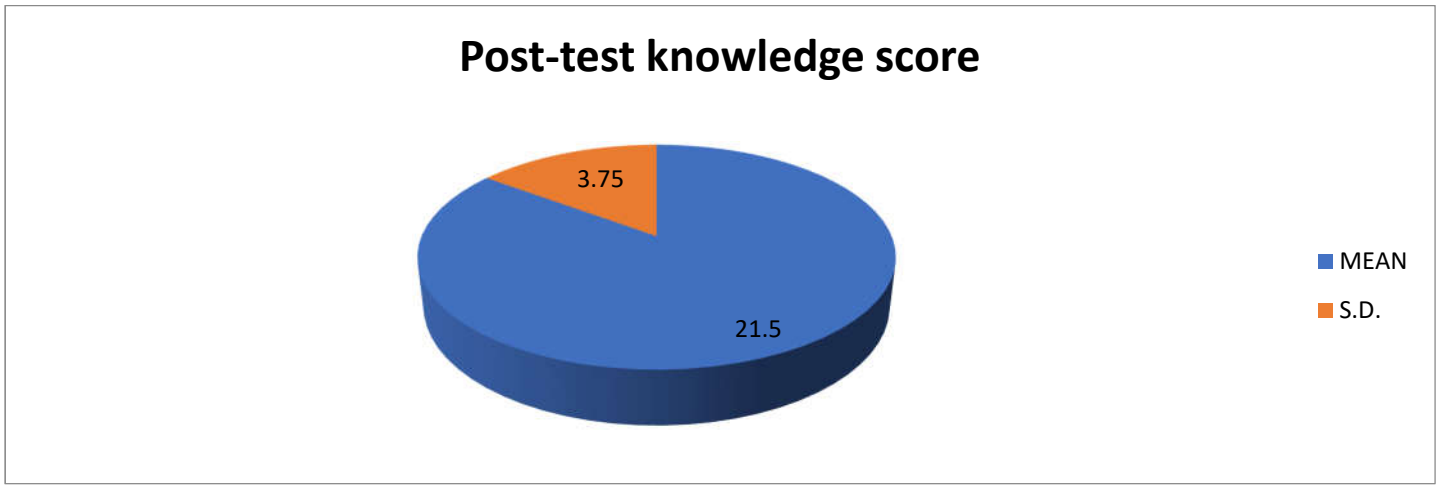

FIG.-2.2.2. - Mean ($\overline{X}$) and standard Deviation (s) of knowledge scores:

TABLE 2.2.3: Impact of awareness program by calculating Mean, SD, Mean Difference and 't' Value of Pre-test and Post-test knowledge.

Knowledge Score of Mothers	Mean ($\bar{X}$)	S. D. (s)	Std. Error of Mean	D. F.	t-value	Significance
Pre-test	**8.09**	**2.90**	0.71	43	**-19.05**	P<0.05
Post-test	**21.50**	**3.75**				

When the mean and SD of pre-test & post-test were compared & 't' test was applied. It can be clearly seen that the 't' value was -19.05 and p value was 0.05 which clearly show that awareness program was very effective in enhancing the knowledge of Mothers.

SECTION-III Association of knowledge scores between test and selected demographic variables:

Table- 3.1 Association of age of Mothers with pre-test scores:

Age	Test scores			Total
(in years)	**POOR (1-10)**	**AVERAGE (11-20)**	**GGOD (21-30)**	
18-22	10	1	0	**11**
23-27	20	6	0	**26**
28-32	6	0	0	**6**
Above 32	1	0	0	**1**
Total	**37**	**7**	**0**	**44**
X= 2.70	p>0.05 (Insignificant)			

The association of age & test scores is shown in present table 3.1. The probability value for Chi-Square test is 2.70 for 3 DF which indicated insignificant value (p>0.05). Hence, it is identified that there is insignificant association between age & test scores. Moreover, it is reflected that age isn't influenced with current problem.

Table- 3.2 Association of educational status with pre-test scores:

Educational status	Test scores			Total
	POOR (1-10)	**AVERAGE (11-20)**	**GOOD (21-30)**	
No formal	5	0	0	**5**
Primary	4	2	0	**6**
Secondary	12	3	0	**15**
Higher sec.	15	2	0	**17**
UG & PG	1	0	0	**1**
Total	**37**	**7**	**0**	**44**
X= 2.90	p>0.05 (Insignificant)			

The association of educational status & test score is shown in present table 3.2. The probability value for Chi-Square test is 2.90 for 4 degrees of freedom which indicated educational status and test scores. Moreover, it is reflected that educational status isn't influenced with present problem.

Table- 3.3 Association of family income with pre-test scores:

Family income	**Test scores**			**Total**
	POOR (1-10)	**AVERAGE (11-20)**	**GOOD (21-30)**	
10000-15000	10	2	0	**12**
15001-20000	16	3	0	**19**
Above 20000	11	2	0	**13**
Total	**37**	**7**	**0**	**44**
X=0.008	p>0.05 (Insignificant)			

The association of family income & test score is shown in present table 3.3. The probability value for Chi-Square test is 0.008 for 2 degrees of freedom which indicated family income and test scores. Moreover, it is reflected that family income isn't influenced with present problem.

Table- 3.4 Association of types of family with pre-test scores:

Types of family	**Test scores**			**Total**
	POOR (1-10)	**AVERAGE (11-20)**	**GOOD (21-30)**	
Nuclear	25	4	0	**29**
Joint	7	3	0	**10**
Extended	5	0	0	**5**
Total	**37**	**7**	**0**	**44**
X= 2.52	p>0.05 (Insignificant)			

The association of types of family & test score is shown in present table 3.4. The probability value for Chi-Square test is 2.52 for 2 degrees of freedom which indicated types of family and test scores. Moreover, it is reflected those types of family isn't influenced with present problem.

Table- 3.5 Association of previous knowledge related to common bottle-feeding problems with pre-test scores:

Previous Knowledge	Test scores			Total
	POOR (1-10)	**AVERAGE (11-20)**	**GOOD (21-30)**	
Yes	3	2	0	**5**
No	34	5	0	**39**
Total	**37**	**7**	**0**	**44**
X= 2.44	p>0.05 (Insignificant)			

The association of previous knowledge & test scores is shown in present table 3.5. The probability value for Chi-Square test is 2.44 for 1 degrees of freedom which indicated previous knowledge & test scores. Moreover, it is reflected that previous knowledge isn't influenced with current problem.

Results

The result of this study indicates that there was a significant increase in post-test knowledge scores compared to pre-test scores of common bottle-feeding problems. The mean percentage knowledge score was observed 8.09± 2.90 in pre-test & after implementation of awareness program post-test mean percentage was observed with 21.50± 3.75.

Conclusion

Thus, after the analysis and interpretation of data we can conclude that the hypothesis RH1 that, there will be significance difference between pre-test knowledge score with post-test knowledge score among Mothers at ($P<0.05$) is being accepted. Furthermore, awareness program related to common bottle-feeding problems among Mothers may consider as an effective tool when there is a need in bridging & modifying knowledge.

Limitations

- This was limited to in selected community area of Gandhi Nagar, Gujrat.
- This was limited to 44 Mothers.

RESEARCH ARTICLE

A Descriptive Study to Identify Perceived Performance Obstacles Faced by the Staff Nurse's working in Psychiatry Department in Government Hospital of Gujarat State

Parul Makwana
Assistant Professor, Aarihant Institute of Nursing, Gandhinagar (Gujarat)
*Corresponding Author E-mail:

ABSTRACT:

Background: Nurses constitute the largest group of health care professionals who care for mental health care users in the psychiatric services field. This places them at the crucial junction of providing quality care while trying to manage the challenges that arise with this patient group. Part of dealing with this requires that nursing education be aware not only of the multifaceted roles of psychiatric nurses but the unique and sometimes daunting challenges involved in nursing mentally ill patients. While the roles of psychiatric nurses have received growing attention; little research exists on the roles and challenges associated with psychiatric nursing at mental health care facilities. The current study explored the challenges associated with perceived perform duties obstacles of staff nurses working in psychiatric department. **Objectives:** The study's objectives are :- (1) To assess perceived performance obstacles faced by staff nurses working in government hospital of Gujarat state. (2) To identify the obstacles that affect in perform duties of staff nurse's working in government hospital of Gujarat state. (3) To associate demographic data of staff nurse's with perceived performance obstacle faced by staff nurse's working in government hospital of Gujarat state. **Material and methods:** The study was conducted among 150 staff nurses working in psychiatric department in government hospital of Gujarat state using Convenient Sampling Techniques. Descriptive survey approach was used as a research design. A collection of the data, investigator has used Self-Structured Dichotomous Questionnaire to assess perceived performance obstacles faced by staff nurses working in psychiatric department in government hospital of Gujarat state with a view to develop an information booklet. Descriptive and inferential statistics were used to calculate the analysis from the samples. The reliability of tool was determined by testing test retest method before data collection whereas the association was determined by using Chi square formula. **Results and findings:** The study revealed that majority of samples has Perceived Performance Obstacles where fully present is 44.7% and moderately present is 52.7% hence it is seen that Perceived Performance Obstacles is truly faced by staff nurse working in psychiatric department in Government hospital of Gujarat state. Significant association was found between Gender, and Type of family and perceived performance obstacles score. There was non-Significant association was found between Age, Marital Status, and Educational Status and perceived performance obstacles score. Information booklet has been developed for the nurses to help in managing and understanding of perceived performance obstacles and own mental health needs. We should try to reduce the Perceived Performance Obstacles, to achieve promotion of mental health of staff nurses to prevent stress and encourage coping, to upgrade the standard of their performed duties.

KEYWORDS: Perceived performance obstacles, Staff nurse, Psychiatric department.

INTRODUCTION:

Mental health is a level of psychological well-being, or an absence of a mental disorder; it is the "psychological state of someone who is functioning at a satisfactory

level of emotional and behavioral adjustment". From the perspective of positive psychology or holism, mental health may include an individual's ability to enjoy life, and create a balance between life activities and efforts to achieve psychological resilience.

The Performance obstacles can be defined as the work factors in the work setting that increase their workload beyond what is expected that negatively affect their quality of work life. Performance obstacles may be related to one or more elements of the work system, such as those related to tasks which include, dealing with many professional issues, and performance obstacles related to tools as unavailability of necessary equipment in a timely manner were considered among the categories of performance obstacles that prevent staff nurses from accomplishing their tasks.

Additionally, The effect of stress has been considered an important cause of decreasing health and reduction in the level of self-efficiency of nurses, decreasing nursing personnel in long-term psychiatric facilities, have displayed higher levels of stress, lower job satisfaction, and a higher propensity to quit than providers working in other types of health care settings. Caring for both the mental and physical health of the psychiatric patient is especially important for psychiatric nurses; thus, their roles have continued to expand over the years, in association with increases in the mental health services supplied by psychiatric departments. Self-efficacy is a key factor in nursing that may lead them to feel confident to perform well in complex situations.

NEED FOR STUDY:

Nursing stress is considered a problem that affects the practice worldwide. Job stress is a harmful response physically and emotionally when the nurses' skills, resources, and needs could not fulfill the requirement of the job**.** This study was aimed to assess job stress and self- efficacy among psychiatric nursing working in mental health hospitals at Cairo, Egypt. The study was conducted in mental health hospital and institute of Psychiatry affiliated to Ain shams university hospitals**.** [3]

Association between Performance Obstacles And Quality Of Work Life among Intensive Care Nurses. Performance obstacles domains as reported by the study subjects: Shows the domains of performance obstacles as reported by nurses in the two studied hospital. MGH was higher in the following domains: Physical work environment, work organization, technology and tools, nursing tasks (55.5%, 37.0%, 33.3%, 74.1% respectively) than MUCH (43.3%, 20.3%, 30.0%, 36.8% respectively).With highly statistically significance. [1]

Job Stress and Self- Efficacy among Psychiatric Nursing Working in Mental Health Hospitals at Cairo, Egypt Shows the socio-demographic characteristics of psychiatric nurses: and found that more than half of nurses were ranged from 20 to <35years and had experience between 5- 10 years constituting (53.1%). Regarding their sex, it was found that more than two-third of them (69.4%) were female. Concerning marital status (77.5%) were married. In addition to there was no one of them had master or doctorate degree, while about two third of them were a diploma nurse and working as a staff nurse constituted (64.3%) and (61.2%) respectively. [4]

Staff Nurses' Performance Obstacles and Quality of Work Life at Benha University Hospital. Frequency distribution of studied staff nurses according to their general characteristics shows:_clarifies that more than three fifths (63.9%) of the studied nurses were in age group less than 25 years and the majority of them (93.3%) were females. As regards to marital status of studied staff nurses; near to two thirds (65.5%) were married, as well as more than two thirds (67.2%) of them were graduates of technical institute of nursing. In relation to years of experience more than half (60.5%) of studied staff nurses had less than or equal 5 years of experience. [2]

OBJECTIVES:

The study's objectives are :-

(1) To assess perceived performance obstacles faced by staff nurses working in government hospital of Gujarat state.

(2) To identify the obstacles that affect in perform duties of staff nurse's working in government hospital of Gujarat state.

(3) To associate demographic data of staff nurse's with perceived performance obstacle faced by staff nurse's working in government hospital of Gujarat state.

MATERIAL AND METHODS:

The study was conducted among 150 staff nurses working in psychiatric department in government hospital of Gujarat state using Convenient Sampling Techniques. Descriptive survey approach was used as a research design. A collection of the data, investigator has used Self-Structured Dichotomous Questionnaire to assess perceived performance obstacles faced by staff nurses working in psychiatric department in government hospital of Gujarat state with a view to develop an information booklet. Descriptive and inferential statistics were used to calculate the analysis from the samples. The reliability of tool was determined by testing test retest method before data collection whereas the association was determined by using Chi square formula. Research setting was Govt. Hospital for Mental Health,

Gujarat State. The data was analyzed by using Descriptive and Inferential Statistics.

RESULT AND DISCUSSION:

Section-I:-Demographic Variables:

The demographic variable of the samples regarding level of perceived performance obstacles faced by staff nurses. In the present study data revealed that samples. Out of 150 samples, 97 samples were distributed between 21-30 years of age (64.7%), 33 samples belong to 31-40 years (22.0%), 14 samples belong to 41-50 years of age (9.3%) and 6 samples belongs to 51-60 years of age (4.0%). As regard to Gender all 150, 43 samples were Male (28.7%) and 107samples were Females (71.3%). According to Marital status of all 150 sample, 55 were Married (36.7%), 81 are Unmarried/Single (54.0%), 13 were separated/ divorce (8.7%), 1 is widowed/widower (0.7%). According to Type of Family, 60 was Nuclear Family (40.0%), 78 were Joint family (52.0%) and 12 were extended family (8.0%). Distribution of samples according to Educational Qualification 35 was from G.N.M. Nursing (23.3%), 17 was from Post basic B.SC Nursing (11.3%), 81 was from B.Sc. Nursing (54.0%) and remaining 17 was from M.Sc. Nursing (11.3%).

Section-II:- Level of Perceived Performance Obstacles Faced by Staff Nurse.

Frequency and percentage wise distribution of samples scores regarding level of perceived performance obstacles faced by staff nurse. Out of 150 samples, Perceived Performance Obstacles is not present in 4 samples (2.7%), Perceived Performance Obstacles is Moderately present in 79 samples (52.7%) and Performance Obstacles is Fully present in 67 samples (44.7%). It revealed that majority of samples has Perceived Performance Obstacles where fully present is 44.7% and moderately present is 52.7% hence it is seen that Perceived Performance Obstacles is truly faced by staff nurse working in psychiatric department in government hospital of Gujarat state.

CONCLUSION:

The major conclusions derived from the present study are:-

1. Perceived Performance Obstacles are faced by staff nurses working in psychiatry department in government hospital of Gujarat state.
2. Perceived Performance Obstacles is Moderately present in 79 samples (52.7%) and Performance Obstacles is Fully present in 67 samples (44.7%).
3. There is Significant association was found between perceived performance obstacles score and demographic variable like Gender, Type of family.
4. There is No Significant association was found between perceived performance obstacles score and demographic variable like Age, Marital Status, and Educational Status.

It was also found that there is No Significant association was found between perceived performance obstacles score and demographic variable like Age, Marital Status, and Educational Status and There is Significant association was found between perceived performance obstacles score and demographic variable like Gender, Type of family. Hence, there is need of develop an information booklet for people in general so that they can be aware about perceived performance obstacles faced by the staff nurses working in psychiatry department, to help promote awareness and understanding of our own mental health needs. So, that they can learn the measures to decrease the perceived performance obstacles faced by the staff nurses working in psychiatry department, and also contribute in preventing mental stress and develop coping skills with obstacles.

Abstract – *Waste water, is any water that has been adversely affected in quality by anthropogenic influence. The sewage from colonies as well effluent from industrial units has been identified as main cause for water pollution across our country. Sewage is a water – carried waste, in solution or suspension that is intended to be removed from a community. Also known as waste water, it is more than 99% water & is characterized by volume or rate of flow, physical condition, chemical constituents and the bacteriological organisms that it contains. During recent year, there has been an increasing awareness and concern about water conservation all over the world. Hence, new approaches towards achieving sustainable development of water resources have been developed internationally. The BOD, COD, TSS concentration of sewage ranges from 80-150 mg/l, 180-230 mg/ l & 90-180 mg/L respectively. Under this research paper, a cut to suit treatment technology has been developed to treat sewage. Treatment technologies adopted are sequencing batch reactor (SBR), Chlorination. A new approach Dual media filter results were very encouraging. The treatment system achieved 94% BOD, 96% COD and 95% TSS removal respectively.*

***Key Words*: Sequencing batch reactors, Activated sludge Process, BOD, Chlorination, COD, TSS, Dual Media Filtration, Reuse, Sewage etc.**

1. INTRODUCTION

Waste water is liquid waste discharged by domestic residences, commercial properties, industry, agriculture which often contains some contaminants that result from the mixing of waste water from different sources [1]. Based on first origin wastewater can be classed as sanitary, commercial, industrial, agricultural or surface runoff. Term wastewater need to be separated from the term sewage, the terms sewage and sewerage are sometimes interchanged. Sewage is contaminated with feces or urine. The sewage generates from residence, hospitals, offices, industries etc.

Domestic sewage contains a wide variety of dissolved and suspended impurities and is the primary source of pathogens and organic substances. All sewage from cities and towns is likely to contain pathogens of some type, potentially presenting a direct threat to public health. There has been an increasing awareness and concern about water conservation all over the world. Hence, a new approach towards achieving sustainable development of water resources has been developed internationally.[1]

1.1 Methods and Material

Methodology:

In this research paper the treatment technologies adopted for the treating sewage are as follows:

1. Sequencing batch reactor (SBR) Process
2. Filtration

1.2 Sewage Treatment Plant

Sewage treatment is the process of removing contaminants from wastewater and house hold sewage, both runoffs (effluents), domestic, commercial and institutional. It includes physical, chemical and Biological processes to remove physical, chemical and biological contaminants. Its objective is to produce an environmentally safe fluid waste stream and solid waste (or treated sludge) suitable for disposal or reuse. The treatment of waste water is not important for our own health but also kept our environmental clean and healthy.[1]

In a sewage treatment plant, the Sequencing batch reactor (SBR) process is a biological process that can be used for one or several of the purpose like oxidizing carbonaceous biological matter, oxidizing nitrogenous matter. Mainly ammonium & nitrogen generation a biological matter, removing phosphate, driving off entrained gases such as carbon dioxide, ammonia, nitrogen generating a biological floc that is easy to settle, generating a liquor that is low in dissolved or suspended material.

SBR (Sequencing batch reactors) are a type of activated sludge process for the treatment of waste water. SBR reactors treat wastewater such as sewage or output from anaerobic digesters or mechanical biological treatment facilities in batches. SBR is a modification of activated sludge process which has been successfully used to treat municipal and industrial wastewater. The difference between the two

technologies is that the SBR performs equalization, biological treatment and secondary clarification in a single tank using a timed control sequence. SBR technology is a method of waste water treatment in which all phase of the treatment process occur sequentially within the same tank.[6]

The SBR is fill draw activated sludge system. In this system, waste water is added to a single "batch" reactor, treated to remove undesirable components, and the discharged.

Five phase of SBR process:

Fill Phase: During this phase, the basin receives influent wastewater. The influent brings food to the microbes in the activated sludge, creating an environment for biochemical reactions to take place.

React Phase: During this phase, no wastewater enters the basin and the mechanical mixing and aeration units are on. This phase allows for further reduction of wastewater parameters.

Settle phase: During this phase, activated sludge is allowed to settle under quiescent condition. The activated sludge tends to settle as a flocculent mass.

Decant phase: Clarified treated effluent is removed from the tank.

Idle Phase: This step occurs between the decant and the fill phase. The idle period is used when the system is waiting for enough effluent to process.[6]

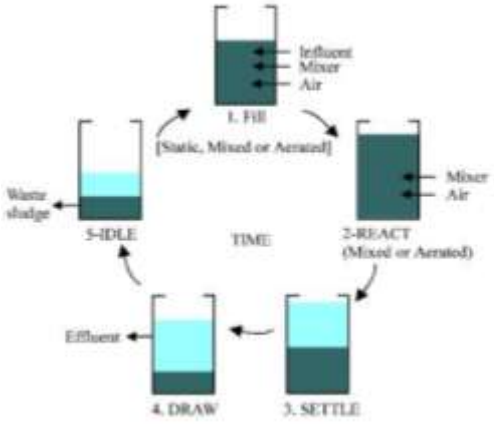

Fig -1: SBR operation for each tank for one cycle

Disinfection of sewage is necessary for healthy rivers and streams. Chlorination is by far the most common method of wastewater disinfection and is used worldwide for the disinfection of pathogens before discharge into receiving streams, rivers or oceans. Chlorine is known to be effective in destroying a variety of bacteria, Viruses and protozoa, including Salmonella, Shigella and vibrio cholera.

1.3 Filtration

Filtration is commonly the mechanical or physical operation which is used for the separation of solids from fluids by in reposing a media through which only the fluid can pass. The fluid that passes through is called filtrate. Two types of sand filter are in use: Slow sand filter and rapid sand Filter. Slow sand filters require much more surface area than rapid sand filters and are difficult to clean. Most modern water treatment plant now use rapid dual media filers following coagulation and sedimentation. A dual- media filter consists of layer of anthracite coal above a layer of fine sand. The upper layer of coal traps most of the large floc, and the finer sand grains in the lower layer trap smaller impurities. This process is called in depth filtration, as the impurities are not simply screened out or removed at the surface of the filter bed, as is the case in slow sand filter. In order to enhance in depth filtration, so calls mixed media are used in some treatment plants. These have a third layer, consisting of fine grained dense mineral called granite, at the bottom of the bed.[4]

2. Dual media Filter:

For this research paper a treated water from the Sewage treatment plant based on SBR (near Ahmedabad) will recycle and reuse water can be used for cooling water makeup, gardening, landscape development, toilet flushing, road washing etc. thus leading towards water conservation. A new Approach is "Sewage treatment plant followed by Dual media filter achieve very encouraging results. The Result achieved 94% BOD, 96% COD and 95% TSS removal respectively.

At Sewage treatment plant preliminary treatment (includes Screening, grit chamber, Parshall flume), SBR tank (Biological treatment) and chlorine contact tank were fabricated.

A lab scale study was conducted to testing of the results.

Table -1: Inlet and Out let parameter of Sewage Treatment plant

Sr no	Parameters	Inlet (mg/l)	Outlet (mg/l)
1.	pH	7.22	7.40
2.	BOD	85	10
3.	COD	190	20
4.	TSS	114	15

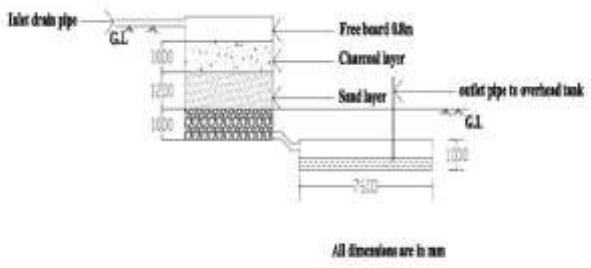

Fig-2: Plan of the Filtration Tank

Fig-3: Dual media model

Dual media filtration has been increasing interest and application in water treatment as well as in advance treatment of effluents for water renovation and for pollution control.[4] It consist of Activated Carbon AC at the top of the filter media, and sand in the bottom portion. The AC with a specific gravity of 2.55 is greater than the sand with sp. Gravity of 2.65. Therefor a lager AC gain has the same settling velocity as much smaller sand gain. This characteristics allows larger AC grains to be placed on the top of the smaller sand grains.[5]Dual media filter may behave much like the two single – medium filters, placed in series, one above the other, each with a different grain size. The top layer of AC particles removes the larger sized impurities as well as some smaller one; while the bottom sand, in its turn, captures the smaller impurities. As a consequence, more depth of filter is utilized for the removal of solids than in the stratified single medium filter.[5]

Sand either fine or core is generally used as a filter media. The size of the sand is measured and expressed by the term called effective size.[4] The layer of Sand may be supported on gravel, which permits the filtered water to move freely to the under drains, and allows the wash water to move uniformly upwards.[4]

The diameter of the activated carbon filter be selected to be 25% larger than the sand filter to reduce the frequency of the servicing.[4]

Filtration unit details:

Materials: Activated charcoal, Sand and Gravel
Top layer: Activated charcoal (granular),
Middle layer: Sand
Bottom Layer: Gravel

The rate of Filtration is 6 $m^3/m^2/hr$. (for this small unit)

Advantages and Disadvantages of Dual media Filter
Advantages:

-Higher filtration rate
-Requires small area
- Automated cleaning using backwash
- Can handle a wide range and more variable water quality than a rapid sand filter.
- Operation can become more automated are requires less man power.

Disadvantages:

-Not as efficient a filtration process and additional monitoring may be required before a high filtration rate can be used.
- A biologically active layer does not form
- Need frequent cleaning using significant amount of treated water.
- Operation requires a higher level of skill and thus more training.

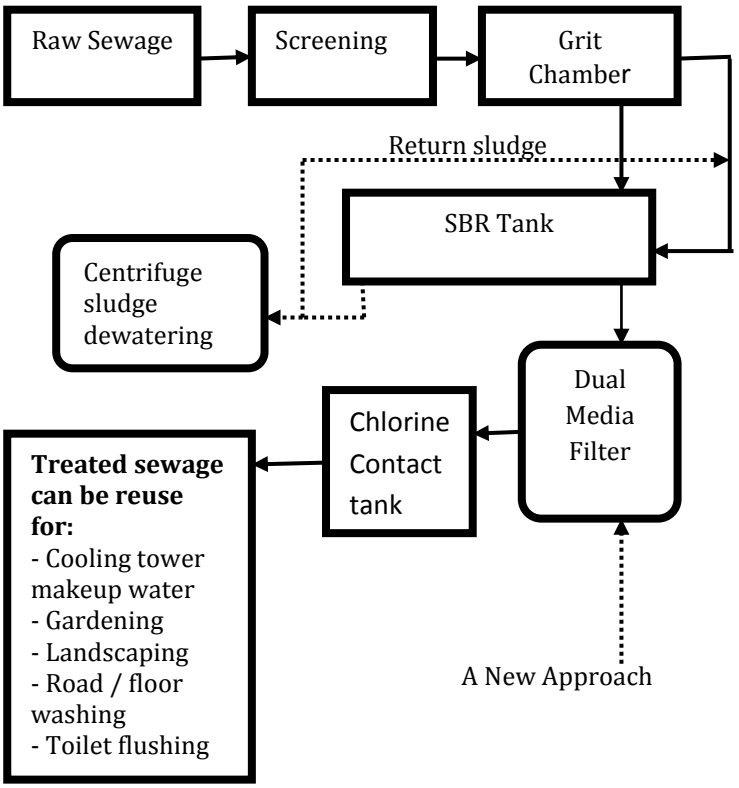

Chart 1: Flow chart of Sewage treatment plant with new approach

3. RESULTS AND CONCLUSIONS

Table -2: After dual media filter Reduction Results

Sr no.		pH	BOD (mg/l)	COD (mg/l)	TSS (mg/l)
1.	Raw Sewage	7.22	90	200	115
2.	SBR tank outlet	7.3	10	20	15
3.	After Dual media filter	7.3	6	8	6
	Reduction in %	**-**	**94%**	**96%**	**95%**

Conclusions:

With the Rapid Development of the cities and domestic water supply, quantity of sewage generation is increasing in the same proportion. Treatment of sewage and its reuse is the need of the hour. One of the Main pollution of surface water in our country is discharge of untreated sewage.

This research paper attempt has been made to treat sewage and put it back for reuse. The sewage has been treated by sequencing batch reactor (SBR) and the results have been very encouraging. BOD, COD and TSS reduction achieved were 10 mg/l, 20 mg/l and 15 mg/l respectively. After Dual media filtration BOD, COD and TSS results very encouraging 6mg/l, 8mg/l and 6mg/l respectively. [2]

The dual media filter system archived 94% BOD, 96% COD, and 95% TSS removal.

The treated sewage can be reused for various purpose like cooling water makeup, gardening, landscape development, toilet flushing, road washing etc. thus leading towards water conversation.

ACKNOWLEDGEMENT

I owe deep gratitude to my guide Prof. Usman shaikh who took keep interest in my project work and guided me during the course work, till the completion of my paper by providing necessary information as and when required for developing a functional system.

HYPERLOOP: THE FIFTH MODE OF TRANSPORTATION

Abstract

Existing conventional modes of transportation consists of four unique types: rail, road, water, and air. These modes of transport tend to be either relatively slow (i.e., road and water), expensive (i.e. air) or a combination of relatively slow and expensive (i.e. rail). Hyperloop is innovative mode of transport that seeks to change this paradigm by being both fast and inexpensive for transportation. This new approach uses both permanent magnets and electromagnets to levitate, propel, and control a pod. The electro dynamic suspension system is emulated as a small pod attached with permanent magnets from the bottom, which resembles a short-rotor linear synchronous motor.

Passengers may enter and exit Hyperloop at stations located either at the ends of the tube, or branches along the tube length. In this study, the initial route, preliminary design, and logistics of the Hyperloop transportation system have been derived. Recently Virgin Hyperloop group plans to inaugurate a hyperloop linking the two INDIAN cities (Mumbai-Pune) that will cut down travel time to 13 minutes, or less instead of 2 hr. with conventional mode.

It quickly becomes apparent just how dramatically the Hyperloop could change transportation, road congestion and minimize the carbon footprint globally. With the Hyperloop, extremely fast, inexpensive intercity travel would be widely accessible. If both people and goods can move more quickly and comparatively cheaply, rapid growth is a logical outcome.

1. Introduction

A Hyperloop is a proposed mode of passenger and/or freight transportation, first used to describe an open-source vactrain design released by a joint team from Tesla and Space X. A hyperloop is a sealed tube or system of tubes through which a pod may travel free of air resistance or friction conveying people or objects at high speed while being very efficient.

The Hyperloop Alpha concept was first published in August 2013, proposing and examining a route running from the Los Angeles region to the Francisco Bay Area, roughly following the Interstate 5 corridor. The Hyperloop Genesis paper conceived of a hyperloop system that would propel passengers along the 560 km route at a speed of 1,200 km/h allowing for a travel time of 35 minutes, which is considerably faster than current rail or air travel times.

If we are to make a massive investment in a new transportation system, then the return should by rights be equally massive. Compared to the alternatives, it should ideally be:

- Safer
- Faster
- Lower cost
- More convenient
- Immune to weather
- Sustainably self-powering
- Resistant to Earthquakes
- Not disruptive to those along the route

2. Background of the Invention

The corridor between San Francisco, California and Los Angeles, California is one of the most often travelled corridors in the American West. The current practical modes of transport for passengers between these two major population centres include:

1. Road (inexpensive, slow, usually not environmentally sound)
2. Air (expensive, fast, not environmentally sound)
3. Rail (expensive, slow, often environmentally sound)

A new mode of transport is needed that has benefits of the current modes without the negative aspects of each. This new high-speed transportation system has the following requirements:

1. Ready when the passenger is ready to travel (road)

2. Inexpensive (road)

3. Fast (air)

4. Environmentally friendly (rail/road via electric cars)

The onboard compressor is also used to improve the efficiency of the pod at higher speeds. Once the pod reaches transonic speeds, the flow around the pod will start to choke, i.e. the flow around the pod will become sonic. At this sonic condition the so-called Kantrowitz limit. The mass flow around the pod is at its maximum. Therefore, when the speed is further increased, not all flow can travel around the pod and is therefore collected in front of the pod. The result is a column of air being pushed by the pod throughout its run. That pressure build-up results in significant additional drag. The Hyperloop Alpha concept therefore introduces the on-board compressor to compress the additional flow and suck it through the pod, while at the same time supplying compressed air to the air bearings.

A new high-speed mode of transport is desired between Los Angeles and San Francisco; however, the proposed California High Speed Rail does not reduce current trip times or reduce costs relative to existing modes of transport. This preliminary design study proposes a new mode of high-speed transport that reduces both the travel time and travel cost between Los Angeles and San Francisco. Options are also included to increase the transportation system to other major population centres across California. It is also worth noting the energy cost of this system is less than any currently existing mode of transport the only system that comes close to matching the low energy requirements of Hyperloop is the fully electric Tesla Model S.

3. Design Description

Hyperloop is a proposed transportation system for travelling between Los Angeles, California, and San Francisco, California in 35 minutes. The Hyperloop consists of several distinct components including:

1. Capsule:

a. Sealed capsules carrying 28 passengers each that travel along the interior of the tube depart on average every 2 minutes from Los Angeles or San Francisco (up to every 30 seconds during peak usage hours).

b. A larger system has also been sized that allows transport of 3 full size automobiles with passengers to travel in the capsule.

c. The capsules are separated within the tube by approximately 23 miles (37 km) on average during operation.

d. The capsules are supported via air bearings that operate using a compressed air reservoir and aerodynamic lift.

2. Tube:

a. The tube is made of steel. Two tubes will be welded together in a side by side configuration to allow the capsules to travel both directions.

b. Pylons are placed every 100 ft (30 m) to support the tube.

c. Solar arrays will cover the top of the tubes in order to provide power to the system.

3. Propulsion:

a. Linear accelerators are constructed along the length of the tube at various locations to accelerate the capsules

b. Stators are located on the capsules to transfer momentum to the capsules via the linear accelerators.

4. Route:

a. There will be a station at Los Angeles and San Francisco. Several stations along the way will be possible with splits in the tube. b. The majority of the route will follow I-5 and the tube will be constructed in the median.

CAPSULE

Two versions of the Hyperloop capsules are being considered: a passenger only version and a passenger plus vehicle version.

Hyperloop Passenger Capsule

Assuming an average departure time of 2 minutes between capsules, a minimum of 28 passengers per capsule are required to meet 840 passengers per hour. It is possible to further increase the Hyperloop capacity by reducing the time between departures. The current baseline requires up to 40 capsules in activity during rush hour, 6 of which are at the terminals for loading and unloading of the passengers in approximately 5 minutes.

Hyperloop Passenger Plus Vehicle Capsule

The passenger plus vehicle version of the Hyperloop will depart as often as the passenger only version, but will

Accommodate 3 vehicles in addition to the passengers. All subsystems discussed in the following sections are featured on both capsules.

For travel at high speeds, the greatest power requirement is normally to overcome air resistance. Aerodynamic drag increases with the square of speed, and thus the power requirement increases with the cube of speed. For example, to travel twice as fast a vehicle must overcome four times the aerodynamic resistance, and input eight times the power.

Hyperloop Passenger Capsule

The maximum width is 4.43 ft (1.35 m) and maximum height is 6.11 ft (1.10 m). With rounded corners, this is equivalent to a 15 ft2 (1.4 m2) frontal area, not including any propulsion or suspension components.

The aerodynamic power requirements at 800-900 kph is around only 100 kW with a drag force of only 320 N, or about the same force as the weight of one oversized checked bag at the airport. The doors on each side will open in a gullwing (or possibly sliding) manner to allow easy access during loading and unloading. The luggage compartment will be at the front or rear of the capsule.

The overall structure weight is expected to be near 3,100 kg including the luggage compartments and door mechanism.

TUBE

The main Hyperloop route consists of a partially evacuated cylindrical tube that connects the Los Angeles and San Francisco stations in a closed loop system. The tube is specifically sized for optimal air flow around the capsule improving performance and energy consumption at the expected travel speed. The expected pressure inside the tube will be maintained around 0.015 psi (100 Pa, 0.75 torr), which is about 1/6 the pressure on Mars. This low pressure minimizes the drag force on the capsule while maintaining the relative ease of pumping out the air from the tube. The efficiency of industrial vacuum pumps decreases exponentially as the pressure is reduced, so further benefits from reducing tube pressure would be offset by increased pumping complexity.

PASASENGER HYPERLOOP TUBE

The inner diameter of the tube is optimized to be 7 ft 4 in. (2.23 m) which is small enough to keep material cost low while large enough to provide some alleviation of choked air flow around the capsule. The tube cross-sectional area is 42.2 ft^2 (3.91 m2) giving a capsule/tube area ratio of 36% or a diameter ratio of 60%. It is critical to the aerodynamics of the capsule to keep this ratio as large as possible, even though the pressure in the tube is extremely low. As the capsule moves through the tube, it must displace its own volume of air, in a loosely similar way to a boat in water. The displacement of the air is constricted by the walls of the tube, which makes it accelerate to squeeze through the gaps. Any flow not displaced must be ingested by the onboard compressor of each capsule, which increases power requirements.

The closed loop tube will be mounted side by side on elevated pillars as seen in Figure 5. The surface above the tubes will be lined with solar panels to provide the required system energy. This represents a possible area of 14 ft (4.25 m) wide for more than 350 miles (563 km) of tube length. With an expected solar panel energy production of 0.015 hp/ft^2 (120 W/m^2), we can expect the system to produce a maximum of 382,000 hp (285 MW) at peak solar activity. This would actually be more energy than needed for the Hyperloop system.

Tube Construction

In order to keep cost to a minimum, a uniform thickness steel tube reinforced with stringers was selected as the material of choice for the inner diameter tube Tube sections would be pre-fabricated and installed between pillar supports spaced 100 ft (30 m) on average, varying slightly depending on Location.

This relatively short span allows keeping tube material cost and deflection to a minimum.

The steel construction allows simple welding processes to join different tube sections together. A specifically designed cleaning and boring machine will make it possible to surface finish the inside of the tube and welded joints for a better gliding surface. In addition, safety emergency exits and pressurization ports will be added in key locations along the length of the tube.

Pylons and Tunnels

The tube will be supported by pillars which constrain the tube in the vertical direction but allow longitudinal slip for thermal expansion as well as dampened lateral slip to reduce the risk posed by earthquakes. In addition, the pillar to tube connection nominal position will be adjustable vertically and laterally to ensure proper alignment despite possible ground settling. These minimally constrained pillars to tube joints will also allow a smoother ride. Specially designed slip joints at each station will be able take any tube length variance due to thermal expansion. This is an ideal location for the thermal expansion joints as the speed is much lower nearby the stations. It thus allows the tube to be smooth and welded along the high-speed gliding middle section.

The spacing of the Hyperloop pillars retaining the tube is critical to achieve the design objective of the tube structure. The average spacing is 100 ft (30 m), which means there will be near 25,000 pillars supporting both tubes and solar panels. The pillars will be 20 ft (6 m) tall whenever possible but may vary in height in hilly areas or where obstacles are in the way. Also, in some key areas, the spacing will have to vary in order to pass over roads or other obstacles. Small spacing between each support

reduces the deflection of the tube keeping the capsule steadier and the journey more enjoyable. In addition, reduced spacing has increased resistance to seismic loading as well as the lateral acceleration of the capsule.

ROUTE

The Hyperloop will be capable of travelling between Los Angeles and San Francisco in approximately 35 minutes. This requirement tends to size other portions of the system. Given the performance specification of the Hyperloop, a route has been devised to satisfy this design requirement.

The Hyperloop route should be based on several considerations, including:

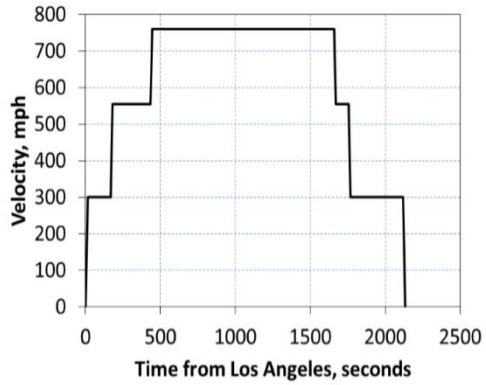
1. Maintaining the tube as closely as possible to existing rights of way (e.g., following the I-5).

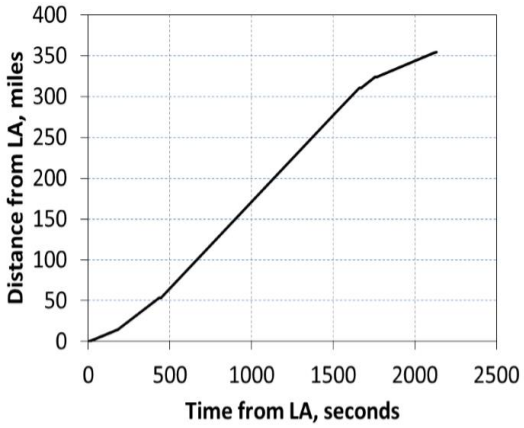
2. Limiting the maximum capsule speed to 760 mph (1,220 kph) for aerodynamic considerations.

3. Limiting accelerations on the passengers to 0.5g.

4. Optimizing locations of the linear motor tube sections driving the capsules.

5. Local geographical constraints, including location of urban areas, mountain ranges, reservoirs, national parks, roads, railroads, airports, etc. The route must respect existing structures.





4. Conclusion

The aerodynamic design strategy was two-fold. First, geometry sweeps were performed using a fast ax- symmetric viscous/in viscid analysis tool, while accounting for different flow rates between the ax symmetric and 3D shape. In the aerodynamic design it was crucial to transition the boundary layer to turbulent close to the front of the pod such that higher adverse pressure gradients are tolerated before separation. Such a design strategy increases friction drag but dramatically reduces pressure drag. Once the ax symmetric shape was decided upon, the final three-dimensional geometry was analyzed using a three-dimensional Naiver-Stokes solver to characterize its final performance at design speed.

Concluding, for the aerodynamic flow regime for this SpaceX Hyperloop Pod Competition, a droplet shaped aerodynamic shell is most elective at delaying flow separation, lowering the drag substantially. By investigating the performance of the design at transonic speed, it was also found that violating the Kantrowitz limit could lead to three-fold increase in drag coefficient for an increase in Mach number from 0.65 to 0.80.

Abstract— Looking to the present status for compliance of Common Effluent Treatment Plans (CETPs), no new permissions for accepting effluent to CETP are permitted as Central Pollution Control Board, a statutory Body has imposed direction under section 18(1) B of the Water Act 1974.This retards the growth of industries which have potential to expand. Keeping this restriction in view, If alternative of CETP is explored, a situation may come up in favor to the industry which will not only comply the prevailing imposition of restriction under 18(1) b of the Water Act 1974 but also will allow industrial unit to grow. Alternative is not to discharge waste water to the CETP, instead it is to be evaporated keeping the air emission within National Ambient Air Quality Standards. As discussed in this paper, cost of evaporation of waste water bears higher cost than conventional treatment, products having good profit margin can go for pursuing alternative of spray drying of effluent. A case study of spray drying of treated waste water of Acid Black 194 is considered where the spray dryer is already existing for drying the products.

Keywords: Common Effluent Treatment Plant, Central Pollution Control Board, Reactive Dyes, Azo Dyes

I. INTRODUCTION

Honorable High Court of Gujarat in the year 1995, (in the case of Pravinbhai C Patel v/s Government of Gujarat and Others) issued closure to the industrial units causing pollution in Ahmedabad. In the order, it was directed to develop environmental infrastructure facilities namely Treatment, Storage, Disposal Facilities for solid waste (TSDF), and Common Effluent Treatment Plants (CETPs) for safe disposal of industrial effluent. As a result CETPs and TSDF at GIDC were come up. Due to change in market scenario over two decades, industrial units felt expansion with making of different range of products to meet international demand and at the same time performance of the CETP was also required to be improved. Keeping noncompliance of CETPs for discharge of waste water, Central Pollution Control Board (CPCB) issued direction under 18(1) b of The Water Act 1974 restricting them to accept additional hydraulic as well as organic load of effluent. This situation has compelled all the concerned to think of alternative of a CETP with making no additional discharge of waste water to CETP and pursue zero liquid discharge. Further, the industrial units started optimum use of water with reduction in volume of waste water. Following the zero liquid discharge scenario, Industrial units have started use of multiple effect evaporators (MEE), Agitated thin film dryers (ATFD) and spray dryers.

II. STUDY AREA

A study for evaporation of wastewater originated from manufacturing of Acid Black 194 to assess the adequacy of evaporation as well as economy of evaporation is performed at the industrial unit having facility of spray dryer for the product at the industrial unit located in Gujarat Industrial Development Corporation, Vatwa. GIDC, Vatwa is an industrial cluster located in the eastern side of the Ahmedabad City, Gujarat, India established in the year 1968. It has total area of 527 hectare and houses about 2500 industries most of them are Dyes and Dye Intermediates. It has common infrastructures like Common Effluent Treatment Plant and Treatment, Storage and Disposal facilities (TSDF) for hazardous waste.

III. METHODOLOGY OF THE STUDY

- Identification of manufacturing process of Acid Black 194.
- Collection of samples of waste water from manufacturing process of Acid Black 194 and after its primary treatment.
- Conduct of trial evaporation run in spray dryer for evaporation of waste water of Acid Black 194 which is already existing for spray drying of Acid Black 194.
- Collection of air emission sample during trial run from the stack attached to the Spray dryer followed by Air Pollution Control Devices.
- Comparing techno-economic feasibility between conventional treatments versus spray drying of waste water of Acid Black 194.

A detailed study of manufacturing process of Acid Black 194 revealed there is generation of 3500 kg of Acid Black 194 along with generation of waste water of 5884 Litre. A material balance is given in Table 1.

Sr. No	Input Quantity in kg		Sr. No	Output Quantity in kg	
1	Beta Napthol	300	1	Effluent to ETP	5884
2	Caustic	285	2	Acid Black 194	3500
3	Sodium Nitrate	154			
4	Water	1000			
5	ICE	2955			
6	6 Nitro 1-Diazo 2 Napthol 4 Sulphonic Acid	600			
7	Steam	2540			
8	Salicylic Acid	50			
9	Basic Chromium Sulphate	300			
10	Salt	1200			
	Total	9384	Total		9384

tank of primary ETP and a sample is also collected from the treated waste water tank after primary treatment and results are given in Table 2.

Sr No.	Parameters	Unit	Untreated waste water of Acid Black 194	After Primary Treatment of waste water of Acid Black 194
1.	pH	pH Scale	7.0-8.0	7.5-8.5
2.	T.S.S	mg/l	150	80-90
3.	C.O.D	mg/l	6500-7500	5000-6500
4.	TDS	mg/l	120000-125000*	130000-45000

Table 2: Effluent Characteristics of Acid Black 194 before & After Primary Treatment

*Out of 1200 Kg Salt for isolation, around 80-85% salt goes with effluent

After primary treatment of effluent, possibility of the evaporation is explored in spray drier maintaining flow of 900 litre per hour with temperature profile 150 Deg C-250 Deg C which caused complete evaporation of the high TDS waste water. The evaporation occurs in spray dryer as effluent is allowed to pass through main chamber of spray dryer followed by cyclone separator, bag filters and water scrubber wherein majority of suspended particulates are settled and scrubbed with water. The scrubbed water is further recycled to spray dryer. Final emission complying prescribed norms is allowed through stack. As explained above, economy of the spray drying of waste water comes to be Rs 2.10 per litre if imported coal is used in hot air generator and it comes to 3.30 if natural as is used in hot air generator. A trial run is conducted for evaporation of waste water bearing characteristics mentioned in Table 1 in spray drier which is existing for spray drying of Acid Black 194 itself to evaluate feasibility. A sample of air emission through stack of spray dryer is collected during trial run for emission of Particulate Matter under iso-kinetic condition and emission results analyzed as 66.24 mg/NM3 which is well within National ambient air quality standard prescribed as 150 mg/NM3. Cyclone separator, bag filter followed by water scrubber are provided with spray dryers to control emission of particulate within norms.

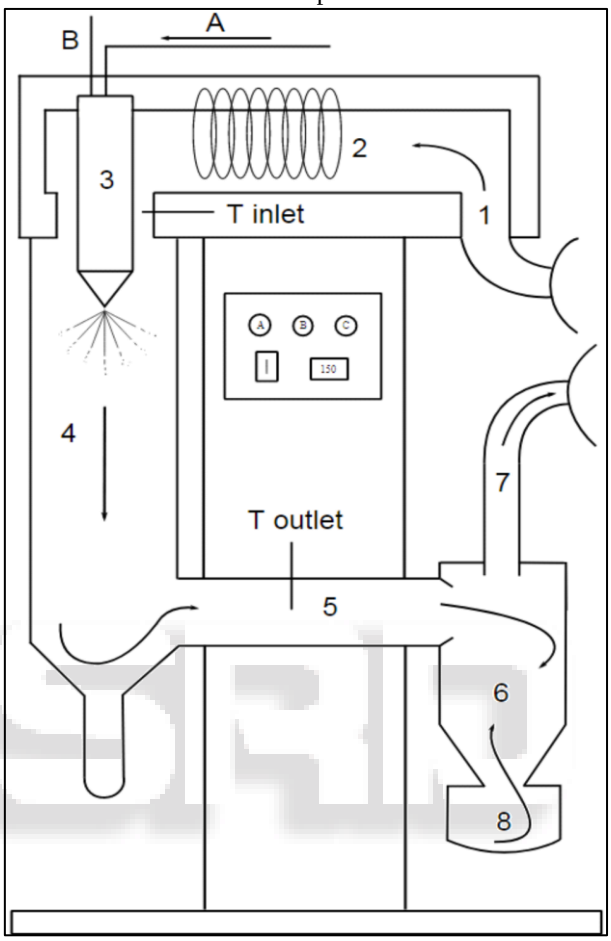

Fig. 1: Schematic Diagram of Spray Dryer

A Comparing scenario for the merits and demerits among conventional effluent treatment versus spray drying of waste water of Acid Black 194 is discussed in Table 3 given below.

Sr. No.	Particular	Disposal Through CETP	Disposal Through Spray Drier
1.	Area	Space restriction in small plant to installation and modification	Collection Tank is required for neutral wastewater
2.	Capital Cost	Capital Cost for primary treatment	Higher Capital Cost for installation of spray drier and its APCM
3.	Dosing Chemical	Area required to store chemical dosing and manpower is also required	No chemical dosing required for neutral wastewater
4.	Sludge	Separate Sludge storage area is required	No sludge storage area is required as direct drying occurs
5.	Norms	Inlet norms to CETP are to be maintained	No norms to be monitored as wastewater is without any VOC and spray drying emission falls within norms passing through Air Pollution Control Devices.
6.	Operation	0.50 INR per Liter of effluent	3.30 INR per litre of effluent in Natural Gas

All rights reserved by *www.ijsrd.com*

	Costing		2.10 INR per litre of effluent in Imported Coal
7	Manpower	Manpower required for ETP Operation	No manpower required as Operation is auto controlled by computer.
8	Operation and Maintenance	Easy to maintain and operate	For only wastewater disposal, it's difficult to operate but for dual purpose of spray drying of product as well as effluent, it is feasible based on product profit margin
9	Efficiency	Affected by manual error and dosing chemical properties	Time duration depend on TDS in wastewater. Higher TDS gets good result in evaporation.

Table 3: Comparison of Disposal Method of Waste Water of Acid Black 194

IV. Results & Discussion

The waste water generation from manufacturing of Acid Black 194 is explored to be evaporated in spray drying instead of its discharge to CETP. The discharge of treated waste water to CETP is restricted as per the inlet norms of CETP failing to which additional penalty is levied by CETP authority. In addition to this, due to nonperformance of CETP, expansion of the industrial unit is not permitted. Pursuing evaporation of waste water in spray drying with relatively higher cost than the conventional treatment, opens up scope of industrial unit to grow by obtaining statutory permissions from the concerned authorities.

The following facts come up after going through an experimental study of evaporation of waste water of Acid Black 194.

1) Net Profit to manufacture one kg of Acid Black 194: 12 INR/kg
2) Profit of 3500 Kg Acid Black 194 (One Batch) : INR 42000/-
3) Effluent quantity is 5884 litre for 3500 Kg of product and hence economy for conventional treatment of effluent in ETP considering 0.50 INR per litre= INR 2942/-
4) Spray drying based on natural gas for evaporation of 5884 litre of Acid Black 194 effluent considering Unit cost of evaporation as INR 3.3 per litre=INR 19,417/-.
5) Spray drying based on imported coal for evaporation of 5884 litre of Acid Black 194 effluent considering Unit cost of evaporation as INR 2.10 per litre=INR 12,356/- .

Considering above, it reveals that even after spray drying of effluent of Acid Black 194 with natural gas as fuel, it is acceptable to manufacture Acid Black 194 with selection of alternative to conventional ETP followed by its discharge to CETP. This can allow industrial unit to grow amidst prevailing strictures of CPCB under section 18-1-b of the Water Act 1974.

V. Conclusion

Waste water of Acid Black 194 can be evaporated in spray dryer complying prevailing norms which is certainly a costlier affair (cost of evaporation is 6.5 times higher than conventional treatment), however can be implementable to all dye making units for sustainable existence. In addition to above , tangible benefits for spray drying of effluent are (1) Energy conservation by switching over run of product to run of waste water for similar product (2) Ease of getting Statutory permission considering Zero Liquid Discharge units(3)Product loss if any can be recovered as bleed of scrubber thereby maintaining minimum loss.

VI. Declaration

A. Authors Contribution

All the authors make a substantial contribution to this manuscript. DT, and DS participated in drafting the manuscript. DT wrote the main manuscript; all the authors discussed the results and implication on the manuscript at all stages.

B. Acknowledgements

The authors are grateful to Swarnim Startup & Innovation University, School of Engineering for the permission to publish this research.

C. Availability of Data & Material

All relevant data and material are presented in the main paper.

D. Competing Interests

The authors declare that they have no competing interests.

E. Funding

ABSTRACT

The auto rickshaw is one of the important transport medium for end to end connectivity in many cities. A motor assisted battery driven Hybrid rickshaw can provide a relatively comfortable non-polluting and a silent transport system for urban and rural areas of India. The primary focus of this research was to develop an Electric Hybrid Rickshaw without requiring significant changes to the structure of widely popular existing rickshaws. The proposed model is a modified form of conventional electric rickshaw and combination of a battery operated motor driving system with the solar battery charge system for ideal time. The model was developed so as to save energy, limit overuse, and keeping the identity and driving mechanism of old rickshaws. An idea of battery charging infrastructure using Solar-Battery-Charging-Station is also mentioned. The performance test revealed that the hybrid vehicle provides satisfactory speed, easier motion control and good scope of manipulating the shares of human effort and motor power. Besides reducing air and sound pollution, such rickshaws demanding less physical effort, may provide large scale employment in urban and rural areas of India.

1. INTRODUCTION

E-rickshaws are small vehicles, with three wheels and use electric power from batteries to run. They use an electrical motor of 650-1400W as engine which draws the electric power from the rechargeable batteries installed in rickshaw body. These battery operated vehicles are perfect for small distance transport, both cargo and people; they are perfect for running on narrow streets because of their small size. But biggest reason for their popularity is operating cost and zero pollution. They are like normal rickshaws but operated by electric motor instead of petrol or diesel. They are best for pollution free, environmental friendly transport system in short distances.

E-rickshaw is a good option due to less human effort and cost of fuel if compared with auto rickshaw and human pulled rickshaw. The pollution coming out from E-rickshaw is immensely less and it provides last mile connectivity that means it provides door to door service. Recently in India battery operated E-rickshaw are in much demand. Its comfortable and economic mode of transport has gained E-rickshaw popularity in India[1].

A study of travelling and charging of E-rickshaw patterns revealed that till today a household socket is the only option for the vehicle owners to charge their vehicle. As electricity comes from thermal power plants which emit CO_2 the e-rickshaw cannot be considered as a zero emission vehicle unless it will operated fully with the help of solar panel. 1.281 kg of CO_2 per unit of electicity generated is emitted in Coal-fired thermal power plant. 1.52 kg per litre of CO_2 is emitted by combustion of LPG. In combustion of diesel 2.71 kg per litre of CO_2 is emitted. From the figures in the table 1 given below it can be analyzed that e-rickshaw is more efficient than other vehicle [6].

TABLE 1 CARBON DIOXIDE EMISSION OF VARIOUS THREE WHEELERS

Sr.No.	**Vehicles**	**Specific CO2 emissions (gm/passenger-km)**
1.	Auto-rickshaw(LPG)	23.556
2.	Auto-rickshaw(Diesel)	21.51
3.	E-rickshaw	19.129

E-rickshaws are now of the preferred modes of transport in streets because of its low maintenance cost, eco-friendliness, being non noise pollutant, easy to drive. The motor is brushless DC motor manufactured mostly in India and China. The electrical system used in Indian version is 48V DC can run 90 to 100 km/full charge. Basic capacity is driver plus 3 passengers.

The main objective is to develop a model of e-rickshaw and interfacing system with solar panel. E-rickshaw is a basically battery operated vehicle which is directly equipped with battery and solar panel. The main aim to develop the pollution free vehicle with use of hybrid mechanism (battery and solar panel).

- To construct rickshaw light in weight
- Use of good material for a long life.
- To developed rickshaw is easy to operate.
- Non-polluted

To fulfill this objective this experimental research work involved the following processes:

• Study the structure and driving features of the existing conventional rickshaws and electric auto-rickshaws.

• To find a cost effective, feasible design and fabrication of parts for transforming conventional rickshaw to a hybrid one.

• Performance test of the hybrid vehicle to evaluate its feasibility and effectiveness compared to conventional and electric motor assisted rickshaws.

2 DESIGN AND CALCULATION ON TECHNICAL ASPECTS

The basic components require for experimental setup to develop prototype are BLDC motor, controller, Lithium ion battery, solar panel, Speedometer, Differential, LDR module, Tyre, Uno Arduino, Servo motor, Ultrasonic sensor.

2.1 BLDC MOTOR

Electronically commutated motors (ECMs) popularly known as Brushless DC electric (BLDC) motor. These are synchronous motor operated on DC power supply. In order to control the torque and speed of the motor the controller must capable enough to provide current pulses for the windings of motor[4]. The rotor consists of permanent magnets in the traditional configuration. The rotor whereas surrounded by the three stator windings. One of the trending applications of BLDC includes electric transportation system.

Calculations is carried out for Total Mass of electric vehicle: 350kg including weight of chassis (90kg), battery (45kg), person weight(1+2 person of total weight 250kg), Other weight (50kg) and for standstill or Initial velocity of EV: 0 and max velocity: 35km/hrs.

Parameter for calculation:
I = 22A
V = 48v

P = 900w
N = 2700 RPM
Pole=8

Torque: $T = \frac{60*P}{2*\pi*N} = \frac{900*60}{2*\pi*2700}$ = 3.18 N/M

Output Power:

$W = \frac{2*\pi*N}{60}$ = 282 rad/sec

Pout = T x W = 899.12

Efficiency:

Pin = V x I = 48 x 22 = 1056

% $\eta = \frac{Pout}{Pin} = \frac{900}{1056}$ *100 = 85.22 %

Now based on efficiency motor power should be greater than 900 W.

The existing BLDC motor to propose the controller for the same and the specification for the existing motor as follow:

- Voltages : 48Vdc
- Rated power : 1000W
- Speed : 2700 rpm
- Rated torque: 10Nm
- Peak torque : 25Nm
- Efficiency : > 85%
- Cooling options : air or liquid cooling

Figure-1 BLDC motor

2.2 CONTROLLER

Motor controller usually supplied with AC power. The power that comes in to a controller is at a set frequency. The motor controller first turns that AC to DC then turns the DC back into AC at right frequency. It use device called rectified to make DC current. The speed of a BLDC motor controlled by controlling the input DC voltage/current. The higher the voltage more is the speed. Many different controller algorithms have been used to provide the control the BLDC motor speed. The motor voltage is controlled by using a power transistor operating as a linear voltage regulator

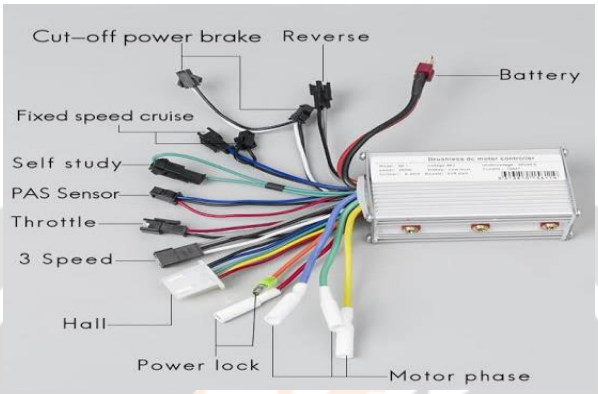

Figure-2 BLDC Motor controller

2.3 LITHIUM- ION BATTERY

The electrolyte carries positively charged lithium-ions from the anode to the cathode and vice versa through the separator. The movement of the lithium-ion creates free electrons in the anode which creates a charge at the positive current collector. The separator blocks the flow of electrons inside the battery.

Calculation of Lithium Ion Battery

P=VI
P=2400 watt
V=48 volt
2400=48×l
I=50 (50A for protection elements design)

Calculation of AH
2400watt×1hr=2400w-hrs.
Battery efficiency is around 85%
2400whr×1.15=2760
2760w-hr ÷ 48v =57.5 = 58 AH

Rated watt –hour capacity = Rated AH capacity x Rated battery voltage
= 58 x 48
= 2784 Watt – hour

Charging current 100rating / Charging current = 58 / 10 = 5.8 hrs.

To charge fully discharged battery Approx 5.8 hrs. is required. And for fast charging AH should be more which reduce charging time.

Specification

- Nominal voltage : 48 v
- Nominal capacity : 50A
- Weight : Approx 0.7kg
- Max. Charging current : 1.0C
- Max. Discharging current : 30-50A
- Cycle life : >500 times

Figure-3: Lithium-ion battery

2.4 DIFFERENTIAL

The axle is a part in e rickshaw which supports the differential and motor. We provide an axle designed to support motor weight and differential and also enhance performance of e-rickshaw. The quality of axle is important for safety and durability of the vehicle.

Figure-4: Differential

Specification:-

- Corrosion free
- Robust construction
- 1 ton load capacity
- Size 34 inches

2.5 SOLAR PANEL

Principle of solar panne : The photovoltaic effect, the photovoltaic effect is the conversation of sunlight energy into electricity. In pv system the pv cells exercise this effect.Semiconductor material in PV cells are dropped to from P-N structure as an internal electrical field[7].

Specifications:

- Maximum power : 330 W
- Maximum power voltage : 39V
- Maximum power current : 8.47A
- Short circuit current : 8.98A
- Open circuit voltage : 44.5V
- Maximum system voltage : 1000V

Figure-5: Solar panel

2.6 LDR MODULE

The automatic light used in E-RICKSHAW, it will provide a better solution for manual lighting of vehicle. It will sense the outside intensity of light and turns on the light automatically. The working principle of an LDR is photoconductivity, that is nothing but an optical phenomenon. When the light is absorbed by the material then the conductivity of the material reduces. When the light falls on the LDR, then the electrons in the valence band of the material are eager to the conduction band.

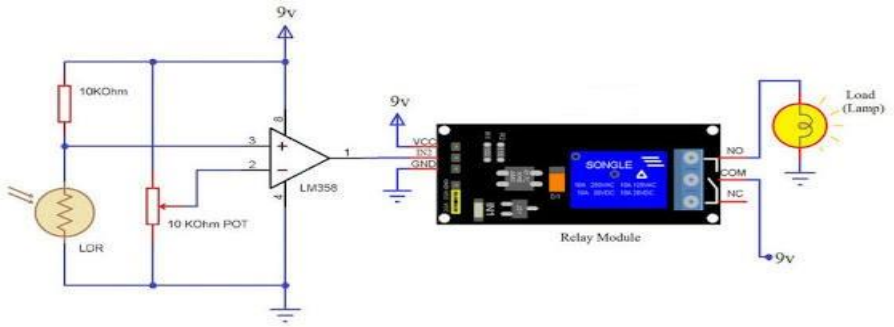

Figure-6 Automatic light controller using relays and LDR module

Specification:

- Operating Voltage : 3.3V to 5V DC
- Operating Current : 15milli amps
- LEDs indicating output and power
- Output Digital - 0V to 5V, Adjustable trigger level from preset

2.7 UNO ARDUINO R3

The automatic dustbin used in E-RICKSHAW. Which helps to create clean, safer, more hygienic environmental and enhanced operation efficiency while reducing Management costs , reduced, and rode side emissions.
The dustbin opens automatically when it receives the signal and closes it 'hatch. Also the dustbin consists of level sensing ultrasonic sensor that constantly measures the level of garbage in the dustbin and automatically detects if it is about the fill up.

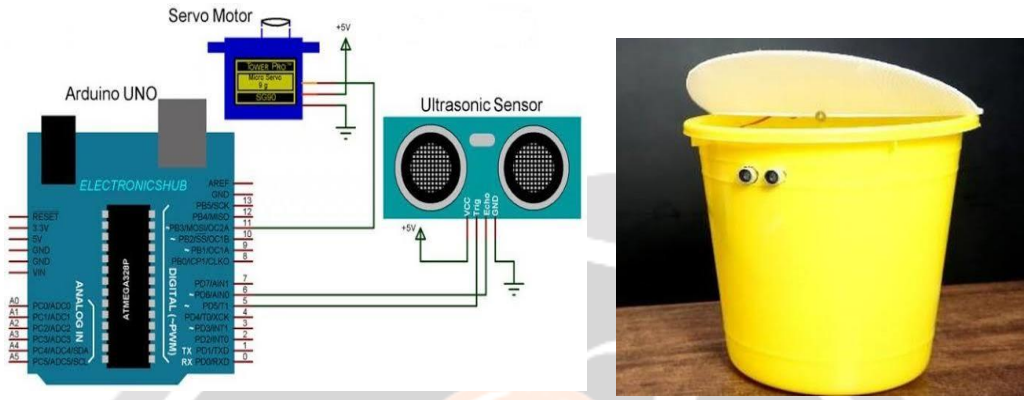

Figure-7: Circuit diagram smart dustbin using Uno Arduino R3

3 DESIGN METHODOLOGY

There are various factors and parts of the project that either had to be designed or selected. The major ones are given below with criteria for selection or design of each. In this e- rickshaw we have used a electric and mechanical controlling technology which is used to operate a mechanical & electrical equipment. The BLDC MOTOR controlled by controller using PWM technique having MOSFET. Motor controller usually supplied with AC power. The power that comes in to a controller is at a set frequency. The motor controller first turns that AC to DC then turns the DC back into AC at right frequency. It use device called rectified to make DC current. The speed of a BLDC motor controlled by controlling the input DC voltage/current. The higher the voltage more is the speed.
Many different controller algorithms have been used to provide the control the BLDC motor speed. The motor voltage is controlled by using a power transistor operating as a linear voltage regulator.

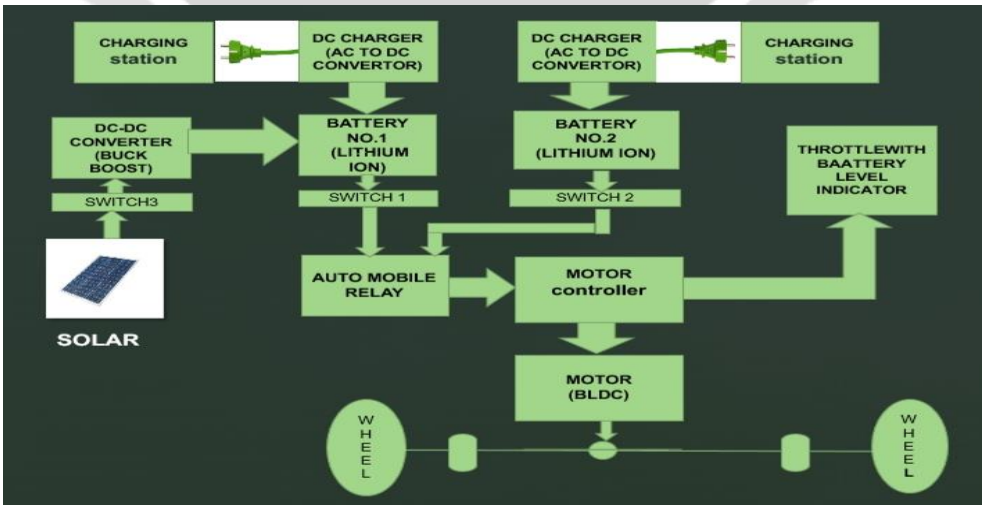

Figure-8 : Block Diagram of System

The block diagram gives whole process about the control system for vehicle. We are using two batteries connected through Automobile relay. The charged battery gives the supply for controller. The controller controls whole automated controlling devices. The controller gives respective commands to the motor, speedometer etc. Proper commands given from the input were further given to the controller and controller operates. Controller drives the motor which deal to move the vehicle. Automation controller controls the whole automation devices which are based on the user input.

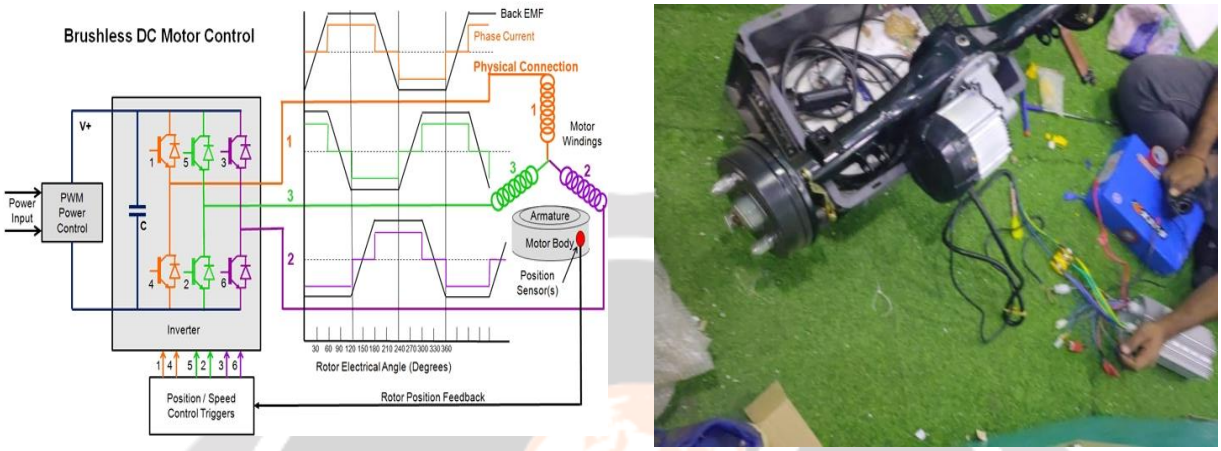

Figure-9 : Interfacing of BLDC motor with differential

Three Hall device embedded in the motor are usually used to provide digital signals which measure rotor position within 60 degree sectors and provide this information to the Motor controller. Because at any time ,the current in two of the winding are equal in magnitude and the third is zero.

This method can only produce current space vector having one of six different directions. As the Motor turns, the current to the motor terminals is electrically switched (commutated) ever 60 degree of rotation so that the current space vector is always within the nearest 30 degree of the quadrature direction.

Figure-10: Electrical and Mechanical testing

In the mechanical system such as in E-RICKSHAW, the brake shoes as actuated by a cum, which is attached to the brake linkage and pedal. When press the brake pedal, the cum turns. The friction between the brake linings and the drum causes the drum to stop rotating, there by stopping the wheel.

4 CONCLUSION

The study revealed that the e-rickshaws are energy efficient than other forms of motorized public road transport vehicles in the state. But the major challenges are required to be addressed for the proper implementation of these e-rickshaws. The paper shows the custom design of electric vehicle. While designing the vehicle there are different consideration and calculations. The one of main point is the selection of the motor and battery and its capacity. The design of chassis is also play the vital role in vehicle manufacturing. The points considered in this paper are the basic need of the designing of electric vehicle.

ABSTRACT

Now a day's water vending machines are available and operated on only one coin but we aim to design a water vending machine that is operated on different coins. In India, there is a problem with safe drinking water therefore we are going to provide mineral water. The rapidly rising population and changing lifestyles have increased the need for freshwater. It would be clear that in most rural areas, households are paying far more for water supply than the often-normal rates charged in urban areas.In summer we face the problem of drinking water.This project is based on coin operation. The water vending machine dispenses water on the detection of the right coin. It can be used in public places like Roads, Railway stations, Shopping Malls, etc. It can prove to be of great use and comfort for people.

Keyword: - Water vending machine, Programmable Logic Controller (PLC), Coin Sensor, RFID, Multi Coin operated

1.INTRODUCTION

The rapidly rising population and changing lifestyles have increased the need for freshwater. In summer, we face the problem of drinking water. So is the panic over drinking water supply in the city as well as in villages. The reservoir has just 35.63 feet of water, which is not even half of the total water level. We are going to design a project which is based on coin operation or RFID operation. It has been specially designed for village people. It is also use on Railway station, Bus station, public places etc. This system is based on PLC. The inputs to the PLC are coin and RFID tag and output in the form of water. Looking at the specifications required for water dispensing system and for simplicity of our application, microcontroller was found to be best suited. The machine has numerous input and outputs to provide service to the customer. The main motto of this system is to avoid the environmental pollution and also to avoid the wastage of water with the help of water control valve and give purified water to the customer. We know that the available water resources have initiated towards the end. This problem is quietly related to poor water allocation, inefficient use, and lack of adequate and integrated water management. Water Vending machine is going to be developed in such a way that water will get served to the customers.

Existing Systems In most of the developed countries the vending machines are situated at public places. These machines dispense the snacks, cold drinks, coffee, tea, etc. to the people. Also in developing countries the vending machines are used to provide these things. The basic idea of proposed system is originated from these existing systems. Majorly we are developing a system in which there are two water tanks to provide water to customer. The two major water tanks are as follows 1. Primary Tank (Front Tank) 2. Secondary Tank (Back Tank) Primary tank is only to give the required quantity of water to customers after inserting a coin in machine & secondary tank is connected to the hub tank (Central Tank) through the technique of pipelining[1]. Pipelining is useful to provide the water to the back tank (secondary tank) from the Hub tank (central tank). The Central Tank will be the main source of water to distribute water to secondary tank. Secondary tank will have two water levels empty & full respectively. These two water levels are controlled with the help of IC555 . Here PLC will be interfaced to maintain the constant water in the secondary tank using sensor.

2. TECHNICAL ASPECTS

2.1 PROGRAMMABLE LOGIC ONTROLLER

A Programmable Logic Controller is a solid-state industrial controller that performs discrete sequential logic in a factory environment. It is originally developed to mechanical relays, timers and counters. PLCs are used to perform difficult control operations in a plant. A sequence of instructions is performed by the user to the PLC memory and when the program is executed, the controller operates a system to the correct operating specifications.

A Programmable Logic Controller is currently defined by the National Electrical Manufactures Association (NEMA) as a digital electronics device that uses a programmable memory to store instructions and to implement specific functions such as logic, sequence, timing, counting and arithmetic operations to control machine and processes.

Figure 1 Programmable Logic Controller

2.2 SWITCHED MODE POWER SUPPLY

A switch mode power supply is a power converter that utilizes switching devices such as MOSFETs that continuously turn on and off at high frequency; and energy storage devices such as the capacitors and inductors to supply power during the non-conduction state of the switching device. The supplies have higher efficiencies of up to 90%, are small in size and widely used in computers and other sensitive electronic equipment.

SMPS offers advantages in terms of size, weight, cost, efficiency and overall performance. These have become an accepted part of electronic gadgets. Basically, it is a device in which energy conversion and regulation is provided by power semiconductors that are continuously switching “on” and “off” with high frequency.

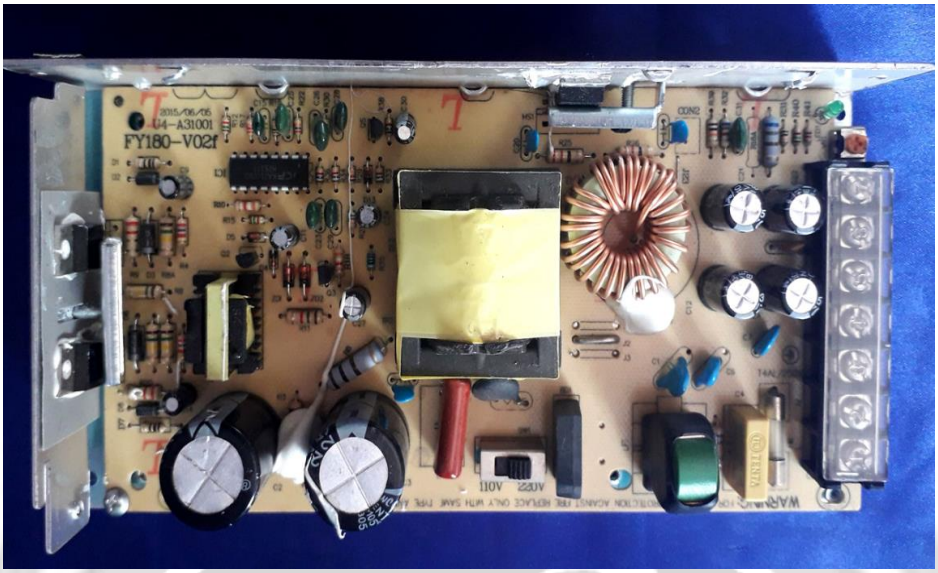

Figure 2 Switched mode power supply

2.3 COIN SENSOR

Coin sensor is the device which is used to detect the correct coin. The coin sensor uses the thickness, diameter and fall time of the coins to identify them. CH-926 is a multi-coin selector, can accept up to 6 kinds of different coins at the same time. This type of coin selector is widely used in Vending machine, Arcade Game, Message chair, and other self–management system. CH-926 is mainly based on material, weight and size to identify coins. It has the most up to date algorithm to design software. Therefore, CH-926 is very stable and accurate even when environment changes such as temperature, and humidity etc. In order to increase the accuracy, we suggest different version of coins use different channel to set up.

Figure 3 Coin Sensor

2.4 RFID SENSOR

A radio frequency identification reader (RFID reader) is a device used to gather information from an RFID tag, which is used to track individual objects. Radio waves are used to transfer data from the tag to a reader.RFID is a technology similar in theory to bar codes. However, the RFID tag does not have to be scanned directly, nor does it require line-of-sight to a reader. The RFID tag it must be within the range of an RFID reader, which ranges from 3 to 300 feet, in order to be read. RFID technology allows several items to be quickly scanned and enables fast identification of a particular product, even when it is surrounded by several other items.RFID tags have not replaced bar codes because of their cost and the need to individually identify every item.

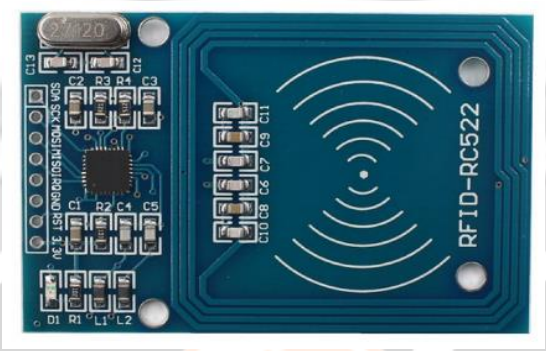

Figure 4 RFID sensor

2.5 SOLENOID VALVE

This is simple on\off type 9V dc supply valve. This type of valve is used in motors. This module consists of interface between vending machine and water output valve with the help of PLC. The switch is "Normally closed". (Automatic flush and shut off, auto power cut-off when filling, extends pump duration) when you connect it with high pressure switch. It shuts off the water supply when the tank is full. Normally controlled in the RO system by the booster pump High pressure switch.

Figure 5 Solenoid valve

2.6 PUMP

This water pump is use to take water from water tank or well. This water pump is connected between the water tank or well and tap where we can get water. In our project we use 0.5 HP, 0.37 kw monoblock water pump. Featuring brass impeller and copper winding, the special motor design of this water pump can work on UPS as well. This water pump is capable of priming up to 3 meters static suction lift without a foot valve at rated head and discharge. Well known for high performance, durability, efficiency, and reliability, this water pump can withstand with wide voltage fluctuation from 180 to 240 volts. With 33.6 LPM water flow and 50 hertz frequency, this water pump is applicable for use at household as well as commercial places.

Figure 6 Pump

Pump specification

Phase	Single phase
Motor body	Cast iron
Discharge	35 LPM
Suction delivery	25×25 mm
Voltage	230 volt
Motor power	0.5 HP
Frequency	50 Hz
Current	2 A

2.7 LCD

A liquid-crystal display (LCD) is a flat panel display, electronic visual display, or video display that uses the light modulating properties of liquid crystals. Liquid crystals do not emit light directly. LCDs are available to display arbitrary images (as in a general purpose computer display) or fixed images which can be displayed or hidden, such as preset words, digits, and 7- segment displays as in a digital clock. They use the same basic technology, except that arbitrary images are made up of a large number of small pixels, while other displays have larger elements.

Figure 7 LCD

3.DESIGN AND IMPLEMENTATION

3.1 Working Principle

This water vending machine is specially designed for village people to provide purified water. Machine is operated with the help of two sensors that are coin sensor or RFID sensor. The RFID sensor is designed for village, industry, company where people use this machine daily. So they have not to insert coin daily, they just need to scan their

RFID card and get water. Whereas the coin sensor operated machine is use every public place like Bus station, Railway station, garden or highways. They use coin of Rupee 1, 5 or 10.

A customer has to be insert coin in machine or RFID card is scan on sensor. The coin is checked whether the coin is correct or not by the coin sensor. The coin sensor uses the thickness, diameter and fall time of the coins to identify them. The RFID card is sense by the RFID sensor.

Now, when inserted coin or RFID card are appropriate or right the Programmable Logic Controller gives signal to the relay and relay will switch the R.O pump which is connected to the water tank. So the R.O pump will lift the water from water tank. Then water is flowing through the flow sensor. Flow sensor is sensing devices which continuously measure the amount of water. When flow sensor measures that amount of water which is defined for different coins, it will give signal to PLC and PLC give signal to the solenoid valve so valve will be off and water flow is stop. Solenoid valve controls the flow of water automatically. So customer will get purified water in the jug or any other watering vessel. Connection diagram is shown in figure 8.

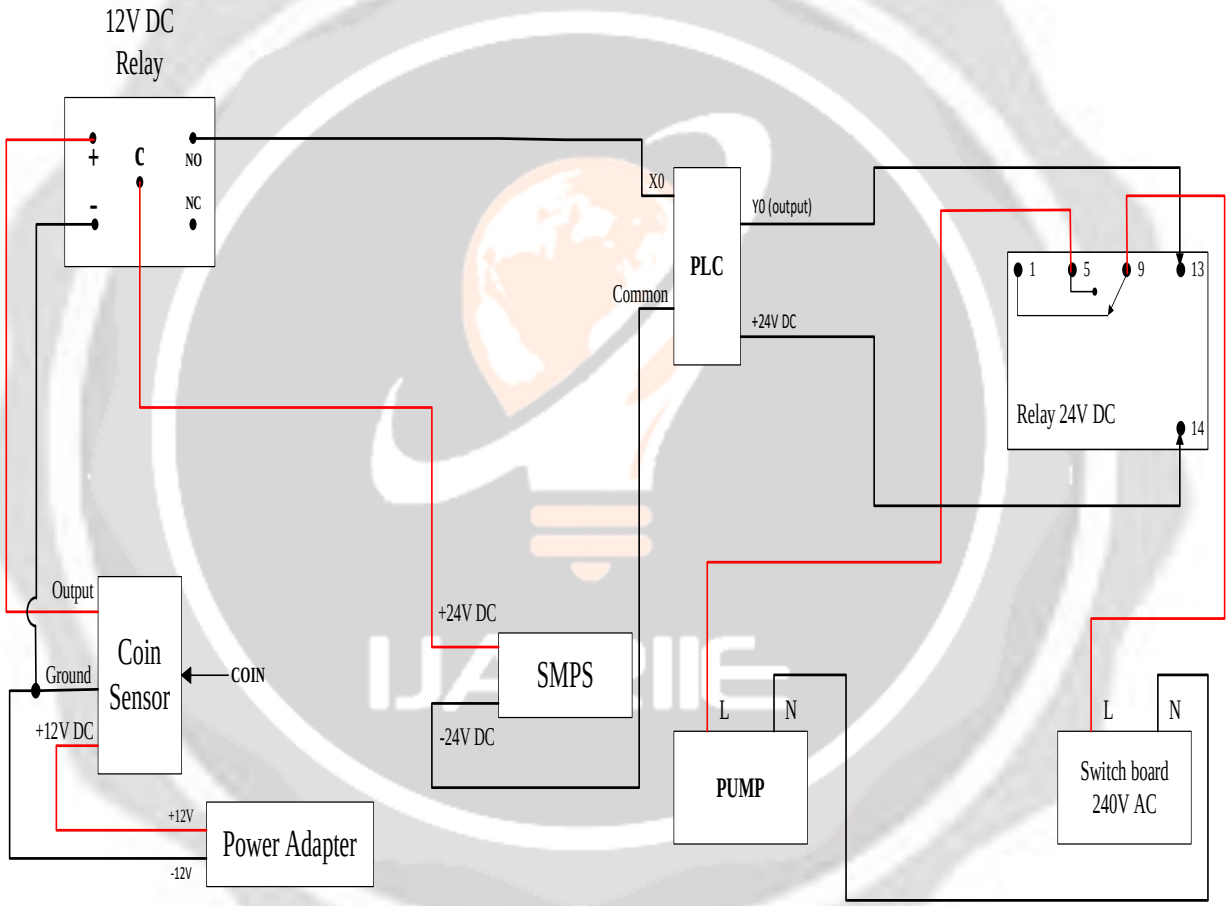

Figure 8 Connection Diagram

3.2 Flowchart of Water Vending Machine

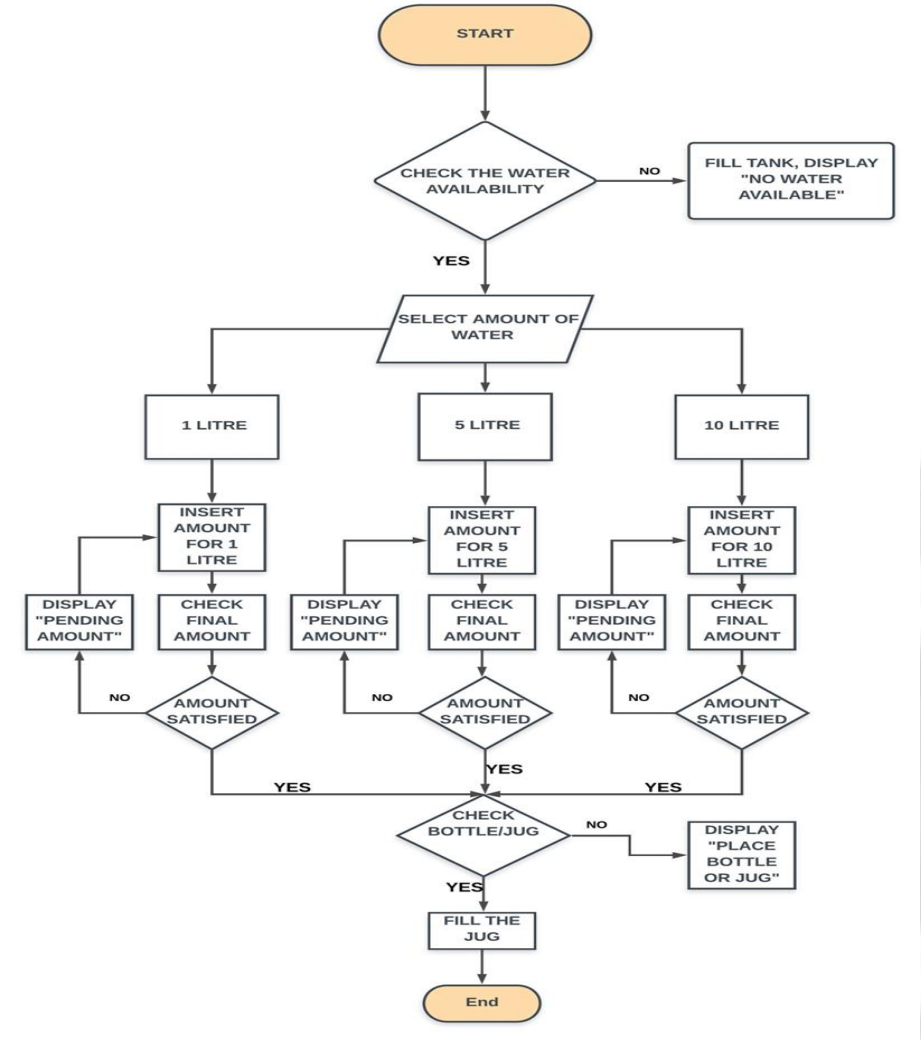

Figure 9 Flow Chart

The flow chart of water vending machine is shown as above. First machine check the status of the water in the water tank if there is no water then the LCD is displaying “Fill tank and No water available” and if water is available then the LCD is displaying “Select the amount of water”. Customer will select the amount of water that are one litre, five litre or ten litre. After that insert coin or scan the RFID card for selected amount of water. Now if the coin is correct then system will check the glass, bottle or jug is placed or not. So system will check whether glass or jug is placed or not. If jug is not placed then LCD displaying message “Place bottle/jug” and if the jug is place properly then water is dispatch into that jug. This way customer will get water and system is complete.

4. SIMULATION AND RESULTS

In this, we have done interfacing of coin sensor with PLC in winproladder software. Win Pro Ladder is easy to learn and use, and allows users of all types, beginner or expert to operate the software in a very efficient manner. For use in a Windows operating environment, completely designed in accordance with Windows environment operation methods. With run time editing feature, during the simulation process the program can be modified without stop the execution.

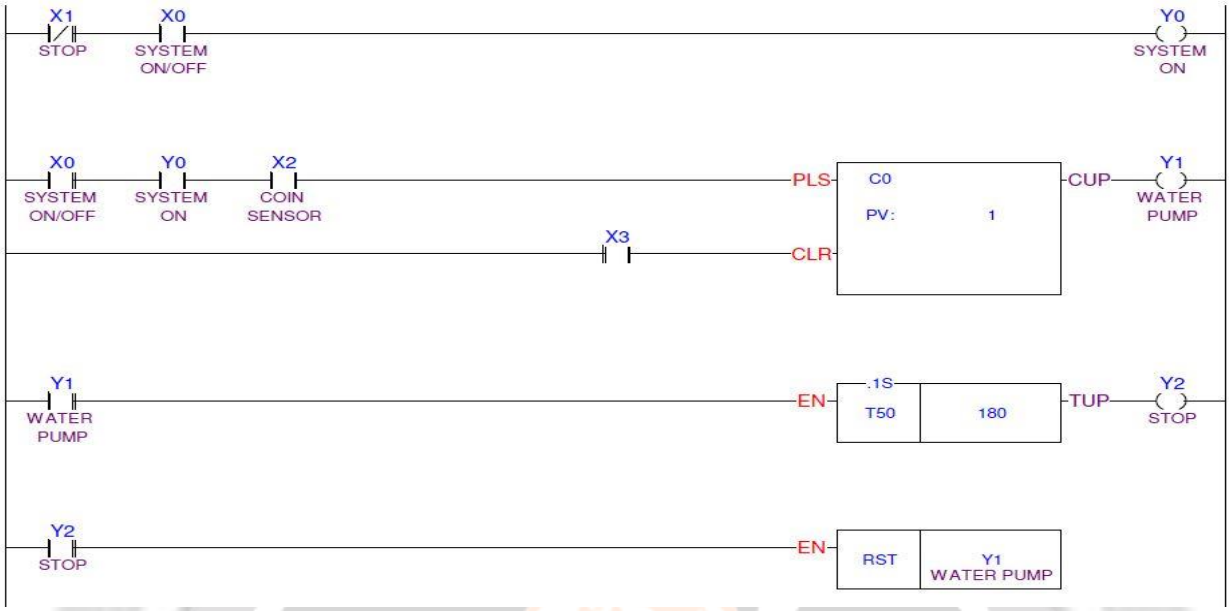

Figure 10 Ladder Diagram of interfacing of coin sensor with PLC

This is the ladder diagram of PLC done on win proladder software.

Here,

X0 = System on/off

X1 = Stop

Y0 = System on

X2 = Coin Sensor

Y1 = Water pump

C_0 = Counter

X3 = Push button for clear function

T50 = Timer

When push button X0 is processed our system is ON i.e. Y0 here X2 is our coin sensor so when coin is inserted it turns On and counter C_0 is increased by 1. So, our water pump Y1 is ON. There is one timer T50. When Y1 is on our timer T50 is ON for 180 seconds. After 180 seconds timer output turned ON the output coil Y2. The output of Y2 is given to reset function. In this reset function when done bit is given to it, the output associated with this function will be off. Here water pump Y1 is associated with reset function so after 180 seconds with the help of reset function water pump Y1 will be off.

In our project we conclude that acceptance ratio is almost 100% and vending machine works on arduino controller To develop low cost water vending machine. To avoid wastage of water.

5.FUTURE SCOPE

An increase in the diameter of the water solenoid valve and pipes would increase the flow rate. Hence, taking lesser time to fill in the tumbler. The whole product can be redesigned for it to be aesthetically pleasing and for its better usability. It can be used for other beverages and drinks also.

6.CONCLUSION

Implementation of Coin-Operated Automatic Drinking Water Machine is the step towards the future technology and it is a step to enter in eco-friendly world. This machine is easy to use and can be easily accessed by the ordinary person .We have developed a water vending machine which is an improved version of the normal water vending machine. This water vending machine reduces human efforts, less time consuming, economical and power consumption of the control system is less. A water vending machine is designed, developed, and demonstrated to give purified water at economical cost. Customers just have to insert coins or scan RFID card. By implementing this type of system, we can provide water at the village, public places like Bus station, Railway station, garden, and isolate place like highways.

ABSTRACT

Urbanization which is one of the most serious problems in 21st Century causes many environmental problems such as concrete areas and population increase. Although the decreasing urban green areas cause many environmental problems, it provides a basis for developing vertical garden. The vertical gardens are defined as gardens that cover façade walls with using various plant species by systems. This paper primarily focuses on monitoring and controlling of Green wall environment parameters and automatically. The proposed system is based on various sensors such as moisture sensor and temperature sensor for continuous monitoring the various parameters responsible for plant growth. The present control system is designed using recent ARDUINO due to some important features such as sleep mode, 10- bit ADC, wide input voltage range and also higher memory capacity. A step-by-step approach to design the arduino-based system for monitor and control of the three essential parameters for vertically grown plant growth, i.e. Soil moisture and temperature has been followed. The measurement shows that the system performance is accurate and quite reliable.

Keyword: - *Vertical Gardening, Automatic watering, Capacitive soil moisture sensor, Temperature sensor, Arduino, solar charging controller and Renewable energy source*

1. Introduction

A green wall is a new and creative idea of growing greenery in an urban and indoor environment. Green walls consists special type of plant containers attached to wall structure at particular angle. Structures can be free standing or attached to wall. This advance greenery is eye catching, good looking and improves the look of once plain walls. Green walls are becoming more and more popular recently across the globe. These are widespread in Europe and also in other areas of higher temperatures. They can be made in the colder climates, with the proper plant variety. The system presented here maintains moisture in soil and controls the microclimatic parameters of a green wall environment. The system consists of sensors, ARDUINO, Relays, LCD display water pumps and Solar cells. The soil moisture sensors are deployed in the plant root zones. Aim of this system implementation is to demonstrate that the project can be used to save water, time and labor cost. When any of the environmental parameters cross a safety threshold value which we have to be maintained for plants growth, the sensors sense this change and send to controller at its input port through Arduino. Microcontroller then performs the necessary actions by actuating relays until the strayed-out factors have been brought back to its required advantageous level. For real time display of data received from various sensors and status of some other devices a Liquid crystal display (LCD) is also used. The system proposed here is an economical, low maintenance, runs on renewable

energy source and portable for green wall applications, especially in developing countries.

2 HARDWARE REQUIREMENTS

The basic components of our projects are Arduino UNO R3, solar panel, dc pump, capacitive soil moisture sensor, LM35 temperature sensor and SPDT relay.

2.1 LM35 Temperature Sensor

The temperature sensor used in this project is thermistor. It is basically thermal resistor which changes its resistance with change in temperature. The sensor circuitry is not subjected to oxidation normally It is sealed. It can measure temperature accurately. It also has low self–heating property and does not exceed more than 0.1oC temperature rise in still air. Its operating temperature limit is from -55°C to 150°C.

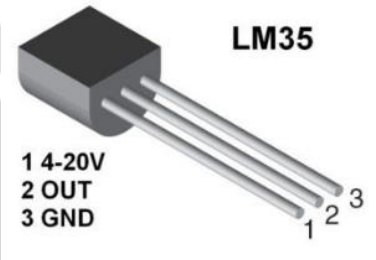

Figure -1: LM35 Temperature sensor

2.2 Capacitive soil moisture sensor

This moisture sensor consists of 2 copper conductors that are located at small distance from each other. For demonstration purpose, water pump is used and three soil moisture sensors for detecting soil moisture sensor. Both probes of soil-moisture-sensors are placed in soil. When no moisture is sensed by soil-moisture sensor in soil then the system turns on the motor or water pump until sensor senses the moisture in soil. Small potentiometer adjusts the Sense level. Its operating voltage ranges from 3.3V-5V.

Figure-2: Capacitive soil moisture sensor

2.3 Arduino UNO R3

This Arduino board has 14-digital I/O pins, a power jack, analog i/ps-6, ceramic resonator-A16 MHz, a USB connection, an RST button, and an ICSP header. All these can support the microcontroller for further operation by connecting this board to the computer. The power supply of this board can be done with the help of an AC to DC adapter, a USB cable, otherwise a battery.

Figure-3: Arduino UNO R3

2.4 Relay 12V DC

Relay is an electromagnetic device which is used to isolate two circuits electrically and connect them magnetically. They are very useful devices and allow one circuit to switch another one while they are completely separate. They are often used to interface an electronic circuit (working at a low voltage) to an electrical circuit which works at very high voltage. For example, a relay can make a 5V DC battery circuit to switch a 230V AC mains circuit. Thus a small sensor circuit can drive, say, a fan or an electric bulb.

Figure-4: SPDT Relay

2.5 DC Pump

DC powered pumps use direct current from motor, battery, or solar power to move fluid in a variety of ways. Motorized pumps typically operate on 6, 12, 24, or 32 volts of DC power. Solar-powered DC pumps use photovoltaic (PV) panels with solar cells that produce direct current when exposed to sunlight.

Figure-5: DC water pump

2.6 Solar charging controller

A charge controller is an important component in a battery based solar system and are not used in straight grid tie systems. The primary role is to manage charging the battery bank, prevent it from overcharging and many control the rate of the current and voltage at which it charges.

Figure-6: Solar charging controller

3. OBJECTIVES

In non conventional energy era, solar energy is one of the most effective energy sources , so solar cells are used to power our circuit .The main objective of this project was to design a greenwall monitoring system that is be highly reliable, cheaper in cost and efficient for growing the plants. Our project mainly focuses on the control of parameters such as-temperature and soil moisture. The block diagram of the green wall monitoring system has been shown in Figure 6.

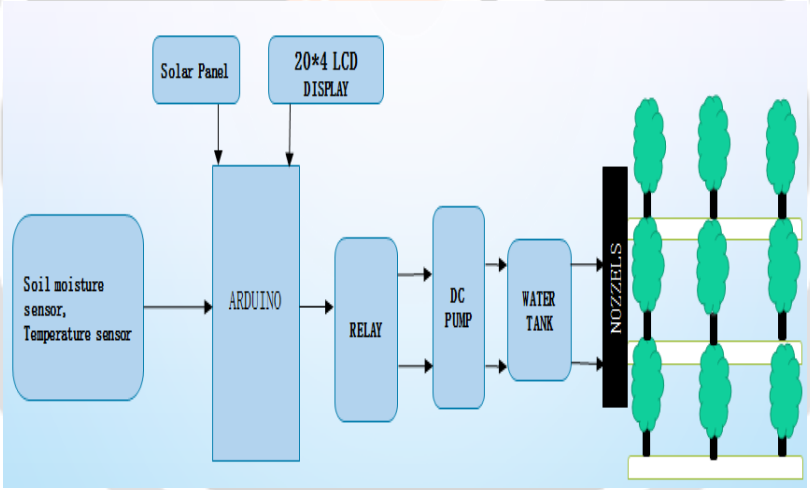

Figure-7: Block diagram of system

4. Methodology

System is switched on by solar panel or 9-volt dc battery and a Dc supply by solar panel to the pump. Solar panel provides the 7 to 9-volt supply to the Arduino. Sensor is connected to Arduino its getting power though the Arduino. Sensors output is given to ADC which provides digital signal at input port of microcontroller. Then controller generates necessary control signals to switch the Relay to operate the pump. The thermistor is used for sensing temperature. When temperature exceeds from a predefined level or critical level, then the system automatically switches on the sprinkles and also displays information of all parameters (Temperature, soil sensor and Electrical appliance on/off position) on LCD. And when the temperature falls below in normal range or comes to the predefined level pump will turns off automatically. Moisture sensor is used for sensing moisture in soil. When moisture comes down from a defined level, controller turns on the water pumps automatically to maintain moisture level in soil and made off in presence of moisture. The individual outputs from the sensor are in the analog form. Sensed analog signal is for further processing. Thus, the analog values are given to the Arduino to

indicate status of devices on LCD. The Arduino will read the sensor periodically and updates the value of sensor. If any of the Green wall parameters exceeds the threshold value set by the user, necessary control action will take place automatically. If the Green wall parameter falls below the threshold value, the controller will be turned off the device.

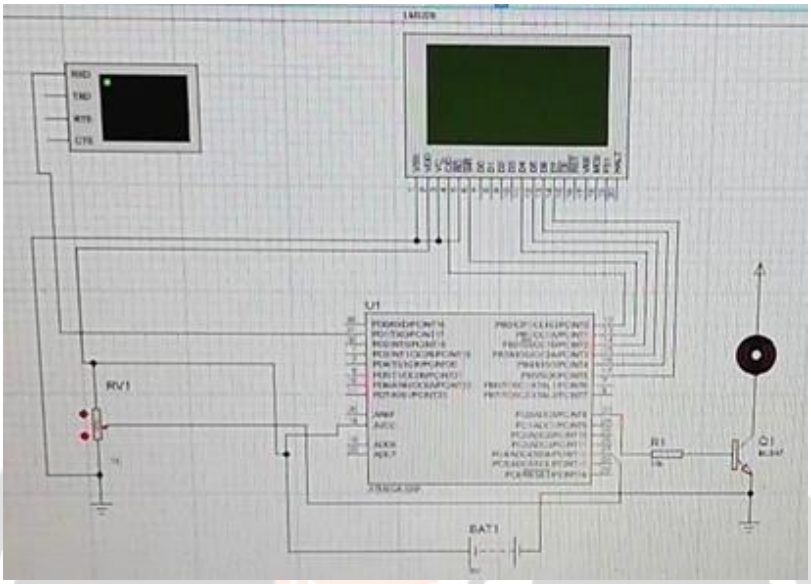

Figure-8: Simulation in proteus with atmega-328

The Proteus Design Suite is a proprietary software tool suite used primarily for electronic design automation. The software is used mainly by electronic design engineers and technicians to create schematics and electronic prints for manufacturing printed circuit boards.

In above simulation there is a sensor work as soil sensor which will give us an output of analog signal. This sensor is set on value of 51%. If the value is above the 51% the condition will be normal, which means soil has enough water for plants, so the motor doesn't work. But when the value of sensor goes below the 51% immediately the motor will start working by itself, and the display will keep showing the soil moisture level respective to sensor's output.

Efficient results have been obtained from the following project. Table 1 shows the recorded data in several days. The sensor that we are using are giving good results and performing to the expectations.

Table-1: Recorded Data

Soil moisture level	Relay	Water Pump ON/OFF
100%	Turns off	OFF
67%	Turns Off	OFF
48%	Turns On	ON
33%	Turns On	ON

5. Hardware arrangement

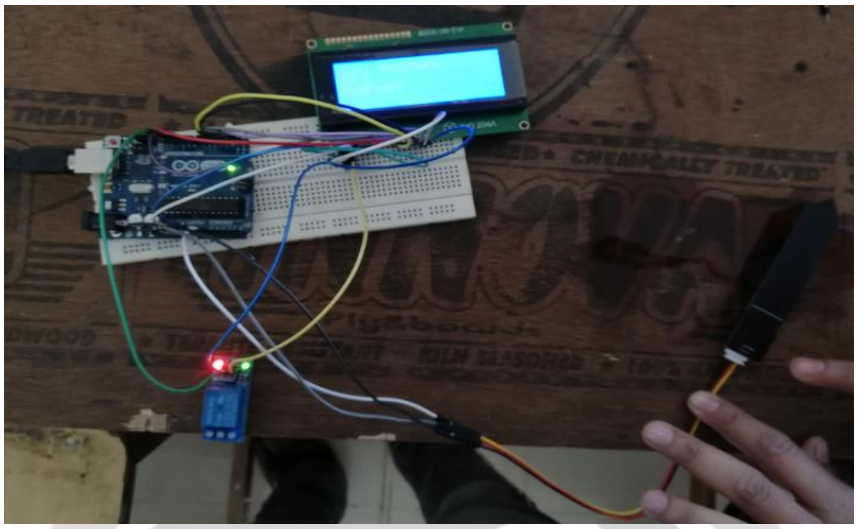

Figure-9: Hardware Arrangement

The same as interface in simulation Here we have connected soil moisture sensor and LCD display and arduino with the help of bread board. There are two different pots one with dry soil and another one with wet soil. As we put moisture sensor in wet soil, sensor passes the signal to the arduino that soil is wet so the pump should not be start. The moisture level shows on the LCD display. As we put moisture sensor in the dry soil, sensor detects it and passes the signal to the arduino that pump should be ON. As the soil getting wet by supplying the water the corresponding moisture level displays on the LCD display in percentage.

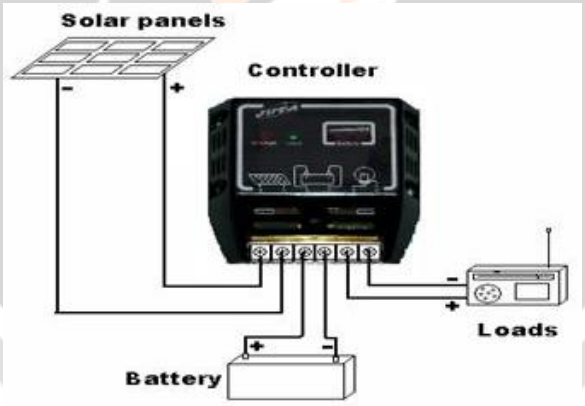

Figure-10: Solar charging controller connction

The most essential charge controller basically controls the device voltage and opens the circuit, halting the charging, when the battery voltage ascents to a certain level. More charge controllers utilized a mechanical relay to open or shut the circuit, halting or beginning power heading off to the electric storage devices. Generally, solar power systems utilize 12V of batteries. Solar panels can convey much more voltage than is obliged to charge the battery. The charge voltage could be kept at the best level while the time needed to completely charge the electric storage devices is lessened. This permits the solar systems to work optimally constantly. By running higher voltage in the wires from the solar panels to the charge controller, power dissipation in the wires is diminished fundamentally. The solar charge controllers can also control the reverse power flow. The charge controllers can distinguish when no power is originating from the solar panels and open the circuit separating the solar panels from the battery devices and halting the reverse current flow.

6. FUTURE SCOPES

- This system can be connected to the communication devises like cellular phone, modems, or satellite terminals for the remote collection of the recorded data.
- This system can be improved with the use of data logger and graphical LCD panel showing the sensor data after a period of time.
- Adding a Fertilizer sensor and automatic control on it will be a good improvement in this system.

7. CONCLUTION

A step-by-step approach to design the Arduino based system for monitor and control of the two essential parameters for vertically grown plant growth, i.e. Soil moisture, and temperature, has been followed. The measurement shows that the system performance is accurate and quite reliable. The designed system has successfully overcome the drawbacks of the previous system by reducing maintenance, complexity and the power consumption, at the same time providing very precisely management of providing the waters. Less amount of water is used due to controlled irrigation and it helps to save water and time. Use of multiple sensors reduces quantity of dead plants and increases quality and productivity of plants. Well developed and good quality plants results a beautiful living green wall. Thus, the system is efficient and compatible to change the environment.

ABSTRACT

In this project mainly focused on the design and implementation of new topology in a single phase cascaded H-bridge multilevel inverter by using only MATLAB software. The main objective of this project is to increase number of levels with a low number of switches and sources at the output without adding any complexity to the power circuit. The main merit of the new topology is to reduce the lower total harmonic distortion, lower electromagnetic interference generation and high output voltage. In this project, various carrier sinusoidal pulse width modulation techniques are proposed, which can minimize the total harmonic distortion and enhances the output voltages from proposed work of multilevel inverter. The various switching topologies of single-phase cascaded H-bridge multilevel inverters have been analysed in this paper.

Keywords: *single phase H-Bridge Inverter, Spwm technique using Matlab software.*

I.INTRODUCTION

While for high power applications multilevel inverters are the best available alternative, for medium or low power applications a controversy takes place. Experts on high frequency converters point out the compactness and reduced cost that can be achieved by employing high frequency switching. On the other hand, experts on low frequency converters claim that the very best efficiency and robustness belong to the topologies based on low frequency switching.

Cascaded H-bridge (CHB) multilevel inverter is One of the popular converter topologies used in high-power medium-voltage (MV) inverter. It is composed of a multiple units of single-phase H-bridge power cells. The H-bridge cells are normally connected in cascade on their ac side to achieve medium-voltage operation and low harmonic distortion. In practice, the number of power cells in a CHB inverter is mainly determined by its operating voltage and manufacturing cost. The CHB multilevel inverter requires a number of isolated dc supplies, each of which feeds an H-bridge power cell the single-phase H-bridge power cell, which is the building block for the CHB inverter, is reviewed. Various inverter topologies are introduced. Two carrier- based PWM schemes, phase-shifted and level-shifted modulations, are analyzed and their performance is compared. A staircase modulation with selective harmonic elimination is also presented.

II.INVERTER TOPOLOGY

Fig.1(a) shows a three-level diode-clamped inverter.The output voltage is expressed as v an where n is chosen as the neutral point. The series-connecting bulk capacitors C1and C2 can split the DC bus voltage V dc into three levels. The switching state for different output is shown as follows:

- When the output voltage van = Vdc/2, the upper two switch S1 and S2 are closed.
- When Van = 0, the switch S2 and S1' are closed.
- When Van = −Vdc/2, the lower two switch S1' and S2' are closed.

The clamping diodes D1 and D2' play as an important role in this kind of inverter which can clamp the switch voltage to half of the DC link voltage. The output voltage van = Vdc2 is served as an example. In this case, the switch S1 and S2 should be closed. D1' is used to balance out the voltage sharing between the two switch S1 and S2. The voltage across C1 is blocked by S1' and the voltage across C2 is blocked by S2'

The five-level diode-clamped multilevel inverter is shown in Fig.2-1(b). The DC link voltage Vdc is evenly shared by four capacitors C1, C2, C3 and C4. The output voltage van and the corresponding switch state are shown in figure 1

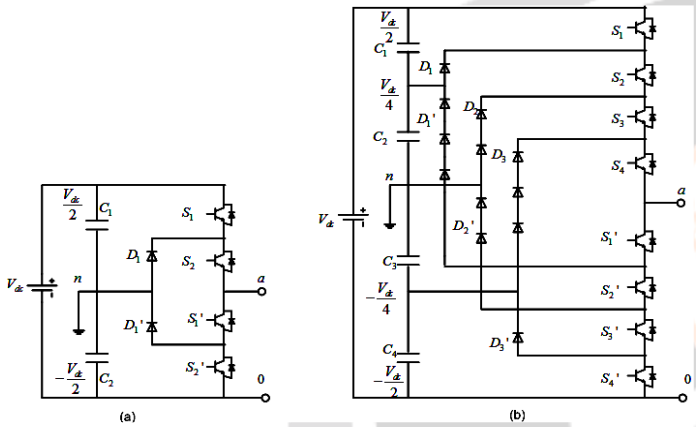

Fig. 1: Diode-clamped multilevel inverter topologies: (a) Three-level. (b) Five-level.

Voltage van	Switch State							
	S1	S2	S3	S4	S1'	S2'	S3'	S4'
van = Vdc/2	1	1	1	1	0	0	0	0
Van=Vdc/4	0	1	1	1	1	0	0	0
van = 0	0	0	1	1	1	1	0	0
van = −Vdc/4	0	0	0	1	1	1	1	0
van = −Vdc/2	0	0	0	0	1	1	1	1

Table 1.1. Switching states for a 5 level Diode-Clamped.

2. CAPACITOR-CLAMPED MULTILEVEL INVERTER

In Fig.2, the topologies of the three-level and five-level capacitor-clamped multilevel inverter are presented. They have similar structure as the diode-clamped multilevel inverter. The capacitors are used in the topology instead of diodes.

The three-level capacitor-clamped multilevel inverter is shown in Fig.2-2(a). One advantage of this kind of topology is that it can provide some redundancies for a certain output voltage. Taking the three-level Capacitor-Clamped Inverter as an example, for Van = 0, either pair (S1, S1') or (S2, S2') needs to be turned on. The number of redundancies will increase as the output voltage level increases. The switch state and its corresponding output voltage for five-level capacitor-clamped Inverters are shown in Table 2.2. With these redundancies, the capacitor voltages can be easily balanced with some control strategies and modulation methods since it is possible to choose which capacitor is to be charging and which one is to be discharging.

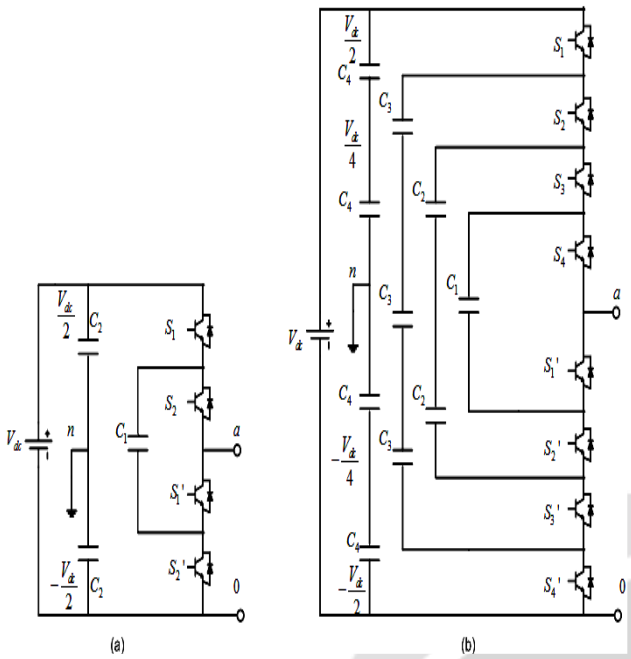

Fig. 2: Diode-clamped multilevel inverter topologies: (a) Three-level.(b) Five-level.

Voltage van	Switch State							
	S1	S2	S3	S4	S1'	S2'	S3'	S4'

−Vdc/2	0	0	0	0	1	1	1	1

Table 2.2. Switching states for a 5-level Capacitor-Clamped Inverter.

3. CASCADED H-BRIDGE MULTILEVEL INVERTER

The Cascaded H-Bridge (CHB) multilevel inverter is based on the series connection of single phase H-bridge inverters with separate DC sources. The topology is shown in Fig.2-3. The output phase voltage is synthesized by the addition of the voltages that are generated by different modules. If the separate DC sources have the same voltage level (Vdc), the resulting phase voltage will be able to range from −nVdc to nVdc which would have (2n + 1) levels. And n is the number of the total modules or the number of separate DC sources. As the number of DC sources increases, there would be more levels in the output voltage. So the output voltage waveform will be nearly sinusoidal, even without filtering.

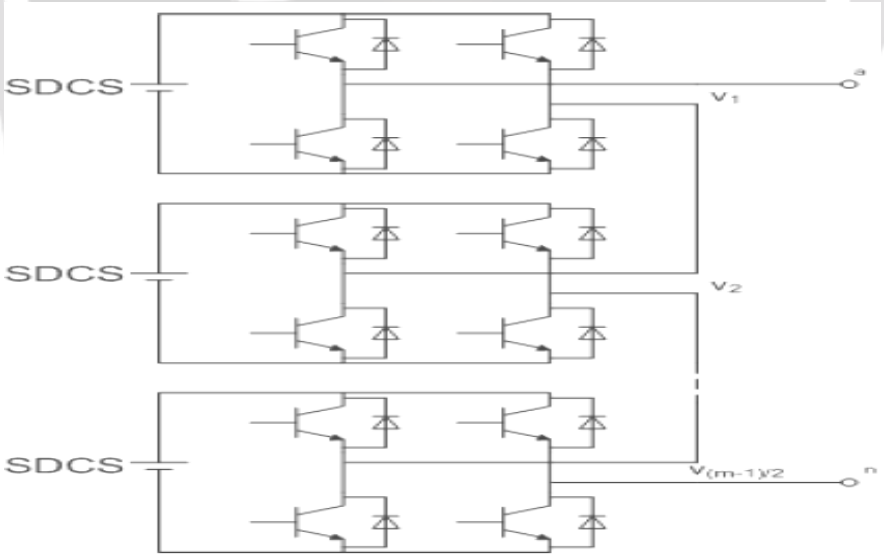

Fig. 3: CHB multilevel inverter topology.

III. MULTILEVEL MODULATIONS

When it comes to multilevel inverter modulation there are several ways to classify modulation techniques. Here, the way shown in is adopted and graphically presented in Fig.4. Multilevel modulations are meant to produce an average output voltage proportional to the reference given by some external algorithm, while multilevel controls are meant to apply an output voltage calculated by them, like Multilevel Direct Torque Control (MDTC).

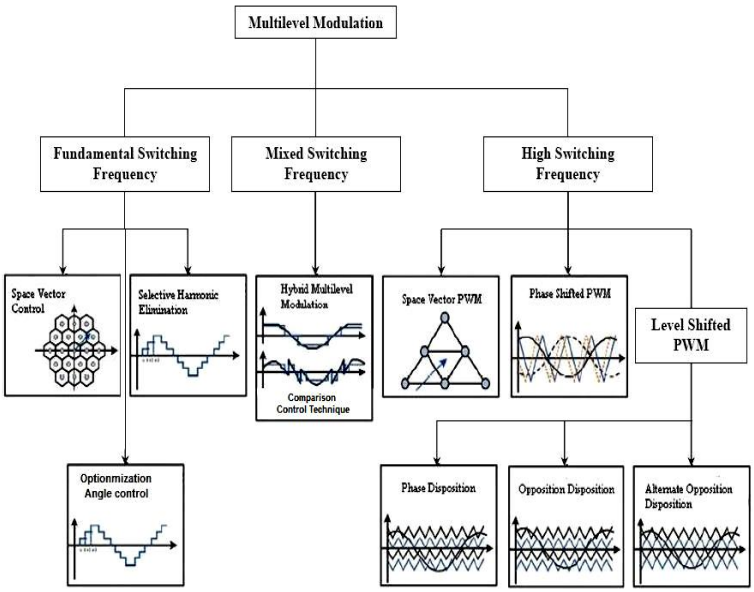

Fig.4: Classification tree for multilevel modulations.

III.PROBLEM IDENTIFICATION AND PROPOSED SOLUTION

Generally we are performing the simple inverter simulation in power electronics practical than we can't get efficient output voltage. Now a day requirement is better power quality. So we think about the less total harmonics distortion in output of the inverter voltage. And when controlling of power electronics switch at low frequency than harmonics is more in voltage. And also simple inverter is used for low power application and it have high THD ratio.

So we decided work on multilevel inverter for better output voltage. It is also use for high power application. and in multilevel inverter we are also use different technique like PWM and SPWM.

IV LEVEL SHIFTED PWM (LSPWM)

IV.I In Phase Disposition (IPD):- Level Shifted PWMs use more carriers, with the same amplitude and frequency, but translated in level as pictures in Fig, 5, show for a 5-level inverter. The number of carriers needed to generate the driving signals for an n-level converter is the same as PSPWM that is n-1.There are three major kinds of LSPWMs depending on how the carriers are disposed. The most evident method, depicted in Fig.5, is called In Phase Disposition (IPD).

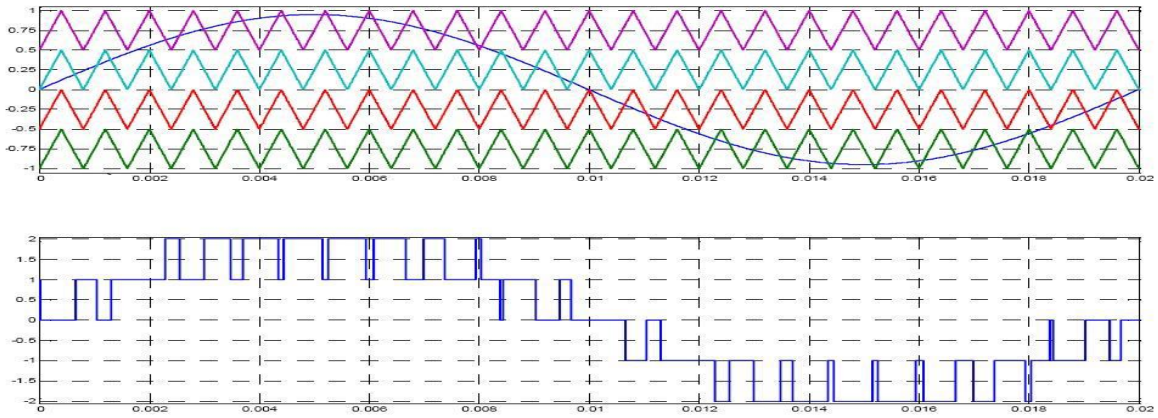

Fig. 5**:** LSPWM carriers and reference for a 5-level converter, In Phase Disposition (IPD)

The interval of possible voltage reference values is subdivided into one zone for each carrier which modulates the output only when the reference belongs to its zone. When the reference does not belong to a zone, associated carrier comparison output is fixed to high or low level: it is high when the reference is above the carrier; vice versa it is low when the reference is under the carrier. The comparison output, obtained in this way, and its negation can directly drive a couple of switches in diode-clamped. The sum of all the comparison outputs, shown in Fig.5, is a signal proportional to the instantaneous required output level.

IV.II Phase Opposite Disposition (POD):-

The **Phase Opposition Disposition** (**POD**) uses the same translation of carriers as IPD, but the carriers associated to negative levels are in opposition of phase as depicted in Fig.6. Fig.6 shows the signal obtained as sum of comparison output signals and it is proportional to the level required.

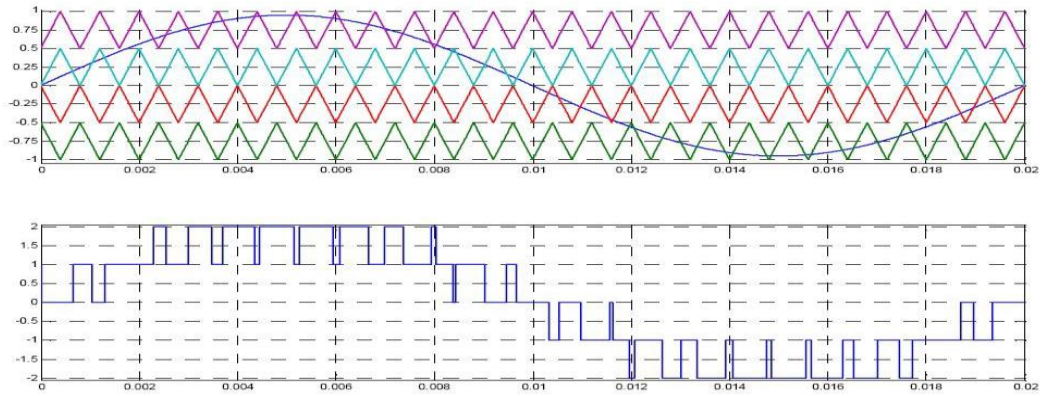

Fig.6**:** LSPWM carriers and reference for a 5-level converter, Phase Opposition Disposition (POD)

IV. III Alternative Phase Opposition Disposition (APOD):-

The **Alternative Phase Opposition Disposition** (**APOD**), depicted in Fig.7, has the carriers alternatively in phase or in opposition. Fig. 7 shows the output required by this kind of modulation.

As it can be seen comparing Fig.5, 6 and 7, the difference among these three LSPWMs is related to the symmetry of the output they produce. Indeed, POD and APOD have odd symmetry, while IPD positive half-wave can be mirrored and translated to coincide with the negative one. Each switch commutates at the carrier frequency only

when the reference belong to the zone related. Otherwise the switch is hold, but the converter is still commutating. This means that the switching frequency of the converter is equal to the carrier frequency (fcar), but the average switching frequency of the single switch (fsw) is lower and, for a n-level converter, it is given by (1)

$$fsw = \frac{fcar}{(n-1)} \quad \text{----------(1)}$$

Anyway, the carrier frequency has to be suited for the characteristics of the chosen switchs, so in LSPWM do not really allow to increase the output frequency as PSPWM does.

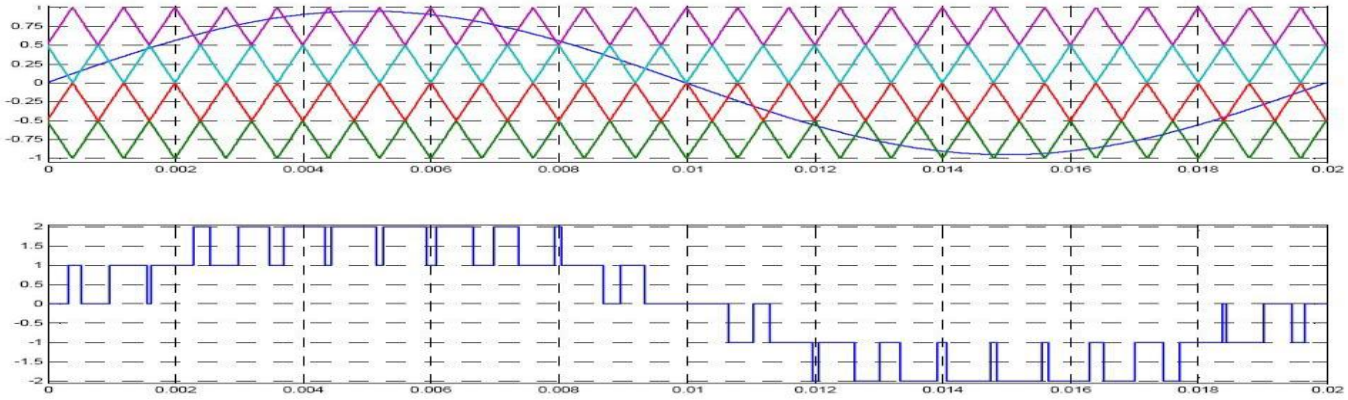

Fig. 7**:** Level Shifted PWM carriers and reference for a 5-level converter, Alternative Phase Opposition Disposition (APOD).

V. SIMULATION RESULT

V.I. SIMULATION RESULT 3 LEVEL SPWM INVERTER USING IN PHASE DISPOSITION (IPD) LEVEL SHIFTED PWM:-

The Matlab Simulink Model analysis for single phase 3-level 5 level and 7 level MLI using Level Shifted PWM Technique in phase disposition is shown in Fig.8. However few changes of no. of carriers and phase change of triangular carrier waves are required according to modulation techniques. LSPWM carriers and reference for a 3-level 5 level and 7 level converter, and variance gate pulse on Mosfet In Phase Disposition (IPD) MLI and LSPWM carriers and reference for a 3-level 5 level and 7 level converter, and variance gate pulse on Mosfet In Phase Disposition (IPD) MLI and Output voltage and FFT of 3-level 5 level and 7 level Converter using IPD, modulation techniques is shown in fig.9, 10 and 11 respectively.

V.I. SIMULATION RESULT 3 LEVEL SPWM INVERTER USING IN PHASE DISPOSITION (IPD) LEVEL SHIFTED PWM:-

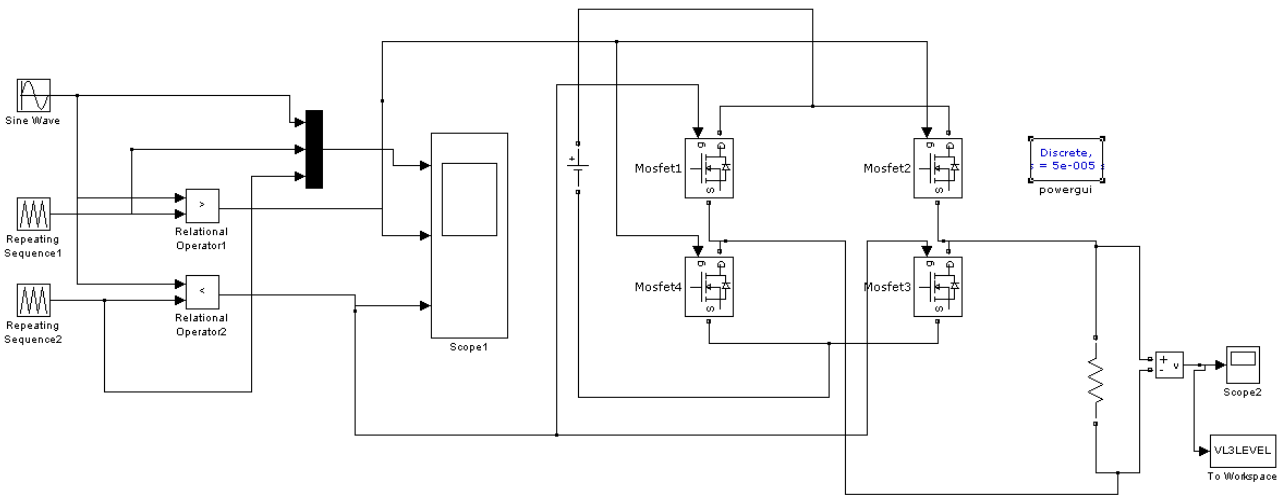

Fig.8 3-Level SPWM Inverter Simulation Circuit.

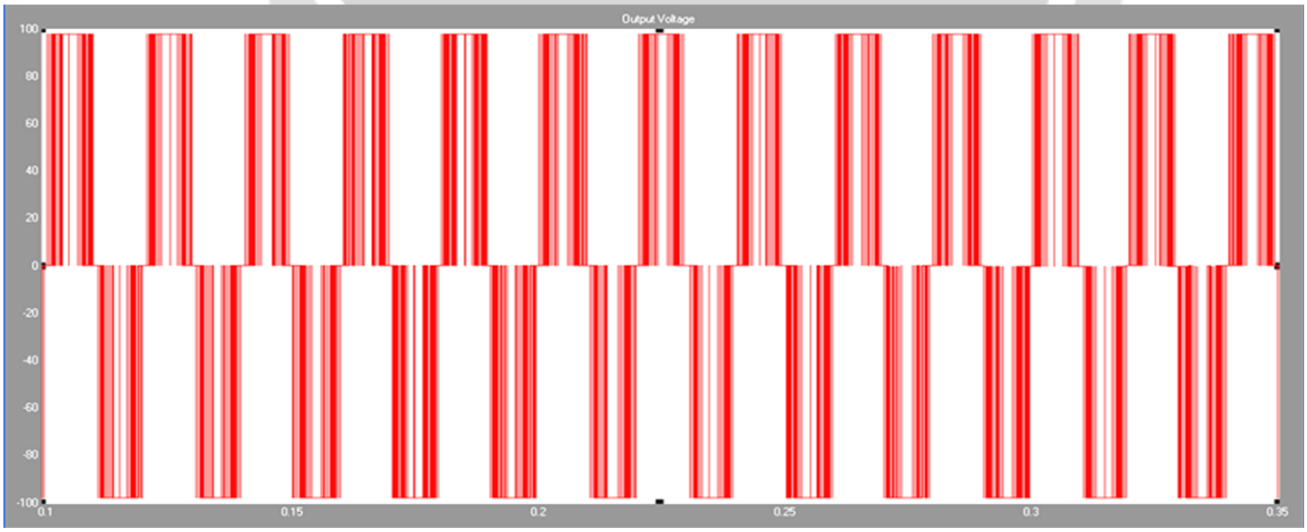

Fig.9.3-Level SPWM Inverter output voltage.

V.II. SIMULATION RESULT 5 LEVEL SPWM INVERTER USING IN PHASE DISPOSITION (IPD) LEVEL SHIFTED PWM:

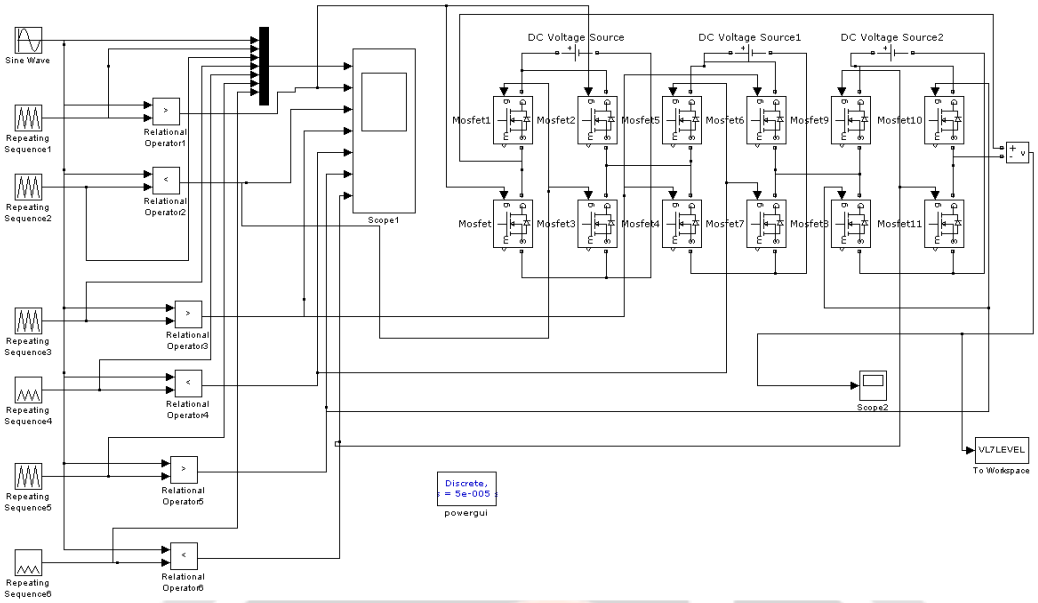

Fig.14. 7-Level SPWM Inverter Simulation Circuit.

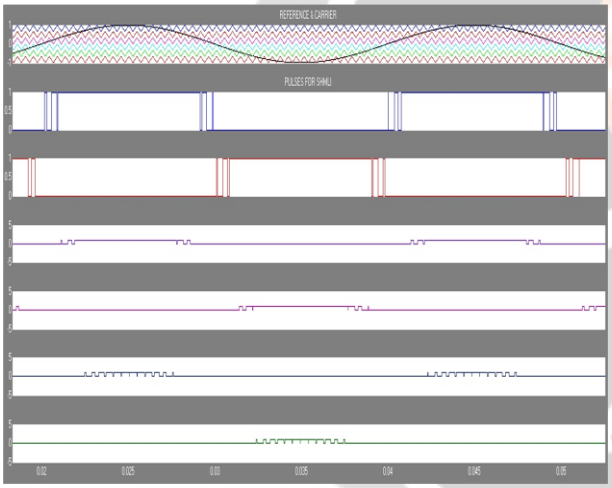

Fig. 15: Gate Pulse for a 7-level IPD- MLI

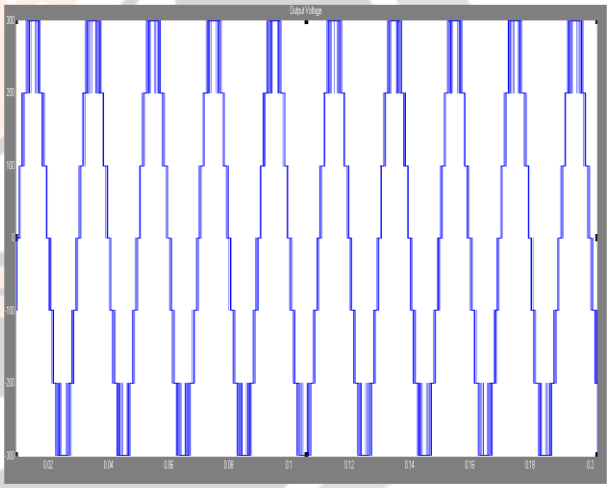

Fig. 12**:** Output voltage for a 7-level IPD- MLI

V.IV. COMPERATIVE ANALYSIS 3 LEVEL 5 LEVEL AND 7 LEVEL SPWM INVERTER USING IN PHASEDISPOSITION (IPD) LEVEL SHIFTED PWM:

Comparative analysis 3 level 5 level and 7 level spwm inverter using IPD PWM.

Sr No.	Level of MLI	METHOD	THD (%)
1	3	SPWM-IPD	4.08%
2	5	SPWM-IPD	2.01%
3	7	SPWM-IPD	1.38%

VI .CONCLUSION

In this paper Simulation result achieved High Switching Frequency H-Bridge Multilevel Inverter Using Level Shifted In Phase Disposition (IPD) Modulation using MATLAB Software, and desired output voltage THD is 1.55%,in this LSPWM is good opportunity for the realization of the single-phase inverter control and reduced harmonic distortion.

ABSTRACT

Now a day's water vending machines are available and operated on only one coin but we aim to design a water vending machine that is operated on different coins. In India, there is a problem with safe drinking water therefore we are going to provide mineral water. The rapidly rising population and changing lifestyles have increased the need for freshwater. It would be clear that in most rural areas, households are paying far more for water supply than the often-normal rates charged in urban areas.In summer we face the problem of drinking water.This project is based on coin operation. The water vending machine dispenses water on the detection of the right coin. It can be used in public places like Roads, Railway stations, Shopping Malls, etc. It can prove to be of great use and comfort for people.

Keyword: - Water vending machine, Programmable Logic Controller (PLC), Coin Sensor, RFID, Multi Coin operated

1.INTRODUCTION

The rapidly rising population and changing lifestyles have increased the need for freshwater. In summer, we face the problem of drinking water. So is the panic over drinking water supply in the city as well as in villages. The reservoir has just 35.63 feet of water, which is not even half of the total water level. We are going to design a project which is based on coin operation or RFID operation. It has been specially designed for village people. It is also use on Railway station, Bus station, public places etc. This system is based on PLC. The inputs to the PLC are coin and RFID tag and output in the form of water. Looking at the specifications required for water dispensing system and for simplicity of our application, microcontroller was found to be best suited. The machine has numerous input and outputs to provide service to the customer. The main motto of this system is to avoid the environmental pollution and also to avoid the wastage of water with the help of water control valve and give purified water to the customer. We know that the available water resources have initiated towards the end. This problem is quietly related to poor water allocation, inefficient use, and lack of adequate and integrated water management. Water Vending machine is going to be developed in such a way that water will get served to the customers.

Existing Systems In most of the developed countries the vending machines are situated at public places. These machines dispense the snacks, cold drinks, coffee, tea, etc. to the people. Also in developing countries the vending machines are used to provide these things. The basic idea of proposed system is originated from these existing systems. Majorly we are developing a system in which there are two water tanks to provide water to customer. The two major water tanks are as follows 1. Primary Tank (Front Tank) 2. Secondary Tank (Back Tank) Primary tank is only to give the required quantity of water to customers after inserting a coin in machine & secondary tank is connected to the hub tank (Central Tank) through the technique of pipelining[1]. Pipelining is useful to provide the water to the back tank (secondary tank) from the Hub tank (central tank). The Central Tank will be the main source of water to distribute water to secondary tank. Secondary tank will have two water levels empty & full respectively. These two water levels are controlled with the help of IC555 . Here PLC will be interfaced to maintain the constant water in the secondary tank using sensor.

2. TECHNICAL ASPECTS

2.1 PROGRAMMABLE LOGIC ONTROLLER

A Programmable Logic Controller is a solid-state industrial controller that performs discrete sequential logic in a factory environment. It is originally developed to mechanical relays, timers and counters. PLCs are used to perform difficult control operations in a plant. A sequence of instructions is performed by the user to the PLC memory and when the program is executed, the controller operates a system to the correct operating specifications.

A Programmable Logic Controller is currently defined by the National Electrical Manufactures Association (NEMA) as a digital electronics device that uses a programmable memory to store instructions and to implement specific functions such as logic, sequence, timing, counting and arithmetic operations to control machine and processes.

Figure 1 Programmable Logic Controller

2.2 SWITCHED MODE POWER SUPPLY

A switch mode power supply is a power converter that utilizes switching devices such as MOSFETs that continuously turn on and off at high frequency; and energy storage devices such as the capacitors and inductors to supply power during the non-conduction state of the switching device. The supplies have higher efficiencies of up to 90%, are small in size and widely used in computers and other sensitive electronic equipment.

SMPS offers advantages in terms of size, weight, cost, efficiency and overall performance. These have become an accepted part of electronic gadgets. Basically, it is a device in which energy conversion and regulation is provided by power semiconductors that are continuously switching “on” and “off” with high frequency.

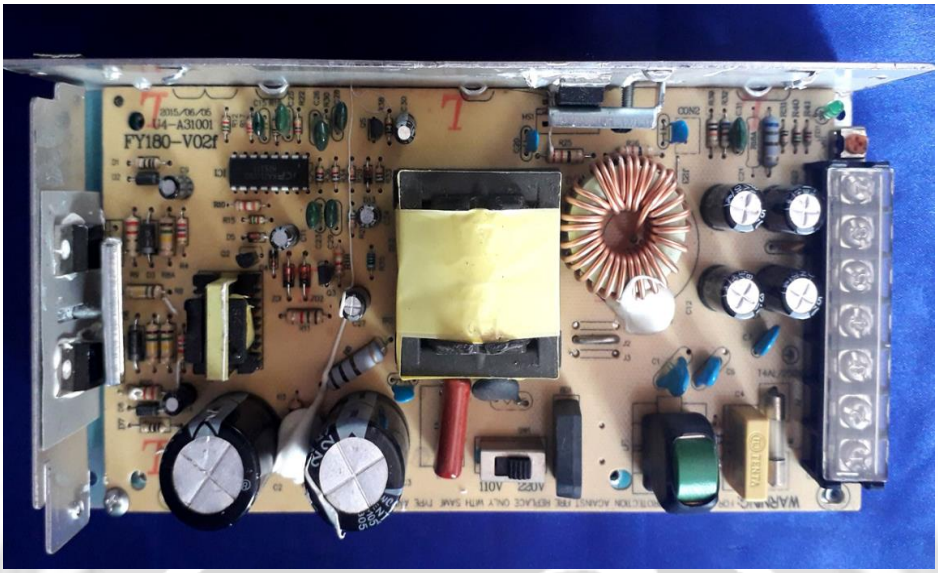

Figure 2 Switched mode power supply

2.3 COIN SENSOR

Coin sensor is the device which is used to detect the correct coin. The coin sensor uses the thickness, diameter and fall time of the coins to identify them. CH-926 is a multi-coin selector, can accept up to 6 kinds of different coins at the same time. This type of coin selector is widely used in Vending machine, Arcade Game, Message chair, and other self–management system. CH-926 is mainly based on material, weight and size to identify coins. It has the most up to date algorithm to design software. Therefore, CH-926 is very stable and accurate even when environment changes such as temperature, and humidity etc. In order to increase the accuracy, we suggest different version of coins use different channel to set up.

Figure 3 Coin Sensor

2.4 RFID SENSOR

A radio frequency identification reader (RFID reader) is a device used to gather information from an RFID tag, which is used to track individual objects. Radio waves are used to transfer data from the tag to a reader.RFID is a technology similar in theory to bar codes. However, the RFID tag does not have to be scanned directly, nor does it require line-of-sight to a reader. The RFID tag it must be within the range of an RFID reader, which ranges from 3 to 300 feet, in order to be read. RFID technology allows several items to be quickly scanned and enables fast identification of a particular product, even when it is surrounded by several other items.RFID tags have not replaced bar codes because of their cost and the need to individually identify every item.

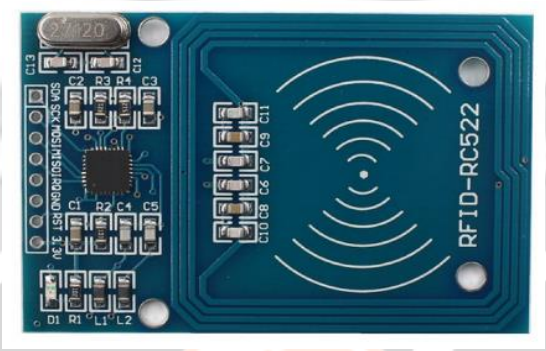

Figure 4 RFID sensor

2.5 SOLENOID VALVE

This is simple on\off type 9V dc supply valve. This type of valve is used in motors. This module consists of interface between vending machine and water output valve with the help of PLC. The switch is "Normally closed". (Automatic flush and shut off, auto power cut-off when filling, extends pump duration) when you connect it with high pressure switch. It shuts off the water supply when the tank is full. Normally controlled in the RO system by the booster pump High pressure switch.

Figure 5 Solenoid valve

2.6 PUMP

This water pump is use to take water from water tank or well. This water pump is connected between the water tank or well and tap where we can get water. In our project we use 0.5 HP, 0.37 kw monoblock water pump. Featuring brass impeller and copper winding, the special motor design of this water pump can work on UPS as well. This water pump is capable of priming up to 3 meters static suction lift without a foot valve at rated head and discharge. Well known for high performance, durability, efficiency, and reliability, this water pump can withstand with wide voltage fluctuation from 180 to 240 volts. With 33.6 LPM water flow and 50 hertz frequency, this water pump is applicable for use at household as well as commercial places.

Figure 6 Pump

Pump specification

Phase	Single phase
Motor body	Cast iron
Discharge	35 LPM
Suction delivery	25×25 mm
Voltage	230 volt
Motor power	0.5 HP
Frequency	50 Hz
Current	2 A

2.7 LCD

A liquid-crystal display (LCD) is a flat panel display, electronic visual display, or video display that uses the light modulating properties of liquid crystals. Liquid crystals do not emit light directly. LCDs are available to display arbitrary images (as in a general purpose computer display) or fixed images which can be displayed or hidden, such as preset words, digits, and 7- segment displays as in a digital clock. They use the same basic technology, except that arbitrary images are made up of a large number of small pixels, while other displays have larger elements.

Figure 7 LCD

3.DESIGN AND IMPLEMENTATION

3.1 Working Principle

This water vending machine is specially designed for village people to provide purified water. Machine is operated with the help of two sensors that are coin sensor or RFID sensor. The RFID sensor is designed for village, industry, company where people use this machine daily. So they have not to insert coin daily, they just need to scan their

RFID card and get water. Whereas the coin sensor operated machine is use every public place like Bus station, Railway station, garden or highways. They use coin of Rupee 1, 5 or 10.

A customer has to be insert coin in machine or RFID card is scan on sensor. The coin is checked whether the coin is correct or not by the coin sensor. The coin sensor uses the thickness, diameter and fall time of the coins to identify them. The RFID card is sense by the RFID sensor.

Now, when inserted coin or RFID card are appropriate or right the Programmable Logic Controller gives signal to the relay and relay will switch the R.O pump which is connected to the water tank. So the R.O pump will lift the water from water tank. Then water is flowing through the flow sensor. Flow sensor is sensing devices which continuously measure the amount of water. When flow sensor measures that amount of water which is defined for different coins, it will give signal to PLC and PLC give signal to the solenoid valve so valve will be off and water flow is stop. Solenoid valve controls the flow of water automatically. So customer will get purified water in the jug or any other watering vessel. Connection diagram is shown in figure 8.

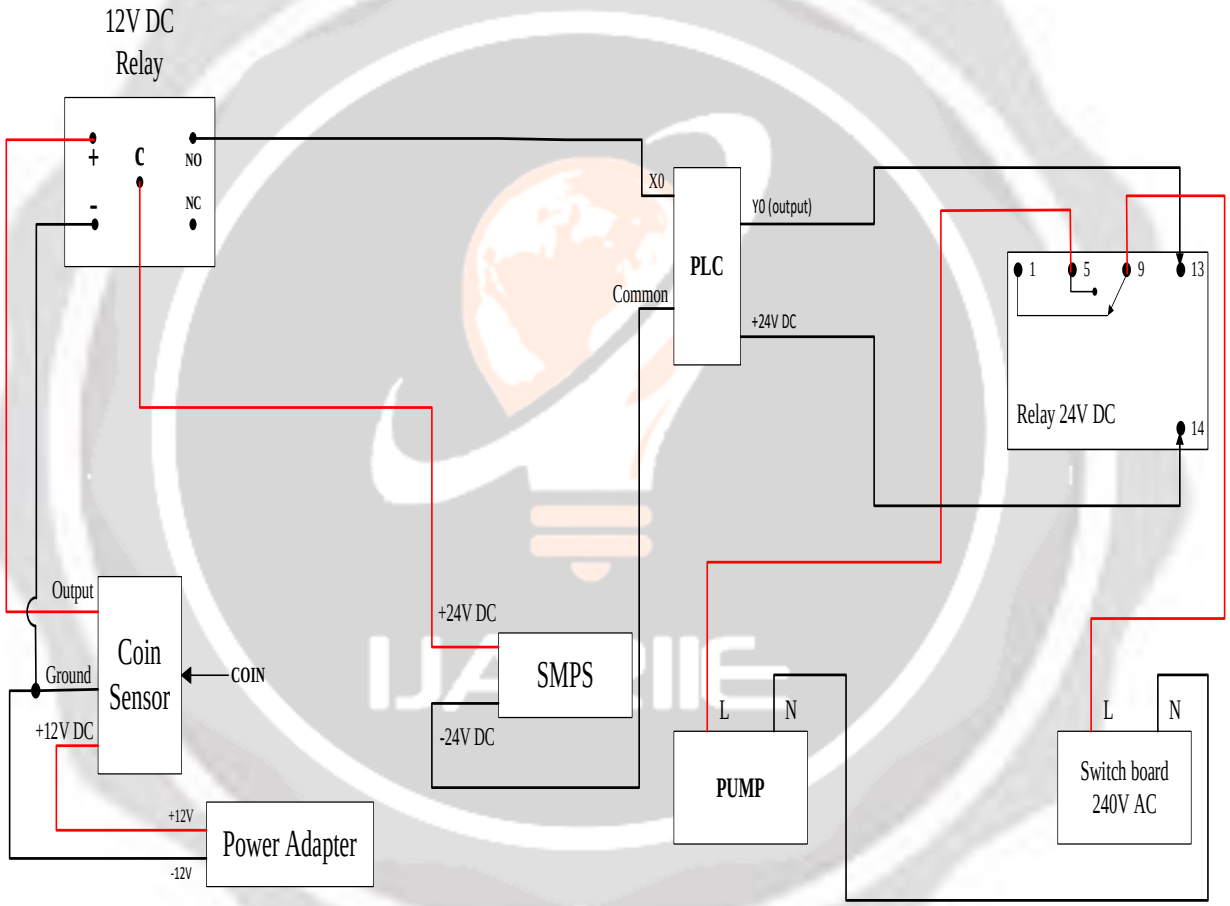

Figure 8 Connection Diagram

3.2 Flowchart of Water Vending Machine

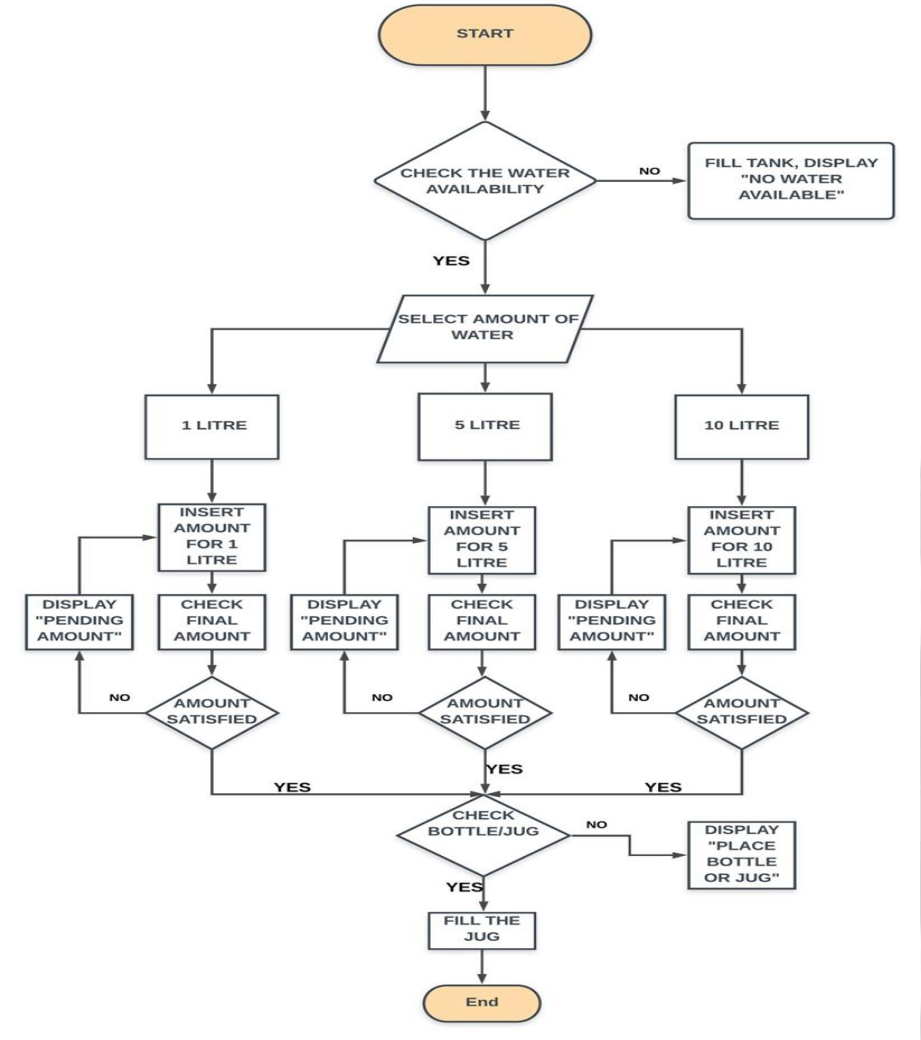

Figure 9 Flow Chart

The flow chart of water vending machine is shown as above. First machine check the status of the water in the water tank if there is no water then the LCD is displaying “Fill tank and No water available” and if water is available then the LCD is displaying “Select the amount of water”. Customer will select the amount of water that are one litre, five litre or ten litre. After that insert coin or scan the RFID card for selected amount of water. Now if the coin is correct then system will check the glass, bottle or jug is placed or not. So system will check whether glass or jug is placed or not. If jug is not placed then LCD displaying message “Place bottle/jug” and if the jug is place properly then water is dispatch into that jug. This way customer will get water and system is complete.

4. SIMULATION AND RESULTS

In this, we have done interfacing of coin sensor with PLC in winproladder software. Win Pro Ladder is easy to learn and use, and allows users of all types, beginner or expert to operate the software in a very efficient manner. For use in a Windows operating environment, completely designed in accordance with Windows environment operation methods. With run time editing feature, during the simulation process the program can be modified without stop the execution.

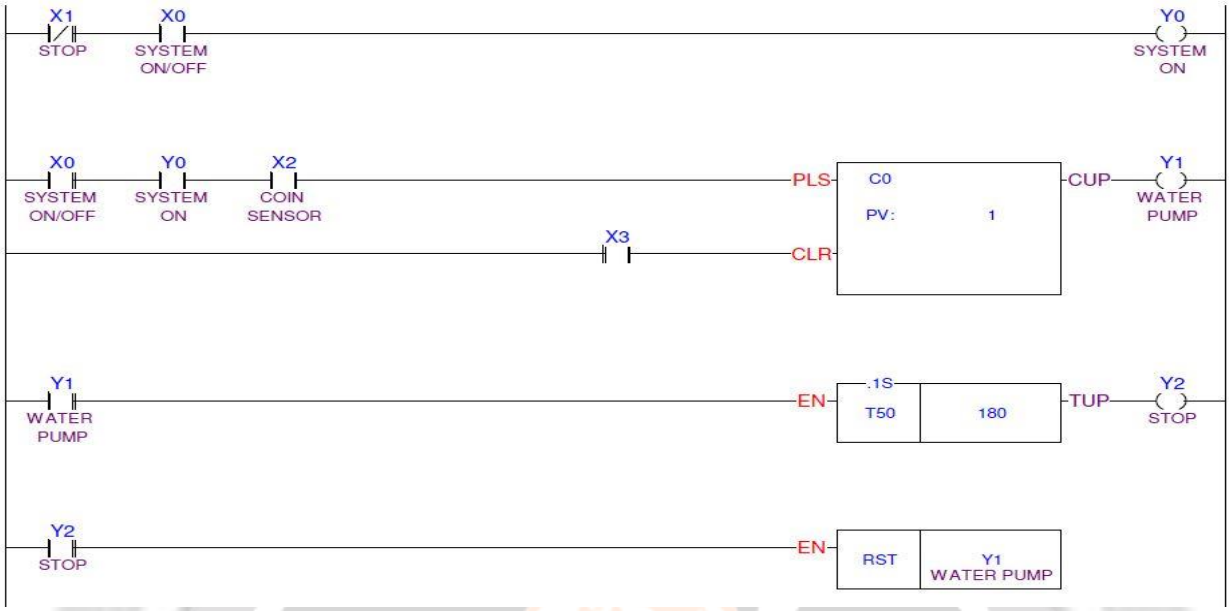

Figure 10 Ladder Diagram of interfacing of coin sensor with PLC

This is the ladder diagram of PLC done on win proladder software.

Here,

X0 = System on/off

X1 = Stop

Y0 = System on

X2 = Coin Sensor

Y1 = Water pump

C_0 = Counter

X3 = Push button for clear function

T50 = Timer

When push button X0 is processed our system is ON i.e. Y0 here X2 is our coin sensor so when coin is inserted it turns On and counter C_0 is increased by 1. So, our water pump Y1 is ON. There is one timer T50. When Y1 is on our timer T50 is ON for 180 seconds. After 180 seconds timer output turned ON the output coil Y2. The output of Y2 is given to reset function. In this reset function when done bit is given to it, the output associated with this function will be off. Here water pump Y1 is associated with reset function so after 180 seconds with the help of reset function water pump Y1 will be off.

In our project we conclude that acceptance ratio is almost 100% and vending machine works on arduino controller To develop low cost water vending machine. To avoid wastage of water.

5.FUTURE SCOPE

An increase in the diameter of the water solenoid valve and pipes would increase the flow rate. Hence, taking lesser time to fill in the tumbler. The whole product can be redesigned for it to be aesthetically pleasing and for its better usability. It can be used for other beverages and drinks also.

6.CONCLUSION

Implementation of Coin-Operated Automatic Drinking Water Machine is the step towards the future technology and it is a step to enter in eco-friendly world. This machine is easy to use and can be easily accessed by the ordinary person .We have developed a water vending machine which is an improved version of the normal water vending machine. This water vending machine reduces human efforts, less time consuming, economical and power consumption of the control system is less. A water vending machine is designed, developed, and demonstrated to give purified water at economical cost. Customers just have to insert coins or scan RFID card. By implementing this type of system, we can provide water at the village, public places like Bus station, Railway station, garden, and isolate place like highways.

Process Enhance of PCB Micro-Drilling

Hardik Prajapati

Swarrnim Institute of Technology, Gujarat, India

Abstract

In this growing world of technology miniaturization is a key word. Drilling is one of the most fundamental machining technologies and is moving toward high precision/high speed application for productivity enhancement. The drill tools play a critical role is increasing the productivity of a cutting process. Although the price of a cutting tool itself is relatively low, the costs caused by tool failures are considerably higher. Therefore, from the viewpoint of cost and productivity, modelling and optimization of drilling processes are micro drilled holes are utilized in many of today's fabrication processes. Precision production processes in industries are trending toward the use of smaller holes with higher aspect ratios, and higher speed operation for micro hole drilling .Experiment was conducted on FR-2 as a work piece material using carbide drill having 0.7 mm diameter.FR-2 sheet with copper foil lamination on one or both sides is widely used to build low-end consumer electronic equipment.In the present work, spindle speed and feed are chosen as machining parameter to see the effect of circularity and taper angle on workpiece.Usingtaguchi methodology, L27 orthogonal array has been chosen and experiment has been performed as per orthogonal array design. For validation of the predicted value and optimization result, confirmation experiments have been performed with optimum levels of machining parameters. It is experimentally found that spindle speed is more influencing parameter for hole quality in terms of circularity and taper angle.

Index Terms—*Micro-Drilling, PCB, Speed, Feed*

I. INTRODUCTION

Printed circuit boards (PCBs) are widely used in industries such as aviation, microelectronics, instrumentation, precision machinery and medical equipment. The base material of PCBs is a copper clad laminate (CCL), which is a multi-material sheet. It consists of dielectric layer (resin/glass fiber cloth) and high purity metal conductor (copper foil).CCL is a heterogeneous, anisotropic material. The machining properties of CCLs are quite different from homogenous metallic material. Qualities of holes are one in which the deposited copper layer can be connected stably at each layer of circuit with repeated thermal shock. Controlling the quality of the holes drilled and increasing the wear resistance of micro-drilles have become an important issue. To optimize the PCB micro-hole drilling, the drilling mechanism, drilling force, circularity and taper of hole should be studied systematically. Many studies of chip curling in machining had been performed.J.Prasanna [1] said that higher spindle speed engendered to lesser thrust force and produce holes with good circularity and lesser taper angle .Micreaancau [2] said that as the number of stacked PCBs increases, the stack thickness to be drilled increases and so the drill rout for a single hole increases accordingly. Lijuanzheng [3] said that the PCB drilling process was complex because it included both continuous chip formation and brittle chip formation. The continuous chip formation mainly occurred at the glass fiber cloth layer.H.Nakagawa [4] said that a reduction in the workload caused by friction is effective for improving the quality of micro drilled hole. In this study, several experimental tests were conducted to quality of hole when drilling PCBs. It was important to study circularity and taper of hole during the PCB drilling process as this process affected the hole quality. The drilling process was digitally photographed and the basic removal mechanism of the PCB was analyzed. Additionally, the hole quality including entry hole diameter and exist hole diameter were observed, measured and analyzed. The influence of drilling conditions (feed and spindle speed) on the drilling process and hole quality were also studied.

II. EXPERIMENTAL DETAILS

In this experiment, small holes of diameter 0.7 mm were drilled on FR2 plate of thickness 4.8 mm under different combinations of spindle speed and feed rate. The drill used was twisted carbide tool. The accuracy of the drilled holes was analyzed in terms of circularity and taper angle. Each experiment was repeated 3 times in order to make the database reliable.

Machining Setup

The drilling experiments were conducted on a high speed drilling process. The thrust force measurements were made using a Kistler dynamometer and simultaneously the values were sent to Kistler charge amplifier and stored in a personal computer. The work piece was fastened on to the dynamometer which was placed on the machine table as shown in Fig. 1. The hole quality assessment was done by 2D Vision System, which is shown in Fig.2

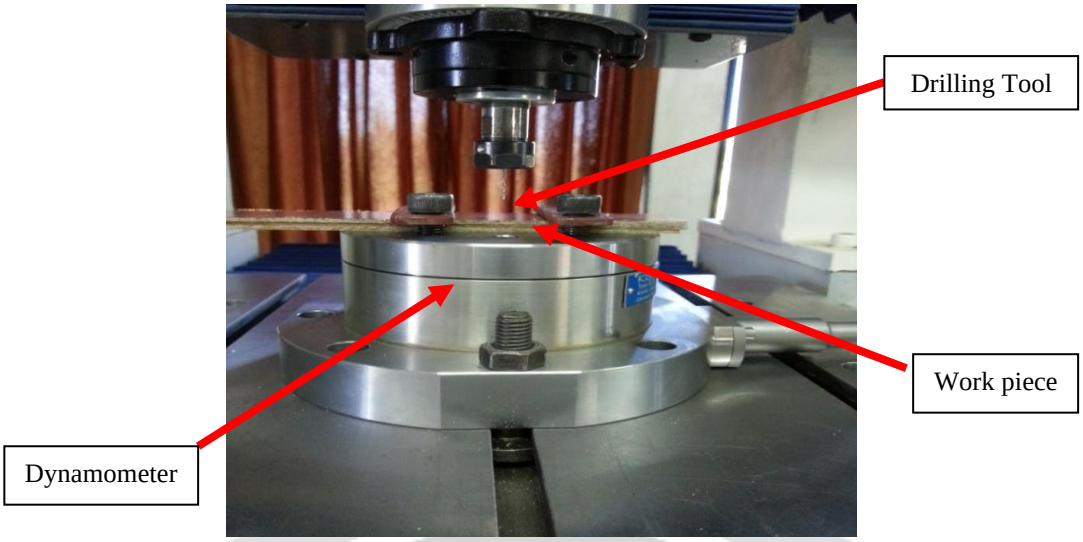

Fig.1. Experimental set-up

Fig.2. 2D vision system.

Measurement Procedure of Performance Parameter

Circularity: The roundness error of the machined hole is proposed in terms of circularity. The error of circularity is defined as the distance between the minimum circumscribing circle diameter and the maximum inscribing circle diameter .The circularity error exists both at the entrance and the exit of the machined hole, their maximum value was used for evaluating the circularity of the machined hole [1].

Taper: Taper angle between the entry and exit surface was calculated by using the formula given below

$\text{Tan}\theta = \frac{(D-d)}{2L}$

Where D is the average diameter of the entry surface, d is the average diameter in exit surface; L is the depth of cut [1].

Optimization and Modeling

The experiments were conducted using Taguchi L9 design approach. The significance and contribution of each process parameter on the performance characteristics were found out using ANOVA method. The objective of this research was to determine the process parameters required to achieve minimum circularity and taper. Therefore, the quality characteristics of 'smaller is better' for all performance characteristics were engaged in this study. The ANOVA results were developed by using the statistical software MINITAB. Each process parameter was designed to have three levels which are shown in Table 1 and the experimental results are presented in Table 2.

Table.1 Experimental Parameters and Their Levels

Process parameter	Symbols	Level	Level	Level
		1	2	3

III. RESULT AND DISCUSSION

The experiments were conducted using L27 orthogonal array. The force, circularity and taper were calculated as per discussed erlier.The experimental results for force, circularity and taper is given in table 2.

Analysis on Thrust Force

In order to see the effect of machining parameter on thrust force, Experiments were conducted using L27 OA.The experimental result data for thrust force is given in table 2.The thrust force is smaller the better type quality characteristics. So S/N ratio is calculated for smaller the better criteria. Main effect plot for S/N ratio are plotted in figure 3.

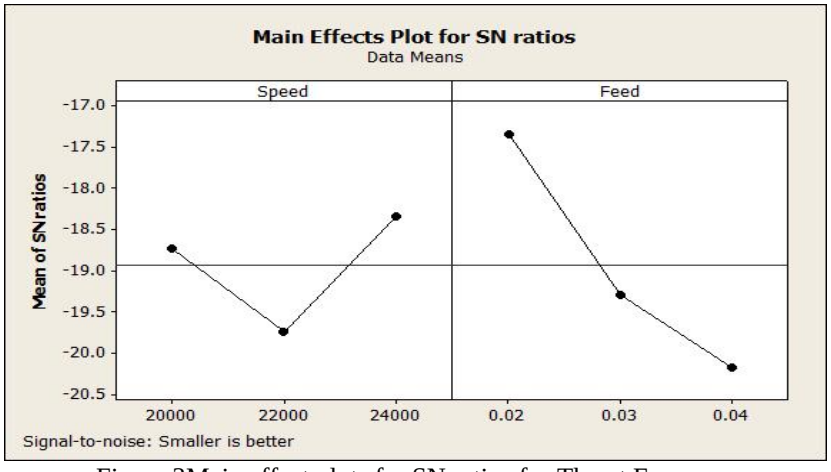

Figure 3Main effect plots for SN ratios for Thrust Force

Figure. 3 shows that feed has main effect on thrust force as the speed increases feed also increase. From taguchi analysis the range of speed and feed 22000 rpm and 0.04 mm/rev respectively are better for creating the good hole accuracy. The speed has not significant effect as much as feed on thrust force. It is seen from the figure 4 that there is very weak interaction between the machining parameters affecting the thrust force since the performance at different levels of machining parameter value are almost parallel.

In order to study the significance of the machining parameter on thrust force, taguchi analysis was performed.Taguchi analysis for thrust force versus speed and feed is given in table 3.The table includes rank based on delta statistics, which compare the relative magnitude of effects. The delta statistic is the highest minus the lowest average for each factor. Minitab assign rank based on delta values, Rank 1 to the highest delta value, Rank 2 to second highest delta and so on. The rank indicates the relative importance of each factor to the response. From table 3, the rank and delta values show that feed has the greatest effect on Thrust force. As thrust force is the 'smaller is better' type quality characteristic, it can be seen from figure 3 that second level of speed (22000) and third level of feed (0.04) provide minimum value of thrust force.

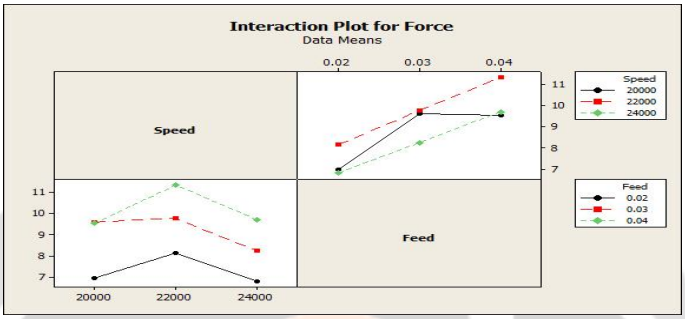

Figure 4. Interaction plot for SN ratios for Thrust Force

Table 3. Response table for S/N ratio

Level	Speed	Feed
1	-18.73	-17.33
2	-19.73	-19.28
3	-18.33	-20.17
Delta	1.40	1.65
Rank	2	1

Analysis on Circularity

In order to see the effect of Machining parameters on the Circularity, experiments were conducted using L27 OA.The experimental data for circularity is given in table 4.

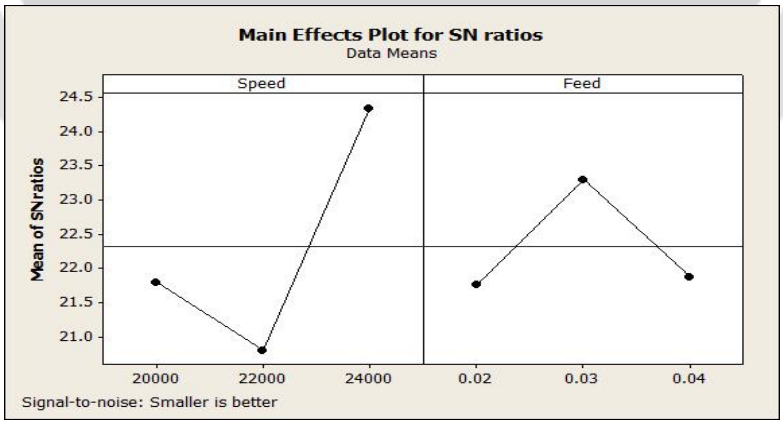

Figure 5Main Effect plot for SN ratio

Circularity is smaller the best type quality characteristic so the S/N ratio was calculated for smaller the better criteria. The main effect plot for circularity is plotted as shown in figure 5.It is seen from the figure 5that speed has the most significant effect on the circularity. Circularity increases with increase in speed of spindle. Circularity increases sharply when feed rate increases from 0.02 mm/rev to 0.03 mm/rev and circularity again gradually reduces from increase in feed rate from 0.03 mm/rev to 0.04 mm/rev.It is observed from the figure 6 that there is a slight interaction between spindle speed and feed rate.

The response table for signal to noise ratio for circularity is shown in table 4.The rank and delta values show that speed has the greatest effect on circularity.

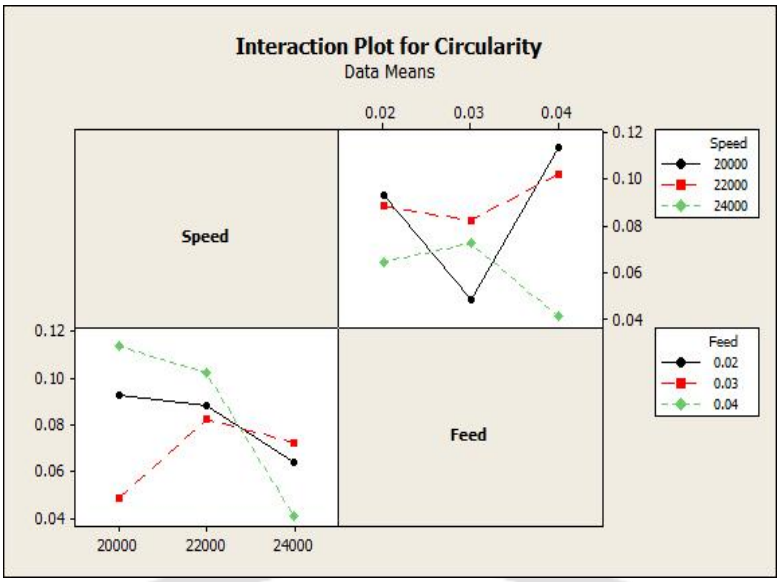

Fig 6 Interaction Plot for Circularity

Table 4 Response table for S/N ratio

LEVEL	SPEED	FEED
1	21.80	21.77
2	20.81	23.31
3	24.35	21.88
DELTA	3.53	1.54
RANK	**1**	**2**

As circularity has "lower is better" characteristic, from the figure 5, second level of speed (22000), first level of feed rate (0.02), third level of feed rate (0.04) for reducing circularity.

Analysis on Taper

In order to see the effect of machining parameters on the taper, Experiments were conducted using L27OA.The experimental data is given in table 2. Taper is smaller the better type quality characteristic so S/N is calculated for the Smaller the better type. The main effect plot for S/N is given figure 7.when spindle speed increases from 20000 rpm to 22000 rpm the taper angle reduces and when spindle speed increases from 22000 rpm to 24000 rpm the taper angle increases.Increasing in feed rate from 0.02 mm/revto 0.03 mm/rev, first taper is reduces but after increases feed rate from 0.03 mm/rev to 0.04mm/rev, taper angle is increases. It is clear from the figure 8 that there is moderate interaction between speed and feed rate.

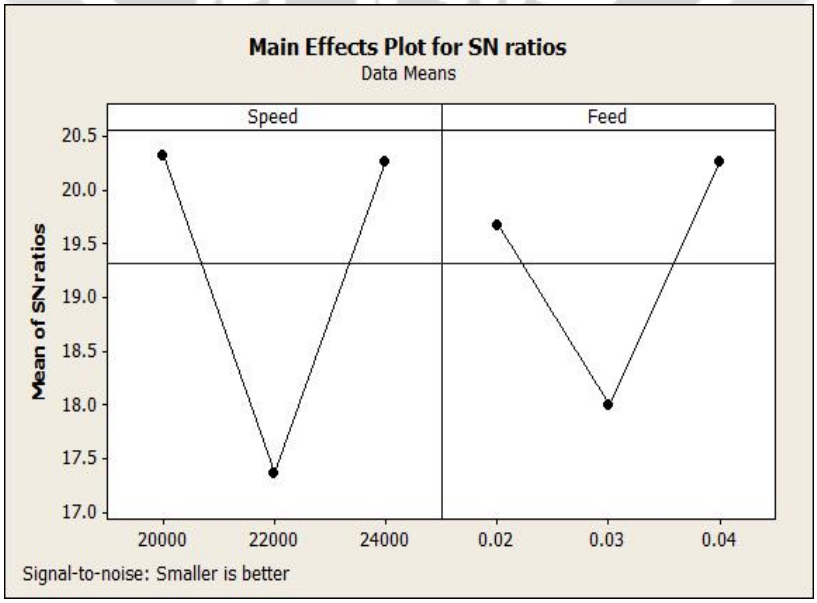

Figure 7 Main Effect plot for SN ratio

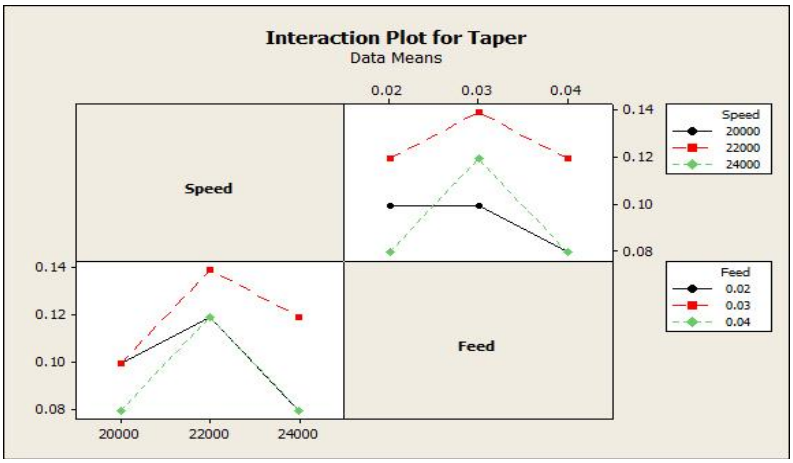

Figure 8 Interaction plot for Taper

The response table for Signal to Noise ratio for taper is shown in table 5.The rank and delta values show that speed has the greatest effect on taper.

Table 5 Response table for S/N ratio

LEVEL	SPEED	FEED
1	20.32	19.68
2	17.37	18.01
3	20.27	20.27
DELTA	2.95	2.26
RANK	**1**	**2**

As taper has "lower is better" characteristic, so from figure 7 second level of speed (22000), second level of feed rate (0.03) for reducing taper angle

IV. ESTIMATION OFOPTIMUM MACHINING PARAMETER

In this section, the optimal values of the process parameter i.e. thrust force, circularity, taper angle have been predicted. The optimal levels of the machining parameter for Performance parameter have been identified from taguchi analysis and S/N Ratio. The optimal value of machining parameter is predicated considering the significant parameter only. The response table 2 using Taguchi method is employed here to calculate the effect of each level of machining parameter on Process parameter. It is done by sorting the mean values of machining characteristics corresponding to levels of the process parameter in each column of the orthogonal array, and taking an average on those with same level

V. CONCLUSION

In the present study, the effect of machining parameter on process parameter i.e. thrust force, circularity and taper angle of the FR2 plate using carbide drill have been investigated for micro-drilling process. The experiments were conducted under various machining parameter setting of spindle speed and feed rate. L27 OA based on taguchi'sdesign was performed, Minitab 16 software was used for analysis the result an optimal set of process variables that yields the optimum quality features to machined parts produced by micro-drilling process has also been obtained. The important conclusions from the present research work are summarized in this chapter:

- The minimum thrust force is obtained at spindle speed of 22000 rpm and feed rate 0.04 mm/rev.
- The minimum circularity is obtained at spindle speed of 22000 rpm and feed rate 0.04 mm/rev.
- The minimum taper angle is obtained at spindle speed of 22000 rpm and feed rate 0.03 mm/rev.

Abstract

An Independent wheel suspension system is used nowadays in almost all new modern cars. The conventional system which uses dependent suspension is not of much use as it creates more jerk in the car body. Normally, when any bump or hindrance comes across the vehicle, the suspension system reduces the disturbance in the car. The dependent system is connected with chassis and car body frame. So with any jerk, the car body faces the disturbance. In Independent wheel vehicle suspension, the spring is connected with the wheel, which absorbs all shock and does not allow any jerk in the car body.

The research paper covered a brief literature review on the analysis of the independent suspension system. First studied existing suspension design as per standard design procedure then identifying design issue in existing design by using mechanism calculation. By using CAD tools like Solid work for a critical component of independent suspension for analysis purposes and according to result for the conclusion. Optimization of taper spring concerning material properties and plot result.

1. INTRODUCTION

A suspension system is an assembly of springs, shock absorbers and linkages that connects a vehicle to its wheels. In a running vehicle, it is the suspension system that keeps the occupants comfortable and isolated from road noise, bumps, and vibrations. The suspension system also provides the vehicle excellent handling capabilities, allowing the driver to maintain control of the vehicle over rough terrain or in case of sudden stops. Additionally, the suspension system prevents the vehicle from damage and wear.
The basic components of the suspension system include springs, shock absorbers, kinetic parts, and auxiliary devices. The springs absorb impacts and provide cushioning when a wheel hits a bump in the road. The springs also resist the wheel's movement and rebounds, pushing the wheel back down. The type, number, and location of the springs differ based on a different type of suspension system, which will be demonstrated in the next section. The shock absorbers (dampers) restrain the spring motions and prevent the spring from continuing vibrating. In a suspension system, one shock absorber is located at each wheel.

2. LITERATURE SURVEY

Mahmoud Omar, M.M. El-Kassab, Walid Abdelghaffar **[1]** were represented the active performance compared against the passive is performed experimentally and numerically utilizing SIMULINK's Simscape library. Both systems are modeled as single-degree-of-freedom to simplify the validation process. Economic considerations were considered during the rig's implementation. The rig consists of two identical platforms fixed side by side allowing testing two independent suspensions simultaneously. Position sensors for sprung and unsprung masses on both platforms are installed.

Tian Mi, Gabor Stepan, Denes Takacs**[2]** was presented to study the shimmy problem of the electric vehicle with independent suspensions, a 5 DoF model is established using the Lagrange Equation. Gyroscopic moment and tire nonlinearity are both considered, and tire-road constraint equations are derived on the non-slip assumption. Stability charts are conducted with the linearized model, while the numerical simulation is also made so that these two methods can verify each other. The results show that bifurcation occurs at certain vehicle forward speeds. Suspension structural parameters, such as caster angle, affect wheel shimmy. Furthermore, the presented model enables the analysis of any parameters in the system, and as an example, the influence of dampings on shimmy is investigated.

Carlos Arana, Simos A. Evangelou, Daniele Dini **[3]** had represented the potential of the Series Active Variable Geometry Suspension (SAVGS) for comfort and road holding enhancement. The SAVGS concept introduces significant nonlinearities

associated with the rotation of the mechanical link that connects the chassis to the spring-damper unit. Although conventional linearization procedures implemented in multi-body software packages can deal with this configuration, they produce linear models of reduced applicability.

Jan Dizo, StasysSteisunas, Miroslav Blastnicky**[4]** had focused on the vibration analysis of the coach, which wheel is damaged by the wheel-flat. Analyses are carried out in multibody software and results are evaluated in terms of influencing suspension parameters to change on accelerations output signals. The article consists of two parts. The first part is aimed at the problem of the damaged wheel's origin and its consequence during rail vehicles running on tracks during real operation. There is also included the system of forces and accelerations measurement during rail vehicles running on the given track section. The second part is focused on the assessment of selected measured parameters of a rail vehicle with wheel-flat which are obtained from computer simulations. As evaluation parameters signals accelerations in the selected location during passenger car running on the straight track for various stiffness of coil spring of the primary and secondary suspension were assessed.

Anirban. C. Mitra, Gourav. J. Desai, Saaish. R. Patwardhan**[5]** had represented one of the challenging tasks for engineers. The main function of any suspension system is to reduce or eliminate the road excitations transmitted to the vehicle body. An effort has been made in this paper for a passive suspension system by using an optimization technique called the Genetic algorithm to absorb vibrations as per ISO 2631-1: 1997 standards. The spring stiffness (ks), damping coefficient (cs), sprung mass (ms), unsprung mass (mu), tire stiffness (kt) are optimized in such a way that ride comfort is increased. The quarter car and driver seat with the driver's body is simply modeled together as four degrees of freedom (DOF) system by using SIMULINK for analyzing the ride comfort.

A.A. Koshurina, M.S. Krasheninnikov, R.A. Dorofeev**[6]** had represented a universal Arctic rotary-screw rescue vehicle (URV) was chosen as an object of the research. At the moment this rescue vehicle is being developed at the NNSTU named after R.E. Alekseev. A distinctive feature of the URV is the original design of an operated equalizing beam suspension, which has not previously been used for this kind of vehicle. The analysis of the equalizer beam various designs is presented in the article. Calculation schemes and simulation models are developed following the specificity of the rotary-screw vehicle motion. The models and strength calculations have been carried out with standard tools of Autodesk Inventor 2015. The article presents the stress-strain states of different equalizing beam embodiments. The conclusion about the reasonability of the application of the particular equalizer beam embodiment for developing a rotor-screw rescue vehicle is based on the performed comparative analysis of researched constructions.

PanosBrezas, Malcolm C. Smith, Will Hoult **[7]** had represented the problem of optimal control for semi-active vehicle suspensions. A specific goal is to develop an algorithm that is capable of optimizing ride and handling behavior simultaneously in an experimental situation. A time-domain optimal control approach is adopted in which ride and handling are modeled as exogenous disturbances acting on the vehicle: road disturbances (modeled stochastically), and driver inputs (treated as deterministic quasi-static disturbances). A control algorithm is derived from a solution of the stochastic Hamilton–Jacobi–Bellman equation for the finite horizon case. The advantages of the approach are demonstrated experimentally on a test vehicle performing a steering maneuver on a bumpy roundabout.

Werner Scheele, Igor Iroz**[8]** had represented, to random excitation by the unevenness of the road. For a dynamical analysis, vehicle models of the vertical vibrations, as well as guideway models of the road unevenness, are required. The fundamental dynamics of vehicle suspensions can be already modeled by a quarter car featuring the decoupling of the car body motion and the wheel motion. This suspension model is characterized by five design parameters where two of them, the shock absorber and the tire spring, are highly uncertain due to wear and poor maintenance. For the assessment of the vehicle's performance three criteria have to be used: ride comfort, driving safety, and suspension travel. These criteria depend on all the five design parameters resulting in a conflict or a Pareto-optimal problem, respectively. In this paper, the uncertainties of the parameters are projected into a criteria space to support the decision to be made based on a Pareto-optimal problem. Simulations with uncertainties support the robust suspension design. It is shown that controlled suspension parameters remain uncertain due to the unpredictable decisions made by the driver.

M. Soleymani, M. Montazeri-Gh, R. Amiryan**[9]** had represented the design of an adaptive active suspension system, to simultaneously improve ride comfort and travel suspension under various traffic conditions, is addressed in this paper. For this purpose, using a full-vehicle model, with eight degrees of freedom, two separate fuzzy controllers are designed for front and rear suspensions. The parameters of the fuzzy controllers are then tuned for various traffic conditions of a driving pattern, using a multi-objective Pareto-optimal solution.

VladimírGoga, Marian Klúcik**[10]** had represented vehicle suspension is to achieve good driving stability and passenger comfort regardless of the road surface. These requirements are often contradictory. This article aims to show the possibilities offered by a combination of modeling in a virtual environment and evolutionary computation in the process of optimization. The mathematical half-car model was created in Matlab/Simulink. Passive suspension parameters (damping and stiffness coefficients) were optimized with the use of evolutionary computation. Results from simulations of the model with original and optimized suspension parameters were compared.

SamantSaurabh Y., Santosh Kumar, Kaushal Kamal Jain, Sudhanshu Kumar Behera**[11]** had represented in detail the design procedure of the front double A-arm pushrod suspension system for a formula student race car. The type of suspension system used generally is reviewed. The CAD models of the components in the suspension system are made using SolidWorks and the Finite element analysis of the components is done using ANSYS Workbench. Both kinematic and dynamic analysis of the designed suspension system is performed. The results of vibration or ride analysis and roll steer analysis are also presented for the designed suspension system. The method for spring design is elucidated. This work emphasizes the method for designing and analyzing the suspension system for a race car in various aspects.

KameshJagtap, YogeshRathod, AnmayShedge, MitaliGramopadhye, Prof. VivekDiware**[12]** had represented an On-Road Commercial Vehicles in terms of its all-terrain capability due to its large travel and Ride Quality; also it has to face various ground conditions such as mud, ice, rocks, bumpy tracks, etc. Hence it needs to be Robust enough to sustain in such frequently occurring Undulations. Suspension systems of commercial vehicles are designed considering normal road conditions. While designing the suspension system of an ATV, various terrain conditions have to take into consideration. This paper gives a review of suspension systems for ATV.

Prof. Sameer Verma, Parvez Raza **[13]** had represented a very popular and efficient form of the suspension system. It has one control arm and a strut assembly. Coil spring and shock absorber will normally from parts of the strut assembly. Macpherson suspension system is generally used as the front suspension system in passenger cars. Coil spring may be mounted on the control arm instead of being around the strut. On this type, the shock absorber connects the knuckle to the frame. This type of suspension strut is often also used on the rear suspension system. Macpherson strut is set up is still popular in high-performance passenger cars.

Reena Mishra, AnandBaghel**[14]** had represented the significant increase in the research activity on the front wishbone in the last few years, the present article identifies and highlights the various research that is most relevant to the design, analysis, and optimization of the front wishbone suspension system. Present work is focused in the field of the material selection methods, impact load, deformation of the material, stress, weight reduction for ATV vehicle for improving the stability and handling of the vehicle to minimizing the un-sprung mass, better durability and less expensive also. The outcome of the discussed research is intended to give the reader a brief verity of the research carried out on the front wishbone suspension system.

Dongchen Qin, Junjie Yang, Qiang Zhu, Peng Du **[15]** had represented one of the key parts in vehicles, which can directly influence such performances as steering stability and ride comfort. The multi-body dynamics model of multi-purpose vehicles (MPV) front suspension is built with ADAMS/VIEW, and the location parameters of the front wheel are simulated. To improve the kinematics performance and steering stability, the sensitivity analysis and optimization design for the front suspension are carried out. The results can provide some guide and reference for the R&D of the MPV.

Jihui Liang, Lili Xin **[16]** had represented Suspension system transfers force and torque between the wheel and automobile frame, guides, and controls the relative motion of the wheel and automobile body to ease up the impact from the road surface and the shock from attenuation system. Kinematic characteristics of the suspension refer to variation regularities of parameters such as kingpin inclination angle, camber angle, caster angle, and the like when automobile wheels jump up and down, namely, wheels and vehicle bodies have relative movement in the vertical direction. Rational choice of suspension structure and performance parameters has a great and direct influence on the traveling smoothness, steering stability, and comfortableness of the automobile.

P. Nagarjuna, k. Devaki Devi **[17]** had represented the Suspension system of an automobile plays an important role in ensuring the stability of the automobile. Although it has been achieved to a considerable extent, another major aspect of the suspension system is passenger car is luxury. A lot of research is going on in this direction, which led to the development of an independent suspension system. The control arm plays a major role in an independent suspension system. It is generally made of forged steel which has considerable disadvantages such as weight, cost, etc. The project involves the development of sheet metal control arm, which has many advantages over forged metal. The component has been modeled using the curves extracted from the workspace available in PRO-E. This model is translated into a STEP file, which is then retrieved in 'Unigraphics' for analysis. The model is subjected to different load conditions and thus analyzed using Structures P.E solver. The stress and stiffness of the model are studied from the results obtained from the analysis to verify the success of the design.

Mohammad ImanMokhlespourEsfahani, MasoudMosayebi**[18]** had represented Simulation accuracy by recent dynamic vehicle simulation multidimensional expression significantly has progressed and acceptable results not only for passive vehicles but also for active vehicles normally equipped with advanced electronic components is also provided. Recently, one of the subjects that have been considered, is increasing the safety car in design. Therefore, many efforts have been done to increase vehicle stability, especially in the turn. One of the most important efforts is adjusting the camber angle in the car suspension system. Optimum control camber angle in addition to vehicle stability is effective in the wheel adhesion on road, reducing rubber abrasion and acceleration and braking. Since the increase or decrease in the camber angle impacts the stability of vehicles, in this paper, a car suspension system mechanism is introduced that could be adjusted camber angle and the mechanism is an application and also inexpensive. To reach this purpose, in this paper, a passive double wishbone suspension system with a variable camber angle is introduced and then a variable camber mechanism designed and analyzed for study the designed system performance, this mechanism is modeled in Visual Nastran software and kinematic analysis is revealed.

Arvin Niro**[19]** had represented a big part of NASA's curiosity into exploring what is beyond our atmosphere and NASA's rovers have allowed us to do just that. They are equipped with state of the art technology that allows us to see and measure if life can exist elsewhere. In this project, we aim to design and build a suspension system that can be incorporated onto a rover that was constructed last semester at Kapi'olani Community College by Eric Caldwell and Lee Do. This rover features wireless technology and a mecanum drive system that allows it to be extremely maneuverable. However, due to its maneuverability, this generates uncontrollable vibration in the rover. In an attempt to suppress the vibration, a double-wishbone suspension design was used with a spring and damper system to reduce and dampen the vibration generated from the mecanum wheels. The result of this allowed a suspension system to be designed and optimized for this specific rover by utilizing SolidWorks and finite element analysis to decide the overall design of the system.

Dr. Naser LAJQI, Dr. Azem KYÇYKU, Dr. Shpetim LAJQI **[20]** had represented the research methodologies utilized for developing a suspension system for four-wheel-drive terrain vehicles. The main research methods can be identified as literature studies; design processes by applying CAD systems, numerical analysis methods, mathematical modeling and simulation, optimization of the mechanical systems, as well as the comparison, analysis, and evaluation of the obtained results. The proposed suspension system for the terrain vehicle was successfully derived from a classic double-wishbone control arm. Optimization of the suspension parameters for passive ones is performed by Multi-Objective Genetic Algorithms, whilst for active damping force by employing the Hooke-Jeeves non-linear programming method. Based on comprehensive analysis it is shown the active systems are more adequate. The proposed suspension design provides relatively small lateral wheel motion, zero camber angles, and effectively absorbs the vibrations caused by road excitation.

3. OPTIMIZATION OF TAPER SPRING

The simulation and analysis of coil spring were done with different materials. The materials selected were steel structure, copper alloy, and carbon composite. The coil spring was simulated with Solidworks 2020 with specific dimensions which are listed in Table 5.1.

Table 1 The Specification of Taper Spring

No	Specification	Value
1	Outer diameter	135 mm
2	Inside diameter	115 mm
3	Wire diameter	10 mm
4	Free length	160 mm
5	Number of active coils	5
6	Pitch	35 to 8 mm
7	Taper angle	270°

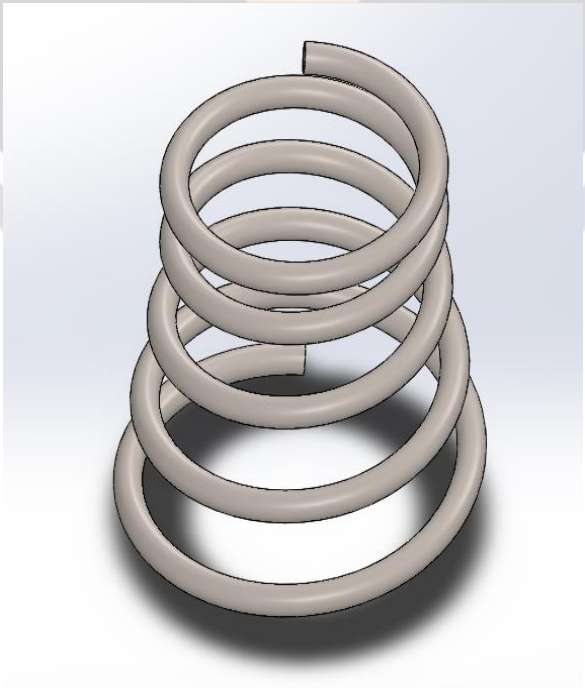

Fig. 1 The Taper Spring

The properties of materials used for producing the coil spring in this paper listed in Table 2.

Table 2 Properties of Material

Materials	Steel Structure	Copper Alloy
Density	7850 kg/m3	8300 kg/m3
Young Modulus	2 X 1011 Pa	1.1 X 1011 Pa
Poisson ratio	0.3	0.34

The numerical analysis was done by using a finite elements analyzer in Solidworks 2020. The spring has meshed with programmed generated mesh with fine meshing. The mesh of taper spring shown in Figure 2.

Fig. 2 The Mesh of Taper Spring

Mesh Information
The mesh type is solid mesh.
Mesher used curvature-based mesh.
Total nodes are 100855.
The total elements are 61482.
The spring was fixed in the bottom end and the load was subjected to the upper end with different values (1500, 2000, 2500) N to get the total deformation, stress, strain, and shear stress. The analysis was carried out with static analysis in Solidworks 2020. The analysis steps could be summarized as the flow chart in Figure 3.

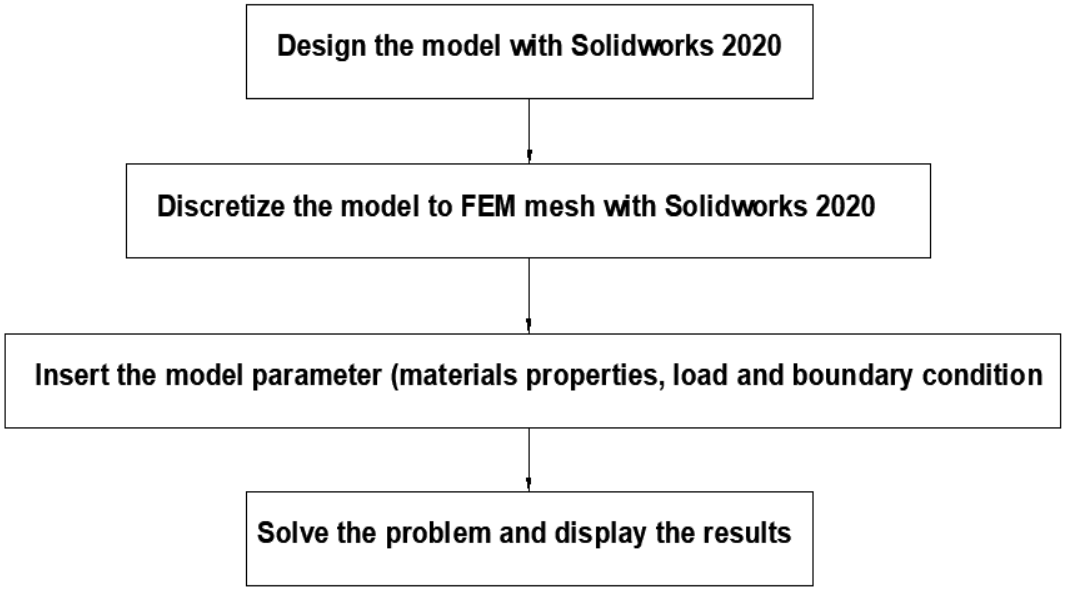

Fig. 3 Flow Chart for Analysis Process

5.2 RESULTS

The total deformation, stress according to von – Mises theory, strain, and shear stress were obtained numerically for the three materials with various values of the load to compare between them and choose the best material that can be used in the production process of the tapered spring in modern automobiles. For the value of load (1500N), the maximum total deformation happened in taper spring made of Steel Structure and it was (167 mm) as shown in Figure 4 below.

Fig. 4 Total Deformation in Spring Made of Steel Structure

While the minimum total deformation happened in spring made of Copper Alloy and the value was (133 mm) as shown in Figure 5 below

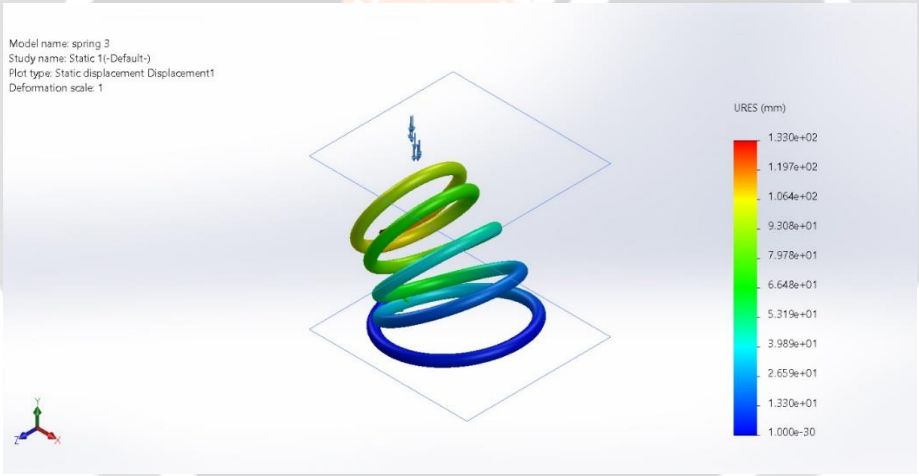

Fig. 5 Total Deformation in Spring Made of Copper Alloy

For the stress, under load (1500N) the maximum stress according to von-mises theory occurred in spring made of steel structure and the value was (1902 MPa) as shown in Figure 6 below.

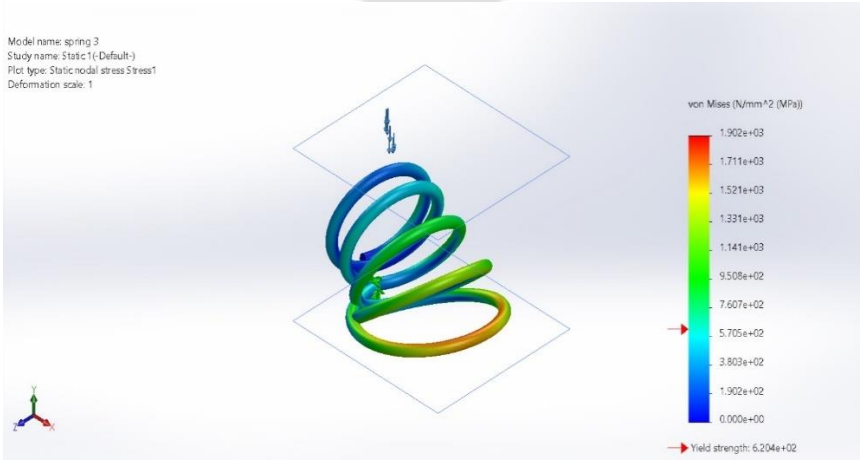

Fig. 6 The Stress in Spring Made of Steel Structure

The minimum value of stress under load (1500) N happened in Copper Alloy with the value (723.2 MPa) as shown in Figure 7.

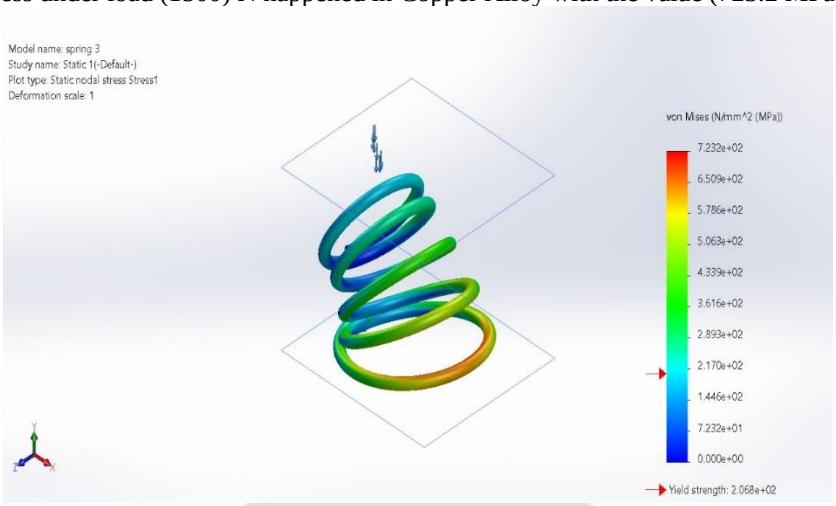

Fig. 7 The Stress in Spring Made of Copper Alloy

For the strain under load (1500N), the maximum strain occurred in spring with copper alloy with value (0.005341mm/mm) as shown in Figure 8 below.

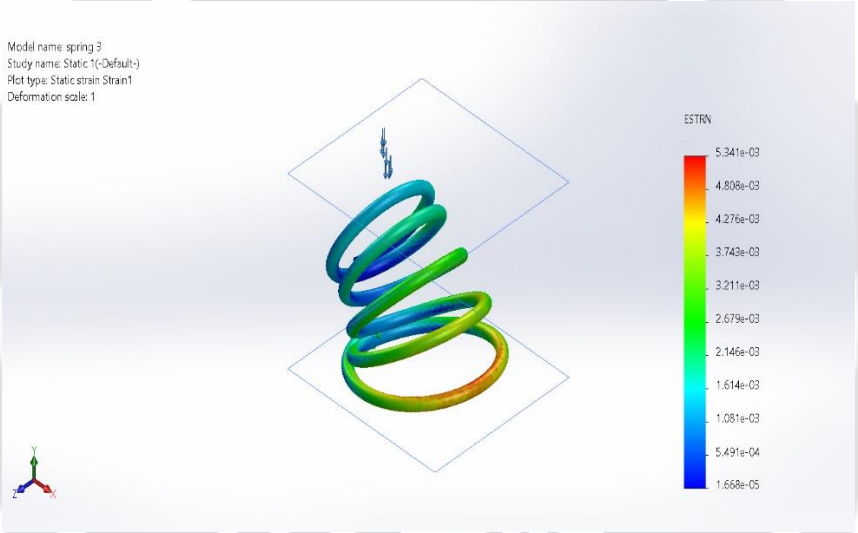

Fig. 8 The Strain in Spring Made of Copper Alloy

The minimum strain occurred in spring made of carbon composite and the value of strain was (0.006849 mm/mm) as shown in Figure 9 below.

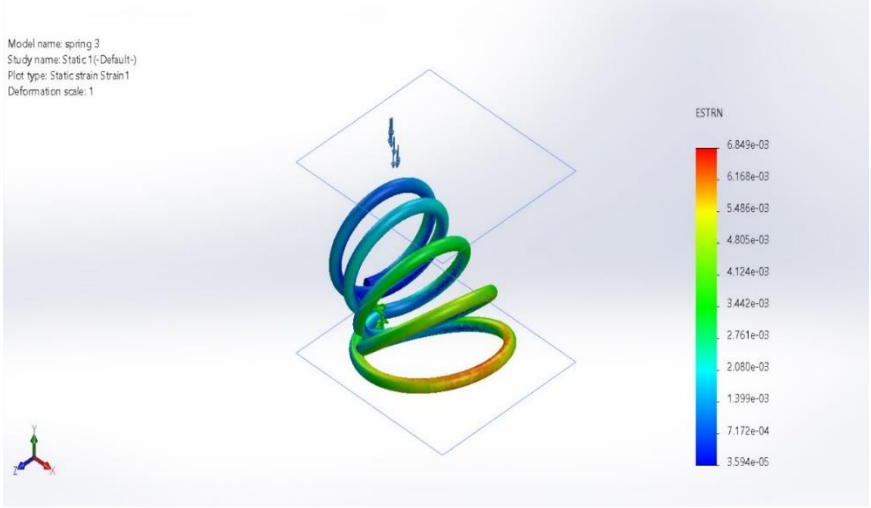

Fig. 9 The Strain in Spring Made of Steel Structure

The results (total deformation, stress, and strain) for different loads (1500) N for the three materials could be summarized in Table 3 below.

Table 3 Result for Load (1500N)

Materials	Load (N)	Total Deformation (mm)	Stress (MPa)	Strain (mm/mm)
Steel Structure	1500	167	1902	0.006849
Copper Alloy	1500	133	723.2	0.005341

The results (total deformation, stress, and strain) for different loads (2000) N for the three materials could be summarized in Table 4 below.

Table 4 Result for Load (2000N)

Materials	Load (N)	Total Deformation (mm)	Stress (MPa)	Strain (mm/mm)
Steel Structure	2000	160.4	1811	0.006520
Copper Alloy	2000	118.8	631.4	0.004667

The results (total deformation, stress, and strain) for different loads (2500) N for the three materials could be summarized in Table 5 below.

Table 5 Result for Load (2500N)

Materials	Load (N)	Total Deformation (mm)	Stress (MPa)	Strain (mm/mm)
Steel Structure	2500	220.6	2650	0.009617
Copper Alloy	2500	109.8	575.4	0.004257

The comparison of total deformation at various values of load for the two materials shown in Figure 10.

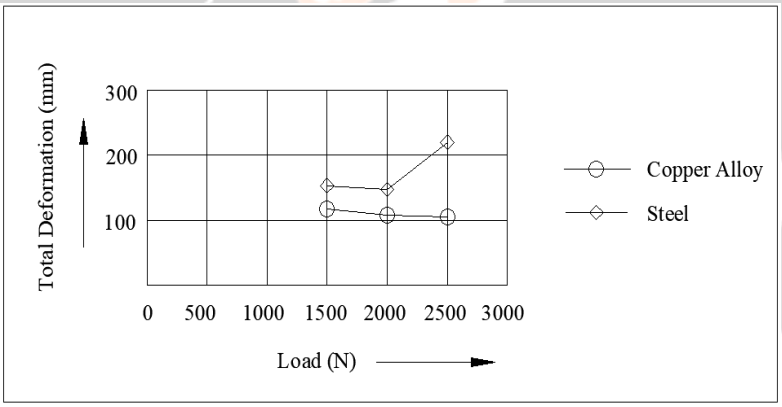

Fig. 10 Total Deformation (mm) vs. Load (N)

The comparison of stress at various values of load for the two materials shown in Figure 11.

The comparison of strain at various values of load for the two materials shown in Figure 12.

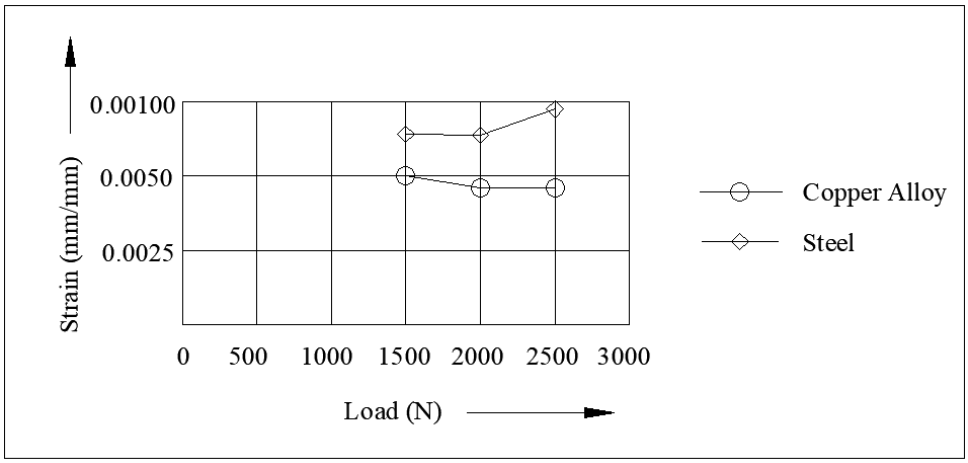

Fig. 12 Strain (mm/mm) vs. Load (N)

CONCLUSION

In this study, the simulation and analysis of tapered spring which is the main part of the suspension system in modern vehicles were carried out by using Solid works 2020. Two different materials were chosen to manufacture the spring under various values of the load. The results showed that the less value of total deformation happened in spring made of copper alloy for all the values of the load. The deformation reduced by 20% in copper alloy comparing with the deformation in the steel. The deformation, strain, and stress increased by increasing the load in case of steel material. It could be concluded that the copper alloy is the suitable material to fabricate the tapered spring in the suspension system in automobiles.

A Review Paper on Vibration Monitoring of Lathe

Hardik Prajapati

Swarrnim Institute of Technology, Gujarat, India

Abstract

In any machining operation vibration is frequently problem, the vibration signatures for different arrangement are recorded to determine the dynamic characteristics of the system,. These vibration signatures are analyzed to determine causes of inaccuracy in the manufacturing process and faulty components. Many condition monitoring techniques are available to monitor the machine experimentally. Among these techniques vibration monitoring is the most widely used technique because most of the failures in the machine tool could be due to increased vibration level. Experimental vibration analyses are conducted for a lathe system to detect the possibility of faults and to develop accurate cutting process. Experiments are carried out using the condition monitoring instrument Accelerometer to measure vibration severity for different cutting speed, depth of cut, feed rate for different work piece material.

Keywords: *Machine conditioning monitoring, Accelerometer, DAQ, Lab view.*

I. INTRODUCTION

Approximately half of all operating costs in most processing and manufacturing operations can be attributed to maintenance. This is ample motivation for studying any activity that can potentially lower these costs. Machine condition monitoring is one of these activities Condition monitoring of machinery is the measurement of various parameters related to the mechanical condition of the machinery (such as vibration, bearing temperature, oil pressure, oil debris, and performance), which makes it possible to determine whether the machinery is in good or bad mechanical condition. If the mechanical condition is bad, then condition monitoring makes it possible to determine the cause of the problem. The modern trend of machine tool development is required to produce precise, accurate and reliable product which are gradually becoming more prominent features. In a machining operation, vibration is frequent problem, which affects the machining performance and in particular, the surface finish and tool life. Severe vibration occurs in the machining environment due to a dynamic motion between the cutting tool and the work piece. The monitoring of manufacturing processes and equipment conditions are the essential part of a critical strategy that drives manufacturing industries towards being leaner and more competitive. Many sensors were used for tool condition monitoring system namely; touch sensors, power sensors, vibration sensors, temperature sensors, force sensors, vision sensors, flow sensors, acoustic emission sensors and so on. All operating machines, having rotary and/or reciprocating parts give rise to vibration. Machine tools are liable to deterioration in their performance level. With respect to time due to various causes such as wear and tear, ageing, unbalance, looseness of parts etc., and produce a corresponding increase of the vibration level. Machine tool vibration, if uncontrolled, can adversely affect the surface finish, dimensional accuracy and tool life. About 70% of the failures in the machine tool could be due to increased vibration level of the machine. Lathe is one of the most important machine tool in manufacturing industries. The extraction of vibratory signatures can be a valuable diagnostic tool to predict impending failures of the bearing and tool post. In all the cutting operations like turning, boring and milling, vibrations are induced due to the deformation of the work piece, machine structure and cutting tool. Today, the standard procedure adopted to avoid vibration during machining is by careful planning of the cutting parameters and damping of cutting tool.

II. TYPES OF CONDITIONING MONITORING TEQNIQUE

There are two types of Conditioning Monitoring System.

1) Periodic monitoring
2) Permanente monitoring

A. Periodic monitoring

In a periodic monitoring system (also called an off-line condition monitoring system), machinery Vibration is measured (or recorded and later analyzed) at selected time intervals in the field, then an analysis is made either in the field or in the laboratory. Intermittent monitoring provides information at a very early stage about incipient failure and usually is used where,

1) Very early warning of faults is required,
2) Advanced diagnostics are required,
3) Measurements must be made at many locations on a machine,
4) Machines are complex.

B. Permanent monitoring

In a permanent monitoring system, transducers are mounted permanently at each selected measurement point. For this reason, such a system can be very costly, so it is usually used only in critical applications where:
No personnel are available to perform measurements (offshore, remote pumping stations, etc.).

1) It is necessary to stop the machine before a breakdown occurs in order to avoid a catastrophic accident,
2) An instantaneous fault may occur that requires machine shutdown, and
3) The environment (explosive, toxic, or high- temperature) does not permit the human

Involvement required by intermittent measurements.

III. CONDITION MONITORING TECHNIQUE

1) Vibration monitoring – this is the most commonly used and effective technique to detect internal defects in rotating machinery.
2) Acoustic emission monitoring – this involves detection and location of cracks in bearings, structures, pressure vessels and pipelines.
3) Oil analysis – lubrication oil is analyses and the occurrence of certain microscopic particles in it can be connected to the condition of bearings and gears.
4) Particle analysis – worn machinery components, whether in reciprocating machinery, gearboxes or hydraulic systems, release debris. Collection and analysis of this debris provides vital information on the deterioration of these components.
5) Ultrasonic monitoring – this is used to measure thickness of corrosion or crack on pipelines, offshore structures, pressure vessels.
6) Thermography – this is used to detect thermal or mechanical defects in generators, overhead lines, boilers, misaligned coupling and cell damage in carbon fiber structures on aircrafts.
7) Performance monitoring – this is used to determine the performance problems in equipment. The efficiency of machines provides a good inside on their internal conditions

In this review paper mainly focused on Vibration monitoring on lathe machine.

LITERATURE REVIEW

Nidhi gupta, sawan arya, nitin rai [1] were carried out experiment on center lathe machine measured vibration using conditioning monitoring instrument vibrometer. They were measure vibration in axial and tangential direction at three level of cutting speed, feed rate, and depth of cut. then they were plotted Graff between R.M.S value and feed rate at different cutting speed for different depth of cut in both the direction for two different tool material carbon tool and diamond tool and indicate that increase in above parameters, there is a continuous increase in cutting tool vibration value. With the help of vibration data the optimum condition of parameter for running the machinery can be identify and increased tool life by reducing vibration. They were also concluded vibration level is increased in diamond tool as compare to carbon tool.

Dr.Pratesh jayaswal, Nidhi gupta [2] in this paper they were carried out experiment on center lathe machine measured vibration using vibrometer. they were measure vibration in axial and tangential direction at tool post and Bering, vibration signal collected through vibrometer data acquisition system they were varied parameter at four level and plotted graph between r.m.s value verses feed rate at different spindle speed and at depth of cut finally they were conclude that the parameter which is highly affect the vibration is cutting speed then depth of cut and then feed rate. The optimal condition for working on centre lathe machine is cutting speed of 230-350 rpm, feed rate of 0.1-0.2 mm/rev and depth of cut up to 1 mm so it is not advisable to work on high cutting speed, feed rate and more depth of cut because it directly affect the tool life it also shows that vibrations at bearing and in tangential direction are highly occurred comparatively at tool post and in axial direction.

Jagdish.M.S,H.VRavindra[3] studied that the Finite Element Method to study the effect of defective spindle bearing and unbalance forces on the vibration characteristics of the lathe structure by performing Eigen value, frequency response and transient dynamic analysis. Experiments were carried out to determine the vibration velocity level on the headstock both at the front and rear bearing. plot the graph vibration velocity verses spindle speed and then Experimental results were compared with the theoretical results and conclude that Transient dynamic analysis showed that the vibration velocity level increases as the damage in the outer race increases. It was also found that the vibration velocity level depends upon the location of the defect. The value of vibration velocity obtained from frequency response analysis considering unbalance force is lower compared with the experimental value because in actual practice, the various effects like vibration due to belt tension fluctuations, gear tooth frequencies at the mating gears, defects in bearing and due to unbalance rotors were also included. From the experimental analysis, it was found that vibration velocity increases with the increase of spindle speed. Hence the theoretical results are agreement with experimental results. The present work shows that the FEM is a valuable tool in finding sources of increased or undesirable vibrations from various defects. Thus Finite Element Analysis is not only helpful during the development of new structures but also helpful to analyze the existing lathe structure under given circumstances.

S.s abhutakeer p.v mohnram g.mohan kumar[4] In this paper, Experiments were conducted on CNC lathe using CCGT-0930FL carbide turning insert, machining variables such as cutting tool vibration in tangential and axial direction were measured in CNC machining processes based on the vibration signal collected through a Lab VIEW data acquisition system and controlled by using Viscoelastic material (VEM) neoprene. The effect of cutting parameters such as cutting speed, depth of cut and feed rate on machining variables is evaluated. The testing result showed that the developed method was successful.

Julie and Joseph [5] have been trying to demonstrate tool condition monitoring approach in an end-milling operation based on the vibration signal collected through a low-cost, microcontroller-based data acquisition system.

Marlon C. Battery and Hamid R. Hamidzadeh [6] has done analytical and experimental vibration analyses for a lathe system to detect the possibility of faults and to develop an accurate cutting1process.the vibration signatures were analyzed to determine cause of inaccuracy in the manufacturing process and faulty components. Problem causing components for several case studiers (different speeds feed rate and tool lengths) were identified.

Kirby and Chen [7] the researchers determine mean amplitude of vibration using accelerations in both directions along the axes.

Tasks [8] have proposed the On-line vibration control system for turning operation uses a closed loop Feedback circuit which measures the relative vibration between the cutting tool and the work piece. There have been many investigations on vibration prediction and controlling based on periodic measurements of various machining conditions using accelerometer and active vibration controller.

Choudhury et al [9].has developed a computer program using Visual Basic programming language in order tana-alyze one and two degree of freedom of machine toolch-atter vibrations.

Vinay.V.N [10] was studied that The mass correction effected on the Motor-spindle assembly for the purpose of

unbalance correction should not be altered in any manner. Doing so would alter the balance quality achieved. Any change in the rotating mass of Motor-spindle assembly will change the balance quality achieved.

S.Saravanan, G.S.Yadava and P.V.Rao [11] In this study, critical subsystems and components have been identified for lathes using failure data. The application of condition monitoring techniques like vibration, acoustic emission (AE) and surface roughness monitoring have been successfully implemented for diagnosing faulty bearings in a lathe. they were conclude that Headstock subsystem is critical because it faces a longer downtime and frequent failures of components like spindle bearings and gears For defective bearing conditions, overall vibration levels at headstock spindle beatings are higher than those in defect free lathes. This increase in vibration level is much greater at higher feed and depth of cut values. For defective beating conditions, significant peaks at the beating fault frequencies are observed. Larger sized contamination particles increase surface waviness considerably. As a result, the vibration level increased considerably at larger particle sizes. AE levels show an increasing trend with an increase in feed rate and depth of cut. For defective bearing conditions, AE levels are higher than those measured under healthy conditions. The increase in AE levels is much greater for higher values of feed and depth of cut. For defective bearing condition, surface roughness value increases sharply.

Robert X. Gao[12] Extensive research over the past decade has turned neural networks into an indispensable tool for solving a wide range of problems in both scientific labs and on the factory floor. In the specific areas of machine condition monitoring, fault diagnosis, and remaining service life prognosis, neural networks will play an increasingly important role, and its ability will be continually enhanced through other innovative and complementary technologies. Research is continuing in the author's group, with the ultimate goal to develop effective and efficient bearing condition monitoring and diagnostic techniques that can be applied to solving real-world problems.

Amit R Patel [13] in this paper Test rig for vibration monitoring of bearing have been designed. The design of test rig includes design of Shaft, Bearing selection, pedestal selection, motor selection, and base preparation. A 3-D model have been developed using Pro-engineer modeling software. The vibration signals generated by the healthy/faulty bearing can be captured by the accelerometer mounted on the test bearing. The analysis of the vibration signal is useful for the condition monitoring of rolling Element bearings.

Sutej Reddy Dr. S. P. Gupta, Dr. Vinod Kumar [14], in this paper a remote condition monitoring system has been developed using Lab VIEW. This developed system enables the transfer of the digital data simultaneously from the plant location to the several remotely placed control stations through internet or any other transmission networks like LAN, WAN e.tc. Particular attention has been paid to the wavelet analysis of the vibration signal for demonstrating the condition monitoring of the induction motor. The developed system has been tested for the bearing fault identification of the Laboratory test motor. A key feature of this work is the development of the sophisticated GUI at the server and the client locations thus facilitating the operators at both the ends with not only customized and user friendly but also efficient remote condition monitoring system.

CONCLUSION

From the above study we can conclude that lots of works have already been done in the area of vibration measurement. All experiment done using the same material of work piece to find the optimum machining parameter. Further study can be done on Lathe machine measuring vibration for different work piece material by putting NI instrument Accelerometer at tool post Which is connect to Portable data acquisition system(DAQ) Which is supported by Lab view software And can calculate optimum condition of lathe machine for working on different work piece material.

ABSTRACT: Abrasive water jet cutting is a cutting process which in which abrasive particles are entrained into a jet of water which is accelerated to high velocities by use of pressures normally in excess of 130MPa.The particle-laden water jet impinges onto the surface of the work piece and material is removed by an erosion process. Maraging 300 grade steel is widely used in aerospace and tooling sector because of practical application. It have excellent properties like medium to high carbon material as it doesn't endure issues like high carbon content advancing the erosion or furthermore, making the break. This study investigates the effect of process parameter (like travel speed, abrasive mass flow rate, standoff distance and pressure) on the kerf width, material removal rate and surface roughness. The analysis of variance (ANOVA) and regression models will be developed based on experimental results. In this study, the multi objective optimization has been carried out to find optimal process parameter.

While studying the effect of the process parameters on the material removal rate, it was observed that cutting speed, standoff distance, pressure and abrasive mass flow rate, square effect of abrasive mass flow rate are the influencing parameter.it has been found that standoff distance, square effect of stand of distance are the influencing parameter for kerf width.

The grey relational analysis have suggested the optimum process parameters value of traverse speed of 100 mm/min, 200 gm/min of abrasive mass flow rate, 1 mm of standoff distance and 400 Mpa of pressure. From the confirmation test, it has been found that the suggested model is very excellent in terms of accuracy.

KEYWORDS: Abrasive Water Jet Machine (AWJM), Surface roughness, Material removal rate, Kerf width, Grey Relational Analysis (GRA), Regression.

I. INTRODUCTION

Abrasive Water Jet (AWJ) machining is non traditional or non conventional machining process. Mechanical energy of water and abrasive phases are used to achieve material removal or machining. Profitable technique and can be more competitive than laser cutting if several cutting heads are used. New machining technology in that it makes use of the impact of abrasive material to erode the work piece material. Maraging steel is offering an appealing alternative to the medium to high carbon material as it doesn't endure issues like high carbon content advancing the erosion or furthermore, making the break.

There are many advantages of this such as Cut virtually any material & are very safe extremely fast setups and programming, Very low side forces during the machining, No heat generated on the part, Machine thick plates, Capital cost is low, Clean cutting process without gasses or oils.

Abrasive Water Jet Cutting process applied on many industries like Paint removal, Cleaning, Cutting soft material, Textile & leather industry, Cutting, Drilling, Turning, Pocket milling.

[1] Radovanovic, (2020) has investigated the abrasive water jet cutting process with help of cutting various types of material and thickness of it. For that, it has been used various input parameter like water pressure, water flow rate, orifice diameter, nozzle diameter, abrasive mass flow rate, traverse speed and standoff distance. In order to conduct study, it had used carbon steel S235 as a

International Journal of Advances in Engineering and Management (IJAEM)
Volume 3, Issue 6 June 2021, pp: 1090-1109 www.ijaem.net ISSN: 2395-5252

material; also applying the multi objective optimization to find optimal process parameter for productivity and operating cost. It had considered three constrain like perpedicularity tolerance, surface roughness limit and traverse speed for separation cut. It has revealed that optimal process parameter at 6.5 mm thick: traverse rate vf=127 mm/min, abrasive flow rate ma=300 g/min and standoff distance h=1 mm. they have concluded that machining time needed to produce a unit of cut surface is t=7.266 s/cm2 (productivity is Q=8.258 cm2/min) and operating cost per meter of cut is C=2.048 EUR/m.

[2] Schwartzentruber, Spelt, & Papini, (2017) have used three dimensional techniques to predicate the surface roughness while cutting of composite material by abrasive water jet cutting process. They have revealed that individual particle of abrasive material would be generated crater which one was follow by the multi particle impact profile in case of two dimensional model for said study. In case of three dimensional model, it can be concluded that the conical crater has been developed until steady surface roughness found. At the end of study. It has been found that average error of 10 % and 16% were found for the 2D & 3D models respectively.

[3] Ravi Kumar, Sreebalaji, & Pridhar (2018) have conducted researched based on the aluminium/ tungsten carbide composites by abrasive water jet cutting process. For that, they have fabricated composite material by using various sizes (like 2, 4, 6, 8 and 10 wt% tungsten carbide) of tungsten carbide. They have used response surface methodology to investigate the said process. They have varied speed of cutting, stand-off distance and percentage of carbide in material to optimize the material removal rate and surface roughness. They have found that the surface roughness is being varied by the carbide content in material. They have seen the breaks, bulge of the tungsten carbide and voids in the material while microstructure examination. Multi Response Optimization dependent on attractive quality is utilized to assess the arrangement of information measure boundaries to increase material removal rate and limiting surface roughness. They have concluded that optimal process parameter are following: standoff distance 4.22mm, cross over speed-223.28 mm/min, and rate tungsten carbide- 2.10%.

[4] Tudor & Andrea, (2013) have carryout the study for optimisation of abrasive jet cutting by means of taguchi methods. They have been influenced the process parameter like jet pressure, feed speed, stand-off distance, abrasive graining, mass flow, etc. The roughness of the machined surfaces and the thickness of the cut part are output quantities of the system, their values depending on the input parameters and the influence of various disturbing factors (noises). They obtained surface roughness consequently to abrasive jet cutting. By assigning these optimum set points to the input quantities the machining system becomes robust, and consequently the roughness of the machined surfaces will not deviate from the desired and predicted value.

[5] Narayanan, Balz, Weiss, & Heiniger, (2013) have developed the model of abrasive particle energy in water jet machining. They took process parameter with wide variations in cutting-head geometry, operating pressure, and abrasive mass flow rates. The cross-sectional averaged abrasive particle velocity at the exit of the focussing tube has been predicted with good accuracy over the whole range of experiments.

[6] Begic-Hajdarevic, Cekic, Mehmedovic, & Djelmic, (2015) have investigated on surface roughness through effects of material thickness, traverse speed and abrasive mass flow rate during abrasive water jet cutting of aluminium. They show that traverse speed has great effect on the surface roughness at the bottom of the cut. They discussed the correlation between the surface roughness and other abrasive water jet cutting variables. The surface being cut by the abrasive water jet was characterized by two types of surface texture. The first texture was located at the beginning of the cut and was characterized by the smooth surface. The second texture was located at the bottom of the cut and was characterized by the rough surface. They suggested optimal solution is the choice of medium traverse speed with which can be achieved higher productivity with acceptable surface roughness.

Problem definition

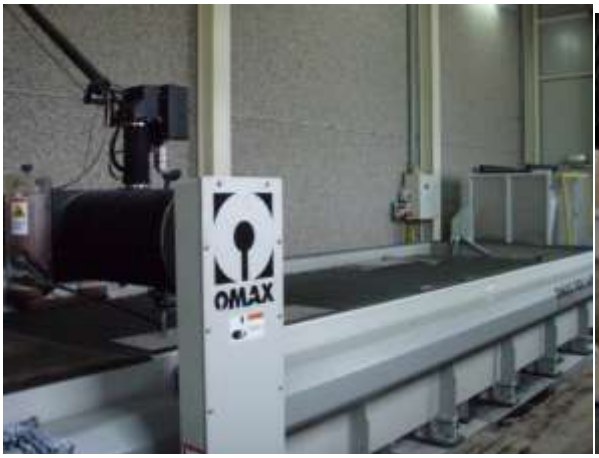
Facing problem like higher surface roughness of machined surface, lower material removal rate, taper of cutting as well as the kerfwidth in the plate, Kerf taper, the wear of nozzle, limited machining capability.

Confused about following problem.

- How thick is the metal want to cut?
- Traditional way of cutting takes a lot of time.
- The most important factors that influence the cutting process?
- What type of material is to cutting?
- What are the best conditions to achieve optimum performances?

International Journal of Advances in Engineering and Management (IJAEM)
Volume 3, Issue 6 June 2021, pp: 1090-1109 www.ijaem.net ISSN: 2395-5252

II. EXPERIMENTAL SETUP AND DETAILS



The equipment used for machining the samples will Abrasive Water Jet Machine of model 2626 OMAX Jet Machining Centre equipped with OMAX High- Pressure Pump with the design pressure of 345MPa (50,000 psi) and the nozzle diameter was 0.75mm. The OMAX variable speed, high-pressure pump is an electrically driven, variable speed, positive displacement, crank shaft drive triplex pump designed for use with the OMAX precision jet machining system and other applications requiring high pressure water required by the OMAX jet machining system to operate. The pump control panel provides a keypad display screen, and pumps start/stop controls. When the pump is attached to an OMAX jet machining centre, controls sheared between the Jet machining centre controller and the pump.

Maraging steel is offering an appealing alternative to the medium to high carbon material as it doesn't endure issues like high carbon content advancing the erosion or furthermore, making the break. These may be answerable for the startling disappointment of the part or the durability. The low carbon substance of maraging steel diminishes the danger of unpredicted failure. Generally, the maraging steel are widely popular in die and mould making industries as aforesaid reasons. Moreover, the H13, P20 steel is used to make the die and mould, but it have high carbon percentage which leads aforesaid problem. The application of the maraging steel does not limit upto the tooling industries, but it also widely used in aerospace and automotive sector as has excellent corrosion resistance and high remarkable mechanical properties[7]-[9]. Experimental specimens having dimension 850mm X 150mm x 14mm have been prepared for the experimental work. The material for test specimen is maraging steel 300 grades.

Table 2.1 Chemical composition of maraging steel 300 grade.

Element	Grade 300
Iron	Balance
Nickel	**18.0-19.0**
Cobalt	8.5-9.5
Molybdenum	4.6-5.2
Titanium	0.5-0.8
Aluminum	0.05-0.15

Process parameters:

The process parameters include parameters relating to the forming of the AWJ. These parameters can be sorted into four following sub-groups :

International Journal of Advances in Engineering and Management (IJAEM)
Volume 3, Issue 6 June 2021, pp: 1090-1109 www.ijaem.net ISSN: 2395-5252

1. Hydraulic parameters including water pressure and orifice diameter.
2. high pressure water
3. orifice abrasive supply mixing chamber focusing tube

-Mixing parameters including focusing tube (or nozzle) diameter and focusing tube length.

Abrasive parameters including

1. abrasive material,
2. abrasive particle size,
3. abrasive shape, and
4. abrasive mass flow rate.

Cutting parameters including

1. standoff distance,
2. impact angle,
3. traverse rate and
4. number of passes.

III. METHODOLOGY

3.1 Design of experiment

Design of experiment is powerful way to deal with limit the quantity of analyses yet separate all the information about the reliance of result on the procedure boundaries. It is basic to follow a methodology of experimentation where input boundaries of procedure might be fluctuated all the while to contemplate their impact on the procedure yield. The connection among yield and at least one info process boundaries might be direct or non straight in nature. The choice of structure of trials relies upon the straight or the non-direct nature of the procedure. The information about nature of variety is important to sort the issue either as straight or non-direct [10].

3.2 Analysis of variance (ANOVA)

The aim of this research, to analyzed the output response parameters like MRR (mm^3/min), Surface roughness (µm), Kerf width (mm) by Considering Traverse speed (mm/min), Abrasive mass flow rate (gm/min), Stand-off distance(mm), Pressure (MPa) as input parameters for VCR engine. The corresponding response parameters were noted, when experiments are carried out as per the run order of the minitab-17 input parameters given by Box behnkhen method. The model was analyzed by using Analysis of variance (ANOVA). RSM was used for optimized output parameters with highest desirability.

3.3 RSM Methodology

There are four types of design experiments such as Factorial, Response surface, mixture and Taguchi in Minitab. Minitab provides analytical and graphical tools to help understand the results after the following steps to crate, analyze, and graph of experimental design.

Response surface methodology (RSM) is a collection of mathematical and statistical techniques that are useful for the modeling and analysis of problems in which a response of interest is influenced by several variables and the objective is to optimize response. In practice the requirement of RSM for to chose the sample point such that the sufficient accurate model can be generated with the minimum number of experiments. Response Surface Method is used to examine the relationship between a response and a set of quantitative experimental variables or factors.

3.4 Determination of independent variables and their levels

Select the parameters (variable) that have major effects on output. The levels of the parameters are determined. All variable will be tested over the same range. Range of the variable are forced between the ranges of coded variable -1 to 1. Equation of coding is given below:

$$X = (x-[x_{max}+x_{min}]/2)/([x_{max}-x_{min}]/2) \quad \ldots\ldots(1.1)$$

Where, X = coded variable

x = natural variable

xmax ,xmin = maximum and minimum values of the natural variable.

3.5 Box-Behnken Method

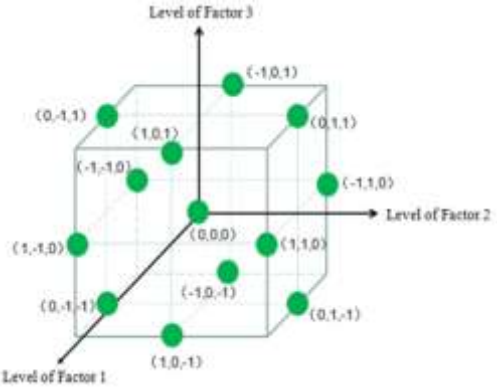


Figure 3.1 Box–Behnken designs for three factors

Appeared differently in relation to the CCD, this structure has preferences. The three-factor BBD requires just 12 test runs with notwithstanding the repeats at the inside point, while its CCD has 14 non-focus focuses. Generally speaking, the amount of test focuses is given by $2k(k-1) + nc$ (where, k= no. of factor and nc = runs at focus). Similarly, each factor is learned at only three levels, with some critical highlights in some exploratory circumstance. While, using $\alpha = 1$ out of a CCD also achieves three levels for each factor. In

International Journal of Advances in Engineering and Management (IJAEM)
Volume 3, Issue 6 June 2021, pp: 1090-1109 www.ijaem.net ISSN: 2395-5252

most certified applications, these differentiations are apparently not unequivocal in making sense of which configuration to use, in any occasion for this number of variables. In various sensible assessments that require RSM, specialists are inclined to require three fairly scattered levels. Thusly, the BBD is a beneficial decision and point of fact an imperative differentiating choice to the CCD (Yang, 2008). Note that the Box–Behnken plan (BBD) is very equivalent in various structure focuses to the CCD for k = 3 and k = 4. (There is no BBD for k = 2). For k = 3, the CCD contains 14+ nc runs while the BBD contains 12+ nc runs. For k = 4 the CCD and BBD both contain 24+ nc structure points. In BBD, just three degrees of procedure boundary have been required to run the investigation, likewise there is no focuses lie on the vertices of the trial region. This is the fundamental trait of the BBD techniques [11], [12], [12]–[14].

Box-Behnken structures never incorporate runs where all elements are at their extraordinary setting, for example, the entirety of the low settings, in contrast to focal composite plans. Besides, In Box-Behnken structure there are less plan focuses than focal composite structures which brings about more affordable to run with a similar number of variables. Response Surface strategies are utilized to look at the connection between at least one reaction factors and a lot of quantitative exploratory factors or factors. These strategies are frequently utilized after distinguished the significant controllable variables and to discover the factor choice that upgrades the reaction [15], [16].

3.6 Performance characteristics

3.6.1 Surface Roughness

Roughness is a measure of the texture of a surface. It is quantified by the vertical deviations of a real surface from its ideal form. If these deviations are large, the surface is rough; if they are small the surface is smooth. Roughness is typically considered to be the high frequency, short wavelength component of a measured surface. Surface roughness normally measured. Roughness plays an important role in determining how a real object will interact with its environment. Rough surfaces usually wear more quickly and have higher friction coefficients than smooth surfaces (see tribology). Roughness is often a good predictor of the performance of a mechanical component, since irregularities in the surface may form nucleation sites for cracks or corrosion. In this thesis, the average surface roughness is measured and calculated. The average surface roughness is the integral of the absolute value of the roughness profile height over the evaluation length and is denoted by the following equation [17], [18].

$$Ra = \frac{1}{L\int_0^L Y(x)dx}$$

Where L is the length taken for observation, and Y is the ordinate of the profile curve.

3.6.2 Kerf Width

Kerf width is one of the important performance measures in WEDM. Kerf width is the measure of the amount of the material that is wasted during machining. It determines the dimensional accuracy of the finishing part. The internal corner radius to be produced in WEDM operations are also limited by the Kerf width [19], [20]. The setup for the kerf width is shown in fig. 3.3. the technical specification of the profile projector as per table 3.4.

3.6.3 Material removal rate

The material removal rate can be defined as the volume of material removed divided by the machining time. Material Removal Rate (MRR) is defined by following formula [21], [22].

$$MRR = (Wi - Wf) / (\rho w T)$$

Where,

Wi = initial weight of work piece (g)

Wf = final weight of work piece material (g)

T = cutting time(s)

ρw = Work piece density (g/ mm3)

4.2 Main effect of input parameter on the response

In this section, it has been discussed the effect of various input parameter like Traverse speed (mm/min), Abrasive mass flow rate (gm/min), Pressure (MPa) and Stand-off distance (mm)on the targeted response like material removal rate, surface roughness and kerf width.

International Journal of Advances in Engineering and Management (IJAEM)
Volume 3, Issue 6 June 2021, pp: 1090-1109 www.ijaem.net ISSN: 2395-5252

4.2.1 Main Effects Plot of material removal rate

The main effects plot for material removal rate versus Traverse speed (mm/min), Abrasive mass flow rate (gm/min), Pressure (MPa) and Stand-off distance (mm)is shown in fig.4.2, which is generate from the value of material removal rate as per table 4.1 in minitab-17 statistical software. It is useful to find out optimum parameter value for response variable. Fig. 4.2 shows that high material removal rate will meet at transverse speed 200 mm/min, 300 gm/min of abrasive flow rate, 1 mm of stand of distance and 500 Mpa of pressure. The graph generates by use of minitab-17 statistical software for material removal rate is shown in fig. 4.2

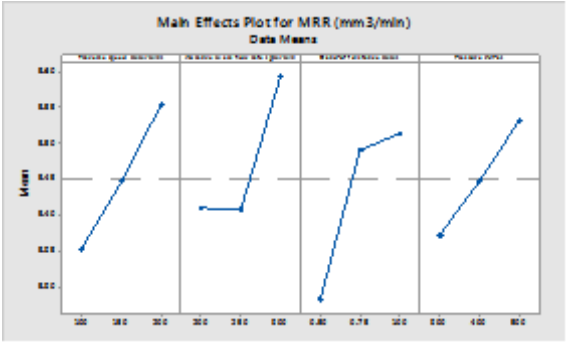

Fig. 4.2 Effect of control factor on material removal rate

From the fig. 4.2, it has been concluded that the optimum combination of each process parameter for high material removal rate is meeting at high cutting speed[A3], high abrasive mass flow rate [B3], high standoff distance[C3] and high pressure [D3].

This aforesaid combination is representing the single objective response optimization where material removal rate is getting higher without considering other response. The reason behind this optimum process parameter has been discussed here. It very well may be seen that the Width of the grating plane progressively grows because of spreading as the separation from spout tip increments and therefore speed (or kinetic energy) of the rough particles diminishes. Since kinetic energy bestowed by the abrasive is utilized to bit by bit dissolve material from work surface, bigger standoff distance brings about lower infiltration just as lower material material rate. Then again, in the event that stand off distance is too little, adequate section won't be accessible for the pre-owned rough abrasive to come out from the machining zone after impact. It can considerably reduced speed of new abrasive as a result of impact that can prompt decreased adequacy of the jet regarding material disintegration. Hence, at first with expansion in standoff distance, both the MRR and entrance increment slowly; notwithstanding, after certain breaking point, both diminishing with additional increment in standoff distance. Along these lines an ideal worth of deadlock distance is needed for acquiring good execution in rough stream machining.

4.2.2 Main Effects Plot of Kerf width

The main effects plot for kerf width versus Traverse speed (mm/min), Abrasive mass flow rate (gm/min), Pressure (MPa) and Stand-off distance (mm)is shown in fig.4.3.

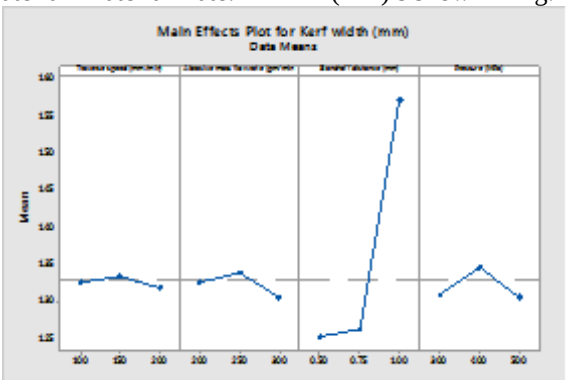

Fig. 4.3 Effect of control factor on Kerf width

International Journal of Advances in Engineering and Management (IJAEM)
Volume 3, Issue 6 June 2021, pp: 1090-1109 www.ijaem.net ISSN: 2395-5252

From the fig.4.3, it has been conclude that the optimum combination of each process parameter for low Kerf width is meeting at high cutting speed [A3], high abrasive mass flow rate [B3], low stand off distance[C1] and high pressure [D3].

This aforesaid combination is representing the single objective response optimization where Kerf width is getting lower without considering other response. The reason behind this optimum process parameter has been discussed here. It has been seen that the rough particles have an adequate degree of active energy to destruct the material. This little harmed district is portrayed by a little adjusted corner at the top edge because of the plastic miss happening of material brought about by the underlying AWJ assault. As the grating particles infiltrate into the material, a portion of the energy is utilized in disintegrating the material in loses dynamic energy. A fly with lower energy will in general avoid the typical way to the plane of cutting, which will bring about striations to be shaped on the cutting surface. As the rough fly stream crosses the part, the stream is diverted, henceforth bringing about the formation of a one of a kind cutting math. The level of diversion increments with speeding up.

4.2.3 Main Effects Plot of surface roughness

The main effects plot for surface roughness versus Traverse speed (mm/min), Abrasive mass flow rate (gm/min), Pressure (MPa) and Stand-off distance (mm)is shown in fig.4.4, which is generate from the value of kerf width as per table 4.1 in minitab-17 statistical software. It is useful to find out optimum parameter value for response variable. Fig.4.3 shows that the lower surface roughness will meet at transverse speed 200 mm/min, 300 gm/min of abrasive flow rate, 0.5 mm of stand of distance and 500 Mpa of pressure.The graph generate by use of minitab-17 statistical software for material removal rate is shown in fig.4.2

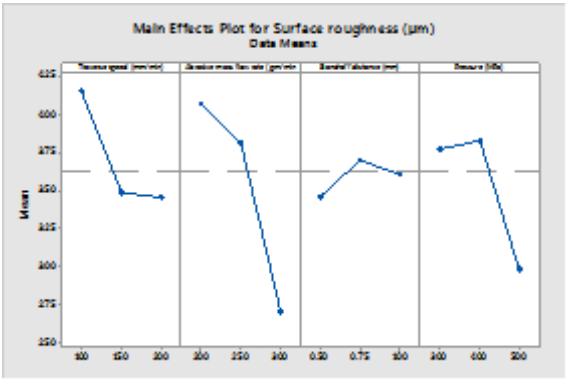

Fig. 4.4 Effect of control factor on surface roughness

From the fig.4.3, it has been conclude that the optimum combination of each process parameter for low surface roughness is meeting at high cutting speed [A3], high abrasive mass flow rate [B3], low stand off distance [C1] and high pressure [D3].

This aforesaid combination is representing the single objective response optimization where surface roughness is getting lower without considering other response. From the test results, it very well may be seen that an increment in the cutting speed causes a consistent expansion in the surface unpleasantness. This might be expected as expanding cutting speed permits less cover machining activity and less grating particles to encroach the surface, reducing the surface finish.

4.3 Analysis of Variance

In this section, the analysis of variance for the responses like material removal rate and surface roughness has been discussed. The analysis of variance is representing the effect of the input parameter on the responses in terms of the p- test and F test.

Analysis of variance (ANOVA) is a statistical model which can be used for find out effect of independent parameter on single dependent parameter and also it can be use full to find out the significant machining parameters and the percentage contribution of each parameter.

4.3.1 Analysis of Variance for the material removal rate

According to the analysis done by the MINITAB 17 software, if the values of probability are less than 0.05, it indicated that the factors are significant to the response parameters. Comparing the p-value to a commonly used α- level = 0.05, it is found that if the p- value is less than or equal to α, it can be concluded that the effect is significant.

Model Summary

S	R-sq	R-sq(adj)	R-sq(pred)
0.558033	84.80%	67.07%	12.46%

The confidence level (CL) used for investigation is taken 95% for this investigation. The parameter R-Sq described the amount of variation observed in surface roughness is explained by the input factor. R-Sq= 84.80 % which indicate that the model is able to predicate the response with high accuracy.

4.4 REGRESSION MODEL

The regression model for predicting the response parameters in turning can be derived using methods like Regression analysis.
Regression analysis is often used to:

- Determine how the response variable changes as particular predictor variable changes.
- Predict the value of the response variable for any value of the predictor variable, or combination of values of the predictor variables.

4.4.1 Regression Equation for Material removal rate

The regression equation for the material removal rate is following:

Material removal rate (mm3/min) =
7.39 + 0.00902 A - 0.02793 B + 3.64 C - 0.00607 D + 0.000004 A*A + 0.000033 B*B - 1.167 C*C + 0.000001 D*D - 0.000009 A*B - 0.00200 A*C- 0.000011 A*D - 0.00100 B*C + 0.000038 B*D - 0.00220 C*D .....(4.1)

4.4.2 Regression Equation for Kerf width

The regression equation for the kerf width is following:

Kerf width (mm) =
2.645 - 0.00062 A - 0.00222 B - 2.610 C - 0.00153 D + 0.000009 A*A + 0.000005 B*B + 2.513 C*C - 0.000000 D*D - 0.000007 A*B - 0.00100 A*C+ 0.000001 A*D - 0.00180 B*C + 0.000005 B*D + 0.000200 C*D.....(4.2)

4.4.3 Regression Equation for surface roughness

The regression equation for the surface roughness is following:

Surface roughness =
-8.7 - 0.1340 A + 0.0474 B + 15.95 C + 0.0709 D - 0.000014 A*A- 0.000263 B*B - 7.05 C*C - 0.000068 D*D + 0.000510 A*B + 0.0004 A*C+ 0.000008 A*D + 0.0092 B*C - 0.000033 B*D - 0.0186 C*D.....(4.3)

V. MULTI OBJECTIVE OPTIMIZATION

5.1 Grey Relational Analysis

The grey relational analysis, a grey relational grade can be obtained to evaluate the multiple performance characteristic. As a result, optimization of the complicated multiple performance characteristic can be converted into the optimization of a single grey relation grade. For multiple performance characteristic optimizations using GRA, following steps are followed:

1. Conduct the experiments of different settings of parameters based on available design of experiment.
2. Normalization of experimental result for all performance characteristics.

International Journal of Advances in Engineering and Management (IJAEM)
Volume 3, Issue 6 June 2021, pp: 1090-1109 www.ijaem.net ISSN: 2395-5252

3. Performance of grey relational generating and calculation of grey relational coefficient (GRC).
4. Calculation of grey relation grade using weighing factor for performance characteristics.
5. Analysis of experimental results using GRG and statistical analysis of variance (ANOVA).
6. Selection of optimal levels of process parameters.
7. Conducting confirmation experiment to verify optimal process parameter settings.

5.2 Main Effect of Factors on Grey Relational Grade (GRG)

For the combined response maximizatoin, fig.5.1 gives optimum value of each control factor. It interprets that level A1, B1, C3 and D2. The desired result of each response namely maximum material removal rate, minimum kerf width and minimum surface roughness has been attained at the value of traverse speed of 100 mm/min, 200 gm/min of abrasive mass flow rate, 1 mm of stand off distance and 400 Mpa of pressure. The mean of grey relational grade for each level of the other machining parameters can be computed in similar manner.

International Journal of Advances in Engineering and Management (IJAEM)
Volume 3, Issue 6 June 2021, pp: 1090-1109 www.ijaem.net ISSN: 2395-5252

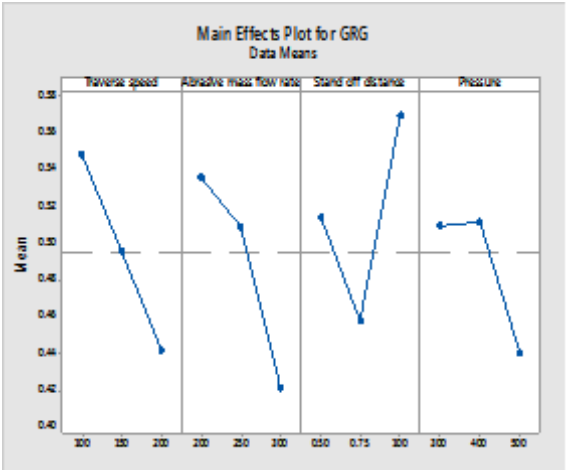

Fig 5.1 – Main effect of factor on Grey Relational Grade

Table 5.3 Main effect of factors on Grey Relational Grade

Symbol	Control factor	Level 1	Level 2	Level 3
A	Traverse speed	**0.5485**	0.4955	0.4419
B	Abrasive mass flow rate	**0.5361**	0.5088	0.4211
C	Standoff distance	0.5144	0.4579	**0.5700**
D	Pressure	0.5096	**0.5116**	0.4406

As per the grey relational theory, it can be said that higher grey relational grade value will give optimum value of material removal rate, surface roughness and Kerf width. Thus it is revealed that response will be optimum at value of traverse speed of 100 mm/min, 200 gm/min of abrasive mass flow rate, 1 mm of stand off distance and 400 Mpa of pressure.

VI. CONCLUSION

In this study, the experimental investigation and analysis are carried out on AISI1045 steel material by using abrasive water jet cutting process. The following conclusions are made.

1. The material removal rate is increased with increase of cutting speed, stand off distance, pressure and abrasive mass flow rate. It has been observed that the high material removal rate will meet at transverse speed 200 mm/min, 300 gm/min of abrasive flow rate, 1 mm of stand of distance and 500 Mpa of pressure.
2. While studying the effect of the process parameters on the material removal rate, it was observed that cutting speed, standoff distance, pressure and abrasive mass flow rate, square effect of abrasive mass flow rate are the influencing parameter.
3. The optimum condition for surface roughness is A3 B3 C1 D3. The said combination is like, lower surface roughness will meet at transverse speed 200 mm/min, 300 gm/min of abrasive flow rate, 0.5 mm of stand of distance and 500 Mpa of pressure.
4. It has concluded that optimum kerf width can be attained at the, transverse speed 200 mm/min, 300 gm/min of abrasive flow rate, 0.5 mm of stand of distance and 500 Mpa of pressure. From the table of analysis of variance, it has been found that stand off distance, square effect of stand of distance are the influencing parameter for kerf width.
5. Thus, aforesaid single objective optimization can be provided / utilized for the single targeted goal. Hence engineer can be targeting the response as per requirement. However, in multi contradictorily goal, multi-objective optimization has been applied.
6. The grey relational analysis have suggested the optimum process parameters value of traverse speed of 100 mm/min, 200 gm/min of abrasive mass flow rate, 1 mm of standoff distance and

400 Mpa of pressure.

7. From the confirmation test, it can be seen that the error between the predicted and actual experiment are less that the -/+10 %. Hence, it can be said that the predication accuracy of suggested model is excellent.
8. Regression analysis have been carried out simultaneously for the individual response, so, engineer can manipulate value of process parameters for this particular work- material.

A Review on Laser marking by Nd-Yag Laser and Fiber Laser

Jitendra Prajapati[1]

[1] *Assistant Professor, Mechanical Department, Swarrnim Institute of Technology, Gujarat, India*

ABSTRACT

Laser marking provides a unique combination of speed, permanence and versatility. Laser engraving is a manufacturing method for those applications where previously Electrical Discharge Machining (EDM) was the only choice. Laser engraving technology removes material layer-by-layer and the thickness of layers is usually in the range of few microns. Also there is many types of laser machines are available in recent time. Therefore for Optimum Use of Laser energy it is necessary to optimum use of process parameters to get best marking speed, Quality. This review paper presents various important work on Laser marking and its parameters i.e. Width, Depth, Contrast of Marking.

Keyword: - *Laser Marking, Nd-YAG laser, Fiber Laser*

1. INTRODUCTION

In the past decades, laser has been widely used in cutting and welding operations. Quite recently, this technology has been adopted in other industrial processes like marking, selective ablation and machining of different materials, thanks to the introduction of laser sources characterized by short and ultra-short pulses having from nanosecond to femtosecond duration.[3]

Marking is a process to make a mark on a product for the purpose of product identification. There are many marking methods, such as ink-marking, mechanical engraving and electro-chemical methods. Laser marking is a new marking method. There are many advantages in laser marking compared with conventional marking methods, such as no wear on tools, high degree of automation, free programming and choice of characters [1].

The main advantages of laser process are non-contact working, high repeatability, and high scanning speed, worked area comparable to the laser spot, high flexibility and automation. Furthermore, the use of shorter wavelengths, which are better absorbed by the material, allows smaller feature sizes to be worked, while the use of shorter pulses reduces heat-affected zone and opens new ways for nanometric accuracy [3].

The mark qualities, especially mark clearance, are most important in the marking process. In order to obtain a clear mark, suitable processing parameters must be selected. There are mainly three processing parameters used in laser marking: pulse frequency, Focal point and scanning speed, in which the pulse frequency of the laser has significant effects on mark quality. The laser marking process of EN8 Bearing steel with a Q-switched Nd:YAG laser and Fiber Laser was studied in this work. The aim was to find the relationship between the pulse frequency of the laser and the mark quality characteristics so as to be able to obtain high quality marks.

2. LASER MARKING PHENOMENA

(1) Vaporization

The laser beam is focused to a small spot, which greatly increases the energy density. When the energy is high enough, and the surface temperature is raised well above the melting point, most of the material on which the beam is focused will vaporize.

(2) Softening/Melting
Some materials are melted by infrared laser radiation, e.g. metals, epoxies. In the case of metals, mark contrast is achieved by oxidation or incorporation of impurities into the melt. In the case of plastics, the material melts and forms ridges. Depending on types of material, different colours may appear.

(3) Layer removal/ablation
Layer removal/ablation is actually a form of controlled vaporisation . A thin layer of plastic film, paper, ink or paint is vaporized exposing the different coloured under-layer.

(4) Colour change
At certain energy densities (below melting point), materials can undergo chemical changes when exposed to laser radiation of a specific wavelength. The chemical change can be either light or heat induced, e.g. excimer laser induced photo-chemical colour change for aircraft cable marking (white to black), and CO2 laser-induced (heat-induced) colour change on PVC (gray to red-brown). The color change is due to changes in chemical composition or in molecular structures

3. LITERATURE REVIEW

J. Qi, K.L. Wang, Y.M. Zhu [1] studied on the influence of the pulse frequency of the laser beam on the mark depth, width and mark contrast. A Q-switched Nd:YAG laser was used in the laser marking process of stainless steel. The mark contrast is the ratio of the apparent brightness between the mark and unmarked areas which shows the clearance degree of the mark. An optical microscope, scanning electron microscope and surface profile instrument were used to measure the effects of pulse frequency on the mark depth and width. An image-analysis system with a frame-grabber card and a charged-couple-device (CCD) was used to measure mark contrast. Also they have Investigated that The pulse frequency of a Q-switched Nd:YAG laser has a significant effect on the mark quality. There is maximum maximum mark depth when the pulse frequency is about 3 kHz, while the mark width remains almost constant at different pulse frequency. With the increase in pulse frequency, evaporation of material decreases, whilst at the same time oxidization is more significant, which leads to the improvement of mark contrast. The highest mark contrast was obtained when the pulse frequency of the laser was about 8 kHz.

T.W. Ng, S.C. Yeo [2] has studied on the CIE colour difference formula was applied to evaluate four types of material surfaces; anodized aluminium, stainless steel, poly-butylenes tetra-phthalate (PBT), and phenol formaldehyde, marked using a Nd:YAG laser, and viewed under three common modes of illumination; tungsten, Fluorescent and daylight at different speeds. The colour difference values were based on the spectral reflectance readings obtained from a spectrophotometer. The plots of colour difference value against laser marking speed revealed different trends for the materials and illumination modes applied. In terms of operational laser marking speeds, stainless steel could be classified as low, anodized aluminium as medium, and PBT and phenol formaldehyde as high. In terms of maximal colour difference values, anodized aluminium could be classified as low, PBT and stainless steel as medium, and phenol formaldehyde as high.

C. Leone, S. Genna, G. Caprino, I. De Iorio [3] has carried out Laser marking tests to determine the correlation occurring between working parameters (i.e. pulse frequency, beam scanning speed, and current intensity) and resulting mark visibility on AISI 304 steel, using a Q-switched diode pumped Nd:YAG laser. The latter was evaluated as the contrast index measured from digital images of the marks. . To characterize mark features, its width and roughness were estimated, and analyses employing optical and scanning electron microscopy coupled with energy dispersive X-ray technique were carried out. From the experimental results they have concluded that within the range of process parameters employed, mark width is only moderately affected by operating conditions. Mark contrast is affected by both surface roughness and oxidation, with the former probably prevailing at low contrast, and the latter at high contrast. If the aim is obtaining good mark visibility, relatively low frequencies and average powers should be used. The best mark visibility achievable is strictly dependent on the operating features of the particular laser system used. An empirical model was built, and from it the best processing conditions for optimum mark visibility, taking into account the operating constraints of the laser system used, were drawn.

Janez Diaci, Drago Bracun, Ales Gorkic, Janez Mozina [4] has presented a novel method for rapid and flexible laser marking and engraving of tilted, curved and freeform work-piece surfaces. The method is based on integrating

a three-dimensional (3D) laser measurement system into a 3D laser marking system. The same laser source and optics for measurement and processing with a minimum of additional hardware components were used. A novel method is presented that allows rapid and flexible laser marking and engraving of tilted, curved and freeform work-piece surfaces. An implementation is described where a digital camera is integrated into a 3D laser marking system in such a way that it is possible to measure the 3D shape of the work-piece surface just before processing. The measurement phase takes typically less than 10 seconds. Custom software has been developed which allows 3D surface measurement, placement of the laser mark onto the measured surface and process control. Examples are presented which demonstrate the advantages of the novel 3D system with respect to the existing industrial 2D and 3D systems. This paper has discussed key issues concerning an implementation of the method and presents typical examples of markings and engravings, which demonstrate the advantages of the method with respect to the existing industrial 2D and 3D laser marking and engraving methods. The method can also be applied to flexible laser structuring and micro processing of curved surfaces.

F.Agalianos, S.Patelis, P. Kyratsis, E. Maravelakis, E.Vasarmidis, A.Antoniadis[5] has investigated on the influence of the process parameters on the surface quality when machined by laser engraving. The examined parameters were: the pulse frequency, the beam speed and the layer thickness. The surface quality was determined by the surface roughness for every set of parameters. Based on the experimental work of the present paper in laser engraving of Al7075 using a Q-switched Yb:YAG fibre laser, it can be summarized that the surface roughness strongly depends on the frequency and the scan speed used. In addition it was proven that the resulted roughness depends less by the layer thickness. When considering all the experimental data of the current experimental plan, the best surface roughness was achieved when using a frequency of 20 kHz, a scan speed in the range of 600-700mm/s and a layer thickness of 4 and 6μm. Experimental results on Al7075 material showed that the surface roughness strictly depends on the process parameters used.

Sefika Kasman[6] has investigated the machinability of hard metal produced with powder metallurgy and puts forward a new approach relating to the laser engraving of P/M metals. The main objective of this study is to determine the impact of laser engraving process on Vanadis 10. For this purpose, three process parameters – namely effective scan speed, frequency, and laser effective power – were correlated with the surface roughness (Ra) and engraving depth (D). The Taguchi and linear regression were used in the analysis. The experiments were performed in accordance with an L9 orthogonal array. Based on the S/N ratio for Ra and D, the optimal condition was found as SS3F2P1 for Ra and SS1F2P3 for D. the ANOVA was performed to evaluate the statistical significance of each parameter on the performance characteristics. Also he has determined that

(1) The scan speed appeared to be the main effective parameter for the two performance characteristics. The experimental results showed that increasing scan speed decreases both Ra and D. To minimize Ra, the scan speed should be selected at a high level (800 mm/s), whereas to maximize D, the scan speed should be selected at a low level (200 mm/s).

(2) The optimal level for Ra is where the scan speed is at 800 mm/s, the frequency is at 30 KHz, and power is at 25W (SS3F2P1). Optimal levels for D for each material type were obtained at a scan speed of 200 mm/s, a frequency of 30 KHz, and with power at 50W (SS1F2P3).

(3) After determining the optimal level for each parameter, a confirmation experiment was performed for both Ra and D. The predicted and experimental results were compared, and the results show that there is a high correlation between them. To achieve a good surface finish, a high scan speed at the lower power level is recommended.

(4) ANOVA was performed using the S/N ratio to investigate the significance of each parameter and to determine the percentage contribution to both Ra and D. The effect of scan speed on both Ra and D is 83.84% and 76.69%, respectively. However, the effect of frequency has little that determined by the p value (0.367). The percentage contribution of frequency is 3.47% and 0.56% to the Ra and D, respectively.

(5) To test the predicted linear regression model, a set of experiments at different condition were used to predict both Ra and D. Results show that the predicted results (test results) are very close to the actual value. This means that Ra explains the model of laser engraving process for Vanadis 10. Besides this, the data taken from the test experiments also explain the model for D

4. CONCLUSION

1. In terms of operational laser marking speeds, stainless steel could be classified as low, anodized aluminium as medium, and PBT and phenol formaldehyde as high.

2. In terms of maximal colour difference values, anodized aluminium could be classified as low, PBT and stainless steel as medium, and phenol formaldehyde as high.
3. Mark contrast is affected by both surface roughness and oxidation, with the former probably prevailing at low contrast, and the latter at high contrast.
4. With the increase in pulse frequency, evaporation of material decreases, whilst at the same time oxidization is more significant, which leads to the improvement of mark contrast.
5. To achieve a good surface finish, a high scan speed at the lower power level is recommended. The surface roughness strongly depends on the frequency and the scan speed used. In addition it was proven that the resulted roughness depends less by the layer thickness.

AN AUTONOMOUS BOTTLE FILLING MACHINE ADDING TO THE ACCURACY AND PRECISION ALONG WITH REJECTION MECHANISM

Jitendra Prajapati[1]

[1] *Assistant Professor, Mechanical Department, Swarrnim Institute of Technology, Gujarat, India*

ABSTRACT

Filling is a task carried out by a machine that packs liquid products such as cold drink, water, Medicines Cosmetic Creams or Face wash etc. in current Manufacturing and packaging industries. Traditional methods of bottle filling involved workers and it can be very tedious to handle this kind of stuff for the MNC companies. Traditional methods are time consuming which Adds to the expense. My paper aims at filling of bottle and the rejection of incomplete filled bottle at the same time. It also includes a user-defined volume selection through which the user can input the desired volume to be filled in the bottles .The entire system is more flexible and time saving. The filling and rejection Operations is controlled using microcontroller. This is because microcontroller is very user friendly and easy to program, cost effective, space efficient and reduces complexity. By programming the microcontroller we control the entire system. Hence the changing of data such as flow rate control, delay, counting of bottles, rejection criteria is easily modified. The process is fully automatic; during the process no worker is required so the designation of our project is "Autonomous bottle filling machine".

Keyword: - *Bottle Filling, Bottle Rejection, Micro Controller.*

1. INTRODUCTION

Automation plays an increasingly important role in the world economy. One of the important applications of automation is in the soft drink and other beverage industries, where a particular liquid has to be filled continuously. For these kinds of applications, the trend is moving away from the individual device or machine toward continuous automation solutions. Totally Integrated Automation puts this continuity into consistent practice. Our project is also an application of automation wherein we have developed a bottle filling system .The various processes are controlled using a microcontroller. In the past, Human resources were the Pillar for controlling a system. In recent trends, electricity has been used for control in the filling plant and this electrical control was based on relays. These relays only allow power to be switched on and off without a mechanical switch. It is common to use relay to make simple logical control decisions. The advent of the microcontroller began to be the most common choice for manufacturing controls. Microcontroller has been gaining popularity on the factory floor and will probably remain predominant for some time to come. Mostly because of the advantages mentioned:

- Cost effective for controlling complex systems.
- Flexible and can be reapplied to control other systems quickly and easily.
- Computational abilities allow more sophisticated control.
- Trouble shooting aids make programming easier and reduce downtime.
- Reliable components make these likely to operate for years before failure.

Control systems are an integral part of modern society. There are many numerous applications that uses control system around us. A control system provides a desired output or response for a given input or stimulus. The reason that control system was built is for power amplification, remote control, convenience of input form; and compensation for disturbances. Today control system finds widespread application in the guidance, navigation; Control of missiles and space crafts, as well as it navigates planes and ships at sea. The applications is also expanded

for the process control industry, regulating liquid level tanks, chemical concentrations in vats, as well as thickness of fabricated material.

2. PROCESS TECHNIQUES

Bottle Detection Using Sensor
Bottles are kept in position in their respective holders which are fixed to the conveyor at the input side. Photo electric sensors are used to detect the presence of bottles in the holder. Depending on the output of the sensors the filling operation takes place. A time delay is set in order to set the status of the bottles. If bottle is present the corresponding status bit in microcontroller which leads input to set at "1" else it is set to "0". Depending on this output the filling process of the bottles takes place. Thus for all the "n" bottles present in the input side then the sensor gives the corresponding output to the microcontroller which in turn switches ON the corresponding
Solenoid valve for filling operation to take place. If a particular bottle is not present the corresponding valves remain OFF.

Operating Solenoid Valve
When the sensor senses the bottle, the conveyor belt will be stopped after pre assigned seconds. So the bottle comes in the alignment of the output of the solenoid valve.

Filling Operation
Once the bottles are detected in the input side the conveyor motor switches ON and it starts moving in the forward direction. The bottles then reach the desired position for filling and the conveyor stops. The corresponding pumps in process tank switch ON and filling operation takes place. There are three tanks present in the filling side namely: process tank, concentrate tank (Tank 1) and tank to store liquid (Tank 2).Tank 1 and tank 2 have low level and high level sensors (LLS and HLS) respectively. Process tank has three level sensors (LLS, HLS and MLS). MLS is used to denote the middle level of the tank. When the liquid in the process tank reaches below low level (LLS) pumps in Tank 1 and Tank 2 switches ON and the process tanks get filled. When the level of liquid reaches high level (HLS) the pumps in Tank 1 and Tank 2 switch OFF.

Rejection
The rejection is based on the level of liquid in the bottle. The sensor (self-made sensor) detects the level of the liquid. If the level of liquid is not in the linear line / level of the positioning transmitter and receiver, the bottles will be rejected through the motor connected with the rejection Flap that is placed in the conveyor path.

Controlling
The all the task are controlled by the microcontroller. The programming is done in C language. The modification can easily be done in Set program as per the requirements and the programming module is attached with the computer. The ARDUINO software is used in the project to control the program.

3. MECHANICAL DESIGN

Photoelectric Sensor
The photoelectric sensor is operated on 12V DC and the relay output is given to the PLC input terminal. The sensor we use here is the product of the AUTONICS Ltd.

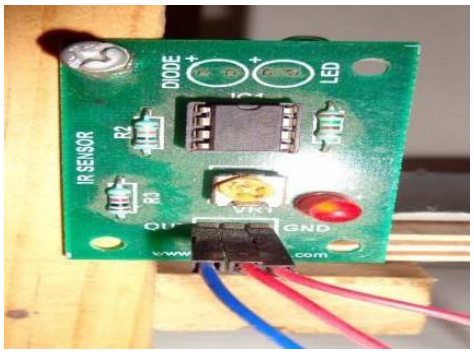

Fig 1: Photoelectric Sensor

Motors

10 RPM, 12V DC geared motor for robotics and multi applications. Very easy to use and also available in standard size. Nuts and threads required to mount on shaft are easily connected and internal threaded shaft for easily connecting it to the roller of the conveyor.

Features

- 10 RPM 12V DC motors with Gearbox.
- 6mm shaft diameter with internal hole.
- 125gm weight.
- Same size motor available in various RPM.
- 2kg-cm torque
- No-load current = 60 mA (Max), Load current = 300 mA (Max).
- The 10 RPM DC gear motor is used in the project to run the conveyor belt. And the 45 RPM DC motor is used to reject the incomplete bottle.

Solenoid Valve

The solenoid valve for liquid is used to allow the liquid to pass to the output. The liquid solenoid valve operates at 12V DC and we use it for ON-OFF condition. When the bottle is exactly under the valve, the microcontroller gives the signal to Open /ON Condition for the valve so the liquid is able to flow. When the bottle filling is completed, the valve gets Closed/OFF and the conveyor belt starts. The valve remains open for the pre assigned time so that bottle filling is done at the desired level.

- Latch time of solenoid valve is calculated with the help of flow rate equation.
- Elevation of tank in our project is not very high so increase of velocity is negligible in pipe.

4. EXPERIMENTAL SETUP

The Line diagram of the entire Bottle Filling Plant has been represented herewith below, as well as main aspects and main parts used are Proximity Sensor, Conveyor belt, Solenoid Valve, Level Sensor, Mechanical Arm, Motor, Roller

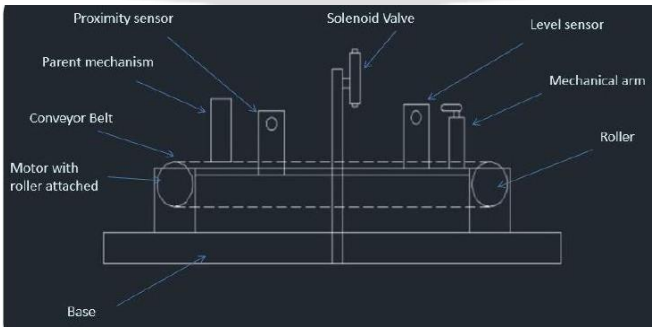

Fig 2: Line Diagram of the Bottle Filling System

The entire plant can be run in the following series as the Bottle to be filled is supposed to be kept on the conveyor belt as with the help of motor and roller the bottle moves in the linear positive direction and proximity sensor senses the bottle after which the bottle moves ahead as pre defined time and stops exactly under the solenoid valve, through which the bottle gets filled, after this process the bottle again moves in linear direction, now level sensor checks the level of liquid if the level is found to be below the Lower Limit than the mechanical arm will reject the bottle and if the level is found to be within the limit of approval than the bottle is preceded for the capping and packaging.

5. CONCLUSION

This project lead us to an effective conclusions, mostly for mass production which is the case in today's industries and MNC's, it is cost effective with high rate of Accuracy and precision which can be run by minimum labor and still the high rate production can be achieved. Secondly it is also time effective and due to reject mechanism the customer satisfaction for the guaranteed amount of goods can be achieved, with future scope point of view, easy operating so that unskilled labour can also operate very easily.

EXPERIMENTAL INVESTIGATION OF EFFECTS OF CUTTING PARAMETERS ON SURFACE ROUGHNESS IN THE WEDM PROCESS

Jitendra Prajapati[1]

[1] *Assistant Professor, Mechanical Department, Swarrnim Institute of Technology, Gujarat, India*

ABSTRACT

The experimental study presented in this paper aims to select the most suitable cutting and offset parameter combination for the wire electrical discharge machining process in order to get the desired surface roughness value for the machined work pieces. A series of experiments have been performed on 1040 steel material of thicknesses 30, 60 and 80 mm, and on 2379 and 2738 steel materials of thicknesses 30 and 60 mm. The test specimens have been cut by using different cutting and offset parameter combinations of the "Sodick Mark XI A500 EDW" wire electrical discharge machine in the Middle East Technical University CAD/CAM/Robotics Centre. The surface roughness of the testpieces has been measured by using a surface roughness measuring device. The related tables and charts have been prepared for 1040, 2379, 2738 steel materials. The tables and charts can be practically used for WEDM parameter selection for the desired work piece surface roughness. Ó 2000 Elsevier Science Ltd. All rights reserved.

Keyword: - *WEDM; Surface roughness; Cutting parameters*

1. INTRODUCTION

In wire electrical discharge machining (WEDM), the cost of machining is rather high due to a high initial investment for the machine and the cost of the wire which is used as a tool in this process. The WEDM process is economical if it is used to cut complex work pieces and difficult to- machine materials. In manufacturing die and meld components like sheet metal press dies, extrusion dies, etc., prototype and special form inserts manufacturing, WEDM is commonly used. As surface roughness is one of the most important parameters in manufacturing, various investigations have been carried out by several researchers for improving the surface roughness of the WEDM process [1–8]. These investigations show that the surface roughness of the process is closely dependent on the machining parameters. However, the published papers available do not provide any specific information on the selection of machining parameters for various machining conditions and materials. Since WEDM is a necessary process with a high cost, it is required that the appropriate machining parameters are selected for an economical machining operation. The machining parameters can be set for optimum machining with the knowledge of the effect of the machining parameters on the surface roughness of the process, as a result of the experimental study [9].

2. EXPERIMENTAL TECHNIQUES AND PROCEDURES

Three different materials have been cut by using a five-axis A500 Fine Sodick Mark XI EDW [10, pp. 8-1, 8-2] and surface roughness values of the specimens are measured in order to find the effects of cutting parameters on surface roughness in the WEDM process. WEDM is used extensively in the fields of blanking, shearing, cold forming and plastic molding. So, for the selection of the materials, we have tried to choose the most commonly used cold work tool steel and plastic mold steel [11, pp. 19–43]. For the experiments, initially a 1040 steel specimen is used because of its cheapness and extensive use in manufacturing. The results of the experiments for the 1040 steel specimen are used to plan the experimental procedure for the cold work tool steel "2379" and plastic mold steel "2738" specimens. Cold work steels, with properties such as good machinability, dimensional stability on heat treatment, high wear resistance, sufficient toughness and compressive strength, are used generally in the fields of blanking,

shearing and cold forming. 2379 is one of the most widely used cold work tool steels [11] and it has a chemical composition of 1.55 C, 12.0 Cr, 0.7 Mo, 1.0 V (in %) [11]. The increasing demands for tools in plastic moulding have necessitated the specific development of tool steels. Tools for the processing of plastics are mainly stressed with regard to pressure and wear. According to the type of plastics, there may in addition exist stressing by corrosion. The various types of plastics and different processing methods impose certain requirements on the tool steel, such as economic machinability or cold-hobbling ability, dimensional stability on heat treatment, good polish ability, great compressive strength, high wear resistance, sufficient corrosion resistance, etc. The selection of a steel for a given tool is governed by these requirements. 2738 is one of the most widely used plastic mold steels [11]and it has a chemical composition of 0.40 C, 1.5 Mn, 1.9 Cr, 0.2 Mo, 1.0 Ni (in %) [11]. For the control of A500 Fine Sodick Mark XI EDW, there are 11 cutting variables and the operator only sets two general purpose parameters, which are the cutting parameter "C" and the offset parameter "H". These two parameters arrange the conditions that are needed for cutting and offset, respectively. The rest of the parameters are adjusted automatically by the machine itself [10]. The cutting parameter "C" and offset parameter "H" are given in a form so that they are followed by three integer numbers. Each "C" parameter defined in this way includes the parameters which control the setting of the pulse energy and the cutting speed adjustment, for instance, pulse width, peak current value, no-load voltage, servo reference voltage, capacitor, servo speed, wire tension, wire speed, etc. [10].

During the cutting, dielectric water is used as the fluid type and the "open" condition is selected for the flushing. A dielectric flow pressure of 1 bar, tension of the wire of 1133 g, diameter of the brass wire of 0.25 mm and a wire speed of 1550 cm/min are kept as constant in all the experiments, since these values are recommended in the tables [10]. For the surface roughness measurements of the workpieces, a portable device called "Surftronic 3+" is used and the traverse length of the experimental measurements is calculated as 4.2 mm for this particular device [12, pp. 1–53]. This value is important, because it is used to decide the length of the experimental cuts. The experimental test section is chosen to be 20 mm in length to be on the safe side. As the wire breakage that may occur during the cuts increases the surface roughness values of that experimental section, the test results may deviate from the true surface roughness values. A 20-mm test cut for each parameter combination gives enough length to measure the true surface roughness values without being affected by the wire breakage. By using different cutting parameter "C" and offset parameter "H" combinations and keeping all the other variables and conditions constant, a series of cuts are performed on 1040, 2379 and 2738 steel specimens [9]. For each different "C" and "H" parameter combination, a section of the material is cut of length 20 mm and is defined as the "test section". At the end of each test section, a cut of 0.5 mm in depth is performed in order to indicate the border of the section.

A hybrid framework to prioritize the performance metrics of reconfigurable manufacturing system: An integrated fuzzy AHP–TOPSIS approach

Abstract:

The Reconfigurable Manufacturing System (RMS) meets the challenges of dynamic customer demands, technological advancements, and reducing lead time, among other things. It is necessary to have a framework that can assist in increasing RMS adoption as well as evaluating its performance. The present study seeks to develop a hybrid framework for prioritizing performance metrics of RMS that helps the designers of the manufacturing system in decision making. A total of 31 indicators for RMS are identified through a literature survey, the weight of each indicator is computed by Fuzzy-AHP (Analytic Hierarchy Process) method and the Fuzzy-TOPSIS (Technique for Order Preference by Similarity to Ideal Solution) method is used to prioritize 22 performance metrics of RMS. The findings of the presented study reveal that among all the main indicators; smart factory indicators have the highest weightage followed by strategy and policy indicators. The prioritization of performance metrics shows that lead time, reconfiguration time, and product flexibility are the top three most important performance metrics for RMS. The feasibility and appropriateness of the framework is tested through a case application of the manufacturing organization. The framework developed has a high capacity to assist designers during the adoption of the RMS and will facilitate the identification of the relevant parameters. Authors believe that researchers and professionals will find this study as a ready reference for stepwise adoption of RMS. The study presented here is likely the first to present a hybrid framework in which a set of indicators and performance metrics are presented together.

1. Introduction

1.1 *Study Motivation*

Customer expectations are constantly changing and are becoming dissimilar due to globalization. The product and its features must therefore be personalized. To achieve such customization, there is a need for a flexible and high-quality manufacturing system that meets the future requirements in complex environments (Haddou Benderbal & Benyoucef, 2019). According to (Yadav et. al., 2018), manufacturing companies face challenges like fulfilling customized product demands, quick supply, and high quality. RMS, which emerged from the configurable computing system used during the design of computing systems around the 1960s, has been introduced to meet such dynamic conditions. It comprises several modules that can be replaced so that reconfiguration is possible (Abdi & Labib, 2003), provides a rapid and cost-effective response to fulfill changing customer needs (Battaïa et al., 2017). Introduced by Koren in 1999, RMS overcomes the limitations of the traditional manufacturing system, it can change its structure rapidly in response to market needs (Koren Y. et al., 1999) and consists of Reconfigurable machines whose function and capacity can be configured. The comparison of advanced manufacturing systems like RMS is carried out with Dedicated Manufacturing System (DMS) and Flexible Manufacturing System (FMS) as shown in Table 1,

Table 1: Comparison of manufacturing systems (Abdi & Labib, 2003)

Comparison of various Manufacturing systems			
Aspects	**Traditional Manufacturing System such as DMS**	**Conventional Manufacturing System such as CMS, FMS**	**Advanced Manufacturing System such as RMS**
Technology used for particular time period	Fixed	Needs to be adaptable to market	Should be responsive to market
Market conditions	Stable	Predictable	Uncertain
Manufacturing Policy	Pushing	Pulling	Customizing
The gap level between Manufacturing system and demand variation	High/Very high	Medium/ High	Low/ Very Low

RMS, capable of manufacturing different product families in a short time, at a minimum cost, without sacrificing the quality of the product, high responsiveness, and performance efficiency (Koren & Shpitalni, 2010). However, for the success of the production system, the time required to bring the product onto the market and the ramp-up time required are becoming more and more crucial. RMS meets most of these challenges in the global market, which traditional manufacturing systems cannot meet due to their

limitations (Abdi & Labib, 2004). The adaption of new products by reconfiguration is now possible due to RMS as depicted in Figure 1.

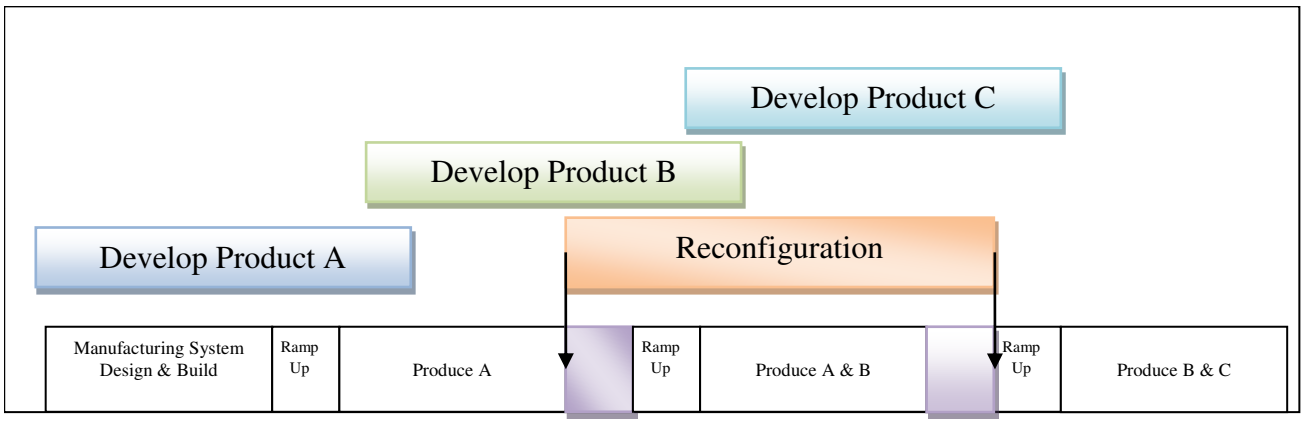

Figure 1: Adaptation to production of new products through rapid reconfiguration (Koren Y. et al., 1999)

1.2 Need of study

Available literature describes various frameworks and methodologies that can be used to implement RMS in industrial applications, however, the results of RMS have not yet been proven (Maganha et al., 2018). The core characteristics of RMS are Modularity, Scalability, Convertibility, customization, and Diagnosability which supports the reconfiguration (Singh et al., 2007, Gumasta et al., 2011). Along with this, it is important to identify the factors that help the system to penetrate RMS and are called Indicators. This will help the designer of the manufacturing system to identify and focus on them while implementing the RMS (David et. al., 2001). Also, it is essential to measure the performance of the manufacturing system based on various performance criteria. Qualitative and quantitative criteria should be included for thorough performance analysis of any manufacturing system (Yurdakul, 2002). These factors are termed as performance metrics that enable the evaluation of the RMS, and attempts can be made to improve performance. Also, it is necessary to prioritize them for successful evaluation of system.

1.3 Research objectives and overall approach

This paper has the following objectives,

- Identify various indicators of RMS and compute their weights.
- Prioritize and rank the performance metrics of RMS.

To achieve the aforementioned objectives, a thorough review of RMS articles is conducted, and 31 indicators and 22 performance metrics are identified. The fuzzy AHP method is used to compute indicator weights, followed by the fuzzy TOPSIS method to prioritise performance metrics using expert opinion.

1.4 Organization of paper

The paper is organized into a total of 8 sections, including the current section. Section 2 presents the literature review, indicators, and performance metrics of RMS. Section 3 describes the research methodology along with the Fuzzy AHP-TOPSIS method and the various steps followed. Section 4 consists of data collection from experts as well as data analysis whereas section 5 represents the findings of the study. Section 6 constitutes theoretical contributions followed by implications of the study in section 7. The conclusions, limitations, and future scope are summarized in section 8.

2. Literature Review

The literature review on RMS, indicators, and performance metrics, along with the MCDM approach used, is presented in this section. Below are some of the findings of the literature review,

2.1 Literature retrieval and selection

The process of collecting various publications is carried out by retrieving publications from the Scopus database. The search applied consists of keywords such as 'Reconfigurable Manufacturing System', 'Indicators', 'Performance Metrics', 'Assessment of RMS', and 'Enablers'. The publications that appeared in peer-reviewed journals, book chapters, and few renowned conference proceedings are included in the study. Many of these publications are found to be irrelevant to our subject and are then excluded. The exclusion is done by reading the abstract and conclusion of each paper served primarily as an initial screening of research papers. The second stage exclusion was done by reading a full-length paper. All relevant papers so collected are then stored in one place so that they can be retrieved as and when required. The word relevant refers to the publications that present various frameworks, indicators, barriers, and assessments of RMS. Finally, 281 papers are selected for the study.

These 281 papers are further divided into three categories; the first category consists of all papers related to frameworks, RMS optimization techniques. The second category consists of papers in which various indicators, RMS assessment, performance metrics are discussed. The third category consists of

papers using various MCDM techniques. Research papers of the first two categories are thoroughly studied to identify indicators and performance metrics for RMS. Certain indicators and performance metrics found to be general, applicable to any manufacturing system, are also considered for study purposes. Initially, all of these indicators and performance metrics are listed in the Microsoft Excel file, regardless of their meaning and repetitive nature. It is noted that most researchers considered the key characteristics of RMS to develop methodologies and frameworks to optimize performance (Chaube et al., 2012; El Maraghy, 2006; Koren et al., 2017). These factors are further sorted and the repetitions are removed. The reframing of these factors is done in such a way as to give them the correct meaning and the list is modified accordingly. References for all of these factors are also added to this table so that the source of the information can be highlighted. The table was finally prepared with 31 indicators as shown in Table 2 and 22 Performance Metrics as shown in Table 3.

2.2 Reconfigurable Manufacturing System (RMS)

RMS is one of the most recent manufacturing systems that can provide flexibility at the lowest possible cost. The design, implementation, reconfiguration control, layout optimization, process planning, and production planning of RMS are key aspects and active research topics (Bi et al., 2008, Bortolini et al., 2018). Reconfigurability is defined as the ability of the manufacturing system to change its production capacity and functionality in a cost-effective way to meet the requirements of a dynamic market (Bi et al., 2008). Also, (El Maraghy, 2006; Mehrabi et al., 2000; Wiendahl et al., 2007) defined RMS as a machine system which with the help of basic process modules that includes hardware and software can be rearranged or replaced in short time duration and reliably. The key enabler of RMS is Reconfigurable Machine Tool (RMT) which is designed specially to customize the product (Chaube et al., 2012). Eguia, et al. (2017), proposed an approach for machine cell design including grouping of machines and cell loading for multiple reconfigurable machine cells having RMT and Computer Numeric Control (CNC). However, the design and implementation of RMS is a major challenge compared to the traditional manufacturing system. Despite the many contributions made by many scientists, the systematic design method of RMS is lacking (Andersen, Brunoe, Nielsen, & Rösiö, 2017). There is limited evidence of a breakthrough in reconfigurability in the manufacturing sector, and therefore further research and contributions from scientists and professionals in this field are needed. Given this need, the authors identified RMS indicators and performance metrics as discussed below.

2.3 Indicators of RMS

Indicators are the factors that help in RMS penetration in the manufacturing industry. In the 21st century, the manufacturing industries are facing unpredictable and high-frequency changes in market demands. Therefore, there is a need for a manufacturing system having high responsiveness at the minimum setup cost and time. According to (Koren Y. et al., 1999), RMS can meet these requirements of the manufacturing system cost-effectively and quickly. Abdi & Labib (2004) has developed a reconfiguration link between market requirements and RMS design and have also developed a design loop for manufacturing system design. He also added some additional criteria that are important for the successful implementation of RMS, such as reusability, various costs, operator skills, motivations, employee training, feasibility, process work, etc. Many researchers have tried to identify the key characteristics of RMS so that designers can focus on these factors for successful implementation (Abdi et al., 2018). Few researchers considered a case study of RMS to identify the prerequisites and barriers to the system and concluded that the development of RMS in the industry is still a challenge and needs to be addressed in future research work. El Maraghy (2006) compared the characteristics of both FMS and RMS. He focused on flexibility and classified it into ten types, such as Machine flexibility, Material handling flexibility, etc., and added that changeability (Changeover ability, Reconfigurability, Flexibility, Transformability, and Agility) is very important for successful RMS implementation. Further, he indexed various enablers of transformability such as Compatibility, Modularity, Scalability, Mobility, and Universality which also helps for RMS implementation. Deif & ElMaraghy (2006) said that mass customization and responsiveness are two main characteristics of today's manufacturing system. He presented architecture to design RMS starting with market demand to a selection of best configuration. Wiendahl & Heger, (2011) described a method that would make it possible to calculate the cost of change in any manufacturing company. Whereas Singh et al. (2007) established a decision-making module to evaluate RMS using tangible and intangible factors. He considered criteria and sub-criteria such as measurement, diagnostics, compensation, etc. had an impact on the judgment. Bi et al. (2008) discussed the requirements of the manufacturing system to meet the customer requirements, including shorter lead time, more variant, low and fluctuating volume, low price, etc. However, Mubarok & Faculty (2010) discussed the SWOT analysis for RMS, considering indicators such as flexibility, quick decision, etc. Gumasta et al. (2011) further categorized core characteristics of RMS, such as detectability, distinguishability, predictability, etc., and tried to measure reconfigurability of RMS. Bortolini et al. (2018) reviewed literature for RMS and included many new factors such as sustainability, Availability, system complexity etc. which contribute to the successful RMS implementation. Prasad &

Jayswal (2019) reviewed the flexibility and reconfigurability of the RMS and discussed various types of flexibility such as machine flexibility, operation flexibility etc. Finally, the selected indicators are shown in Table 2.

Table 2: List of Indicators for RMS

Sr. No.	Name of Indicator	Description	Reference
1	Agility/ Granularity	The system can make changes quickly to respond to changing markets in a short duration of time.	(Sânchez & Pérez, 2001; Wiendahl et al., 2007)
2	Reconfigurability	The ability of the system to switch to another product family in minimum time and effort. It may include the use of artificial intelligence to initiate the reconfiguration process.	(El Maraghy, 2006; Goyal, Jain, & Jain, 2013b; Wiendahl et al., 2007)
3	Evolvability	A manufacturing system can generate adaptive evolution.	(Wiendahl et al., 2007)
4	Integrability	The system can integrate different components.	(El Maraghy, 2006; Gumasta et al., 2011)
5	Scalability	The system can perform under an increased/decreased workload.	(El Maraghy, 2006; Gumasta et al., 2011)
6	Adaptability to market change	The system can change products, businesses, or services as per the need of the market.	(Chaube et al., 2012)
7	Modularity/ Adjustability	Modularity is the degree to which the components can be decoupled and recombined to facilitate economical alterations in the process.	(El Maraghy, 2006; Gumasta et al., 2011; Yurdakul, 2002)
8	Recruitment of Multi-skill Employees	Multi-skill employees enable the system to adapt to changes and maintain performance.	(Abdi & Labib, 2003; Dixit & Gupta, 2013)
9	Innovations in product & Process	The innovative discoveries in products and processes enable easy implementation of RMS.	(Dixit & Gupta, 2013; Koren Y. et al., 1999)
10	Customization and Design flexibility	Customization represents the alterations made in the system to fulfill individual customer requirements which also provide flexibility in designing a product.	(El Maraghy, 2006; Gumasta et al., 2011; Wiendahl et al., 2007)
11	Kanban Methods	Kanban is a method to manage product creation with continual delivery without overburdening development teams.	(Dixit & Gupta, 2013)
12	Distinguishability	The property of the system due to which the functionality loss can be detected. It also includes proper maintenance requirements.	(Dixit & Gupta, 2013; Gumasta et al., 2011; Sânchez & Pérez, 2001)
13	Supplier Integration	It is the extent to which manufacturing system and suppliers takes part in inventory control, forecasting, planning, etc.	(Dixit & Gupta, 2013)
14	Sustainable system culture	A sustainable system refers to maintaining the environmental balance, cultural practices, heritage conservation, etc.	(Chaube et al., 2012)
15	Government promotion & regulations	The encouraging policies and rules of government may promote the RMS implementation.	(Chaube et al., 2012)
16	Advanced Machinery setups	The availability of programmable/reconfigurable machines in the manufacturing system helps the adoption of RMS.	(Goyal & Jain, 2016; Haddou Benderbal et al., 2018)

17	Transformability	The capacity of the system to switch over to a new product. It allows quick changeover between products.	(El Maraghy, 2006; Goyal et al.,2013a, 2013b; Gumasta et al., 2011; Wiendahl et al., 2007)
18	Usage of RFID techniques for Diagnosability	Detectability/Diagnosability using RFID techniques is the quality of the manufacturing system due to which it is being detectable or being countable to quickly and easily identify the quality and reliability-related problems.	(El Maraghy, 2006; Gumasta et al., 2011)
19	Industrial & Social Integration	Industrial integration is the linking of formerly separate enterprises, firms, or processes to reap economies of scale or finance. Social integration is promoting harmonious interaction with all levels of society.	(Chaube et al., 2012)
20	Appropriate practice of automation ability	It represents the ability of a system to automate various processes using advanced technology.	(Wiendahl et al., 2007)
21	Awareness of economic benefits	It represents the awareness of economic benefits among the employees and management due to the implementation of RMS.	(Chaube et al., 2012; Dixit & Gupta, 2013; Haddou Benderbal & Benyoucef, 2019)
22	Digitization of organizational activities	The system can convert and store the information in digital form.	(El Maraghy, 2006; Gumasta et al., 2011)
23	Employee teamwork	It builds creativity and learning, conflict management becomes easy and develops complementary strengths.	(Sânchez & Pérez, 2001)
24	Education and Training of employees	It enables employees to handle new responsibilities which can improve the performance of RMS.	(Dixit & Gupta, 2013; Yurdakul, 2002)
25	Effective utilization of infrastructure	The available infrastructure like space, equipment, etc. may be utilized effectively in RMS.	(Dixit & Gupta, 2013)
26	Appropriate evaluation of Demand of Product Family/ Diversity	It is the ability to predict and evaluate the demand for the product so that the manufacturing system can be selected and implemented successfully.	(Abdi & Labib, 2004; Haddou Benderbal et al., 2018; Sânchez & Pérez, 2001; Yurdakul, 2002)
27	Systematic Inventory Control processes	It is the process of maintaining appropriate stock along with the quality of raw material to meet the customer requirements. It also includes the flexibility of the material handling system.	(Dixit & Gupta, 2013; Koren Y. et al., 1999; Mapes, 2000)
28	CAD/CAM technologies	Advanced software packages for design and manufacturing are very helpful in changing environments. In the case of complex part geometry, such technologies are very useful.	(Dixit & Gupta, 2013; Koren Y. et al., 1999)
29	Effective assessment of PLM and Reliability	PLM provides systematic ways to achieve good quality and reliability using fully integrated methods.	(Haddou Benderbal et al., 2018)
30	Adoption of cyber-physical system	It integrates physical systems, computations, and networking. Its main purpose is to control the physical process through feedback.	(Dixit & Gupta, 2013; Mapes, 2000)
31	Quality Assurance	It is the process of maintaining the desired quality of product through each stage of the manufacturing process.	(Koren Y. et al., 1999; Lozano, Villa, & Eguía, 2017)

2.4 Performance Metrics of RMS

Performance metrics are the factors that reflect the current status of the manufacturing situation, are related to some specific goals in manufacturing, and reveal a real insight into the performance measurement (Hwang, 2014). Kumar, (2013) defined performance metrics as a measurable quantity that indicates an

aspect of the specific performance. The study is carried out to identify the performance metrics of RMS as discussed below.

Garbie (2014) considered manufacturing cost to be one of the criteria for RMS performance analysis and measurement, while (Prasad & Jayswal, 2019b) considered various costs, including manufacturing costs, the sum of all resources used to manufacture the product to evaluate the performance of sustainable manufacturing system. Manpower requirement is another important criterion for assessing the manufacturing system, hence Garbie (2014) while assessing RMS considered overtime costs, which include the amounts paid to workers for additional duties performed by them other than normal working hours. Also, various costs associated with the manufacturing system are important criteria while evaluating RMS hence (Garbie, 2014) considered additional costs, including repairs and maintenance cost of equipment. He also considered depreciation costs of a fixed asset to be other criteria. Likewise, total wages paid to labor (labor cost) indicates overall design effectiveness and overhead expenses is another important factor (Spicer & Carlo, 2007). Overhead expenses may include rent paid, taxes, communication expenses, etc. (Chen & Huang, 2006) while reviewing performance measures of manufacturing system, considered various parameters to evaluate the performance and one of them is process capability or operational capability. Product quality is also to be taken into account when assessing RMS, as a result of which (Garbie, 2014) considered number of defective products produced in particular time period as one of the factor.

Considering the importance of lead time, researchers have tried to reduce it so that the product can be delivered to the customer in minimum time and RMS is one of the ways to reduce the same (Garbie, 2014). Another important factor to evaluate RMS is machine utilization which indicates potential output produced when full capacity is used (Garbie, 2014; Mittal & Jain, 2014; Yurdakul, 2002). While evaluating the performance of a sustainable manufacturing system, (Bi et al., 2008) considered two important factors product durability and product reliability whereas (Mittal & Jain, 2014) supported this by considering these two factors while evaluating RMS. Further, (Abdi & Labib, 2011) emphasized the concept of flexibility and categorized it into various types such as product volume flexibility, product (mix) flexibility, and process flexibility. Flexibility in manufacturing indicates the ability of the manufacturing system to deal with mixed parts, mixed volume, and a mixed process called product (mix) flexibility, volume flexibility, and process flexibility respectively. Further, Garbie (2014) considered system productivity as a criterion to evaluate RMS whereas researchers focused on minimizing work in progress (WIP) which indicates semi-finished products which are entered into the production system but not yet completed. Further, customer complaint as a criterion to evaluate RMS because it indicates the quality of the product as well as the happiness of the

customer regarding that product (Yurdakul, 2002). Lesser customer complaints indicate more customer happiness. Hence, sales growth is yet another important factor related to the performance of RMS (Abdi & Labib, 2004; Yurdakul, 2002). However, Yurdakul, (2002) expressed that waste in the manufacturing system results in an increase in the cost of the product and does not add value to the product. Further, various wastes, such as overproduction/ wages paid for overproduction, transportation wastes, materials, scrap, rework, manpower etc. should therefore be minimized and their impact on plant performance should be taken into account (Mapes, 2000). Gumasta et al., (2011) further added the relationship between performance measurement and manufacturing system design wherein he considered the on-time-deliveries as an important criterion for measuring performance of manufacturing system. The term Reconfiguration time defined as the time required to changeover from one product to another should be minimum to reduce the lead time and cost required for the same called as set up cost is of great significance because RMS is designed to act in dynamic situations (Mapes, 2000). Further, (Touzout & Benyoucef, 2019) also added that the number of accidents that have occurred in that manufacturing system and health issues of employees indicates health & safety of employees which is one of the RMS performance metrics. The performance measures of RMS are also absenteeism and retention of employees. Many researchers have highlighted the importance of the term "Overall Equipment Effectiveness" (OEE). It indicates the extent to which manufacturing facilities/resources are used in relation to their full potential within a scheduled timeframe. According to (Abdi & Labib, 2003; Goyal et al., 2013b), terms such as the Responsive Index (RI) also need to be measured. Furthermore, (Touzout & Benyoucef, 2019) suggested that air, water and land pollution resulting from the production system should also be taken into account while evaluating the production system. Finally, the list of the selected 22 performance metrics are shown in Table 3.

Table 3: **List of Performance Metrics for RMS**

Sr. No.	Name of Performance Metrics	Description	Reference
1.	Productivity	Production rate is the ratio of the number of products produced and the time spent while producing them. Productivity can be considered shift-wise.	(Garbie, 2014; Mapes, 2000)
2.	On-time deliveries	It represents whether the delivery of the product is as per promise or delays.	Gumasta et al., (2011)
3.	Environmental Sustainability	It indicates the rates of pollution creation, depletion of non-renewable sources, etc.	(Touzout & Benyoucef, 2019)
4.	Sales Growth	It is a metric to measure the increase of revenue over a fixed time.	(Abdi & Labib, 2011; Yurdakul, 2002)

5.	Product Flexibility	It indicates the ability of the system to change its production volume, type, and process.	(Abdi & Labib, 2011)
6.	Customer complaints	It represents the number of complaints raised by customers while using the product. It also indicates product durability.	(Mittal & Jain, 2014; Yurdakul, 2002)
7.	Responsive Index (RI)	RI represents the speed and economy at which the machine can handle changes and functional requirements.	(Abdi & Labib, 2003; Goyal et al., 2013a)
8.	Percentage of defective products	It indicates Conformance of quality which is the degree to which the manufactured products meet certain design standards determined by the producer.	(Garbie, 2014)
9.	Total manpower requirements	The term indicates the total cost of manpower required for manufacturing. It also indicates total manpower wastage as well as the cost of overtime given to workers.	(Garbie, 2014; Mapes, 2000)
10.	Manufacturing Cost	It represents the total cost for material, labor, and overhead costs in producing the products.	(Prasad & Jayswal, 2019b)
11.	Equipment Repairs & Maintenance cost	It represents the total amounts required for repairs and maintenance of equipment.	(Garbie,2014)
12.	Machine Utilisation	It represents the measurement of use and performance of machines used in manufacturing.	(Garbie, 2014; Mittal & Jain, 2014; Yurdakul, 2002)
13.	Lead Time	It represents the time required from the start of a process to the completion of the product.	(Garbie,2014)
14.	Process capability	It represents the repeatability and consistency of manufacturing processes when compared with the specification limits of the product.	(Chen & Huang, 2006)
15.	Transportation Wastage	It indicates the unnecessary movement of, double handling of materials, shuffling of inventory, etc. during manufacturing.	(Mapes, 2000)
16.	Material Wastage/ Scrap	It represents the rejected material/ rework required during manufacturing.	(Mapes, 2000)
17.	Overall Equipment Effectiveness	It is the standard used for measuring manufacturing productivity by identifying the percentage of truly manufacturing time.	(Heilala & Voho, 2001)
18.	Energy utilisation/ Electricity/Fuel consumption	It is the measure of the benefits due to savings during utilization of electricity.	(Choi & Xirouchakis, 2015)
19.	Overproduction Wastage	This indicates manufacturing of products before it is ordered.	(Abdi & Labib, 2017)
20.	Health & Safety of employees	It represents total health-related complaints reported by employees.	(Dixit & Gupta, 2013)
21.	Reconfiguration time/ Set up Cost	It indicates the time taken for adjusting machine tools, removing tools, adding new machine tools, and transporting machine tools.	(Mapes, 2000; Mittal & Jain, 2014)
22.	Absenteeism & Retention of employees	It indicates the satisfaction of employees in the present working environment, space, etc.	(Dixit & Gupta, 2013)

2.5 *MCDM techniques used in RMS*

Multi-criteria Decision Analysis (MCDA) or Multi-criteria Decision Making (MCDM) is a branch of Operations research that deals with the design of mathematical and computational tools for the subjective evaluation of the decision alternative in presence of multiple, usually conflicting criteria (Karim & Karmaker, 2016). The MCDM is used for screening, prioritization, ranking, or selection of various independent, incommensurate, or conflicting sets of alternatives. MCDM is further classified into two categories: MADM (multiple attribute decision making) and MODM (multi objective decision making). MADM is generally used for the discrete and limited number of pre-specified alternatives. Furthermore, MODM is concerned with mathematical optimization problems involving more than one objective function and is to be optimized simultaneously. Some of the recent applications are shown in Table 4.

Table 4: Applications of MCDM for various applications

Sr. No.	Author Details & Year	Area of application	Adopted Methodology
1.	(Anand & Kodali, 2008)	Selecting Lean Manufacturing System (LMS)	Preference ranking organization method for enrichment evaluations (PROMETHEE)
2.	(Abdi & Labib, 2011)	Performance evaluation of RMS	Analytic Network Process (ANP)
3.	(Amalnick et al., 2016)	Cloud manufacturing resource allocation	FAHP-FTOPSIS
4.	(Azadeh et al., 2011)	Operator selection of cellular manufacturing system	FAHP-FTOPSIS
5.	(Büyüközkan & Göçer, 2017)	Ranking competing supplier alternatives	Intuitionistic fuzzy AHP
6.	(Sindhwani & Malhotra, 2018)	Ranking of facilitators for Agile Manufacturing System	MOORA, VIKOR
7.	(Yi, Wang, & Zhao, 2018)	Evaluation and optimization of the design schemes of reconfigurable machine tools based on multiple-attribute decision-making	VIKOR
8.	(Singh et al., 2007)	Justification for the selection of an RMS: a fuzzy AHP	AHP

2.4 Gaps identified through literature

Based on the literature review, the gaps identified are as follows,

- Most of the RMS literature focuses on the identification of key characteristics, however, outright identification of indicators seems to be unexplored.
- Few studies presented the evaluation of RMS using a set of criteria, however, there is a need to explore the complete evaluation of RMS using the full set of performance metrics.
- A limited number of studies have published the framework to improve the performance of RMS by identifying and prioritizing performance metrics of RMS.

- Very few studies considered expert opinion to improve the performance of RMS; however, the presented study considers expert opinion for better improvements.
- The literature, strategy, and decision-based problems of RMS reveal that statistical analysis and MCDM techniques can assist in problem-solving.

The above discussion indicates the gap in the literature which highlights the need for MCDM techniques for RMS indicators and performance metrics.

3. Research Methodology

This section describes the complete methodology adopted to carry out the research. Figure 2 depicts the flow chart of the research methodology adopted.

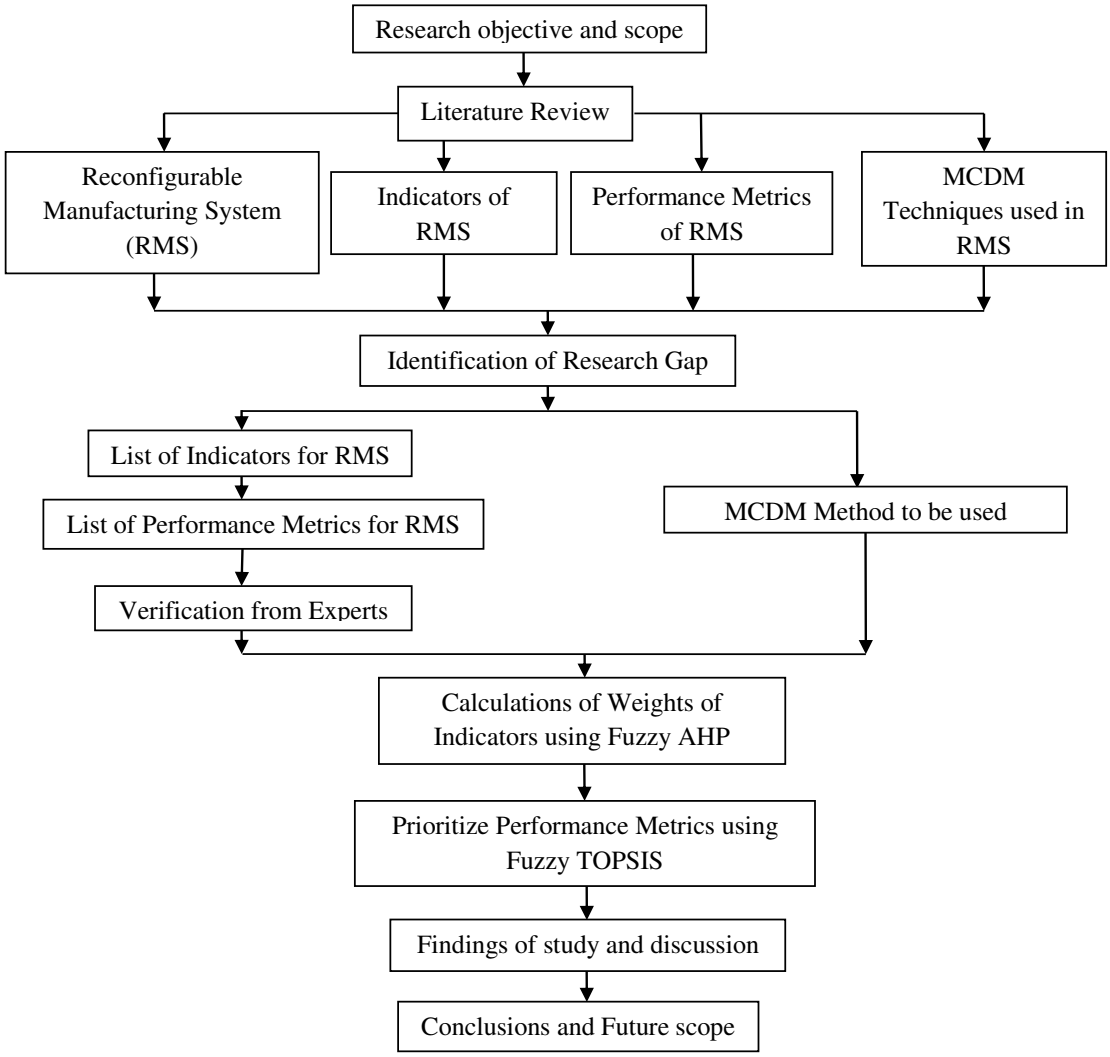

Figure 2: Flow chart for Research methodology

A literature review is carried out to identify various indicators and performance metrics for RMS. The selected indicators were categorized into five major groups: Strategy and policy indicators, Managerial and HR indicators, Organizational indicators, Tangible and intangible indicators, Technical and Smart factory indicators. The inputs from various experts are collected for the hybrid fuzzy AHP-TOPSIS approach. This approach is helpful not only to compute the weights of indicators but also to prioritize the performance metrics of RMS. Figure 4 shows a flow chart of the three-stage hybrid approach used to carry out the above process.

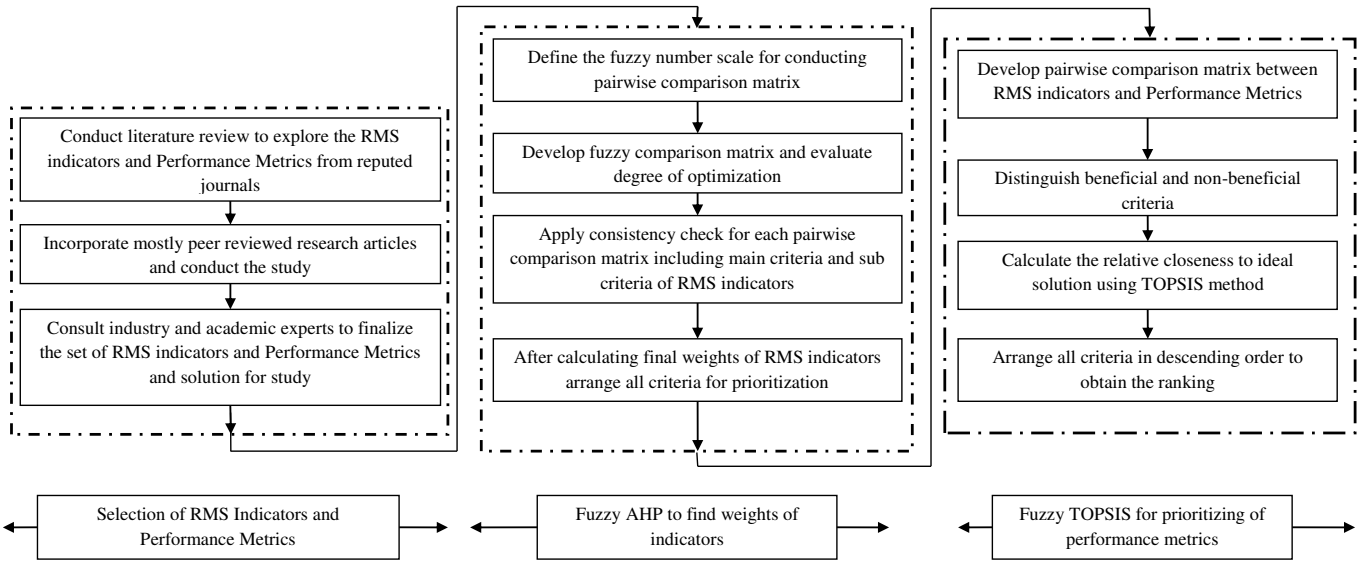

Figure 4: A proposed three-stage hybrid framework

3.1 Determining criteria weights by FAHP

AHP is an MCDM tool for complex decision-making processes based on mathematics and psychology, developed by Thomas L. Saaty (Karim & Karmaker, 2016). While evaluating alternative solutions, we need to attach weights to the criteria to ensure the correct conclusion. AHP is the most accurate method for quantifying the weights of criteria. The degree of relative importance is obtained using a pairwise comparison matrix which is developed using Saaty 1-9 preference scale (Amalnick et al., 2016; Yadav et al., 2018).

In AHP, decision-makers are asked to compare the two individual criteria with finite value, but it is very difficult in practice. In many cases, the decision-maker may be influenced by bias and might contain vagueness during their decision-making. To avoid this, (Chang, 1996) proposed an approach of Fuzzy AHP

based on the extent analysis method and is widely used for supplier selection problems. In this method, linguistic variables are used to express the comparative judgment of the decision-maker. The integrated Fuzzy-AHP process helps practitioners to achieve the best possible solution by considering different types of fuzzy members. The most commonly practiced fuzzy number is triangular fuzzy member wherein the limit range is obtained by considering alpha cut values which are later converted into the crisp number for analysis purposes. The entire fuzzy AHP process is executed using the following steps (Büyüközkan & Göçer, 2017),

i. The relationship between the two criteria is allotted through fuzzy numbers mentioned in the scale of relative importance as shown in table 5.

Table 5: Fuzzy numbers and their membership function

Fuzzy Number	Membership Function
$\tilde{1}$	(1,1,3)
$\tilde{3}$	(1,3,5)
$\tilde{5}$	(3,5,7)
$\tilde{7}$	(5,7,9)
$\tilde{9}$	(7,9,11)

This means that if the fuzzy number 1 is assigned to a relationship between two criteria, it means that, instead of considering a finite value, the whole area covered by the triangle of its corresponding membership function is considered to have a relationship as shown in Figure 3.

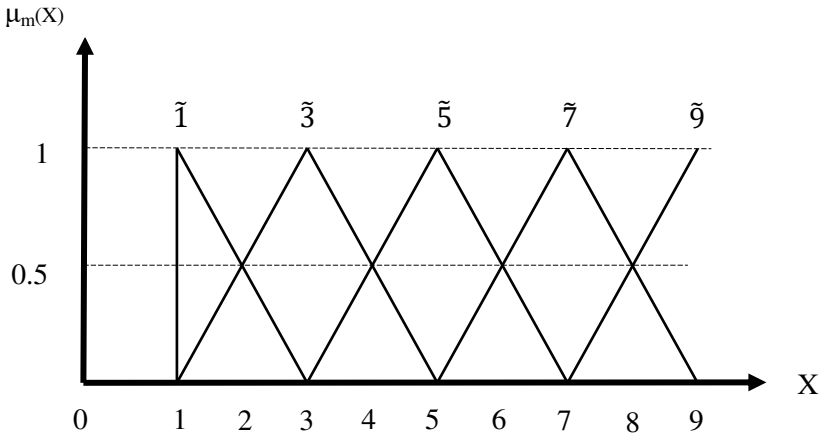

Figure 3: Triangular Fuzzy numbers

ii. After obtaining the membership function, the next step includes defining the range for the comparison between two specific criteria. This range is obtained by following alpha cut values,

$$[l^{\alpha}, \mu^{\alpha}] = [(m-l)\alpha + l, -(u-m)\alpha + u]$$

Where l, u, m are the lower, middle, and upper value of membership function whereas α=0.5

iii. Once the range between comparison allotment is obtained, the next step includes the conversion alpha cut matrix into the corresponding crisp comparison matrix by using the relation as follows,

$$\tilde{a}_{ij}^{\alpha} = \mu a_{ijl}^{\alpha} + (1-\mu) a_{iju}^{\alpha}$$

Where a_{ijl}^{α} is the lower value of the range

a_{iju}^{α} is upper value of the range

μ is the degree of optimization taken as 0.5

iv. Once a crisp comparison matrix is obtained the next step includes the checking of matrix consistency by computing the Eigenvector and then the standard procedure of traditional AHP is followed as explained in subsequent steps.

v. The decision-makers are asked to compare the pair of each criterion in a single matrix. Compute the square of the initial matrix to perform the first iteration.

vi. Take the ratio of the sum of the square matrix and then decide the final column by its sum. This will give first Eigenvector.

vii. It is further required to continuously perform the iterations until you obtain the common Eigenvector in two consecutive iterations.

viii. After obtaining the final Eigenvector, indicate that Eigenvector as 'X' and identify the value of λ_{max} by using the following relation,

$$AX = \lambda_{max} X$$

It is desired to first find the product of AX and later compare it with λ_{max} X.

ix. After computing $\lambda_{max,}$ the next step is to compute consistency index using the relation,

$$C.I. = \frac{\lambda_{max} - n}{n-1}$$

Where n is the number of criteria included in the problem.

x. Finally, it is required to obtain consistency ratio which is obtained by,

$$C.R. = \frac{C.I.}{R.I.}$$

Here, R.I. indicates the random index. It is further required to check whether the consistency ratio is less than 0.1. If the value of C.R. exceeds 0.1 then it indicates that the Eigenvectors obtained are not consistent. The value of R.I. can be obtained from table 6,

Table 6: Random index numbers

No. of Criteria	1.	2.	3.	4.	5.	6.	7.
R.I.	0	0	0.52	0.89	1.11	1.25	1.35

3.2 TOPSIS Method

TOPSIS, developed by Hwang and Yoon in 1981, is a MADM technique based on a comparison of different alternatives with a Negative Ideal Solution (NIS) and a Positive Ideal Solution (PIS). In this method, the ideal solution is the longest distance from the NIS as well as the shortest distance from the PIS (Dağdeviren, 2010). The following steps are to be followed for TOPSIS (Ighravwe & Oke, 2017; Karim & Karmaker, 2016),

i. Construct normalized decision matrix which transforms various attribute dimensions into non-dimensional attributes. We can use,

$$r_{ij} = \frac{x_{ij}}{\sqrt{\sum x_{ij}^2}} \qquad \text{For i = 1, 2, 3, ----------m}$$

j = 1, 2, 3, ----------n

ii. Construct the weighted normalized matrix. Multiply each column of the normalized decision matrix by its associated weight. An element of new matrix is,

$$v_{ij} = w_{ij}.r_{ij}$$

iii. Determine the positive ideal solution and negative ideal solutions using the following relation,

The positive ideal solution,

$$A^* = \{V_1^*, V_2^* - - - - - V_n^*\}$$

$$V_j^* = \{(\max(V_{ij}) \ if \ j \in J), (\min(V_{ij}) \ if \ j \in J')\}$$

The negative ideal solution,

$$A' = \{V_1', V_2' - - - - - V_n'\}$$

$$V_j' = \{(\max(V_{ij}) \ if \ j \in J), (\min(V_{ij}) \ if \ j \in J')\}$$

Where J is associated with beneficial criteria whereas J' is associated with non-beneficial criteria.

iv. Calculate the separation measures for each alternative,

The separation measures for the positive ideal solution (PIS) is,

$$S_i^* = \sqrt{\sum_j (V_j^* - V_{ij})^2}$$

Where, i = 1, 2, 3----------m

Similarly, the separation measures for the negative ideal solution (NIS) is,

$$S_i' = \sqrt{\sum_j (V_j' - V_{ij})^2}$$

Where, i = 1, 2, 3----------m

v. Calculate the relative closeness to the ideal solution,

$$C_i^* = \frac{S_i'}{(S_i^* + S_i')}$$

4. Case application

The authors agreed to check the appropriateness of their hybrid framework for ABC manufacturing organization (established in the year 2008) as a case application, as seen in (Yadav et al., 2018). This helps to understand the working of the hybrid framework as well as demonstrates its ability for researchers and practitioners. It reduces the gap between theoretical studies and practical situations. The main intention of this work is to demonstrate the ability of the developed framework to researchers and practitioners. The considered ABC manufacturing organization is located at Bhiwandi, Thane district. The organization produces a wide range of control valves (such as Globe control valve, Butterfly control valve, Ball valves, Flush Bottom valves, Pressure regulating valve, De-super heater, etc.). The company having a total of around 70 employees operates in general shift and having an approximate turnover of ₹25 crores. The organization supplies its products mainly to Siemens India Limited, Rotork Limited, Space alloys, Siddhi cast, and many more.

4.1 Problem description

ABC manufacturing organization is facing many challenges due to increasing competition, changing customer demands, etc. Hence there is a need for techno-managerial solutions such as indicators, performance metrics in the manufacturing organization to reduce the lead time, manufacturing cost, and many more advantages. The kind of framework developed in this work requires the commitment of top management for implementation, as the training and resources play a vital role for it. The challenges were increasing in front of ABC organization as all competing organizations started to implement various technologies in their organization such as 5S, Kaizen, Industry 4.0, and many more. The management of ABC organization is matured enough and was keen to implement such kind of framework as their products are changing continuously. The experience and cooperation of staff and officers have been very helpful during the framework development. After a proper understanding of the concept, the top management of ABC organization realized that they could reduce lead time and manufacturing costs with the help of a developed framework. During the discussion with ABC management, they also expressed that they could not get some of the orders because they could not supply the product in time which incurred a financial loss to them. Management also realized that the quality of their products can also be improved along with increased profit share due to the implementation of this framework. For this reason, the management of the ABC organization decided to participate in the framework development without wasting any more time.

The management of ABC organization expressed their desire to study all Indicators and Performance Metrics, particularly smart factory indicators, during the first meeting. So the authors decided to handover the detailed list of the same to the ABC management so that they could understand it clearly. This approach of management indicates their interest while developing the hybrid framework and the maturity shown by management was very helpful during the study.

4.2 Data collection and Framework development

Stage 1: Shortlisting of indicators and their performance metrics

As discussed earlier, all the indicators and performance metrics identified through the literature review are presented to the expert panel as observed in the study (Yadav et al., 2018). The expert panel studied the list of all indicators and performance metrics and did the necessary shortlisting. The experts suggested categorizing all indicators into various subgroups: Strategy and policy indicators, Managerial and

HR indicators, Organizational indicators, Tangible and intangible indicators, Technical indicators, and Smart factory indicators as shown in Figure 5.

Stage 2: Identification of indicators weights using Fuzzy AHP

Indicators identified through the literature review were presented to the panel for their expert opinion as per the study (Yadav et al., 2018). They were requested to provide their expert opinion (comparison matrix) necessary for the preparation of the decision hierarchy so that they could be prioritized. The structure in the form of groups as shown in Figure 5 could be adopted for indicators and the proven method for grouping is to seek help from subject experts.

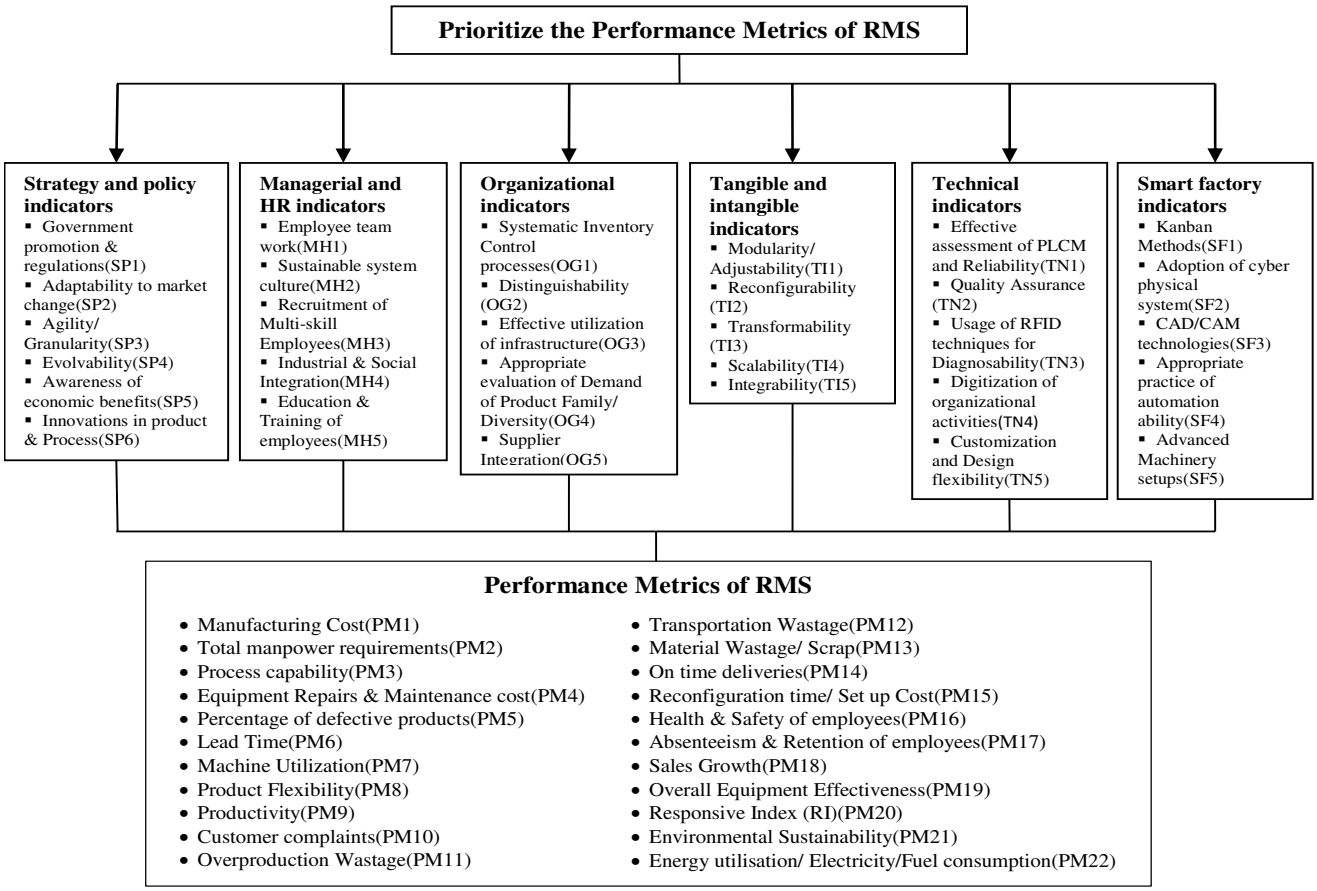

Figure 5: Hierarchical structure of Indicators

The hierarchy of importance of these fuzzy numbers was explained to the experts and asked to prepare an initial pairwise comparison matrix using a five-point scale as shown in Table 7.

Table 7: Relative importance scale (Yadav et al., 2018)

Variables	Fuzzy notification	Corresponding membership function
Equal preference	$\widetilde{M1}$	(1,1,3)
Weak preference	$\widetilde{M3}$	(1,3,5)
Strong preference	$\widetilde{M5}$	(3,5,7)
Very strong preference	$\widetilde{M7}$	(5,7,9)
Extremely strong preference	$\widetilde{M9}$	(7,9,11)

The panel of eight experts from the ABC organization prepared a pair-wise comparison as shown in Table 8-14. The standard procedure of Fuzzy-AHP as described earlier is followed to calculate the weights of all indicators. During this process, complete precautions have been taken for consistency and, if any matrix as stated above is found to be inconsistent, experts are requested to revise their opinion for pair-wise comparison.

Table 8: Pairwise comparison matrix for main criteria indicators

Main Criteria	Strategy and Policy	Organisational	Tangible and Intangible	Managerial and HR	Smart factory	Technical
Strategy and Policy	$\widetilde{M1}$	$\widetilde{M5}$	$\widetilde{M3}$	$\widetilde{M1}$	$\widetilde{M3}$	$(\widetilde{M3})^{-1}$

		TI4	0.2044	0.0232
		TI5	0.1680	0.0191

Stage 3: Prioritization of performance metrics using Fuzzy-TOPSIS

All these weights calculated in the above steps are used in the TOPSIS method for the ranking of performance metrics. The five-point scale is used to collect expert opinions as shown in Table 16 and to compare all indicators with performance metrics.

Table 16: Fuzzy score conversion of linguistic scale (Rao & Patel, 2010; Yadav et al., 2018)

Linguistic Term	Fuzzy Number	Crisp Score
Criteria 'A' is very low significant to criteria 'B'	F1	0.115
Criteria 'A' is low significant to criteria 'B'	F2	0.295
Criteria 'A' and criteria 'B' are equally significant	F3	0.495
Criteria 'A' is more significant to criteria 'B'	F4	0.695
Criteria 'A' is extremely significant to criteria 'B'	F5	0.895

The comparison matrix is presented in table 17, where the numbers presented are fuzzy. Then the various steps explained in 3.2 are followed for the comparison matrix presented in Table 17. The weighted normalized matrix is presented in Table 18 which is obtained by taking the product of the normalized matrix using the crisp score and global weights.

4.3 Data analysis

Various steps for fuzzy-TOPSIS are followed till the distance from the positive ideal solution (PIS), the negative ideal solution (NIS), and the relative closeness from the ideal solution and ranking is obtained. As the values of the relative closeness represent the distance from the negative/worst solution, the highest value is given the top ranking as shown in Table 19.

Table 19: Ranking obtained using TOPSIS

Performance Metrics code	Positive Ideal Solution (PIS)	Negative Ideal Solution (NIS)	Relative closeness	Ranking
PM1	0.0179	0.0269	0.5998	4

5. Findings of the study

Implementation of the RMS is more costly compared to other manufacturing systems, but the benefits accrue are more than other systems. It is therefore important to ensure the correct implementation of the various indicators and performance metrics, otherwise, the performance and efficiency of the system may be affected. The main objective of this study is to develop a hybrid Fuzzy AHP –TOPSIS framework that can be very useful for decision-making during the implementation of the system. The two phases of this study include the computation of the major criterion and the weights of the sub-criterion indicators. Initially, all

the major criterion, as well as the sub-criterion, are ranked within the group by computing their relative weights. This helps to compare indicators both within the group and outside the group with the help of global weight. The second phase is to rank shortlisted performance metrics using the Fuzzy-TOPSIS method.

Finally, the results obtained using Fuzzy-AHP and the ranking obtained using Fuzzy-TOPSIS are analyzed for interpretation, revealing that the 'smart factory' indicators have the highest weight among the other indicators followed by the 'strategy and policy' indicators. It demonstrates that the use of advanced manufacturing and material handling technologies can lead to the successful implementation of RMS, and these indicators can improve many important performance metrics, such as lead time, reconfiguration time, etc. Strategy and policy indicators are also very important, as rigid management policies can act as major obstacles to the effective implementation of the RMS. The utilization of technical resources such as digitization and RFID is the key to success in the successful RMS implementation. It is also observed that the education and training of employees has an impact on implementation, as the skills of employees have a major impact on the system. Among the performance metrics, ‘Lead time’ holds the highest positions which are followed by ‘Reconfiguration time’ and ‘Product flexibility’ offered by the manufacturing system. ‘Manufacturing cost’ is at fourth position, as it is a very important metrics as far as product cost is concerned. ‘On-time deliveries’ is vital if any manufacturing organization wants to sustain itself in the market, hence it is in the fifth position. The later positions of performance metrics are occupied by ‘Productivity’, ‘Process capability’, ‘Machine utilization’, and ‘Percentage of defective Products’ etc.

6. Theoretical contributions of the study

Many researchers discussed the core characteristics of RMS. At the same time, none of the researchers discussed indicators, their weights, and the ranking of performance metrics for RMS. Hence, this study tries to find indicators and performance metrics of RMS along with their ranking using the hybrid Fuzzy AHP-TOPSIS. This hybrid framework is used to compute the weights of the indicators to assess their influence during the implementation of RMS and these weights are used to rank the performance metrics in link with indicators. Authors expect the presented work will save efforts, time, and funds of practitioners of the manufacturing system. This research can be viewed as a significant contribution to MCDM as well as RMS promoting applications in the domain areas.

The main contribution of this study is the identification of RMS indicators and performance metrics. The exhaustive literature survey is conducted, with 31 indicators and 22 performance metrics that are best

suited to the RMS manufacturing environment being finalized. Authors have tried to include highly influential domain-specific indicators and performance metrics for RMS and are prioritized for smooth and successful implementation of RMS.

7. Implications for practitioners and researchers

The main aim of this paper is to develop a hybrid framework for prioritizing RMS performance metrics. To achieve success in the field of techno-managerial solutions, the key requirement is the hybrid framework (Prashar, 2016; Yadav et al., 2018). The inputs are taken from researchers and industry practitioners. The researchers mainly contribute to the creation of a hybrid framework and mathematical calculations, while the practitioner helps with the inputs of the framework (Yadav et al., 2018). The contribution of both researchers and practitioners is therefore essential for the development of such a framework.

Following implications are important for practitioners and researchers interested in application areas of RMS.

- The study illustrates the use of the Fuzzy AHP-TOPSIS hybrid approach to the RMS framework and provides three main inputs. First, many articles in the field of MCDM (Kurttila et al., 2000; Saaty, 2008) used AHP alone as a methodology in which the chances of vagueness and bias cannot be neglected. This is why Fuzzy-AHP is introduced, which gives the decision-maker flexibility for comparison (Yadav et al., 2018). Second, TOPSIS is used to rank alternatives aimed at finding the best alternative that has the shortest distance from the PIS and at the same time the distance from the NIS (Karim & Karmaker, 2016). Using AHP's fuzzy theory to assess the weight of TOPSIS parameters will reduce the ambiguity and uncertainties inherent in making decisions on the most efficient number of operators and the successful calculation of RMS operator assignments. Thirdly, the framework developed in this work can be used in any other field, irrespective of the nature of the problem.
- Many studies (Karim & Karmaker, 2016; Yadav et al., 2018) have tried to focus on the importance of developing a hybrid framework, but there is still a lack of such studies in practice. There is also a need to develop a generalized type of framework that can be used in any application domain with slight modification. This is particularly important in developing countries where the risk of failure to implement cannot be afforded. Such frameworks will therefore be very useful in decision-making areas where indicators and performance metrics play an important role in the manufacturing system.

- The authors of this work agree that not all indicators can be considered and included during the implementation of the RMS, but based on the weights obtained, important indicators with high-intensity weights can be considered and included. The hybrid framework developed here plays an important role and the author wants to encourage this kind of work in other areas.
- The hybrid framework that has been developed in this way offers many benefits to practitioners and researchers that can show new directions in research. There is still a need to explore more opportunities in this area. The hybrid framework can also be used to assess several other issues in the industry. This developed framework can be taken as a foundational step in this direction.

8. Conclusions, Limitations, and Future Scope

The work presented is an initial attempt to improve the adaptability of RMS so that different manufacturing firms wishing to produce different products using the same manufacturing facilities can easily implement RMS. Finalized Indicators and Performance Metrics are evaluated by developing the RMS decision hybrid framework using the Fuzzy AHP–TOPSIS approach. Fuzzy-AHP is used to calculate the Indicators' weights, while Fuzzy-TOPSIS is used to evaluate the Performance Metrics ranking. This will help the practicing managers to take appropriate and timely decisions in the event of RMS adoption and performance measurement. An initial facilitator study can help policymakers understand the potential of actual RMS implementation in the manufacturing industry. The developed hybrid framework is an important techno-managerial solution in the field of RMS. Such work, which can handle both indicators and performance metrics, is rarely reported in the RMS field. The results of this study suggest that 'Smart Factory' indicators have the highest priority, which means that the adoption of the latest and automated manufacturing technologies can improve the performance of RMS. Authors assume that ranking performance metrics will be simpler and more efficient through their analysis and will support the execution of RMS. Manufacturing enterprise management should make a strategic effort to manage RMS applications.

In addition to the above-noted benefits of the study, some of the limitations of the study cannot be neglected. The first major limitation of the study is that if someone is not familiar with MCDM techniques, this framework may increase the complexity of the study. The study presented here is validated by the use of expert data in the form of a matrix of comparison. This work can be extended and simulation-based evaluations can be carried out to compare the results. The experts involved may likely have missed some

important indicators and performance metrics. Authors appeal to researchers and practitioners to use a specific range of indicators and performance metrics to explore this approach. Researchers may also try to apply this framework to other areas of production and the results can be verified. Authors expect both researchers and practitioners to benefit from experimenting with this study in a variety of sectors and to continue this research work.

DECLARATIONS

Funding: The authors did not receive support from any organization for the submitted work.

Conflict of Interest: The authors have no conflicts of interest to declare that are relevant to the content of this article.

Availability of data and material: Not Applicable

Code availability: Not Applicable

Ethics approval: The manuscript in part or in full has not been submitted or published anywhere. The manuscript will not be submitted elsewhere until the editorial process is completed.

Consent to participate: Not Applicable

Consent for publication: The author transfers to Springer the non-exclusive publication rights.

Authors' contributions: All authors contributed in writing the manuscript. Mr. Rajesh Pansare has collected the data and performed the analysis.

Exploring indicators of circular economy adoption framework through a hybrid decision support approach

Abstract: Circular economy (CE) focuses on a circular approach to energy and material resources, which provides economic, environmental and social benefits for manufacturing organisations. CE adoption in emerging economies facilitates in substantial economic growth through appropriate utilisation of energy and material resources across manufacturing industries. This study identifies CE indicators in the context of an emerging economy. The study further develops a framework for the adoption of CE and tests it through a hybrid Best Worst Method and Decision-Making Trial and Evaluation Laboratory approach. The framework is validated through an Indian manufacturing case organisation. While Best Worst Method computes the CE related indicator weights, Decision-Making Trial and Evaluation Laboratory analyses the inter-relationship among indicators. Disparate CE related indicators, e.g. strategic, managerial, informational and technological, supply chain and organisational, influence the CE adoption in an emerging economy context. The findings reveal that the strategic and managerial indicators have the strongest influence on developing other indicators. The causal digraph and relationship diagram assist the practitioners in predicting the inter-relationship of indicators in CE adoption. The study outcomes will help the practitioners, policymakers and researchers to draw a framework for adoption of circular and green practices and usage of resources sustainably.

Keywords: Circular economy; Indicators; Decision-making; Sustainable operations; Emerging economies; India.

1. Introduction

Circular economy (CE) has emerged as one of the important aspects of a nation's economy (Mahpour, 2018). From various definitions of CE reported in the extant literature, it is difficult to have an in-depth understanding of CE (Kirchherr et al., 2017) as the definitions represent different perspectives (Sarkis and Zhu, 2017). Several studies have put an effort to link CE to different areas, such as industrial ecology, reverse logistics and waste reductions. However, CE is not limited to material and/or waste recovery as CE can be extended to energy utilisation, supply chain activities, production activities and sharing economy (Saidani et al., 2017). CE works in a closed or circular loop, but it can also be used in a forward loop (Korhonen et al.,

2018a). Several frameworks, such as BECE (backcasting and eco-design for the circular economy) and ReSOLVE, are proposed for effective adoption of CE (Mendoza et al., 2017).

CE has a direct link to manufacturing organisations. CE adoption in manufacturing industries can be beneficial for nations' growth. Researchers argue that manufacturing organisations play a pivotal role, especially in developing nations such as China, India, Thailand etc., as they are outsourcing hubs to the developed economies (Fang et al., 2017; Lieder and Rashid, 2016). CE adoption in the manufacturing sector is a cumbersome process as it calls for an effective examination of some crucial factors before initiating the process. Some of these factors are CE adoption policies, its feasibility, effectiveness and adaptability to the sector. In literature, the factors are sometimes referred to as indicators, critical success factors, enablers, drivers and facilitators.

Driven by this concern, this study contributes to the literature by identifying the indicators that assist in the CE adoption process. The indicators are the factors that help in enhancing the CE adoption. Indicators possess the different intensity of influence (Govindan and Hasanagic, 2018). The intensity of influence refers to the weightage of each indicator during the CE adoption process. While, the study of Saidani et al. (2019) reports an exhaustive list of CE indicators, it fails to capture their intensity and does not highlight any information related to their inter-relationship. Therefore, another contribution of this study is to bridge this knowledge gap through identifying the intensity of influence of the indicators, the absence of which may hinder practitioners to implement an effective CE adoption process in manufacturing organisations. Further, the mere identification of the intensity of influence of the indicators is not adequate. Therefore, yet another contribution of the study is to analyse causal relationships of the indicators and explore their interaction possibilities in a whole system to facilitate the decision-making process of practitioners and policymakers for CE adoption.

A paradigm shift in the CE literature is reported in this study through the objectives of identifying the CE indicators, analysing their intensity of influence and examining their causal relationship. Here, the paradigm shift refers to explore different diversifying opportunities in CE literature. To address these objectives, a hybrid decision-support approach using the Best Worst Method (BWM) and Decision-Making Trial and Evaluation Laboratory (DEMATEL) methods is employed to analyse a case of an Indian manufacturing organisation. The exhaustive study identifies a set of CE indicators that affect the CE adoption process. These indicators are confirmed and validated through an expert panel. While the intensity of influence of the indicators is ascertained through the BWM approach, the DEMATEL approach explores the causal relationship of the indicators.

This article is organised as follows. Section 2 examines the theoretical foundation of the work through a thorough literature review. Section 3 describes the research methodology. Section 4 elucidates development and testing of the CE adoption framework through the considered case. Section 5 discusses the outcomes of the study. Section 6 provides an insight into the contributions and implications. Finally, in section 7, the article concludes with recommendations for future research.

2. Literature Review

To explore disparate CE indicators, a systematic literature review approach is conducted as set out in Tranfield et al. (2003). The articles considered in this literature review possess a strong focus on CE adoption and its indicators. The following keywords are framed and used in various combinations to identify the extant literature: 'circular economy indicators', 'circular economy enablers', 'circular economy critical success factors', 'circular economy drivers', 'circular economy and manufacturing', 'circular economy and developing economies' and 'circular economy facilitators'. The databases used include: "Web of Science", "Scopus" and "Google Scholar". The titles, abstracts and keywords of the identified articles are further scrutinised based on the following criteria: (a) inclusion of only journal articles which are peer-reviewed and excluding all the conference proceedings, and (b) inclusion of only English language articles. Although CE domain gained its momentum from 2010 (in terms publication of articles), few articles have been observed in the early 2000s. Therefore, the review time horizon is 2000 to 2019. The initial shortlisting left us with 231 articles. While the initial shortlisting of articles is performed according to the above procedure, the final scrutiny of the articles is conducted through forward snowball and backward snowball approach (Wohlin, 2014) which left us with 63 articles.

The articles that strictly focus on the indicators for developing economies and related to manufacturing concerns are though included. This approach assists to identify the articles strongly related to the present study. This review helps in developing a better understanding of CE and building a foundation to enhance various research threads in this domain.

2.1 Circular Economy related Indicators

Although the CE research is in a state of infancy, several publications (de Jesus and Mendonça, 2018; Lazarevic and Valve, 2017) report sets of indicators influencing the CE adoption process. These indicators influence the adoption process in a broader context (i.e. developed and developing nations' context). A study on CE (Mahpour, 2018) reports 'effective

planning and management for CE adoption', 'allocation of financial budgets for CE', and 'top management commitment for CE adoption' as the most critical indicators influencing the CE adoption process. The strategic planning and budget allocation are directly linked to the top management (Bodar et al., 2018) to facilitate building effective strategies. Further, effective strategic planning assists in attaining sustainable resource management (Genovese et al., 2017). Sustainable resource utilisation can directly contribute to the CE adoption process thereby strengthening a nation's economy and future resource managing aspects (Parchomenko et al., 2019).

Govindan and Hasanagic (2018) argued that adoption of CE is a challenge until economic benefits are understood. Therefore, it is significant to have some strong strategies and policies for CE adoption (Kim and Lui, 2015). From this standpoint, the following indicators have emerged as prime importance: 'redesign based on customer feedback', 'effective lifecycle analysis', and 'rewards and incentives for greener activities' (Homrich et al., 2018).

Indicators relating to performance measures that aid in mapping CE performance are required to be considered (Wang and Li, 2006) in the CE adoption process. The indicators viz. 'effective facility layout decision making', 'effective information management system' (e.g. IoT), and 'adoption of innovative quality improvement practices' (Martins, 2018) are considered as key players in the CE adoption process. Adoption of CE requires indicators facilitating advanced technology transfer and constant monitoring on changing market needs (Anzola-román et al., 2018). In this regard, Saavedra et al. (2018) emphasise on the penetration of social media and big data analytics within an organisation. This helps to circulate the information within a correct loop. Availability of advanced technological setups will facilitate the practitioners to carry out their production activities and simultaneously help in providing high-quality products to the end-users (Urbinati et al., 2017).

CE possesses a strong linkage to the supply chain activities in manufacturing organisations (Batista et al., 2018b). Coordination and collaboration among the supply chain members is very essential for building the loop of CE (Geng et al., 2012). This leads to the emergence of the following indicators, viz. 'supplier commitment for recyclable materials' and 'CE education for suppliers'. Adopting reverse supply chain activities, e.g. includes Reverse Logistics (RL) and Extended Product Responsibility (EPR) etc., enhance the CE adoption process (Saridakis et al., 2019). Further, green practices and initiatives, such as green purchasing, green design and green packaging, strengthen the social and environmental dimensions of CE (Kirchherr et al., 2017). Such practices enhance supply chain performance and strengthen the closed-loop

mapping procedures (Whicher et al., 2018). Linking CE to supply chain further assists in maintaining the product cost under control (Yadav et al., 2020).

Some highly impactful indicators for the CE adoption framework are 'adoption of 6R's', 'multi-stage quality check system', and 'reduction in carbon emission' (Heyes et al., 2018). The multi-stage quality check system helps to diagnose the defects at the production stage and recycle the same for corrective actions. Similarly, reduction in carbon emission and using it in other activities enhance the organisational productivity (Wang et al., 2018). The 6R's includes redesign, reduce, recycle, reuse, recover and remanufacturing which strongly correlate to CE (Kazancoglu et al., 2018). Hence, adoption of 6R's significantly improves the CE adoption possibility. Additionally, effective inventory management emerges as one of the key indicators in the CE adoption process (Ormazabal et al., 2018). Employee empowerment and motivation is a requirement for the successful implementation of these identified indicators (Ricciardi et al., 2016). Therefore, focussed training for the CE adoption process is needed. Table 1 identifies and collates the indicators essential for the CE adoption framework.

Table 1: Circular economy related indicators reported in the literature

Sl. No.	Circular economy related indicators	Description	Literature
1	Effective planning and management	Effective planning and management to align resources appropriately for CE adoption	Martins (2018); Homrich et al. (2018)
2	Top management commitment	Top management engagement and involvement enhance opportunities for CE adoption	Saavedra et al. (2018); Bodar et al. (2018)
3	Allocation of financial budgets	Separate budget allocation for the execution of CE practices is crucial	de Jesus and Mendonça (2018); Mahpour (2018)
4	Sustainable resource management	Appropriate usage of sustainable resources is required for CE adoption	Bodar et al. (2018); Genovese et al. (2017)
5	Supportive participation of stakeholders	Stakeholders' participation is essential for the adoption of CE framework	Fang et al. (2017); de Oliveira et al. (2017)
6	Building a brand image	Brand image in effective CE culture boosts the opportunities	Genovese et al. (2017); Lieder and Rashid (2016)
7	Understanding exact implications of CE (economic and social benefits)	Economic and social benefits are required to be understood explicitly for an effective CE adoption	de Oliveira et al. (2017); Wang and Li (2006)
8	Focussed training for CE adoption	Appropriate training sessions facilitate CE adoption process	Martins (2018); Lieder and Rashid (2016)

9	Employee empowerment and motivation	Motivating employees and transferring responsibilities to them to improve the productivity of an organisation	Zhu and Tian (2016); Kirchherr et al. (2017)
10	Multi-stage quality check system	Conducting quality checks for in-process products at checkpoints assist in diagnosing defects at an early stage for necessary rework	Sarkis and Zhu (2017); Urbinati et al. (2017)
11	Adoption of 6 R's	Adoption of 6 R's helps organisation to penetrate CE effectively	Korhonen et al. (2018a); Ghisellini, Cialani, and Ulgiati (2016)
12	Effective inventory management	Appropriate forecasting techniques aid practitioners to manage inventories	Tukker (2015); Zhu et al. (2010)
13	Reduction in carbon emission	Reducing carbon emission and using it further for any productive recycling process boosts the CE adoption process	Merli et al. (2018); Korhonen et al. (2018)
14	Coordination and collaboration among SC members	Effective collaboration and communication among the supply chain entities help to manage supply chain operations	Geng and Doberstein (2008); Heyes et al. (2018)
15	Supplier commitment for recyclable materials	Suppliers' commitment to recyclable materials promotes the CE adoption process	Zhu, Geng, and Lai (2010); Tseng et al. (2018)
16	Adopting reverse supply chain practices (e.g. EPR, reverse logistics)	Effective implementation of EPR and reverse logistic practices indirectly assist in the CE adoption process	Whicher et al. (2018); Kirchherr et al. (2017)
17	Adopting green practices (in purchasing, design and packaging)	Adoption of green purchasing, design and packaging develop a recyclable product	Korhonen et al. (2018b); Lazarevic and Valve (2017)
18	Educating customers for CE practices	The end-users are required to be educated regarding the benefits of CE	Bodar et al. (2018); Lacy and Rutqvist (2016)
19	Adopting innovative practices	Adoption of advanced quality improvement practices at different functional areas of supply chain help in the CE adoption process	Genovese et al. (2017); Fang et al. (2017)
20	Advanced technological transfer and applicability	Availability and applicability of advanced technology transfer help in mapping activities that improve inter-departmental communication within the organisation	van Loon and Van Wassenhove (2018); Lieder and Rashid (2016)
21	Penetrating social media and big data analytics in the organisation	Implementation of big data analytics and social media in the organisation facilitates understanding of customers' requirements to take effective measures	Govindan and Hasanagic (2018); Lazarevic and Valve (2017)

22	Effective facility layout decision making	Allocation of facilities in an optimised manner is extremely important that directly correlates to the product cost	Pomponi and Moncaster (2017); Homrich et al. (2018)
23	Constant monitoring of changing market needs	Observation on changing market needs helps effectively in modifying/developing products	Martins (2018); Fang et al. (2017)
24	Effective information management system (e.g. IoT)	Effective implementation of the internet of things (IoT) in the organisation facilitates in handling complex information management system	Saavedra et al. (2018); Pomponi and Moncaster (2017)
25	Adopting industrial ecology initiatives	Implementation of industrial ecology facilitates the assessment of the system's environmental impact	Geng et al. (2012); Genovese et al. (2017)
26	Availability of CE oriented framework (e.g. ReSOLVE)	Focussed CE framework facilitates its better penetration in the organisation	Martins (2018); Sarkis and Zhu (2017)
27	Redesign based on customer (internal and external) feedback	An effective closed-loop feedback system facilitates appropriate modification in design	Tseng et al. (2018); Geng and Doberstein (2008)
28	Effective life cycle analysis	Review and analysis of product life cycle and its effective implementation facilitates to adapt new products	Merli et al. (2018); Sarkis and Zhu (2017)
29	Rewards and incentives for greener activities	Rewards and incentives boost employee morale to facilitate the implementation of environmentally sustainable activities	Ormazabal et al. (2018); Zhu and Tian (2016)
30	Identifying performance measures for CE	Effective performance measures assist in analysing CE's benefits	van Loon et al. (2017); Urbinati et al. (2017)
31	Supportive government policies	Government regulations for promoting CE and subsequent subsidies and rebate in taxes can enhance the CE adoption process	Govindan and Hasanagic (2018); Lazarevic and Valve (2017)

2.2 Circular Economy in Developing Nations

Although the success stories of CE have broadly captured by the developed economies, the developing economies are struggling to adopt CE effectively across their manufacturing firms. Effective CE adoption is crucial in developing nations as their economies partly depend on outsourcing/off-shoring market and/or foreign direct investments (Saavedra et al., 2018). Developing nations provide cheap labour and deliver final products at low costs. China is considered as one of the largest exporters of electronic goods (Mangla et al., 2019). India and Thailand export electronics manufactured goods to all parts of the globe (Wang et al., 2018).

It becomes an extremely challenging task to adopt CE in these countries when they are compared to the developed nations (Ghisellini et al., 2016). These nations' struggle to meet the basic requirements along with their poor strategic infrastructure find CE implementation an extremely challenging task (Luthra et al., 2019). Adoption of CE in the developing nations will facilitate them to attain economic stability, economic perks (Tseng et al., 2018) and simultaneously set a roadmap for transition from developing to developed nations. Therefore, adoption of CE will help them to get rid of the problem.

Mere understanding of CE is not enough as identification of its indicators plays a pivotal role in its effective adoption (Sarkis and Zhu, 2017). Thus to facilitate the CE adoption process, it is necessary to identify the indicators influencing the CE adoption in the context of developing nations. It is pertinent to note that majority of the studies (Wang et al., 2018) consider cases from China. Literature is scant on the studies highlighting the CE indicators from other developing nations like India, Sri Lanka and Thailand etc.

2.3 Knowledge Gaps

An exhaustive examination of the extant literature identifies the following knowledge gaps:

- While the majority of research articles (Wang and Li, 2006; Homrich et al., 2018) discuss CE adoption benefits, the literature emphasising a framework facilitating the CE adoption process in manufacturing organisations is scant.
- Determination of the intensity of influence the CE indicators are extremely significant for the CE adoption process. The extant literature is unavailable on this aspect of the CE indicators.
- Existing CE adoption frameworks (Bodar et al., 2018; Genovese et al., 2017) do not rely on standard analytical validation treatments justifying the CE adoption process.
- Lack of adequate technological infrastructure and sustainable resources differentiate the nature of the CE indicators of the developing and developed nations because non-availability of these resources makes it extremely difficult for developing nations to adopt CE effectively. Little is known in this regard although a few studies (Lieder and Rashid, 2016; de Oliveira et al., 2017) report some of the key CE indicators. Therefore, indicators related to developing nations need to be identified.
- Literature is unavailable on the causal relationship of the CE indicators. It is important to examine the behavioural aspect of an indicator when it interacts with the others.

These knowledge gaps call for exploring the importance weights of the identified CE indicators in a decision-making context for examining their intensity of influence on the CE adoption process, which is elucidated in the next sections.

3. Research Methodology

Figure 1 illustrates the research methodology and describes the data collection in five phases. This collection procedure is conducted in the case organisation. The CE indicators derived from the extant literature are further verified through an expert panel (see section 4.1 for expert details). These experts are asked to categorise the shortlisted indicators into diverse groups for the development of the CE adoption framework. The hybrid BWM-DEMATEL approach examines disparate feasibility aspects of the developed framework and causal relationship of the indicators.

3.1 The Hybrid BWM-DEMATEL Approach

The hybrid BWM-DEMATEL approach is formulated to examine the feasibility of the developed CE adoption framework. This approach works in two stages. In the first stage, BWM computes the final shortlisted CE indicators and assesses the intensity of influence of each indicator. Researchers' prime choice (Yadav and Desai, 2017) is Analytic Hierarchy Process (AHP) among all other multi-criteria decision-making (MCDM) approaches. These decision-making approaches work on the principle of pair-wise comparison. Computation of weights in these approaches becomes complex when the number of considered criteria is large. Researchers (Gupta and Barua, 2017; Sadeghi et al., 2016) recommend BWM over other MCDM approaches where large numbers of criteria are dealt with. In this study, BWM has emerged as the best approach to compute the criteria weights as there are 31 CE indicators. BWM effectively deals with vagueness and bias within the experts' judgements.

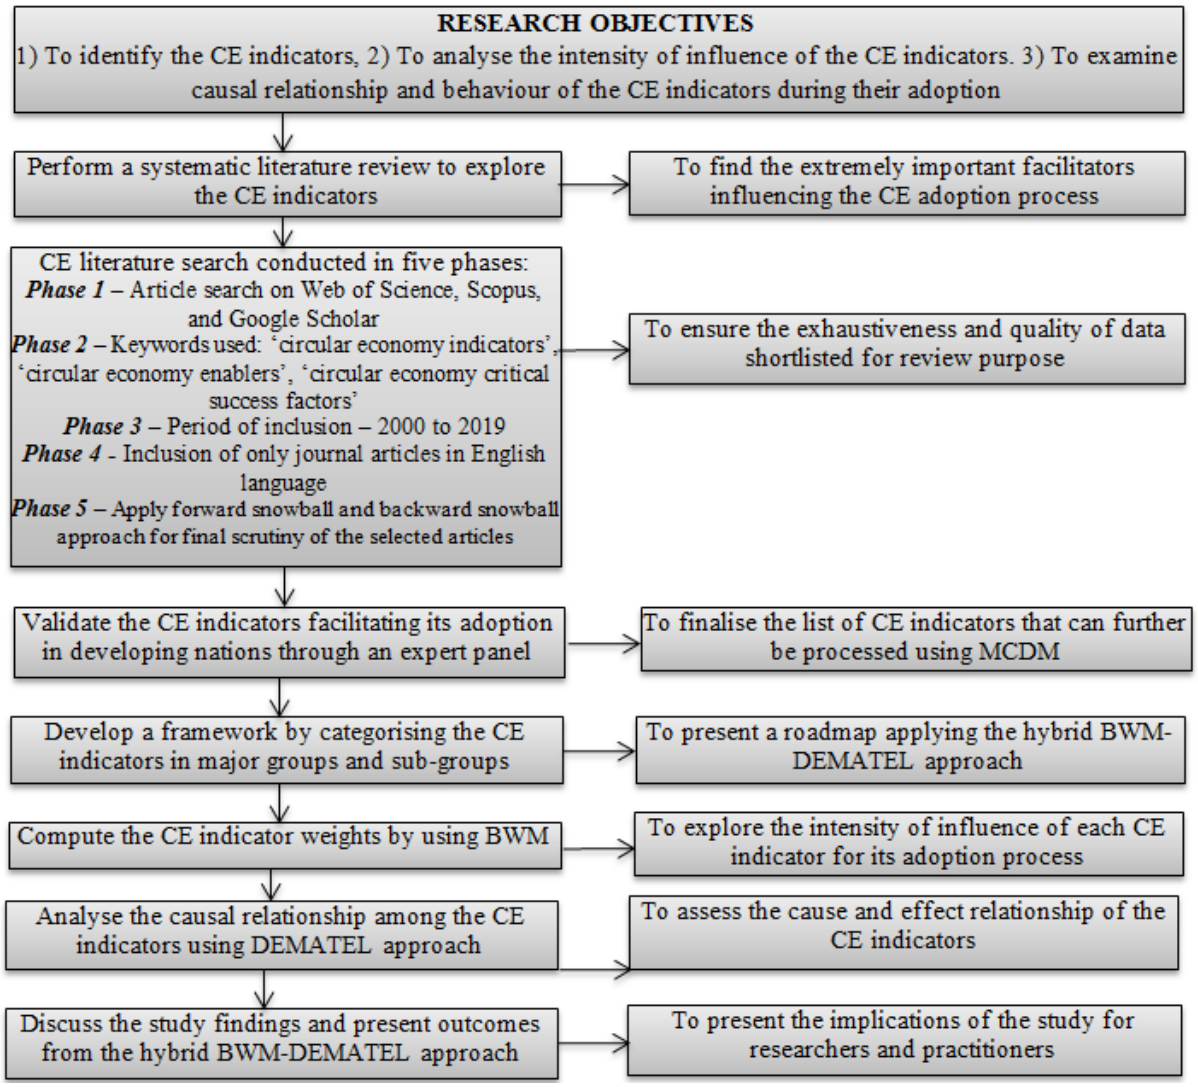

Figure 1: Research methodology

Note: CE- Circular Economy, BWM- Best Worst Method, DEMATEL- Decision Making Trial and Evaluation Laboratory, MCDM- Multi-Criteria Decision Making

The second stage of the two-stage hybrid BWM-DEMATEL approach analyses the causal relationship among the CE indicators. It is significant to assess how one indicator relates to the other. Several MCDM approaches may serve this purpose. Some of these are Analytical Network Process (ANP), Interpretive Structural Modelling (ISM), Fuzzy Cognitive Maps (FCM) and Decision Making Trial and Evaluation Laboratory (DEMATEL) etc. ISM and FCM are preferred in situations where structural hierarchy is required. However, in situations, where the causal relationships among the selected factors need to be examined, DEMATEL emerges as the prime choice. DEMATEL assists in examining the cause and effect factors, which facilitates the practitioners to effectively adopt CE.

4. Development and Testing of the Circular Economy Adoption Framework

4.1 Problem Description

In this study, a case study approach helps provide a theoretical background. The case of a heavy manufacturing company operating in western India is considered. The company is involved in manufacturing of a variety of products, such as motors and hydro turbines, industrial pumps, agriculture and household pumps etc. There are more than 1000 employees in the organisation. The organisation has a turnover of approximately US $10 billion.

The case company has a well-framed organisational mission with an objective of reducing its overall environmental impact and achieving sustainability in business. The company has adopted the CE initiatives, such as carbon neutrality, ISO 14001 and hierarchy of wastes (i.e. rethink and redesign, reduce, reuse, recycle, and dispose) in their business. The management of the company is committed to developing high-quality products and involved in a project titled "*circular economy and sustainability initiatives*". The management seeks to identify possible key indicators for CE implementation and subsequently aim to analyse the indicators for a successful CE adoption process. Additionally, the management is interested to analyse the cause and effect relations within the CE indicators.

To deal with the problem of the case company, an expert panel comprising six members is formed. The panel includes a production and planning manager, procurement manager, general manager, information technology engineer and environmental scientist. The literature reveals that the number of experts between five to eight is sufficient for the application of hybrid BWM-DEMATEL approach (Rezaei, 2016). Unlike other MCDM approaches the selected approach in this study requires less number of decision makers to arrive at the final judgement. Researchers (Ijadi Maghsoodi et al., 2019; Pourhejazy et al., 2019) have used an expert panel comprising four to six members to form case study judgements. Following the same analogy, in this study, a decision panel comprising six experts is formed. This research is employed to a limited setting steered with a case study approach of comparable sample size comprising six experts. However, it sets a ground for future study that could be extended to larger sample to test and validate the outcomes.

The selection of experts is decided based on certain criteria, such as the members' industrial and consultancy experience, decision-making competencies, respective designations and expertise in the domain etc. The experts are contacted for data collection. The framework of the CE indicators is analysed using the hybrid BWM-DEMATEL approach, details of which are provided in the following sections.

4.2 Determining the Circular Economy Indicators' Weights

The experts are initially asked to categorise the CE indicators identified from the literature. The indicators are categorised in five broad groups, viz. managerial indicators, organisational indicators, supply chain indicators, informational and technological indicators, and strategy and policy indicators. The framework developed for the CE adoption process is elucidated in Figure 2.

[Figure 2 about here]

The intensity of influence of the CE indicators is determined using the BWM approach. The steps adopted in BWM are as follows (Rezaei, 2016):

Step 1: Exploring the CE indicators – This step involves identification of the CE indicators influencing its adoption in developing nations. All the indicators are allotted criteria as i_1, i_2, i_3…… i_n.

Step 2: Diagnosing the best and worst indicators – This step involves grouping of the CE indicators across diverse groups and then finding the best and worst indicators for the disparate major groups and each sub-group.

Step 3: Allotment of preference – In this step, a separate table for best and worst comparison is computed through the expert judgements by assigning numerals between 1 and 9. The assignments are performed separately for the main group indicators and sub-group indicators. The best and worst comparison of the major group indicators is illustrated in Tables 2 and 3 respectively. Equation (1) represents the comparison set of Best (A_B) and Worst (A_w) criteria.

$$A_B = (a_{1b}, a_{2b}, a_{3b}\ldots. a_{nb}),\ A_w = (a_{1w}, a_{2w}, a_{3w}\ldots. a_{nw}) \quad (1)$$

Table 2: Best-to-Others (BO) comparisons for the main group indicators

Resp. No.	Best	MG	OG	SP	IT	SC
1	SP	6	3	1	5	2
2	MG	1	4	5	3	6
3	MG	1	4	6	2	5
4	OG	2	1	5	2	4
5	SC	4	5	4	2	1
6	SP	6	4	1	5	2

Note: MG- Managerial Indicators, OG- Organisational Indicators, SP- Strategy and Policy Indicators, IT- Informational and Technological Indicators, SC- Supply Chain Indicators

Table 3: Others-to-Worst (OW) comparisons for the main group indicators

Resp. No.	Worst	MG	OG	SP	IT	SC
1	MG	1	2	6	2	5
2	SC	6	3	2	4	1
3	SP	7	3	1	6	3
4	SP	4	5	1	4	2
5	OG	4	1	2	4	5
6	MG	1	3	6	2	5

Step 4: Computing the CE indicator weights – An objective function along with some constraints is formulated to compute the CE indicator weights,. Equation (2) represents a comparison of each constraint with the best criterion for all values of j. Similarly, equation (3) represents a comparison of each constraint with the worst criterion for all values of j. Equation (4) indicates that the sum of the weights of all the criteria should be equal to 1.

Min ξ

Subject to

$$\left| \frac{wB}{wj} - a_{Bj} \right| \leq \xi, \text{ for all values of j} \quad (2)$$

$$\left| \frac{wj}{ww} - a_{jw} \right| \leq \xi, \text{ for all values of j} \quad (3)$$

$$\sum_j wj = 1 \quad (4)$$

$w_j \geq 0$, for all values of j.

The linear programming model is used for computing weights of the CE indicators. The comparative judgements for the major group indicators are obtained computing the weights using the equations 2 to 4. The local weights obtained for the major group indicators are illustrated in Table 4.

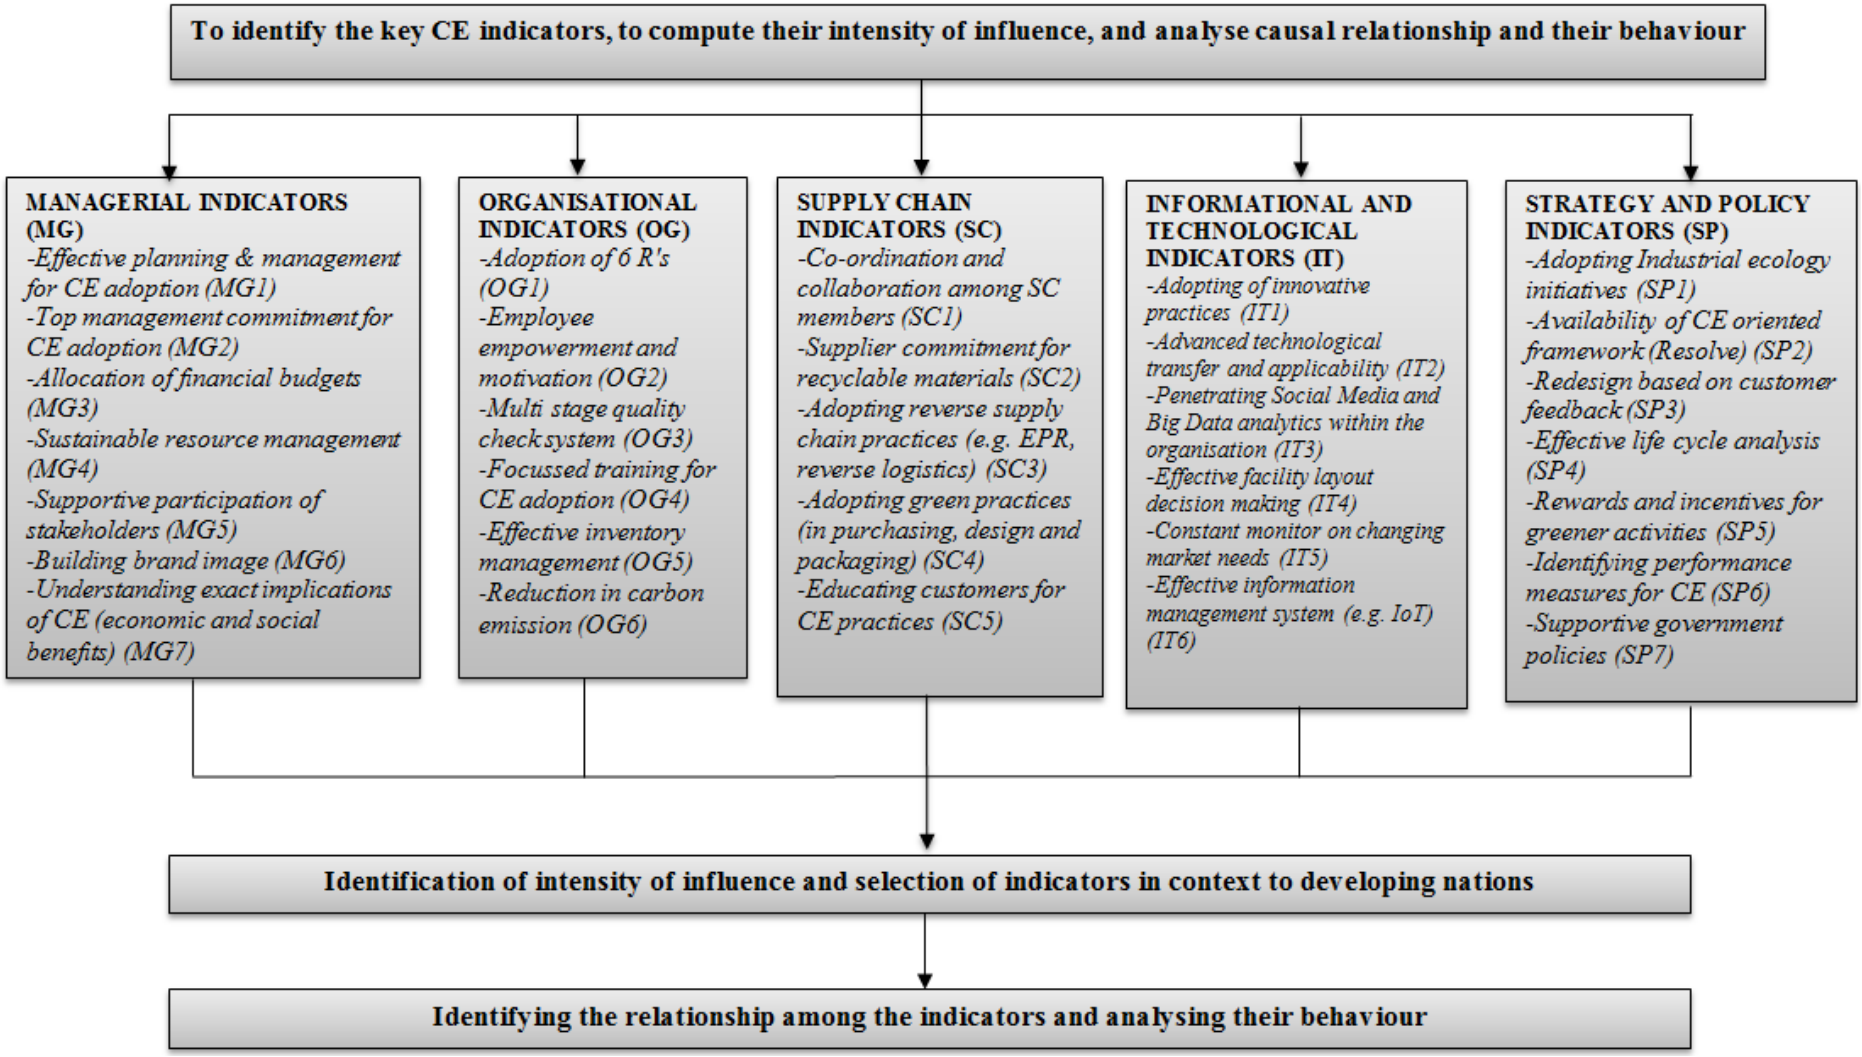

Figure 2: Framework for the CE adoption process

Table 4: Local weights obtained for the main group indicators

Expert number	MG	OG	SP	IT	SC	ξ
1	0.061475	0.163934	0.430328	0.098361	0.245902	0.061475
2	0.487145	0.142084	0.113667	0.189445	0.067659	0.081191
3	0.439883	0.131965	0.058651	0.26393	0.105572	0.087977

5	0.19245	0.074019	0.144338	0.473723	0.11547	0.103627
6	0.064103	0.128205	0.448718	0.102564	0.25641	0.064103
Criteria weight	**0.243924**	**0.171127**	**0.210488**	**0.224418**	**0.150043**	**0.074799**

A similar procedure is used while determining local weights of all the sub-group indicators. The values of ξ for all the group and sub-group comparisons are found to be consistent. The global weights are obtained (Table 5) after determining the local weights for all the sub-groups.

Table 5: Global weights of the CE indicators

Indicator	Major group	Sub-group code	Sub-group local weight	Global weight	Rank
Managerial indicators (MG)	0.244	MG 1	0.174	0.042	6
		MG 2	0.192	0.047	4
		MG 3	0.140	0.034	13
		MG 4	0.160	0.039	7
		MG 5	0.113	0.027	22

		SP 2	0.263	0.055	2
		SP 3	0.038	0.008	31
		SP 4	0.132	0.028	20
		SP 5	0.169	0.036	11
		SP 6	0.108	0.023	27
		SP 7	0.174	0.037	8

Note: For the abbreviation of all the subgroup code please refer to Figure 2

The global weights of all the sub-group indicators form a cluster diagram (Figure 3).

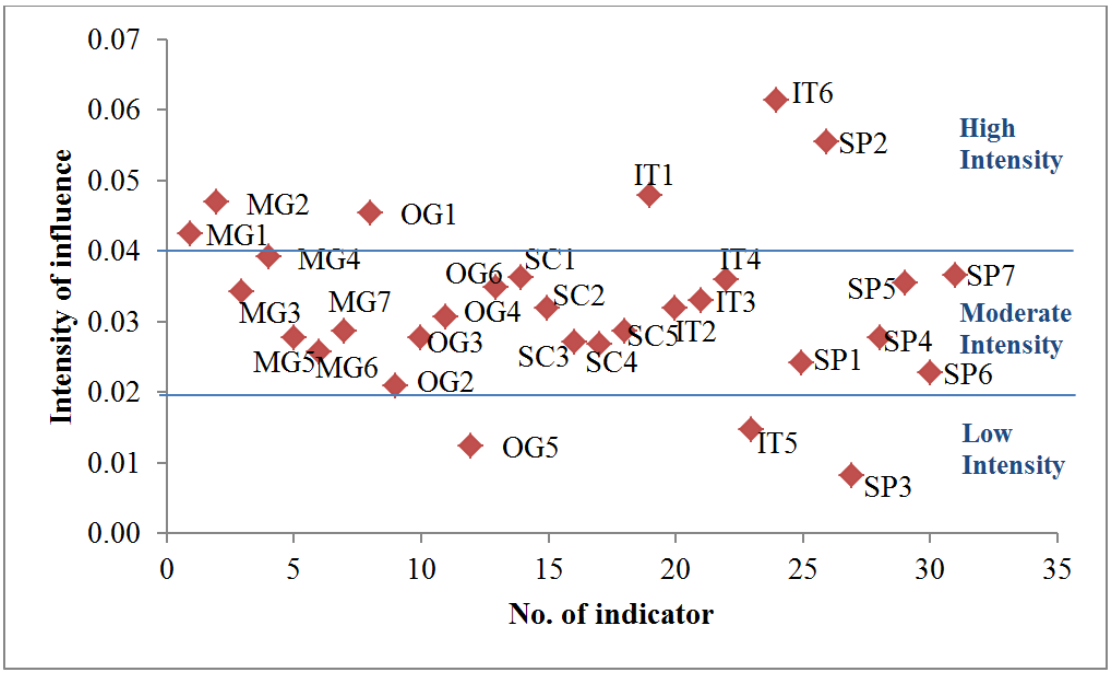

Figure 3: Cluster diagram for the CE indicators

Note: For the abbreviation of all the subgroup code please refer to Figure 2

The cluster diagram represents different intensities of the CE indicators falling in different clusters viz. high intensity, moderate intensity and low-intensity indicators. It is observed that six indicators fall in the high-intensity cluster, twenty-two indicators fall in the moderate-

intensity cluster and three indicators fall under the low-intensity cluster. The low-intensity cluster indicators are 'effective inventory management' (OG5), 'constant monitoring of changing market needs' (IT5), and 'redesign based on customer feedback' (SP3). These results are discussed with the experts, and the indicators found under the low-intensity cluster are excluded for further processing. According to experts, CE concepts are in the very initial stage in developing nations such as India. Both the organisation and its customers are unsure about CE adoption. Hence, at this level, these low-intensity cluster indicators can be dropped from the framework development process.

4.3 Analysing the Causal Relationship of the Circular Economy Indicators

A total of 31 CE indicators are selected at the beginning, which is subsequently filtered to 28 indicators under the five major groups through the BWM approach in the previous stage. The main aim is to analyse the causal relationship among the available CE indicators through the cause and effect indicators. In this regard, the procedure adopted for executing the DEMATEL approach is explained below (Abdullah and Zulkifli, 2015):

Step 1: Defining the CE indicators – All the CE indicators including major and sub-group indicators from the output of the BWM approach are considered as input to this approach. However, the grouping of the indicators is retained as that of the previous stage. Only the indicators dropped in the previous stage are excluded while applying this approach.

Step 2: Development of indirect relation matrix and average matrix – The experts are asked to rate the indicators based on their relationship with the other indicators on a scale of 0 to 4, where, '0 – no influence', '1 – weak influence', '2 –moderate influence', '3 – strong influence', and '4 – extremely strong influence'. Hence, with the input of six available experts, six different matrices are formed for the major group indicators. An average of all these matrices for the major group indicators is determined (in Table 6). A similar procedure is followed for all the sub-group indicators.

Table 6: Average matrix of the major groups of the CE indicators

Major group	MG	OG	SP	IT	SC
MG	0	3.8	3.6	3.6	3.4
OG	2.8	0	3	3.2	2.6
SP	3.2	3.2	0	3.4	3
IT	2.8	3	3.2	0	3.4
SC	2.6	2.4	2.2	3	0

Step 3: Computing normalised direct relation matrix (D) – The average matrix determined in the last step is now converted into a normalised direct relation matrix by using the equation (5):

$$D = M \times S \tag{5}$$

Where, S is computed by using equation (6)

$$\min\left[\frac{1}{\max\sum_{j=1}^{n}|m_{ij}|}, \frac{1}{\max\sum_{i=1}^{n}|m_{ij}|}\right] \tag{6}$$

The normalised matrix found for the major group CE indicators is illustrated in Table 7.

Table 7: Normalised matrix of the major groups of the CE indicators

Major group	MG	OG	SP	IT	SC
MG	0.000	0.264	0.250	0.250	0.236
OG	0.194	0.000	0.208	0.222	0.181
SP	0.222	0.222	0.000	0.236	0.208
IT	0.194	0.208	0.222	0.000	0.236
SC	0.181	0.167	0.153	0.208	0.000

Similarly, this procedure is repeated for computing the normalised matrix for all other sub-group indicators.

Step 4: Development of total relation matrix – The total relation matrix for the CE indicators is found using equation (7).

$$T = D\,(I\text{-}D)^{-1} \qquad \ldots (7)$$

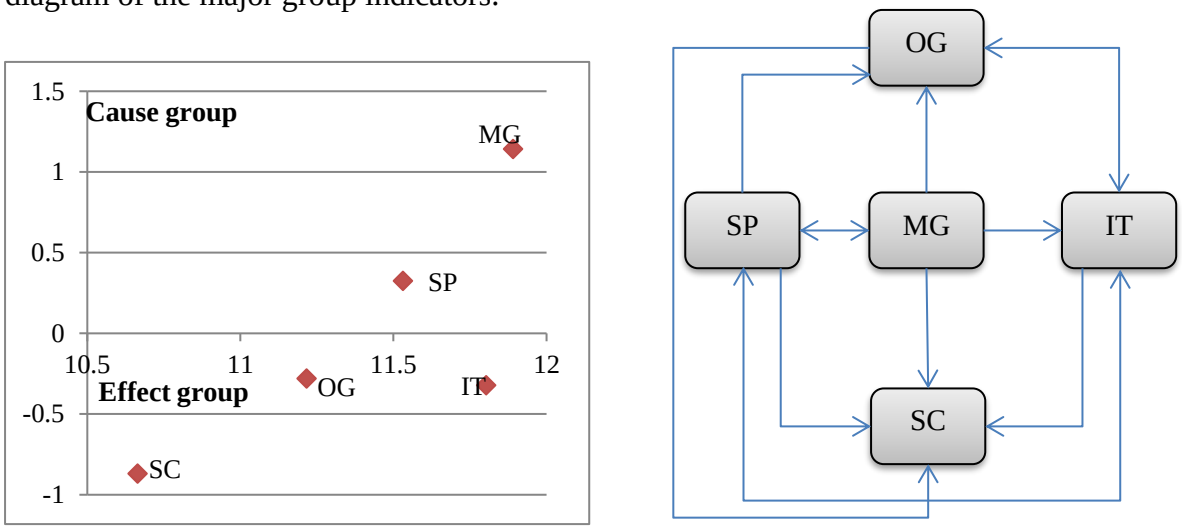
The total relation matrix for the major group indicators is illustrated in Table 8.

Table 8. Total relation matrix of the major groups of the CE indicators.

Major group	MG	OG	SP	IT	SC	ri	ri + cj	ri - cj
MG	1.076	*1.360*	*1.322*	*1.414*	*1.345*	6.517	11.891	1.143
OG	1.066	0.966	1.114	*1.200*	1.122	5.468	11.216	-0.280
SP	*1.161*	*1.229*	1.021	*1.295*	*1.223*	5.928	11.531	0.326
IT	1.111	*1.185*	*1.169*	1.069	*1.208*	5.741	11.803	-0.320
SC	0.961	1.008	0.977	1.084	0.868	4.898	10.664	-0.868
Sum cj	5.374	5.748	5.602	6.062	5.766	***Threshold value = 1.142***		

All the rows and column of the total relation matrix are added together. The row sum (r_i) represents the direct and indirect effect of r_i over other indicators. Similarly, the column sum (c_j) represents the direct and indirect effect experienced by indicator j from all other indicators. However, (r_i - c_j) can be defined as the net effect by which a particular indicator influences the entire system. The positive value of (r_i - c_j) is known as cause indicator while its negative value is termed as effect indicator.

Step 5: Identification of threshold measure – The threshold measure (Table 8) is identified to generate both causal digraph and relationship diagram. Considering all the values above the threshold measure the connections between the indicators are established for generating the relationship diagram. A similar procedure is carried out for computing the total relation matrix for the subgroup indicators. Based on the threshold values and ri, cj values, the causal digraph and relationship diagram are developed. Figure 4 presents the causal digraph and relationship diagram of the major group indicators.



(a) Causal digraph **(b) Relationship diagram**

Figure 4: Causal digraph and relationship diagram for the major group indicators

Figure 4(a) illustrates the causal digraph of major group indicators. It is found that 'managerial indicators' and 'strategy and policy indicators' exist in the cause group cluster. The effect group cluster includes 'informational and technological indicators', 'organisational indicators' and 'supply chain indicators'. The relationship diagram in Figure 4(b) elucidates inter-relationships among other indicators. The managerial indicators and strategic and policy indicators strongly correlate to other major group indicators. The strategic indicators help in developing organisational and supply chain indicators. The strategic indicators are equally dependent on informational and technological indicators. Similarly, the causal digraph and

relationship diagram for the sub-indicators are obtained (shown in Figures A1, A2, A3, A4 and A5 of Appendix A).

5. Results and Discussion

The outcomes from the BWM approach portray that 'informational and technological indicators' (0.244) and 'managerial indicators' (0.243) possess the extreme importance in the CE adoption followed by 'strategy and policy indicators' (0.210), 'organisational indicators' (0.171) and 'supply chain indicators' (0.150). This corroborates with the findings of Lazarevic and Valve (2017) and Lieder and Rashid (2016). Govindan and Hasanagic (2018) emphasised on strategy and policy-related indicators to adopt CE effectively. Among the sub-group indicators, 'effective information management system' (0.061), 'availability of CE oriented framework' (0.055) and 'adopting of innovative quality practices' (0.048) appear to be the most critical indicators strongly affecting CE adoption. However, 'top management commitment for CE adoption' (0.042) and 'adoption of 6R's' are strong facilitators for the CE adoption process. Korhonen et al. (2018b) reported that ignorance of management towards CE adoption and considering the adoption of 6R's on least priority may lead to failure of the CE adoption.

The CE indicators are plotted within clusters based on their calculated weights. Six indicators are found to be in a high-intensity cluster, twenty-two in the moderate-intensity cluster and three indicators in the low-intensity cluster. Based on the discussion with experts, 'effective inventory management' (OG5), 'constant monitoring of changing market needs' (IT5), and 'redesign based on customer feedback' (SP3) are dropped from further assessment. Experts suggest that although these indicators are related to the CE adoption process, in the developing nations' economy context they possess low influence. These indicators must be included after the appropriate assessment when considering CE adoption for the developed nations. Pomponi and Moncaster (2017) indicated that effective inventory management has an indirect effect on the CE adoption process. Therefore, a total of 28 CE indicators are finally considered for the CE adoption framework in the developing nations' economy context. These indicators are taken as input for the second stage of the hybrid approach.

The outputs from the BWM approach are considered as inputs in DEMATEL. DEMATEL generates causal digraphs and relationship diagram for the major group indicators and other sub-group indicators. Among all the major group indicators, managerial indicators and strategy and policy indicators are found to be the cause indicators. These indicators help in developing other indicators, viz. information and technology indicators, organisational indicators and supply chain indicators. Homrich et al. (2018) indicated that managerial indicators are strong

driving factors that assist in developing other indicators for effective CE adoption. Mathur et al. (2012) explained the importance of managerial and strategic indicators considering the case of the Indian manufacturing organisation. They further suggest that by adopting the strategic indicators, the practitioners can execute the organisational indicators more easily. Geng et al. (2012) reported managerial indicators as the most significant indicators for the CE adoption while elucidating a case from China. The relationship diagram (Figure 4b) indicates the influence of managerial and strategic indicators in achieving all other major group indicators. The causal digraph in Figure 4a reveals that for effective implementation of the organisational indicators, it is required to have the strong support of managerial, strategic and informational and technological indicators.

Low penetration of the following indicators reduces the success possibility of the CE adoption, viz. 'effective planning and management for CE adoption', 'top management commitment for CE adoption' and 'supportive participation of stakeholders'. These indicators strongly drive the other indicators. Therefore, it is extremely difficult to adopt CE without the support of top management and stakeholders. This is corroborated in the study of Saavedra et al. (2018) and Whicher et al. (2018). Among the organisational indicators, 'adoption of 6R's' and 'reduction in carbon emission' strongly drive other indicators of its sub-group. This is corroborated in Sarkis and Zhu (2017) when they identify 6R's (i.e. redesign, reduce, recycle, reuse, recover and remanufacturing) as the most essential component for the CE adoption in manufacturing organisations. Within the supply chain indicators, 'co-ordination and collaboration among SC members', 'supplier commitment for recyclable materials', and 'educating customers for CE practices' possess a high impact on other supply chain indicators. Accordingly, suppliers' commitment to supply recyclable materials ensures green practices in purchasing, design and packaging (Zhu et al., 2010).

Among all the informational and technological indicators, 'adopting of innovative practices', 'effective facility layout decision making' and 'effective information management system (e.g. IoT)' possess a strong influence on other indicators in the same group. The results affirm that an effective information system holds a strong relation in achieving other informational indicators. The findings of Kirchherr et al. (2017) corroborate this as they report that poor information flow within an organisation can lead to a failure in the CE adoption process. The findings reveal that within the strategy and policy indicators, 'availability of CE oriented framework', 'rewards and incentives for greener activities', and 'supportive government policies' drive other strategic and policy indicators. Urbinati et al. (2017) reported that the CE oriented framework is responsible for its successful adoption. However, researchers

(Kirchherr et al. 2017; Geng et al. 2012) suggested various frameworks for the CE adoption process and subsequent improvement of the organisational performance.

6. Contributions and Implications

The findings from this study are equally beneficial for researchers, practitioners and policymakers. The findings contribute to theory and practice in the following ways:

- The extant literature on the CE adoption process does not shed any light on the manufacturing sector. This study guides the practitioners in the CE adoption process within the manufacturing organisation. As the study finding guides them to develop the roadmap that improves CE adoption.
- Several studies on CE indicators report a very limited set of indicators facilitating the CE adoption process. This study identifies 31 key indicators that influence the CE adoption process in the context of developing nations' economy. Further, this is a unique study that not only develops a framework for CE adoption but also justifies it through a hybrid BWM-DEMATEL approach. As observed in the literature, very few studies include multi-criteria decision-making treatment for obtaining the inter-relationship of the indicators.
- All the CE indicators cannot be implemented simultaneously. However, if the causal relationship among these indicators is obtained, it will facilitate practitioners and decision-makers of manufacturing companies to plan some effective CE adoption strategies. This study explicitly examines the causal relationship among each set of the major group indicators and sub-group indicators that will assist the practitioners and researchers to understand the behaviour of the indicators.
- The identified CE adoption framework and indicators are in the context of developing nations' economies. However, the same indicators can be employed to developed economies with appropriate modifications by consulting experts. Hence, this can be considered as a unique contribution in context to the developing nations.

6.1 Recommendations for the Developing Economy

Adoption of CE is comparatively easier in the developed nations than the developing nations. Many developing nations, such as China, India, Malaysia, Sri Lanka etc., are initiating various attempts for CE adoption, but could not achieve the success rate as expected. Unavailability of a robust CE oriented framework has been one of the prime reasons behind

the CE adoption failures. Therefore, practitioners are recommended to obtain support from the government. These include the exemption in taxes, rebates and various other incentives to the organisations adopting CE. An effective CE adoption will enhance export possibilities thereby directly contributing to the nation's economy. It is further recommended to adopt industrial ecology initiatives as this will help in improving organisational performance and support sustainability initiatives. Adoption of CE directly relates to sustainability. Therefore, incentives for the adoption of green practices and usage of sustainable resources are recommended. Effective life cycle analysis will help in identifying the disposal period of products, which can support an effective CE adoption process.

7. Conclusions and Scope for Future Research

The manufacturing sector has a strong contribution to building nations' economy, especially in developing countries. This study conducts an exhaustive literature review to identify a unique set of 31 critical indicators facilitating the CE adoption process in the context of developing nations. Further, this study develops a framework for enhancing the CE adoption process through an exhaustive analysis of the indicators. A hybrid BWM-DEMATEL approach is applied to the developed framework to test its feasibility. BWM is adopted to compute the indicator weights. DEMATEL is used to analyse the causal relationship of the indicators through causal digraph and relationship diagram of the major group indicators and sub-group indicators. This study attempts to cover the CE indicators across five major groups among which managerial, informational and technological, and strategic indicators emerge as strongly influencing indicators for the CE adoption process. The results indicate that the managerial and strategic indicators fall in the cause group which facilitate the development of the effect group indicators, viz. information and technological, supply chain and organisational indicators. The case of an Indian manufacturing organisation elucidates in understanding the CE adoption framework, which is extremely useful for developing nations.

Although this study elucidates the CE adoption framework through a case of a manufacturing organisation, CE can be adopted across other industry sectors. Therefore, the same framework can be employed in other business sectors by appropriately tweaking the input indicators. Future research can be conducted through a large scale survey which will strengthen the validity of the CE indicator sets. Future research may adopt other decision-support methods to examine and analyse the CE indicators. Interpretive structural modelling (ISM), fuzzy cognitive map (FCM) and other structural approaches can be adopted to validate the CE indicators and its adoption framework.

Acknowledgements: We express our sincere thanks to the experts from the case organisation for providing the data to perform the case analysis.

A Framework to Achieve Sustainability in Manufacturing Organisations of Developing Economies using Industry 4.0 Technologies' Enablers

Abstract: Sustainability has emerged as one of the most important issues in the international market. Ignorance of sustainability aspects has led many manufacturing organisations to face huge financial losses. It has been observed that developed nations have successfully achieved sustainability in their manufacturing sectors. However, the rate of sustainability adoption in developing nations is significantly poorer. The current business trend offers new technologies such as the Internet of Things, Big data analytics, Blockchain, Machine learning, etc. These technologies can be termed under the Industry 4.0 paradigm when considered within a manufacturing context. It is significant to notice that such new technologies directly or indirectly contribute to sustainability. So, it is necessary to explore the enablers that facilitate sustainability adoption. This study aims to develop a framework to improve sustainability adoption across manufacturing organisations of developing nations using Industry 4.0 technologies. Initially, the enablers that strongly influence sustainability adoption are identified through a literature review. Further, a large scale survey is conducted to finalise the Industry 4.0 technologies' enablers to be included in the framework. Based on the empirical analysis, a framework is developed and tested across an Indian manufacturing case organisation. Finally, Robust Best Worst Method (RBWM) is utilised to identify the intensity of influence of each enabler included in the framework. The findings of the study reveal that managerial and economical, and environmental enablers possess a strong contribution toward sustainability adoption. The outcomes of the present study will be beneficial for researchers, practitioners, and policymakers.

Keywords: Sustainability; Manufacturing supply chain; Industry 4.0; Developing nations; New technologies, Empirical study, Robust Best Worst Method (RBWM).

1. Introduction

The constantly changing market needs and limited profit margins have push manufacturing organisations to revisit their existing process structures [1]. For this purpose, business managers constantly look to adopt new technologies for improving their entire supply chain

and achieve sustainability [2]. Even to compete in the international market, it is essential to develop sustainable products. It has become mandatory to consider the environment and societal aspects of manufacturing along with the economic consideration [3]. Hence, organisations are in search of new technologies that could fulfil their sustainability requirements [4]. Several alternatives such as Circular Economy (CE), Internet of Things (IoT), Big Data Analytics (BDA), Cloud Computing (CC), and Blockchain (BC), etc. have turned up to support the manufacturing, service, and healthcare sectors [5].

These technologies are broadly considered under the umbrella of Industry 4.0, which is considered as the next generation of the industrial revolution [6]. Particularly in developing nations, the manufacturing sector plays a strong role in building the nation's economy [7]. Various Multi-National Companies (MNCs) have shown their interest to develop their manufacturing set up in developing nations such as China, India, Thailand, and Brazil due to low manufacturing costs and cheap labour [8]. However, to improve the supply chain structure and achieve sustainability, Industry 4.0 has emerged as the most prominent solution in the present manufacturing scenario [9]. Nevertheless, Industry 4.0 adoption appears to be successful only in large scale organisations [10], whereas SMEs, especially in developing nations, struggle to achieve sustainability effectively [11].

The emerging economies of the world have succeeded in generating financial gains through their manufacturing sector; but, it is important to notice that these nations have been far away from achieving sustainability within their system [12]. Table 1 represents the status of emerging economies in achieving sustainability.

Table 1. Status of emerging economies in achieving sustainability [6][13][14]

S. No.	Country	GDP (Billion US $)	EPI Score (Global rank)	Renewable energy usage	GHGE (Global %)	MCG (%)	HDI (Global rank)	Type of economy
1	United States	20,494	71.19 (27)	14.7%	14.75%	18.9%	0.924 (13)	Developed
2	China	13,407	50.74 (120)	24.5%	27.50%	39.5%	0.752 (86)	Developing
3	Japan	4,971	74.69 (20)	15.0%	2.99%	29.7%	0.909 (19)	Developed
4	Germany	4,000	78.37 (13)	29.0%	1.98%	30.1%	0.936 (5)	Developed
5	United Kingdom	2,828	79.89 (6)	27.9%	1.20%	19.4%	0.922 (14)	Developed
6	France	2,775	83.95 (2)	17.5%	0.97%	28.9%	0.901 (24)	Developed
7	India	2,716	30.57 (177)	16.98%	6.43%	19.0%	0.64 (130)	Developing

8	Italy	2,072	76.96 (16)	37.3%	0.93%	24.0%	0.880 (28)	Developed
9	Brazil	1,868	60.70 (69)	80.4%	2.25%	21.0%	0.759 (79)	Developing
10	Canada	1,711	72.18 (25)	65.0%	1.63%	28.1%	0.926 (12)	Developed

Note: EPI- Environmental Performance Index, GHGE- Green House Gas Emission, MCG- Manufacturing Contribution to GDP, HDI- Human Development Index

Among the top ten emerging economies based on GDP, there are only three developing nations, namely; China, India, and Brazil. Similarly, the United States holds the highest GDP in the world, but its environmental performance index ranks 27th globally and uses only 14.7% of renewable energy resources for consumption. However, the case of developing nations is even worse. China ranks 120th, India 177^{th,} and Brazil- 69th for EPI. The same is the case for the human development index, where these countries rank 86th, 130th, and 79th respectively. It is painful to know that 35% of global greenhouse emissions are generated by these 3 developing countries collectively. Among these nations, the contribution of the manufacturing sector towards GDP is significant. Hence, it is strongly needed to achieve sustainability among developing nations through the manufacturing sector [15].

It is noticed in various studies that some organisations in developed nations such as Germany, the United States of America, the United Kingdom, etc. have already succeeded in achieving sustainability by adopting new technologies, especially Industry 4.0 [16]. Availability of infrastructure and advanced technological setups act as foundations for these nations, whereas these same factors also act as missing elements for developing nations [17]. Several authors [18–20] have reported a generalised set of Industry 4.0 technologies' enablers that smoothens the pathway to sustainability, but the applicability of these enablers is questionable in developing nations. Accordingly, there is an immediate requirement to identify the key Industry 4.0 technologies' enablers leading to sustainability in the context of SMEs of developing nations by considering economic, environmental and societal aspects [21]. The present study attempts to explore the key Industry 4.0 technologies' enablers that directly influence sustainability in manufacturing organisations of developing economies and determine their intensity of influence for achieving sustainability. Hence, a hybrid empirical-decision making approach is adopted in this study.

Based on the above-discussed issues the following objectives have been defined for the present study:

- To identify an exhaustive set of Industry 4.0 technologies' enablers to achieve sustainability as reported by researchers in the academic literature;
- To develop an Industry 4.0 technologies' enablers based framework within the context of manufacturing organisations from developing nations for achieving sustainability;
- To determine the intensity of Industry 4.0 technologies' enablers and assess their adoption influence by employing a decision-making approach.

To achieve the above-defined objectives the following process has been followed. Initially, an exhaustive literature review is carried out to explore the key Industry 4.0 technologies' enablers to achieve sustainability in manufacturing organisations of developing nations. Further, a large scale survey-based empirical analysis by considering the manufacturing industry of India is carried out to validate and confirm the list of enablers included in the study. India is a developing country and one of the fastest growing economies. Finally, Robust Best Worst Method (RBWM) is used to compute the weights of each shortlisted enabler to assess their intensity in achieving sustainability. The findings of the present study are equally beneficial for researchers as well as practitioners. This is a unique study that reports 29 key Industry 4.0 technologies' enablers to achieve sustainability and portray the directions for improving the status of sustainability in manufacturing organisations in developing nations. Policymakers can retrieve essential inputs to improve the policies for manufacturing organisations of developing nations.

2. Literature Review

It is important to explore the existing work before initiating any research [22]. Hence, a systematic literature review was conducted in order to ensure that the data to be reviewed was as relevant as possible. The literature review is presented in the following three sub-sections that include: article selection, industry 4.0 technologies' enablers, and literature gaps.

2.1 Article Selection

It is essential to consider the most relevant articles before conducting a literature review. Similarly, it is important to ensure the comprehensiveness and quality of the collected articles. Thus, the present study utilised a systematic literature review approach as suggested by [23], [24], and [25]. An initial search of articles was conducted on Scopus, Web of Science and Google Scholar databases. The following keywords were used for searching relevant articles, "new technologies and sustainability for industry 4.0" OR "enablers for sustainability" AND "Industry 4.0 technologies' enablers and sustainability". This initial search provided 988

articles. Later on; various other filters were used, e.g. (a) inclusion of only journal articles (393 articles), (b) inclusion of only English language articles (347 articles), (c) removal of duplicate articles across search databases (112 articles), (d) forward snowball and backward snowball technique (64 articles). The forward and backward snowball technique helped in ensuring that the articles that were shortlisted were strictly co-related with the area of research and served its purpose. Furthermore, the final shortlisted articles were studied individually to determine their relevance for the present research. The industry 4.0 enablers addressed in these studies were initially mapped in an excel sheet and later the repeating enablers were eliminated to ensure that the final list only contained unique enablers. The time horizon taken for the study was 2011- October 2019. The authors included research articles from the engineering, mathematics, computer science, decision science, management and accounting fields. Similarly, only journal articles were chosen for the study while all other types of articles that included book chapters, editorial notes, conference articles, short reviews, erratum, etc. were excluded during the article selection process. Articles 'in press' and 'under review' were considered during the initial screening process. The purpose of focusing on journal articles was to ensure the quality of data required for the present research.

2.2 Industry 4.0 Technologies' Enablers to achieve Sustainability

Manufacturing organisations play a vital role in building a nation's economy. Hence, it is essential to explore the critical enablers that lead to manufacturing sustainability. Liu et al. [26] insisted on the adoption of green design and disposal systems that strongly contribute to sustainability. Manufacturing organisations can proof their future not just by meeting the financial targets [27] but also by merging the environment and societal aspects with it [28]. Liu [29] also pointed out "adoption of sustainable energy resource system", "effective sustainability performance metrics", "adoption of industrial ecology initiatives", and "customer awareness for sustainability" as some crucial enablers leading to sustainability in manufacturing organisations. Similarly, it has been observed that manufacturing companies are one of the primary sources for generating pollution through harmful gas emissions [30]. Hence, companies must focus on preventive measures for reducing the emission leading to the pollution of the environment [8].

The role of stakeholders is extremely important in achieving organisational sustainability [5]. It is required for the management to have a strong involvement and commitment towards the adoption of sustainability [31]. However, Moktadir et al. [32] stated that it is necessary to understand the key benefits and long term implications of sustainability to meet organisational

goals. Managers must be aware of sustainability supportive policies [33]. Koplin et al. [31] highlighted the role of management towards sustainability adoption and listed out some critical enablers namely; “Policies of rewards and incentives for sustainability adoption”, “smart budget allocation”, “management engagement for sustainability adoption”. Management holds a strong command over the financial decisions to be made in alignment with organisational goals [34]. Hence, it becomes critical to allocate the budget smartly over different sections of the organisation. Promotion of industry IoT assists organisations to keep track of global advancement and helps in achieving sustainability throughout their process structure [35].

On the other hand, supply chain and logistics have a strong impact on operational and financial performance [36]. Hence, to withstand global competition, it is essential to digitise supply chain activities, which will help in real-time tracking of suppliers. Xu et al. [37] mentioned that it is extremely important to receive sustainable raw materials from a supplier if it is desired to manufacture a sustainable product. Adopting reverse logistics facilitates the reduction of product development costs and improve organisational profit margins [38]. It is desired to promote the adoption of knowledge management in the supply chain to make it more effective and competent to exert strong pressures of meeting sustainability requirements [29]. Some frameworks [39–41] proposed by researchers to achieve sustainability have focussed on the economic and environmental aspects of the organisations; but, have failed to capture the role of supply chain and logistics in achieving overall sustainability. It is necessary to understand that achieving organisational sustainability is not possible without greening the existing supply chain [42].

According to Beekaroo et al. [43], “many organisations struggle to achieve sustainability due to ignorance of the societal aspects”. Adoption of sustainable human resource management and practising health and safety modules within organisation leads to the roadmap towards sustainability. Moktadir et al. [32] portrayed various enablers such as “enhancement of man-machine-material interaction”, “understanding the implications of sustainability”, and “effective product life cycle analysis” for achieving sustainability in manufacturing organisations. Garbie [44] pointed out in their study that organisations should carefully track various stages of the product based on the life cycle analysis to fulfil the desired quality and after-sales service. Furthermore, the adoption of a decentralised system and constant tracking of stock and in-process inventory helps in the smooth running of the entire production system [45]. Managing data security and privacy strengthens sustainability in many aspects [46].

Apart from the organisational prospects, the information and technology showcase a significant contribution in achieving sustainability [14]. Based on the new technology and industrial revolution, the adoption of cyber-physical system has emerged as an important aspect. Similarly, "adoption of machine learning system", "effective execution of process optimisation techniques", "practising advance quality improvement techniques" are some of the critical enablers that smoothen the pathway to sustainability [47]. Lu [48] insisted on the adoption of an advanced information sharing system, which ultimately helps in analysing the existing process data more effectively. "Adoption of additive manufacturing system" and "penetration of flexible manufacturing system" are extremely important to compete with global competitors [44]. It is desired that the manufacturing system should be flexible enough to adapt to the continuous changes desired by customers to sustain their product globally [49]. A detailed list of Industry 4.0 technologies' enablers influencing sustainability adoption are portrayed in Table 2.

Table 2. Industry 4.0 technologies' enablers reported by existing literature to achieve sustainability

S. No.	Industry 4.0 technologies' enablers	Description	Literature support
1	Green design and disposal system	Adoption of environmentally friendly design and disposal system supports sustainability	[32]
2	Adoption of sustainable energy resources system	Enhancing the usage of sustainable and renewable energy resources will ensure improved performance	[28,29]
3	Educating customers for sustainability	Awareness of sustainability concepts among the customers will enhance its adoption rate	[5,32]
4	Adoption of industrial ecology initiatives	Industrial ecology initiatives promote CE and tackle environmental concerns effectively	[26, 37, 40]
5	Adoption of cyber-physical system	Adopting a cyber-physical system will lead to a sustainable future and facilitate advance technology acceptance	[29,41,48]
6	Adoption of a machine learning system	Machine learning system will reduce human interaction and improve precision in the manufacturing organisation	[38,49,50]
7	Adoption of an additive manufacturing system	Additive manufacturing system reduces manufacturing costs and helps in developing sustainable products	[1,51,52]
8	Penetration of the flexible manufacturing system	Flexible manufacturing system assists in quick product modification to meet sustainability and customer requirements	[37,38]

9	Effective sustainability performance metrics	Adoption of sustainability performance metrics ensures tracking of manufacturing activities and aligning sustainability	[48,53]
10	Continuous monitoring of reduction emission	Reduction in emission is an important aspect to protect the environment pollution	[54,55]
11	Adoption of effective process optimisation techniques	Optimisation techniques help in standardising the manufacturing process and design-related activities	[56,57]
12	Adoption of advanced quality improvement techniques	Adopting quality improvement techniques helps in improving the organisational performance	[58]
13	Advanced information sharing systems	Smooth and effective information sharing system helps in building collaboration among the system aligned activities	[1,5]
14	Sustainable human resource management	Sustainable human resource management is an essential aspect to roadmap sustainability by considering human relations and related activities	[51,52]
15	Adoption of health and safety modules	Health and safety measures adopted within the organisation provides stability to employees and develops a sustainable working culture	[29,43]
16	Constant tracking of stock and in-process inventory	Effective monitoring of existing stocks and in-process inventory will ensure uninterrupted functioning of the manufacturing process	[1,5]
17	Adoption of the decentralised system	Adoption of the decentralised system facilitates the tracking of departmental activities and enhance process focus	[28,29]
18	Enhancement of man-machine-material interaction	Improving the man-machine-material interaction will strengthen the sustainability of the final product	[48,53]
19	Adopting reverse logistics	Reverse logistics ensures the execution of corrective actions on product and process development	[37,38]
20	Adoption of sustainability supportive policies	Government offers various sustainability supportive policies for the manufacturing organisations to develop an overall sustainable environment	[1,50]
21	Promoting Industry internet of things	Promotion of industry IoT helps the organisations to compete at the global level and achieve international standards	[32,50]
22	Smart budget allocation	Smart budget allocation helps in distributing the available financial resources effectively among the entire organisational structure	[51,52]
23	Adoption of smart factory components	Adopting smart factory components ensures overall sustainability including economic, environmental and societal concerns	[29,43]
24	Management engagement towards sustainability adoption	It is necessary to have strong involvement of management and positive perception towards sustainability adoption	[1,5]

25	Policies of rewards and incentives for sustainability adoption	Policies of rewards and incentives for sustainability adoption will enhance the employee involvement towards sustainability	[28,29]
26	Managing data security and handling	Industry 4.0 ensures securing the organisational data and using it for improving the operational performance	[37,38]
27	Understanding the implications of sustainability	It is important to understand the exact implications of sustainability and its impact on the near future	[29,43]
28	Effective product life cycle analysis	Design, analysis, production, promotion, and abortion of product should be analysed based on product life cycle analysis	[1,50]
29	Digitisation of supply chain activities	Digitising the supply chain activities improve supply chain performance and boosts sustainability	[48,53]
30	Real-time tracking of suppliers	Real-time tracking of suppliers assists in keeping the inventory stocks at optimum levels	[32]
31	Promoting knowledge management in supply chain	Practising knowledge management in the supply chain improves supply chain sustainability and logistics performance	[51,52]
32	Supplier commitment for sustainable procurement	It is required to have a strong commitment of suppliers to execute sustainable procurement practices to roadmap sustainable product development	[1,5]

2.3 Literature Gaps

Based on the literature reviewed on Industry 4.0 technologies' enablers for sustainability, the following knowledge gaps in the academic literature were identified.

- The existing literature has highlighted several studies [8,34,51] that helped in showcasing the enablers that assist in achieving sustainability across manufacturing organisations. However, very few studies have pointed out the enablers relating to new technologies.
- Researchers [3,37] in the existing literature portrayed a list of enablers influencing sustainability. Nevertheless, these studies have failed to establish a linkage on how these enablers impact the adoption of sustainability.
- Several studies [38,59] based on the enablers for sustainability adoption in manufacturing organisations have only used empirical analysis as a tool for framework validation. Although, it is essential to employ any decision-making approach.
- The mere identification of enablers supporting sustainability in manufacturing organisations is not sufficient [60]. Hence, it is essential to identify the intensity of

influence of each enabler on sustainability adoption through multi-criteria decision-making approaches.

- Various studies [31,43] have shared success stories of new technology adoption across developed nations. However, very few studies were able to succeed in achieving sustainability among manufacturing organisations in developing economies.
- Few studies [61-63] have developed an enabler specific framework and considered only Technology, Organisation and Environment (TOE) to enhance sustainability adoption. However, these frameworks have not been verified and hence, their applicability is questionable.

The above-mentioned gaps suggest the need for research work that highlights the enablers supporting sustainability adoption across manufacturing organisations in developing nations. Furthermore, it is required to determine the intensity of the influence of these enablers in sustainability adoption. These gaps support objectives defined at the beginning of this study.

3. Research Methodology

This study initially conducted a systematic literature review to explore the key enablers based on Industry 4.0 technologies, which supports sustainability adoption. The identified enablers were further tested through a large scale survey to ensure that the selected set of enablers possessed a strong influence on sustainability adoption across manufacturing organisations of developing economies. An empirical analysis was then carried out to group the selected enablers and finalise them. Later, a manufacturing case organisation was selected to conduct a case analysis. An expert panel was formed by including the members of the case organisation. This panel was utilised to categorise the selected enablers. Then, an enabler based framework to enhance sustainability adoption was developed and supplied to the case organisation. The inputs for the RBWM approach were also obtained through the expert panel. The results of the RBWM approach helped in identifying the intensity of each enabler on sustainability adoption.

3.1 Research Methods Adopted for the Study

The present research was underpinned by a mixed method research approach. The methodological flow of the research is illustrated in Figure 1.

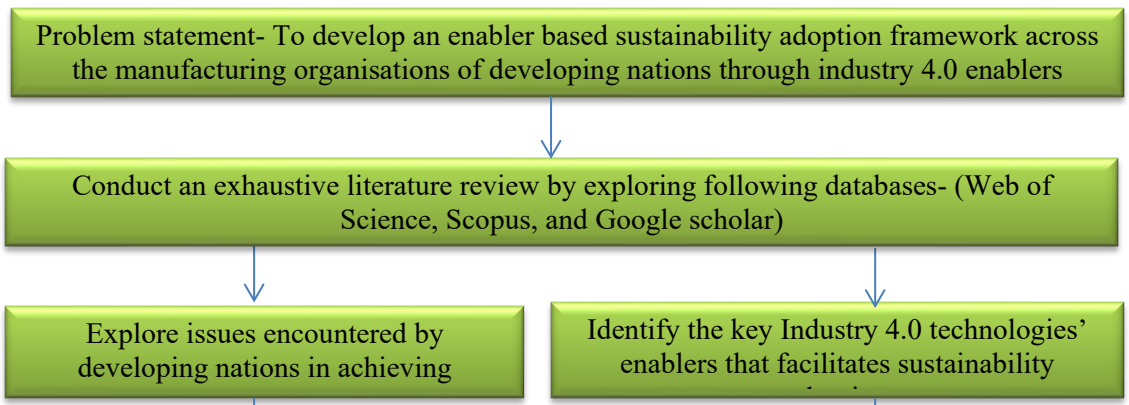

Figure 1. Overall flow of the research methodology that underpinned the present study

3.1.1 Empirical analysis

To provide a strong theoretical foundation for this research work, an empirical analysis which consisted of the combination of both qualitative and quantitative approaches was followed. The main objective of the study was to develop a framework to enhance sustainability adoption across manufacturing organisations of developing nations using Industry 4.0 technologies' enablers. In order to have a better understanding of the enablers, it was essential to perform an empirical analysis. The Statistical Package for the Social Sciences (SPSS) is a software for

editing and analysing data collected from a questionnaire-based survey [64]. Therefore, an investigation through an empirical study was carried out by using SPSS 21.0 to finalise the enablers. Cronbach alpha was used to check the reliability and validity of the collected data [65,66]. Exploratory factor analysis was used to develop a factors structure of the drivers.

3.1.2 Robust-BWM approach

The MCDM literature offers a huge variety of approaches for solving complex decision-making problems [51]. However, the applicability of these approaches depends strictly upon the nature of the problem [29]. In the present situation, it was desired to calculate the weights of enablers influencing sustainability adoption. For this purpose, AHP, SWARA, MOORA and other approaches are available. Nevertheless, Best Worst Method (BWM) offers a better option over these approaches as it uses less paired comparisons and overcomes certain drawbacks of AHP [67]. Furthermore, different variants of BWM are proposed in the existing literature. Among these variants, RBWM is considered to be the most stable as it effectively handles vagueness and uncertainty [68]. It also considers a range of comparisons among two enablers instead of allotting a specific number. This uniqueness of operation enriches the applicability of RBWM for the present case.

4. A Real-World Case Application

This section describes a real-world case application. The details are provided in following subsections.

4.1 Problem Definition and Organisation Description

According to the objectives defined for this study, an automotive manufacturing company was selected as a case organisation. The ABC organisation was established in 1976 and is situated in the central region of India. It holds around 850 employees working in three shifts with an annual turnover of $ 190 million. The organisation has a wide range of clients throughout the country, but they have failed to earn themselves as a brand on the international platform. For this reason, management is constantly working to meet international product standards and achieve sustainability. After a discussion with top management, they agreed to help the authors in developing and testing the framework to achieve sustainability using Industry 4.0 technologies' enablers within their firm.

Initially, an expert panel which consisted of a total of 6 experts was established. This included one top management executive, two project managers, one supply chain and operations head, one R&D head and one warehouse and packaging supervisor. All team members of the expert panel individually held more than 15 years of experience; the two project managers and supply chain head possessed a strong exposure to handling international business while the experts from the warehouse and R&D had handled green and sustainability initiatives in the past. Their expert opinion was sought to develop the questionnaire instrument and perform its content validity. Secondly, inputs for RBWM were also obtained to identify the intensity of the influence of enablers on sustainability adoption.

4.2 Survey Analysis

4.2.1 Questionnaire development and data collection

An empirical study was conducted to check the statistical establishment of all identified Industry 4.0 technologies' enablers to achieve sustainability. A questionnaire was prepared based on a 1-5 scale (i.e. 1 - strongly disagree and 5- strongly agree). The pre-testing of the questionnaire was done with the help of area experts and academics who held large experience in this area. Based on their inputs, the language of some questions was amended and made simpler to understand. After the modification, a final questionnaire was prepared and a small sample was used for pilot testing. The research team initially used a convenience sampling method for data collection but after meeting some respondents, they referred us to the company's staff who were working in the same area. After following this process, the research team was able to collect 247 respondents. However, after the screening process, a total of 230 responses were used to conduct the empirical analysis, which is quite acceptable. The details of the participants' profiles are presented in Table 3.

Table 3. Participants' profiles

Characteristics		**Total**	**Percentage (%)**
Gender	Male	167	72.61
	Female	63	27.39
Education	Undergraduate	50	21.74
	Graduate	74	32.17
	Postgraduate	81	35.22

	Others	25	10.87
Work experience (in years)	0-5	29	12.61
	6-10	48	20.87
	11-15	62	26.96
	16-20	42	18.26
	Above 20	49	21.30
Position	Senior Level Manager	34	14.78
	Medium Level Manager	68	29.57
	Manager	76	33.04
	Others (employee in sourcing, logistics, production, operation, and other services, etc.)	52	22.61
Department	R & D	25	10.87
	Shop Floor	74	32.17
	Warehouse and Logistics	28	12.17
	HR	21	09.13
	Supply Chain	37	16.09
	Others (Marketing, Finance, and other services, etc.)	45	19.57
Type of Manufacturing	Automobile and Automotive Component Manufacturing	79	34.35
	Electronics and Electrical Manufacturing	39	16.96
	Textile and Apparel Manufacturing	26	11.30
	Machine Tools Equipment and Engineering Manufacturing	29	12.61
	Chemical and Pharmaceuticals Manufacturing	27	11.74
	Others (FMCG and Food Manufacturing, etc.)	30	13.04

4.2.2 Measurement of biasness

When primary data is collected, it can be affected by biased views of respondents. To minimise this, the authors kept all the responses opinions anonymous [69]. To make the study objectives more understandable, these were sent to the respondents, alongside a brief description of the study so that they could dedicate more time to filling the questionnaire and provide bias-free responses.

4.2.3 Reliability and validity checks

With the help of reliability and validity tests by using SPSS 21.0, the authors did not only check the accuracy of the collected data but also assessed the 'goodness of a measure'. For measuring

reliability, we used Cronbach's alpha (α) and its recommended values [70]. Field [64] indicates that if the factor loading of each variable is greater than 0.5, there is convergent validity for the data. In this work, the overall Cronbach's alpha (α) value was 0.830, so as per previous literature the data was considered acceptable. Field [64] further reported that if the factor loading of each item is greater than 0.5, it shows both the internal consistency and convergent validity of the instrument. After establishing the factor structure of enablers to achieve sustainability using EFA, the convergent validity of the instrument was measured by calculating the Cronbach alpha value, where the range was between 0.838 and 0.933.

4.2.4 Exploratory Factor Analysis (EFA)

EFA is a multivariate technique that is widely employed to determine the factors structure. With the minimum loss of information, EFA has the ability to reduce the number of variables into a set of structures. In this study, EFA was used to define the factor structure of the identified Industry 4.0 technologies' enablers to achieve sustainability. Before using EFA, the data should be suitable for such purpose. For this, Kaiser-Meyer-Olkin (KMO) and Bartlett's Test of Sphericity were conducted. Eisinga et al. [65] suggest that the KMO value should be greater than the minimum recommended value (0.60) and that the Bartlett's Test of Sphericity to be significant at $p < 0.01$. In this case, the sampling adequacy value for each enabler was above the acceptable value of 0.50. Thus, the analysis showed that the collected data fulfilled the recommended criteria and suitability to apply EFA. Field [64] suggested that with varimax factor rotation, EFA was carried out to determine the factor structure for enablers; an Eigenvalue (>1) was used to obtain the final factor structure. As shown in Table 4, all drivers were structured into five main drivers with a total variance of 71.27%. The factor loading of each main driver under its respective sub-capabilities was in the range of 0.635 - 0.911, above the acceptable level of 0.60. The commonalities range was 0.463 - 0.853, also above the acceptable limit of 0.40. Three enablers, i.e. 'Adoption of an additive manufacturing system', 'Adoption of advanced quality improvement techniques' and 'Constant tracking of in-process and stock inventory' were dropped from further analysis due to low loading as per the acceptable level 0.60 [71].

Table 4. EFA analysis results

Group	Indicator	Loading	Commonalities	Cronbach (α)

Group 1	Adoption of machine learning system	0.911	0.836	0.926
	Adoption of cyber-physical system	0.897	0.815	
	Adoption of effective process optimisation techniques	0.881	0.802	
	Penetration of the flexible manufacturing system	0.872	0.789	
	Adoption advanced quality improvement techniques	0.832	0.714	
	Advanced information sharing systems	0.751	0.598	
	Adoption of additive manufacturing system	0.635	0.472	
Group 2	Continuous monitoring of reduction emission	0.908	0.875	0.933
	Adoption of sustainable energy resources system	0.862	0.778	
	Effective sustainability performance metrics	0.844	0.755	
	Educating customers for sustainability	0.843	0.794	
	Green design and disposal system	0.828	0.710	
	Adoption industrial ecology initiatives	0.751	0.672	
Group 3	Management engagement towards sustainability adoption	0.903	0.843	0.887
	Adoption sustainability supportive policies	0.899	0.844	
	Adoption of smart factory components	0.787	0.658	
	Smart budget allocation	0.762	0.596	
	Promoting Industry internet of things	0.716	0.566	
Group 4	Digitisation of supply chain activities	0.866	0.763	0.838
	Real-time tracking of suppliers	0.864	0.758	
	Adopting reverse logistics	0.744	0.662	
	Supplier commitment for sustainable procurement	0.678	0.509	
	Promoting knowledge management in the supply chain	0.650	0.492	
Group 5	Adoption of health and safety modules	0.904	0.853	0.918
	Sustainable human resource management	0.895	0.828	
	Effective product life cycle analysis	0.868	0.787	

	Enhancement of man-machine-material interaction	0.826	0.779	
	Managing data security and handling	0.781	0.657	
	Understanding the implications of sustainability	0.623	0.463	

4.3 Framework Development

The exploratory factor analysis indicated that out of 32 shortlisted enablers, 29 were found to be suitable for the present problem. These enablers were spread over 5 groups. Thus, the results were further shared with the expert panel to categorise the enablers and develop the framework. Based on the experts' feedback and similarity of the enablers, these groups were named as informational and technological, which contained informational and technological enablers. All environment enablers were in the environmental group. The third group contained all the enablers related to managerial and economical aspects, the supply chain management group contained all the enablers related to supply chain management while the last group contained all enablers related to organisational and social factors. Accordingly, a framework was developed to enhance sustainability in manufacturing organisations. Figure 2 indicates the details of the developed framework. The framework was tested in the case organisation to identify the intensity of influence of the selected enablers in sustainability adoption.

4.4 Multi-Criteria Decision Making Analysis

The framework developed in the previous section was then tested through the RBWM approach. In the RBWM approach, the experts were asked to make the pairwise comparisons major group and subgroup enablers separately [72]. During the process of paired comparison, it was possible for the experts not to be able to overcome the vagueness and fail to handle uncertainty.

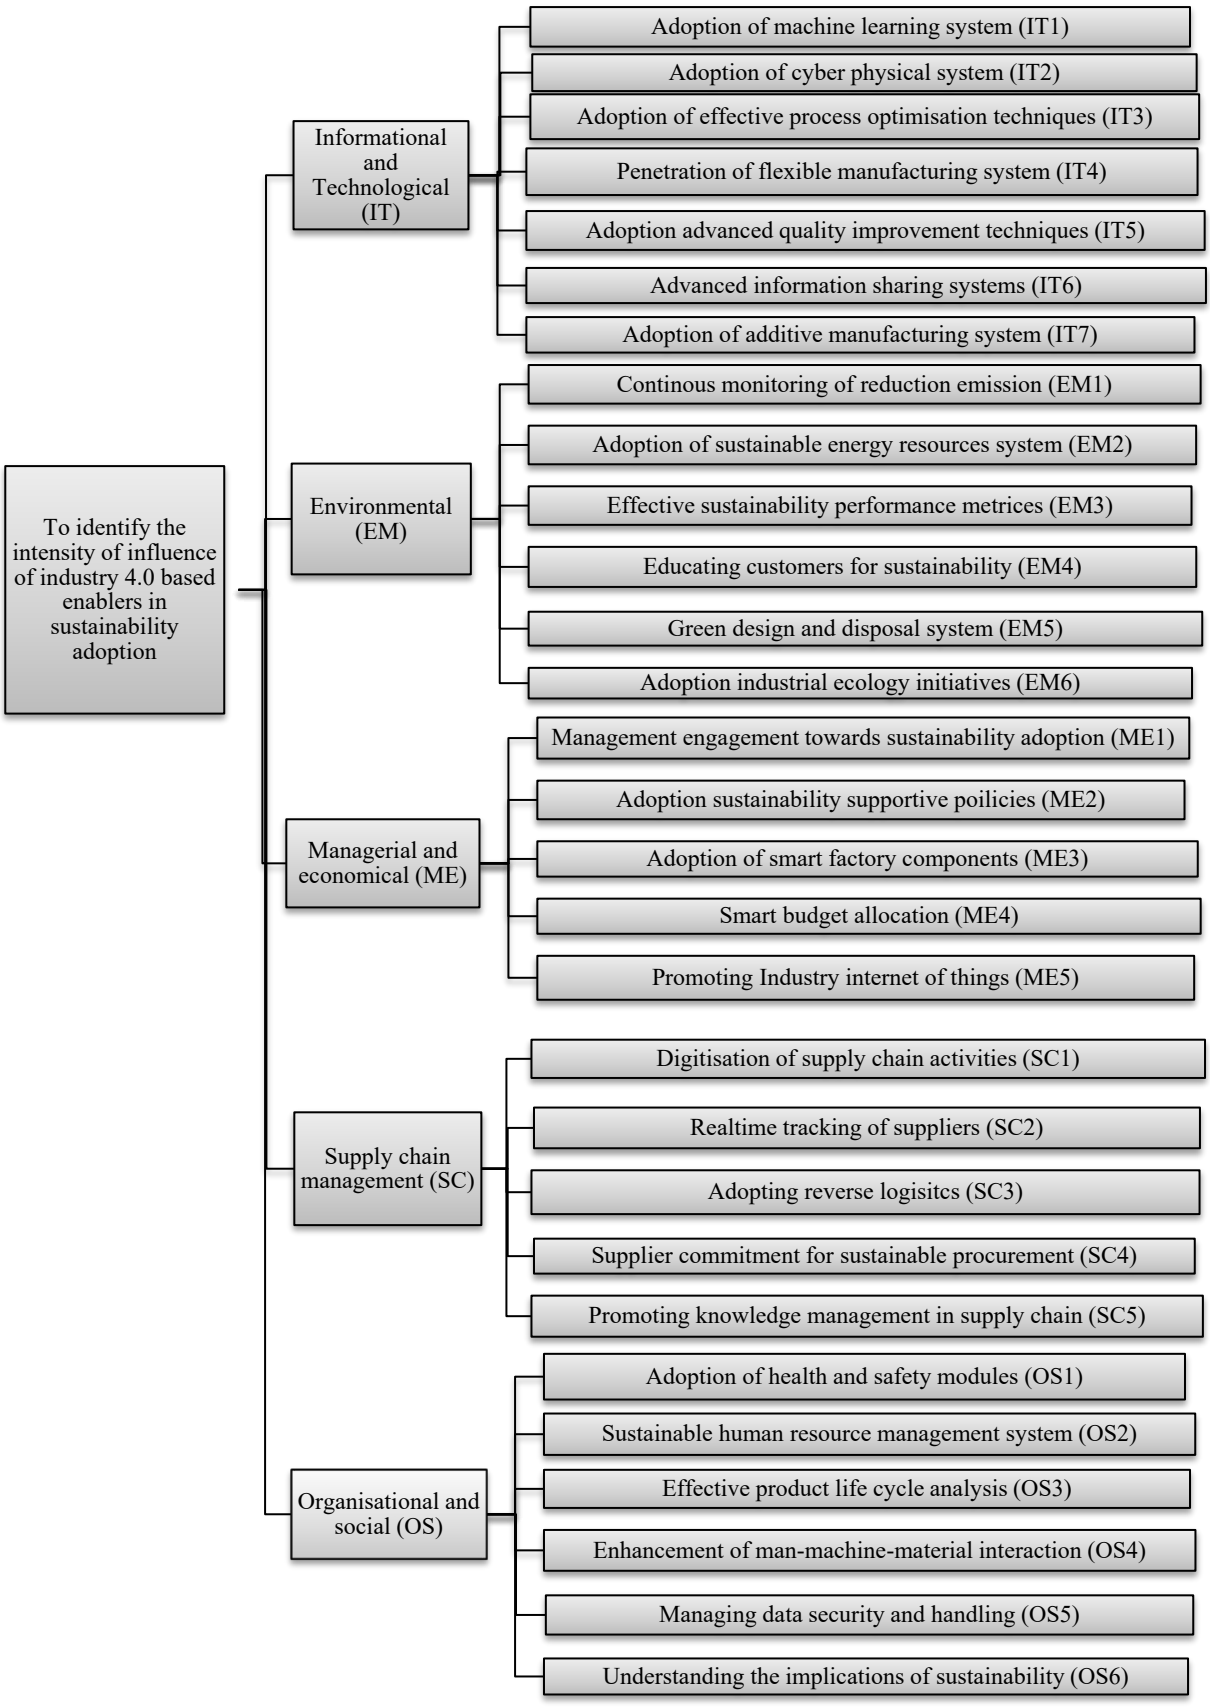

Figure 2. Framework to enhance sustainability adoption

Hence, instead of allotting a crisp value for a comparison of two enablers, a defined range was given. The procedure followed to execute the RBWM is presented below.

Step 1: Finalising the criteria - This step included the finalisation of the criteria that needed to be included for problem-solving. Here, a set of criteria (C_1, C_2, C_3…. C_n) was used to decide between alternatives.

Step 2: Allotment of best and worst criteria - This step included allotting the best and worst criteria across the major group and all the corresponding sub-groups.

$A_B = (a_{b1}, a_{b2}, a_{b3}, \ldots a_{bn})$

$A_W = (a_{w1}, a_{w2}, a_{w3}, \ldots A_{wn})$

Step 3: Determining the paired comparisons - Instead of providing a finite value, a range was provided. For example, the relation between enabler A and enabler B was given in the range of 2.5 and 3.5. Hence, an optimum value within this range was tested rather than allotting a finite value 3.

Step 4: Determining the best solution - To obtain the best solution, the Soyester method was utilised for the present problem. According to the Soyester method, the present problem can be formulated based on the following model.

Min ξ^R

Subject to $W_B - A_{Bj} W_j + A_{Bj} Y_B - \xi^R \leq 0$, $\forall$ j, B

$A_{Bj} W_j - W_B + A_{Bj} Y_{B'} - \xi^R \leq 0$, $\forall$ j, B'

$W_j - A_{jw} W_w + A_{jw} Y_w - \xi^R \leq 0$, $\forall$ j, w

$A_{jw} W_w - W_j + A_{jw} Y_{w'} - \xi^R \leq 0$, $\forall$ j, w'

$-Y_B \leq W_j \leq Y_B$, $\forall$ B, j

$-Y_{B'} \leq W_j \leq Y_{B'}$, $\forall$ B', j

$-Y_w \leq W_w \leq Y_w$, $\forall$ w, j

$-Y_{w'} \leq W_w \leq Y_{w'}$, $\forall$ w', j

$\sum_{j=1}^{n} w_j = 1$

$W, Y \geq 0$,

This approach ensured the protection of uncertainty and helped decision-makers and practitioners predict the best possible influence values of enablers over the sustainability adoption. The comparison ranges, best and worst enablers for the major group provided by the expert panel are shown in Table 5.

Table 5. Best and worst comparisons of major group enablers

Main group enabler	Range	Expert 1	Expert 2	Expert 3	Expert 4	Expert 5	Expert 6	Average Weight
Informational and Technological (IT)	B_{max}	2.25	1	7.5	6.5	2.5	3.5	0.191
	B_{min}	1.75	1	6.5	5.5	1.5	2.5	
	W_{max}	4.25	6.5	1	1	5.5	4.5	
	W_{min}	3.75	5.5	1	1	4.5	3.5	
Environmental (EM)	B_{max}	1	2.5	5.5	5.5	1	6.5	0.234
	B_{min}	1	3.5	4.5	4.5	1	5.5	
	W_{max}	8.45	3.5	2.5	2.5	6.5	1	
	W_{min}	7.55	2.5	1.5	1.5	5.5	1	
Managerial and Economical (ME)	B_{max}	4.5	6.5	1	1	6.5	1	0.263
	B_{min}	3.5	5.5	1	1	5.5	1	
	W_{max}	2.15	1	7.5	6.5	1	6.5	
	W_{min}	1.85	1	6.5	5.5	1	5.5	
Supply chain management (SC)	B_{max}	3.5	2.5	3.5	2.5	5.5	5.5	0.152
	B_{min}	2.5	1.5	2.5	1.5	4.5	4.5	
	W_{max}	3.65	4.5	4.5	5.5	2.5	2.5	
	W_{min}	2.35	3.5	3.5	4.5	1.5	1.5	
Organisational and Social (OS)	B_{max}	8.45	4.5	2.5	2.5	4.5	2.5	0.161
	B_{min}	7.55	3.5	1.5	1.5	3.5	1.5	
	W_{max}	1	2.5	5.5	5.5	3.5	5.5	
	W_{min}	1	1.5	4.5	4.5	2.5	4.5	

Similarly, comparisons were made for each subgroup. The final weights of each subgroup enablers are presented in Table 6.

Table 6. Final weights of enablers influencing sustainability adoption

Main Group	Group Weight	Sub-Factor	Local Weight	Global Weight	Global Rank
Informational and Technological (IT)	0.191	IT1	0.083	0.016	26
		IT2	0.321	0.061	4
		IT3	0.213	0.041	10
		IT4	0.203	0.039	11
		IT5	0.045	0.009	28
		IT6	0.091	0.017	25
		IT7	0.042	0.008	29
Environmental (EM)	0.234	EM1	0.086	0.020	22

		EM2	0.318	0.074	1

5. Study Findings and Discussions

In line with the research objectives of the present study, an exhaustive literature review was conducted to explore the Industry 4.0 technologies' enablers that strongly influence sustainability adoption across manufacturing organisations in developing economies. Later, a manufacturing case organisation was selected to develop and test the framework to enhance the sustainability adoption rate. An expert panel formed within the case organisation was utilised to test the content validity of the questionnaire instrument developed to conduct a large scale survey. The responses obtained through the survey were tested and an exploratory factor analysis was conducted to group similar factors. After conducting the empirical analysis, the findings were utilised to develop an enabler based framework to enhance sustainability adoption.

Further, the RBWM approach was applied to identify the intensity of the influence of enablers on sustainability adoption. The results revealed that among the major group enablers were Managerial and Economical enablers (ME), which obtained the highest weight (0.263),

followed by Environmental enablers (EM- 0.234), Informational and Technological enablers (IT- 0.191), Organisational and Social enablers (OS- 0.161), and Supply Chain Management enablers (SC- 0.152). Khurana et al.'s [73] study support the above results by indicating in their study that managerial and environmental enablers strongly affect sustainability adoption. Among the subgroup of enablers, the adoption of a sustainable energy resource system (EM2- 0.074) held the highest intensity of influence on sustainability adoption, followed by the adoption of sustainability supportive policies (ME2- 0.068), management engagement towards sustainability adoption (ME1- 0.063), adoption of cyber-physical system (IT2- 0.061), and effective sustainability performance metrics (EM3- 0.060). Shankar et al. [2] and Liu et al. [29] also indicated that the adoption of sustainable energy resource systems and consideration of sustainability supportive policies are necessary prerequisites for sustainability adoption.

Among the informational and technological enablers, adoption of cyber-physical system (IT2), adoption of effective process optimisation techniques (IT3- 0.041), and penetration of flexible manufacturing system (IT4- 0.039) emerged as the most prominent enablers that support sustainability. Cai et al. [30] highlighted that if a manufacturing system is rigid, it becomes really difficult for the practitioners to incorporate the changes based on reverse feedback. Similarly, a cyber-physical system transits a manufacturing system towards the next generation and eliminates the chances of errors in the production system. Among the environmental enablers (EM), adoption of sustainable energy resource system (EM2), effective sustainable performance metrics (EM3), and green design and disposal system (EM5- 0.043) were the most critical enablers. The study conducted by Piyathanavong et al. [34] also pointed out that the greening of activities throughout the organisation is essential if the organisation wants to achieve sustainability. They argued that despite adopting greener activities, it is mandatory to have sustainable performance metrics that could monitor and track the activities over sustainability.

Among the managerial and economic enablers, adoption of sustainability supportive policies (ME2), management engagement towards sustainability adoption (ME1), smart budget allocation (ME4- 0.049), and promoting industry internet of things (ME5- 0.045) resulted as the most significant enablers that correlate to sustainability. Niaki et al. [74] insisted on management involvement towards sustainability adoption and stakeholders' participation as an essential component to withstand the business on a global platform. Decisions related to policies, strategies, and finance stands with the management and hence, to penetrate

sustainability effectively their involvement is essential. Among the supply chain management enablers, digitisation of supply chain activities (SC1- 0.041), supplier commitment for sustainable procurement (SC4- 0.035), and real-time tracking of suppliers (SC2- 0.032) turned up as sustainability favouring enablers. Seuring et al. [5] reported that sustainability is extremely difficult to achieve without greening the entire supply chain and logistics. It includes from the idea generation stage and up to after-sales service. Digitisation of supply chain activities helps industrialists in keeping a constant track over the production process and controlling the occurrence of errors with an immediate effect.

Among the organisational and social enablers, sustainable human resource management (OS2- 0.036), adoption of health and safety modules (OS1- 0.030), effective product life cycle analysis (OS3- 0.029), and managing data security and handling (OS5- 0.025) resulted as the most critical enablers that need to be practised by organisations. Xu et al. [37] argued that achieving sustainability in its correct form has always been a debatable topic. Many researchers have discussed the inclusion of economic and environmental aspects to achieve sustainability; but, many of them have missed to capture the social aspect. The contribution of manufacturing organisations towards the handling of social aspects is as important as their contribution to nations' GDPs. Similarly, effective product life cycle analysis helps industrialists to adopt decisions on promotions, modifications, and disposal accurately.

5.1 Study Implications

The present study makes significant contributions to researchers and practitioners working in the sustainability domain. The implications of this study are as follows.

- The literature on sustainability offers a large number of frameworks [16,75] that support sustainability adoption, but the majority of them are generalised. However, the present study develops a framework for sustainability adoption across manufacturing organisations of developing nations using Industry 4.0 technologies' enablers.
- This study identifies a unique set of 29 enablers, based on Industry 4.0 technologies, which contribute to the achievement of sustainability. The identified enablers were verified through experts' opinions. The study can thus be beneficial for industrialists involved in the sustainability adoption process. The exhaustive set of enablers can be utilised by researchers to conduct allied studies in the sustainability domain.

- The majority of sustainability-oriented frameworks [35,76] reported in the literature have not been verified. However, the framework developed in this study was verified empirically and through a multi-criteria decision-making method.
- Researchers in the literature [3,51] have identified the enablers that support sustainability adoption. However, only a few of them have highlighted the intensity of their influence in the adoption process. This study employed the RBWM approach to determine the intensity of each enabler included in the framework.
- The simultaneous adoption of all the enablers is extremely difficult [77]. However, the weights of enablers determined in this study will assist companies involved in sustainability adoption to focus on high-intensity enablers on priority.
- The framework developed in this study was tested in an Indian context. Other developing economies can utilise the present framework by making modifications to it in consultation with the domain experts of that country.

6. Conclusions

This study develops a framework for manufacturing organisations to enhance sustainability adoption. It determines a unique set of 29 Industry 4.0 technologies' enablers that strongly influence sustainability adoption. The study employs a unique combination of empirical and multi-criteria decision-making approaches to solve the present problem. Initially, the study conducts an empirical analysis to finalise the enablers influencing sustainability adoption. Later, a framework was developed and tested in a manufacturing organisation to improve sustainability and compete at an international level. Further, the RBWM approach was utilised to determine the weights of enablers included within the framework. The results reveal that managerial and economical enablers were found to be the most critical for sustainability adoption; while, environmental enablers also possessed a strong influence in achieving overall sustainability. It is important to notice that the adoption of sustainable energy resources systems, adoption sustainability supportive policies and effective sustainability performance metrics were among the top influencing enablers that support sustainability adoption. Accordingly, it is suggested that government policies favouring sustainability adoption through the execution of new technologies will have a positive impact on strengthening nations' economy. Similarly, the promotion of a sustainable energy resource system will create awareness among manufacturing organisations and help them improve their sustainable performance.

6.1 Limitations and Future Research Directions

The present study explored Scopus, Web of Science and Google Scholar to identify the articles and list the key Industry 4.0 technologies' enablers influencing sustainability adoption. Researchers may further increase the number of databases for the literature search in order to identify more articles to support the study as it is possible that some studies that influence sustainability might not have been identified and considered. In this work, an empirical study has been conducted in a single India manufacturing company. Thus, future research can be conducted by considering multiple manufacturing companies and organisations in other industrial sectors and countries. This will increase the reliability and validity of the results obtained from the present study. Similarly, this study highlights the intensity of the influence of enablers towards sustainability adoption. Nevertheless, it does not shed light on the structural relationship among these enablers. Researchers may extend the present study findings by applying various structural techniques such as interpretive structural modelling, decision-making trial and evaluation laboratory, fuzzy cognition maps, analytical network process, etc. to establish the inter-relationships among the enablers included in the developed framework. Finally, the present research is equally beneficial for researchers, practitioners and policymakers. The developed hierarchical framework may be applicable to various Indian manufacturing organisations and other developing countries' manufacturing organisations with marginal or no modifications. The study will, therefore, assist developing nations in achieving sustainability across their manufacturing sector.

SOLAR PASSIVE HOUSE: A REVIEW

Abstract

Houses generally refer to a shelter or building that is meant as a dwelling or place for habitation by human beings.

"Houses" comprise many types of dwellings, ranging from rudimentary huts or nomadic tribes to high -rise buildings.

A significant limitation in fulfilling this need is the spiraling expense of vitality and different changes in atmosphere. Latent sun oriented structures plan to keep up inside warm solace all through the sun's every day and yearly cycles while lessening the necessity for dynamic warming and cooling framework Passive sun powered structure configuration is one piece of green structure. The logical reason for uninvolved sunlight based structure configuration has been created from a blend of climatology, thermodynamics (especially heat move), and human warm solace (for structures to be occupied by people). Explicit consideration is coordinated to the site and area of the residence, the predominant atmosphere, structure and development, sunlight based direction, arrangement of coating and-concealing components, and fuse of warm mass. While these contemplations might be coordinated to any structure, accomplishing a perfect arrangement requires cautious incorporation of these standards.

1. Introduction

New development offers the best open door for consolidating detached sun oriented plan, Passive close planetary system utilize normal vitality streams as the essential methods for reaping sun based vitality, Passive nearby planetary group can give space warming, cooling load evasion, regular ventilation and day lighting.

Passive solar design refers to the use of the sun's energy for the heating and cooling of living spaces. In this methodology, the structure itself or some component of it exploits common vitality attributes in materials and air made by presentation to the sun. Uninvolved frameworks are straightforward, have scarcely any moving parts, and require negligible upkeep and require no mechanical frameworks. Inactive sun powered plan can lessen warming and cooling vitality charges, increment spatial imperativeness and improve comfort.

There are two types of solar design systems: passive and active.

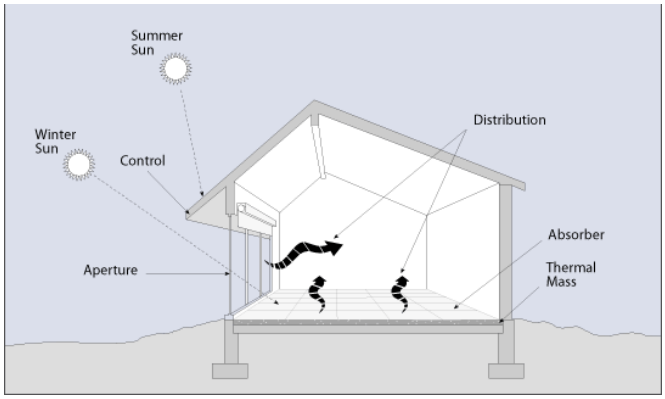
Homes developed as uninvolved sun oriented plan utilize the characteristic development of warmth and air to keep up agreeable temperatures, working with practically no mechanical help. It's called latent sun powered on the grounds that the plan of the home expands the advantages it gets from the sun with standard development highlights. Uninvolved sunlight based exploits nearby breezes and scene highlights, for example, conceal trees and windbreaks, and utilizations a basic framework to gather and store sun powered vitality without any switches or controls.

On the other hand, active solar systems use mechanical devices such as pumps and fans to move heat from collectors to storage or from storage to use. Photovoltaic panels that collect solar energy, turning it into electricity, are also considered an active solar system.

2. Objectives:

1. To control environmental pollution.
2. To preserve the non renewable source of energy like Petrol, diesel etc.
3. To take up energy access programs for rural and remote Areas through solar energy.

3. Elements of Solar Passive House:

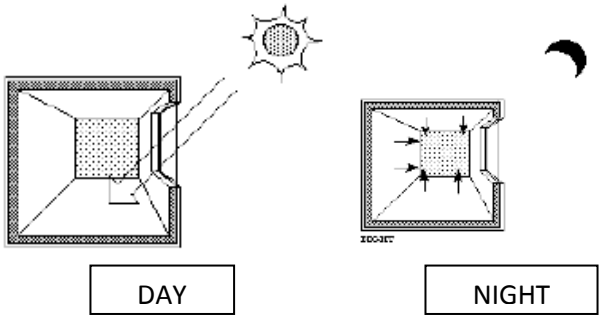


- **Aperture(Collector) :**
  The enormous glass region through which daylight enters the structure. The gap should look inside 30° of genuine south and ought not be concealed by different structures or trees from 9 a.m. to 3 p.m. day by day during the warming season.
- **Absorber:**
  The hard, obscured surface of the capacity component. The surface, which could be a Masonry divider, floor or water compartment, sits in the immediate way of daylight. Daylight hitting the surface is assimilated as warmth.
- **Thermal mass:**
  Materials that retain or store the heat produced by sunlight. While the absorber is an Exposed surface, the thermal mass is the material below and behind this surface.
- **Distribution:**
  Strategy by which sun based warmth flows from the assortment and capacity focuses to various regions of the house. A carefully detached structure will utilize the three characteristic warmth moves Modes-conduction, convection and radiation-solely. In certain applications, fans, Ducts and blowers might be utilized to convey the warmth through the house.
- **Control:**
  Rooftop shades can be utilized to conceal the opening territory during summer months. Different components that control under or potentially overheating incorporate electronic detecting gadgets. Such as a differential indoor regulator that flags a fan to turn on; operable vents and dampers that permits or limits heat stream; low-emissivity blinds; and overhangs.

4. Solar House Heating & Cooling:

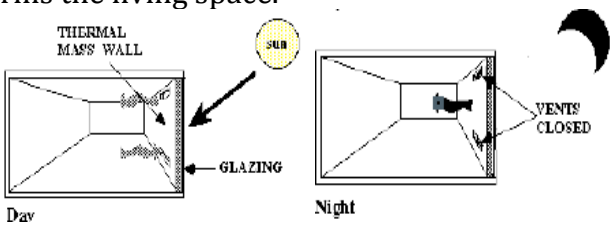
- **Solar House Heating:**
  The goal of passive solar heating systems is to capture the sun's heat within the building's elements and to release that heat during periods when the sun is absent, while also maintaining a comfortable room temperature.

- **Direct Gain:**
  Actual living space is a solar collector, heat absorber and distribution system. South-bound glass concedes sun oriented vitality into the house where it strikes stone work floors and dividers, which assimilate and store the sun powered warmth, which is emanated pull out into the room around evening time. These warm mass materials are regularly dim in shading so as to ingest however much warmth as could be expected. The immediate addition framework uses 60-75% of the sun's vitality striking the windows. For an immediate increase framework to function admirably, warm mass must be protected from the outside temperature to keep gathered sun oriented warmth from disseminating.



- **Indirect Gain:**

Thermal mass is located between the sun and the living space. The thermal mass absorbs the sunlight that strikes it and transfers it to the living space by conduction. The indirect gain system will utilize 30-45% of the sun's energy striking the glass adjoining the thermal mass. The most widely recognized circuitous addition framework is a Trombe divider. The warm mass, a 6-18 inch thick stone work divider, is found quickly behind south-bound glass of single or twofold layer, which is mounted around 1 inch or less before the divider's surface. Sunlight based warmth is consumed by the dividers dull shaded outside surface and put away in the divider's mass, where it transmits into the living space. Sun based warmth relocates through the divider, arriving at its back surface in the late evening or early night. At the point when the indoor temperature falls beneath that of the divider's surface, heat is transmitted into the room. Operable vents at the top and base of a warm stockpiling divider license warmth to convect between the divider and the glass into the living space. At the point when the vents are shut around evening time, brilliant warmth from the divider warms the living space.



- **Solar House Cooling:**

Aloof sunlight based cooling frameworks work by diminishing undesirable warmth gain during the day, delivering non-mechanical ventilation, trading warm inside air for cooler outside air whenever the situation allows, and putting away the coolness of the night to direct warm daytime temperatures. At their most straightforward, latent sun oriented cooling frameworks remember shades or shades for south-bound windows, conceal trees, warm mass and cross ventilation.

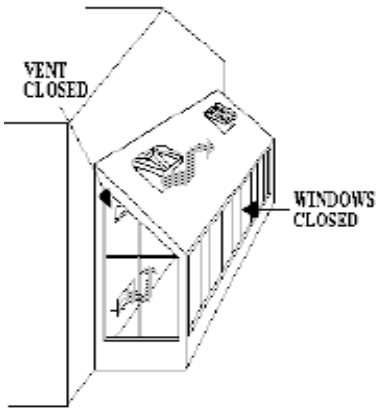
- **Shading:**

To reduce unwanted heat gain in the summer, all windows should be shaded by an overhang or other devices such as awnings, shutters and trellises. If an awning on a south facing window protrudes to half of a window's height, the sun's rays will be blocked during the summer, yet will still penetrate into the house during the winter. The sun is low not too far off during dawn and nightfall, so overhangs on east and west-bound windows are not as successful. Attempt to limit the quantity of east and west-bound windows if cooling is a significant concern. Vegetation can be utilized to shade such windows. Arranging when all is said in done can be utilized to diminish undesirable warmth gain throughout the late spring.

- **Thermal mass:**

Warm mass is utilized in a uninvolved cooling configuration to ingest warmth and moderate inside temperature increments on hot days. During the night, warm mass can be cooled utilizing ventilation permitting it to be prepared the following day to conceivable to assimilate heat once

more. It is utilize a similar warm mass for cooling during the hot season and warming during the virus season.

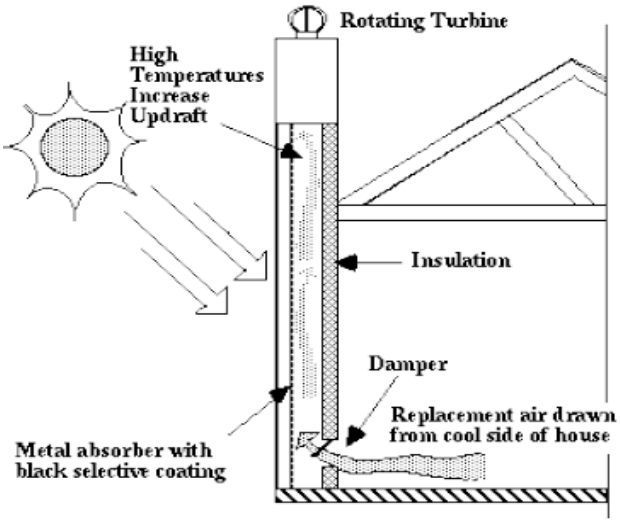


- **Ventilation:**

Characteristic ventilation keeps up an indoor temperature that is near the open air temperature, so it's just a compelling cooling procedure when the indoor temperature is equivalent to or higher than the outside one. The atmosphere decides the best normal ventilation system. In regions where there are daytime breezes and a longing for ventilation during the day, open windows on the structure confronting the breeze and the contrary one to make cross ventilation.

- **Convective Cooling:**

The oldest and simplest form of convective cooling is designed to bring in cool night air from the outside and push out hot interior air. If there are prevailing nighttime breezes, then high vent or open on the leeward side (the side away from the wind) will let the hot air near the ceiling escape. Low vents on the contrary side (the side towards the breeze) will let cool night air clear in to supplant the sight-seeing. At destinations where there aren't winning breezes, it's as yet conceivable to utilize convective cooling by making warm smokestacks. Warm fireplaces are structured around the way that warm air raises; they make a warm or hot zone of air (frequently through sun oriented addition) and have a high outside fumes outlet. The sight-seeing exits the structure at the high vent, and cooler air is attracted through a low vent.



5. Conclusion:

Utilizing a mix of Passive sunlight based vitality and photovoltaic cells can decrease contamination. They can perform easily and discreetly without mechanical or electrical help. Straightforward methods can have an enormous effect in the solace and vitality utilization as the year progressed. The prudent answer for a hotter house in the winter and a cooler house in the late spring is to protect it well, while understanding the development of warmth. It is the hitter arrangement. Cost of Solar System will descend in cost when creation increments.

Use of Nylon Fiber in Road Construction

New material and construction techniques are required to provide Civil Engineering with alternatives to traditional road construction practices. Traditional techniques have not been able to bear the mixed traffic load for a long time. Therefore the pavement requires overlaying. To overcome this problem fiber inclusion in pavements is adopted nowadays. This presentation highlights on the use of discrete fiber in road construction. Fiber can be obtained easily form the waste we throw away in day to day used like plastics PVCs etc.

The main purpose of this project investigation is to identify the effect of fiber mix (Fiber reinforced bitumen can be defined as a composite material consisting of mixtures of bitumen tar and discontinuous, discrete, uniformly dispersed suitable fiber) used in road construction.

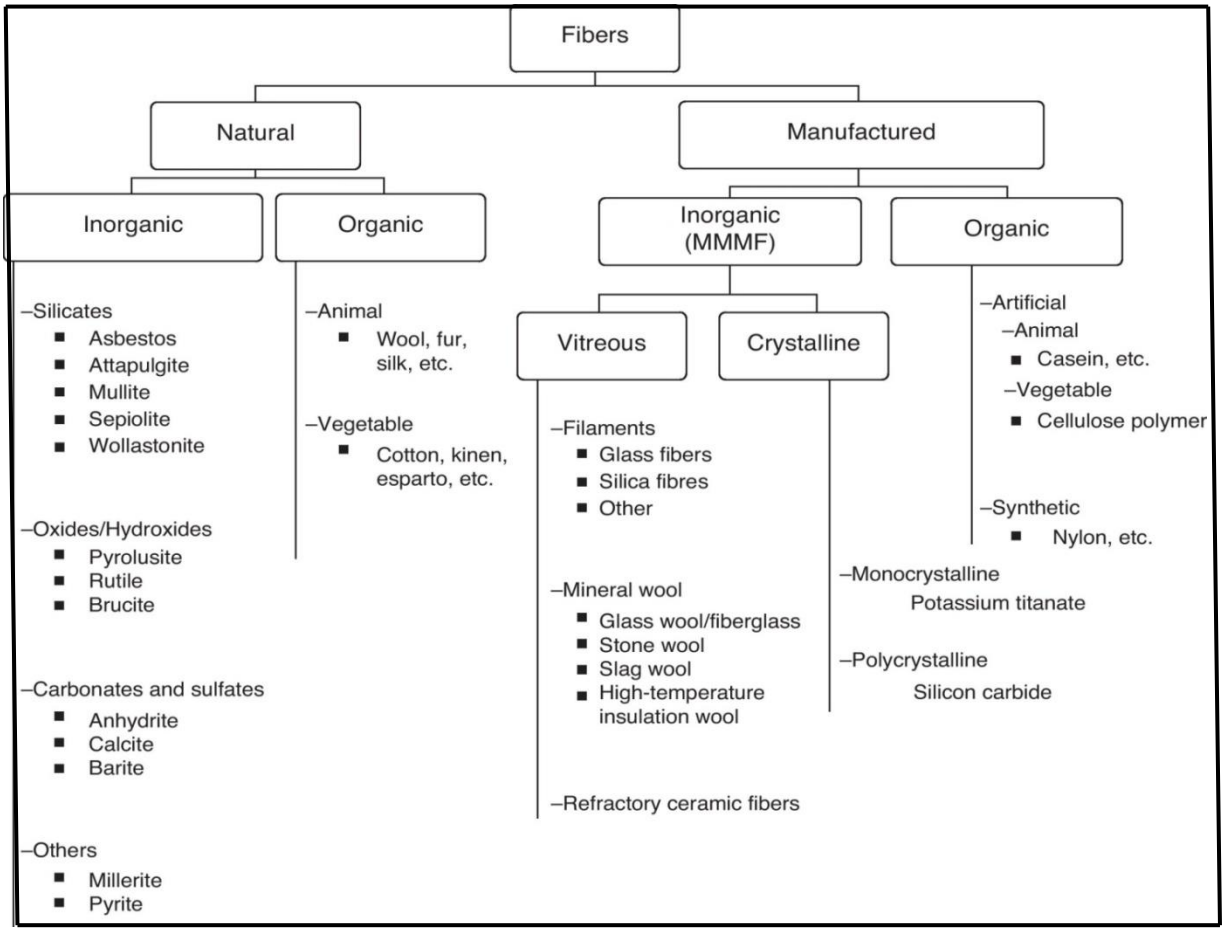
This report describes the laboratory tests conducted on nylon fiber used in road construction material bitumen. The sole purpose is to check whether the fiber mix increase the strength of bitumen or it decreases.

In 80grade bitumen 1, 2 and 3 percentage of nylon fiber was mixed and the length of fiber was divided in 3 cm and 6 cm, so as to make it discrete

The result gives the idea that when the nylon-bitumen mix was tested in ductility test it breaks at nearly approximately 14cm of length which is so much less as compared to 45 cm of normal bitumen and in penetration test it shows 107 mm of penetration which is quite the same to the bitumen only test.

1. Introduction:

Fiber is a small discrete reinforced material produced from steel, polypropylene, nylon, glass, asbestos, coir or carbon in various shape and size. They can be circular or flat. Fiber or fiber (from the Latin fibra) is a natural or synthetic substance that is significantly longer than it is wide. Fibers are often used in the manufacture of other materials. The strongest engineering materials often incorporate fibers, for example carbon fiber and ultra-high-molecular-weight polyethylene. Synthetic fibers can often be produced very cheaply and in large amounts compared to natural fibers continuous meshes, woven fabrics and long wires or rods are not considered to be discrete fiber.

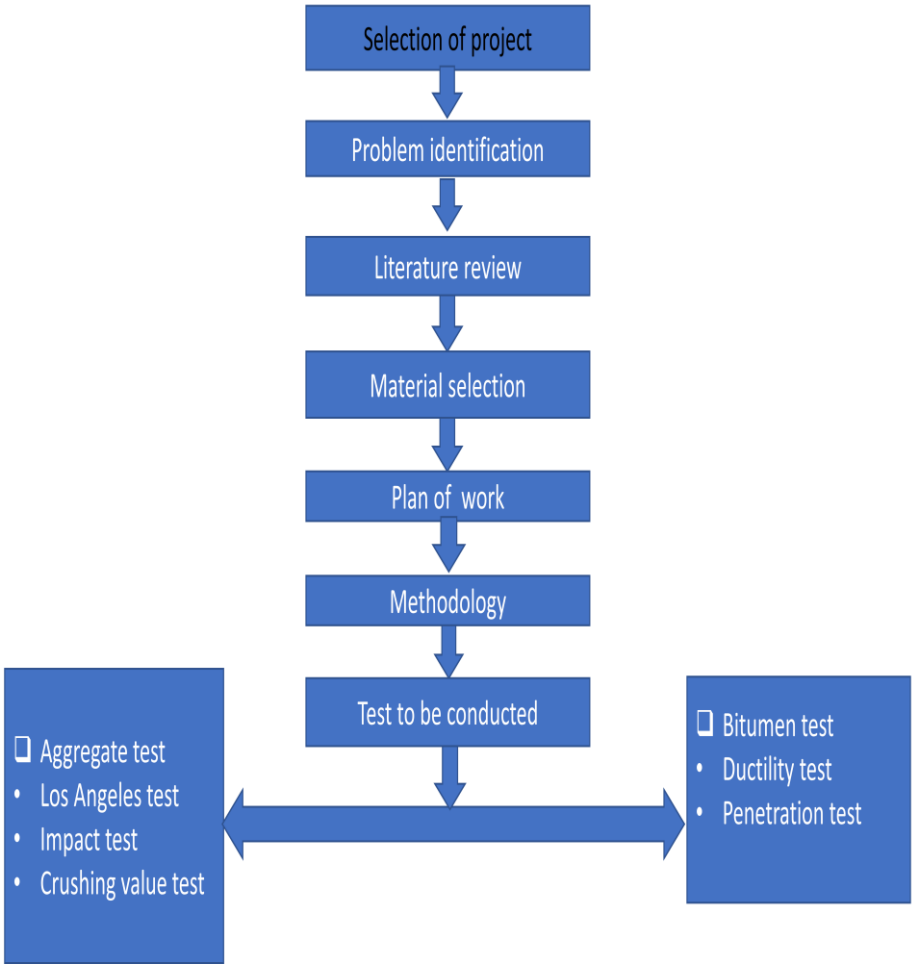


2. Background of the Invention & Literature review:

The purpose of this investigation was to identify and quantify the effect of numerous variables on the performance of fiber-stabilized sand specimens. Laboratory unconfined compression tests were conducted on sand specimens reinforced with randomly oriented discrete fibers to isolate the effect of each variable on the performance of the fiber-reinforced material. Five primary conclusions were obtained from this investigation. First, the inclusion of randomly oriented discrete fibers significantly improved the unconfined compressive strength of sands. Second, an optimum fiber length of 51 mm (2 in.) was identified for the reinforcement of sand specimens. Third, a maximum performance was achieved at a fiber dosage rate between 0.6 and 1.0% dry weight. Fourth, specimen performance was enhanced in both wet and dry of optimum conditions. Finally, the inclusion of up to 8% of silt does not affect the performance of the fiber reinforcement.

This invention relates to a process for producing high-strength yarns or split yarns by slitting an ultra-high molecular weight polyolefin film into tapes and longitudinally stretching the tapes at a high stretch ratio, and also relates to a high-strength, webs-crossed laminate and a process for producing thereof using a meshy web having a unidirectional high-strength as a longitudinal or transverse web in which adjacent yarns remains connected to each other by making slits in a web intermittently or in a shape of perforated line.

3. Methodology:



4. Results and Observations:

4.1 Los Angeles test:

To produce the abrasive action by use of standard steel balls which when mixed with the aggregate and rotated in a drum for specific number of revolution cause impact on aggregate. The %age wear due to rubbing with steel balls is determined and is known as abrasion value.

Sr No.	Description	Sample
1.	Weight of sample , (W_1) gm	5000
2.	Weight of sample retained on 1.70 IS sieve (W_2) gm	4365
3.	Percentage wear (W_2 /W_1) * 100	8.7 %

4.2 Impact test for Aggregate:

This test is done to determine the aggregate impact value of coarse aggregates as per IS: 2386 (Part IV) – 1963. The apparatus used for determining aggregate impact value of coarse aggregates is Impact testing machine.

Sr No.	Description	Sample 1	Sample 2
1.	Weight of sample , (W_1) gm	370 gm	343 gm
2.	Weight of aggregate passing through 2.36mm sieve, (W_2) gm	55 gm	50 gm

3.	Aggregate impact value in % I.V. = (W_2 /W_1) * 100	14.86 %	14.20 %
4.	Average Aggregate crushing Value in %	**14.53 %**	

4.3 Crushing value test for Aggregate:

The aggregate crushing value gives a relative measure of the resistance of an aggregate crushing under gradually applied compressive load. With aggregate crushing value 30 or higher' the result may be anomalous and in such cases the ten percent fines value should be determined instead.

Sr. No.	**Description**	**Sample 1**	**Sample 2**
1	Weight of sample , (W_1) gm	343	352
2	Weight of aggregate passing through 2.36mm sieve, (W_2) gm	57	50
3	Aggregate Crushing = (W_2 /W_1) * 100	16.62 %	14.20 %
4	Average Aggregate crushing Value in %	15.41 %	

4.4 Ductility test for bitumen:

This test is done to determine the ductility of distillation residue of cutback bitumen, blown type bitumen and other bituminous products as per IS: 1208 – 1978.

Type of Bitumen	**Conventional Bitumen**		**Bitumen With Nylon Fiber**	
Reading	**Sample 1**	**Sample 2**	**Sample 1**	**Sample 2**
Initial reading	00	00	00	00
Final reading	41 cm	43 cm	12 cm	16 cm
Ductility	41 cm	43 cm	12 cm	16 cm
Mean value of ductility	**42 cm**		**14 cm**	

4.5 Penetration test for Bitumen:

In this test we examine the consistency of a sample of bitumen by determining the distance in tenths of a millimetre that a standard needle vertically penetrates the bitumen specimen under known conditions of loading, time and temperature.

Type of Bitumen	**Conventional Bitumen**				**Bitumen With Nylon Fiber**			
Sr No.	**Initial reading**	**Final reading**	**Difference**	**Average**	**Initial reading**	**Final reading**	**Difference**	**Average**
1	00	87	-	**93.66**	00	102	---	**109**
2	00	92	5		00	110	8	
3	00	102	10		00	115	5	

5. Conclusion:

The compressive strength of Bituminous mix is one of the most important and useful properties for road construction. In most structural applications bitumen is employed primarily to resist compressive stresses. Therefore, the bituminous mix making properties of various ingredients of mix are usually measured in terms of the compressive strength. The results indicate that the bituminous mix properties were significantly influenced by using fibre. From the penetration test result of

conventional bitumen & Bitumen with Nylon Fiber result, it is clearly show that & Bitumen with Nylon Fiber has highest penetration value with 109 cm and from the ductility test result of conventional bitumen & Bitumen with Nylon Fiber result, it is clearly show that & Bitumen with Nylon Fiber has lowest penetration value with 14 cm, it is evident that for improving the properties of bitumen. In the present investigation, though the available results clearly imply the influence of nylon fibre on the properties of bitumen, it is deemed essential to extend the present studies using different types of aggregate and binders to conclude precisely that the relationships apply irrespective of the constituent types.

ABSTRACT

VOC – Volatile Organic Compound are compound with high vapor pressure and low solubility in water. In industry they are generated in waste gas stream from process with involvement of solvents like toluene, methanol, Iso Propyl Alcohol, Ethyl Acetate etc. Discharging VOC gas into the atmospheric air without any treatment then they are highly dangerous to human health as well as to ecological systems. Many physical and chemical Conventional treatment such as condensation, Scrubber, Incineration, adsorption, absorption are used to treat VOC from waste gas stream.Bbiological treatment for treating VOC is also proved an economic and effective option in industry at large scale level. Objective of the study to controlling VOC emitted from polymers manufacturing industry with the application of Lab-scale up flow bio filtration system. Basic Design & operational parameters such as empty bed residence time (EBRT) of 60-70 s, Media using wood chip (80%) and compost (20%) , Addition of nutrient, Mass loading Rate and removal efficiency (RE) has been studied for effective working. Mainly influencing parameters are pH, Moisture Content, Temperature, Nutrient requirement, EBRT rreviewed. The experiment was performed for three chemicals which are involved on VOC generation in polymer business that are Toluene, Methanol and Epichlorohydrin (ECH).

KEYWORDS: Volatile Organic Compounds, Bio filtration, Elimination Capacity, Empty Bed Residence Time, removal efficiency

I. INTRODUCTION

VOC are now in fall into major pollutant as it is found also in to air through indoor and outdoor source of emission. Most are carcinogenic and lead to photo chemical reactions. Main Source of the Emissions are large scale chemical processes in industry like paints, polymers, intermediates, varnishes and thinners, petroleum products etc. From transportation and biological processes also emit VOCs into air. These VOC gas is harmful to human and environment in many ways. Control on its emission and treatment of waste gas up to standard norms becomes a very necessary for all.

The organic hydrocarbon compound which are easily vaporized recognized as VOC. Technically such compounds are defined as organic compounds which has vapor pressure of 1% at sea level. These compounds may include several aromatic hydrocarbons and considered into the common category due to their similar physical behavior in the atmosphere. Due to its lower boiling point and high vapor pressure they easily vaporized and mixed with the atmospheric air directly.

Toxic volatile organic compounds (VOCs), such as benzene, toluene, Methanol, ethyl benzene, xylenes, and other solvents are air pollutants posing a threat to human health. They are directly associated with emission sources like transportation activity and industrial emission.

Based on nature, There are main three types of treatment techniques – chemically, biologically and physical treatment. Where waste gas flow rate is high and heavy concentration of VOC involved – physio-chemical treatment is suitable. Biological techniques are important where low flow and concentration is low up to 70 – 100 ppm. Main benefit of is Biological method can be operate at normal range of temp. Up to 40 ºC and at atmospheric pressure. Biological processes are very less expensive and simple in operation wise as well as ecologically clean as compared to physio chemical techniques. In this work, we focused on controlling Toluene, Methanol and ECH which is being emitted from polymer manufacturing industry.

II. METHODOLOGY

Basic bio logical process of degradation is shown in Fig. 1. Here Packing media Wood chips and Compost was used in proportion of 80 % & 20 % was used for the experiment.

e-ISSN: 2582-5208
International Research Journal of Modernization in Engineering Technology and Science
Volume:03/Issue:05/May-2021 Impact Factor- 5.354 www.irjmets.com

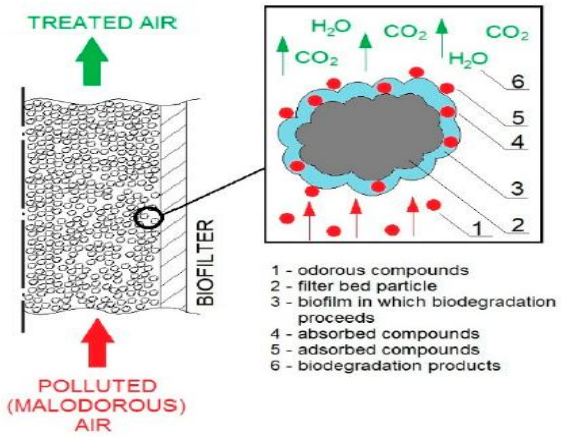

Figure:1 Basic Biological process

2.1 Packing Media Characteristics:

Compost:

Compost in fine shed form which has microorganisms in large diversity, moisture retention capacity is good, pH is 6.5 - 7.5and also contains organic form can be used in mixed proportion with wood chips. Many types of compost available in form of Sewage sludge, Cow dung manure, organic waste from sugar and rise mills, yard waste etc. In study compost from sewage plant is used for treatment.

Wood Chips/pellets:

Saw dust, wood ware or wood chips/pellets which are high in porosity and organic content can be used for mixing with compost. Commercially prepared wood chips or pellets of size 2-3 cm can be used.

Details of use packing media is given in Table : 1

Table 1. Details of used Compost and Wood Chips Medi

Property	Compost	Wood Chips
Moisture content , %	48	14
Porosity, %	72	--
C/N ratio	14.5	107
Microorganisms	Facultative bacteria	--

III. MODELING AND ANALYSIS

Experimental Model:

As shown in Figure 2 – Lab scale Bio filtration model was prepared for the experiment set up. In that model waste gas it means VOC gas will flow from bottom of the tower to top through the inserted packing media. Sample point is given at distance to measure the VOC value.

VOC was measured with the use of VOC gas analyzer of multi Rae Company. Media used in bio filtration is compost (20%) and Wood Chips (80%). Due to its capacity to water retention and organic content and porosity equal flow distribution throughout the bed with temperature around 40 ºC.

Volume:03/Issue:05/May-2021 Impact Factor- 5.354 www.irjmets.com

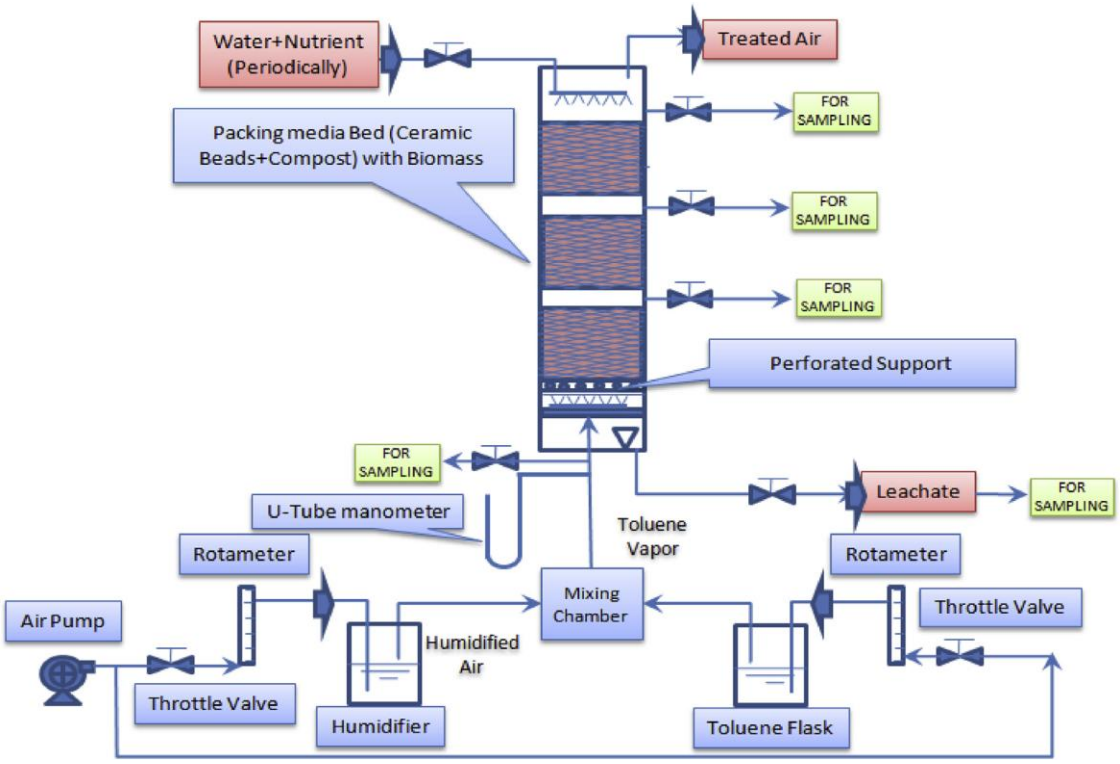

Figure: 2 Schematic diagram of experimental set

A SS Wire Mesh placed at the bottom accommodated the support for packing media for compost. Trial taken with packing media in proportion of 20 and 80 accordingly Compost and Wood Chips. Sampling port of 3 No. were placed with nob valve at equal intervals along the filter bed height of 15 cm. Liquid toluene was vaporized on Heating assembly followed by condenser effect to control temperature and humidified at constant air flow in a mixing chamber before entry to bio filter. Flow in Bio filtration tower was given in up flow mode in counter current direction. Experiment was tried on three types of VOC generating gas of polymer industry which are toluene, Methanol and ECH. Separate chemical was taken in heating assembly to generate VOC. It was mixed with then Air flow to adjust with the flow rate. Pressure drop monitoring gauge was installed I n inlet flow rate. To maintain moisture level in bio filter – water and nutrient spray from the top of the port was done regular interval and leach-ate generated from the tower will be collected at the bottom of the tower will be removed through bottom drain port.

Bio filter was operated in three operational phases and phase wise for removal of toluene, Methanol and ECH Separately. Bio filter was operated at the different flow and EBRT for the all three chemicals and moisture level maintained during experiment.

Detail specification of used bio filter is give in Table 2.

As VOC comes in contact with the bed material it gets degraded with the bacteria and stabilized into simple form.

Bacterial process in filter bed as under:

VOC gas + Media (Microorganisms) $\longrightarrow$ CO_2 (Gas) + H_2O + Bio mass

Figure:6 RE Variation in Toluene - ECH - Methanol

Experimental results are summarized in Table - 3-4-5 and represented in trend as shown in fig - 3-4-5.

Removal Efficiency of ECH chemical was high as compared to methanol and toluene. Though it would be high if we mix compound of VOC.

Experiment is performed with EBRT - 70 to 80 Sec. It is variable with the design parameter according to bed volume and design MLR - Mass loading Rate.

Performance of the Bio Filtration can be measured with basic calculation of Removal Efficiency, Elimination Capacity, EBRT and Mass Loading Rate.

These calculation was done as under:

Empty Bed Residence Time (EBRT):

EBRT is the time for that volume the gas retain in the filter bed during given fflow.

The actual gas residence time in the reactor can be calculated as the EBRT divide by the air-filled porosity available to gas flow, but such porosity is rarely known. EBRT is a simplified, relative measure of chemical residence time in a bio filter.

EBRT=(Vm/Q)/60

Where, Vm=biofilter packed bed volume (m3)

Q=Air flow Rate (m3/min)

EBRT=Empty Bed Residence Time(s).

Elimination Capacity (EC):

The elimination capacity is the amount of the pollutant or VOC removed by per volume of filter bed in unit time.

An overall elimination capacity is defined by Eq.

EC=Q (Ci-Ce)/V [g/m3/ h]

Where, Ci= Inlet concentration (ppm)

Ce= Outlet concentration (ppm)

Q=Airflow rate (m3/min)

V= Volume of bed (m3)

Removal Efficiency:

Removal efficiency is the percentage of removed pollutant fraction from the original inlet pollutant.

It is defined as

RE in % = (Ci-Ce)/Ci*100 %

Where, Where, Ci= Inlet concentration (ppm)

Ce= Outlet concentration (ppm)

Summary given Table 6 and In Figure. 6 Shows that RE of ECH was found high. Average RE for all three chemical was observed up to 60%.

However these data indicates that removal efficiency is not merely a function of loading rate, but also of residence time. For the same loading rate, reduced percentage removal occurred when the inlet concentration was lower and the residence time was decreased.

As bio degradation reaction is exothermic in nature will increase the temperature in filter bed. Temperature increase of 3 to 5 ˚C have been observed in many full scale bio filters. Further, Due to exothermic reaction media will get dry out in the center of the bed. Whereas the media near the reactor wall will remain with moisture content. Spraying of water from the top side of bio filtration tower maintain moisture content up to 50 - 60 % and temperature through the bio filtration tower.

V. CONCLUSION

Following conclusions can be drawn after Practical study and Literature Study:

Bio filtration is the more economical and easy to operate technology then physio-chemical process. As it also give effective result with the maintain of basic parameters like moisture, pH and temperature. In experiment Bio filtration was done for the three types of VOC gas - Toluene, ECH(Epichlorohydrin) and Methanol removal at polymer manufacturing industry by adopting media consisting of compost and wood pellets mixture.

In the Lab scale study, a flow rate maintained between 5 to 7 LPM and inlet concentration was maintained 100 – 130 ppm with EBRT 60 to 85 seconds has been investigated and a removal efficiency (RE) of 50 to 60 % for toluene, 50 to 70 % for ECH and 50 to 60 % for Methanol has been achieved with operating temperature ranging from 35 to 40 ˚C and Moisture content 50 to 60 % has been reported. Study also shows major operating problems such as increase in outlet air temperature by 3- 5 ˚C due to exothermic nature of bio degradation reaction as well as it also causes media dry-out problem. This requires continuous monitoring of outlet air temperature and relative humidity.

Study also reveal data that Inlet stream temperature to be controlled with pre condensing effect or Mixing with Air flow rate. In one run – Adding of pre assimilated Bio Culture in ECH gives better result as their oxidation capacity increased with active bio mass. Addition of nutrient can also impact the Bio Degradation process as like in Waste water treatment.

ABSTRACT

Modern organisations are in quest of initiatives that will facilitate them to be sustainable as well as provide a competitive advantage to remain a continuous stakeholder in the global market. Green Lean Six Sigma (GLSS) is an inclusive approach that not only improves environmental sustainability but also leads to improvement in the financial stability of the organisations. To implement the GLSS strategy, it is essential to integrate Green, Lean, and Six Sigma initiatives under the umbrella of GLSS. In this study, GLSS integration has been proposed based on intangible features like enablers, toolsets, etc. Management dedication, participation, and team effort have been recognised as the most remarkable enablers to implement GLSS in the manufacturing sector. Moreover, this study also proposes a five facet GLSS framework for the manufacturing sector to enhance organisational sustainability. The current work will facilitate managers and practitioners to execute a sustainable GLSS programme in manufacturing firms for increased operational excellence as well as environmental sustainability.

Green lean six sigma; Lean Six Sigma; sustainability; framework; Lean; Six Sigma

1. Introduction

Since the last few decades, increasing levels of greenhouse gases have led to unprecedented changes pertains to increased earth surface temperature, changed rain patterns, extinction of rare species and vulnerable human health (Environmental Protection Authority Report, 2020). Climate change due to the increased concentration of greenhouse gases (GHGs) is affecting human health and society, including changes in Lyme disease, West Nile virus, heat- and cold-related deaths and hospitalisations (Kaswan and Rathi 2020). In 2019, the annual GHGs Index was 1.45, which represents a 45% increase in radioactive forcing (a net warming influence) since 1990 (National Centers for Environmental Information, Global Climate report, 2020). Persistent increment in the concentration of GHGs can be attributed to fossil fuel–based energy methods, changed lifestyle, traditional methods of operations, etc. Industrial organisations consume natural resources in an uncontrolled way and release a substantial proportion of pollutants into the atmosphere (Sagnak and Kazancoglu 2016). Moreover, these organisations are not adopting proper waste disposal measures, which further add to environmental degradation. It has been found that industry contributes nearly one-fifth of the total global GHGs (IPCC 2014). Furthermore, increasing concern about sustainability changed quality perception, and demand for sustainable products forced manufacturing industries to adopt sustainable business practices (Sony and Naik 2020). So, it is imperative for industries especially manufacturing to curb their current level of emission. For this, industries have to changes their traditional business practices to sustainable ones. The manufacturing organisations have the inherent capability to adopt environmental-friendly approaches like Green Lean Six Sigma (GLSS) in their operations (Yacob, Wong, and Khor 2019).

1.1 Why green lean six sigma?

Green technology, Lean and Six Sigma are complementary, each approach has the potential to minimise the disadvantages of the others (Sony and Naik 2020). Lean is valued due to its ability to quantify waste, but it is not able to quantify environmental impacts and possible environmental hot spots (Sreedharan et al. 2018). So, at this juncture, green technology fills this gap and estimate the environmental impacts of generated waste. Green technology is employed in operations management to recommend approaches that are conscious of the environmental effects of production and operations (Deif 2011). The key objective of the green manufacturing concept is to reduce resource usage and pollution or to enhance the environmental performance of the organisation (Kaswan and Rathi 2021). Integrated Green Lean (GL) although able to recognise wastes and quantify ecological impacts but not often provide an actual method to reduce the wastes, and defects associated with the process (Garza-Reyes 2015). Six Sigma is a data-driven approach that fills this gap and provides

CONTACT Mahender Singh Kaswan mahi622@rediffmail.com School of Mechanical Engineering, Lovely Professional University, Phagwara, Punjab 144411, India

© 2021 Informa UK Limited, trading as Taylor & Francis Group

a concrete stepwise methodology to reduce waste (Sreedharan et al. 2020). Although Six Sigma reduces wastes through the reduction of defects, it cannot recognise different wastes and environmental impacts (Hussain et al. 2019). Since the last few decades, various strategies have been evolved (Garza-Reyes et al. 2018; Bhat, Gijo, and Jnanesh 2016) to manufacture high specification products, but an individual strategy is not capable to communicate all the points collectively associated with sustainability (Pandey, Garg, and Luthra 2018). So, it is imperative to integrate three unique methodologies under the umbrella of Green Lean Six Sigma (GLSS).

The Integrated GLSS approach aids organisations considerably to cut their energy use (Kaswan and Rathi 2019). Inclusive implementation of GLSS must be gradual, meaning that industries must estimate their strengths and weaknesses, determine priorities, and choose targets for successful implementation (Gholami et al. 2021). Three different dimensions of sustainability such as environmental, economic, and social are vital factors to be considered by any organisation (Ershadi, Taghizadeh, and Molana 2021). GLSS supplements organisations pursuits towards sustainability through, reduce of wastes, environmental footprints and defects. As GLSS is a novel prospect of sustainability, so it is imperative to comprehend different features that foster its integration, so that an inclusive understanding of this approach can be developed. GLSS is a project-based approach, and it has been found that nearly 40% of the projects have failed due to a lack of understanding of GLSS features and implementation framework (Gandhi, Thanki, and Thakkar 2021). In the literature, the study pertains to a framework of GLSS in construction, Jute industry exists (Banawi and Bilec 2014). But no study exists in the literature that provides a dedicated framework of GLSS with a toolset for manufacturing industries. This study provides integral measures and framework of GLSS pertains to the manufacturing industry. The integration among has been established through theoretical constructs and the framework has been supplemented with different toolsets at each stage of realisation of the GLSS project.

1.2 Research questions

Based on the above discussion, this study has proposed the following research questions:

RQ1. What are measures that foster integration among Green, Lean, and Six Sigma?

RQ2. How a dedicated framework of GLSS pertains to manufacturing is realised in a stepwise manner?

RQ3. What will be the implications of a proposed framework for managers and practitioners?

The rest of the article is organised as follows. Section 2 discusses the background for the research and provides a summary of the most significant studies reviewed so far. Section 3 deals with the adopted method for integration and framework of GLSS. Section 4 reports results and discussion and section 5 presents implications driven from the present work. The final section of the paper enumerates the conclusion and future research agenda.

2. Literature review

The literature review comprises three sub-sections. The first sub-section outlines the literature search methodology. The second one present's literature related to GLSS and the final sub-section depicts identified grey areas of research.

2.1 Article selection scheme and study flow

To select pertinent research articles, authors have used the systematic literature review (SLR) technique. It is a technique that validates a rigorous and translucent, process to literature review (Kaswan and Rathi 2021). It comprises a sequence of phases to ensure that significant precision and lucidity can be assured in the process of literature review (Tranfield, Denyer, and Smart 2003). Figure 1 depicts a systematic literature search methodology. SLR comprises of the following five successive phases: (1) Scope formulation, (2) Locating studies, (3) Study selection and Evaluation, (4) Analysis and Synthesis and (5) Reporting and using of results. SLR phases are as follows:

In the first phase, the scope of the study is decided; here, the study has been conducted with the viewpoint of identification of integral measures and exploration of frameworks. The pertinent research articles were searched using prominent databases in a subsequent phase of SLR. Authors have included research articles from the span of 1990 to 2020. In the study selection and evaluation phase, Context-Intervention-Mechanism-Outcome (CIMO) (Rousseau 2012) was employed to decide the inclusion/exclusion aspects of research strings. So, (lean eco-efficiency), (environmental lean), (lean green six sigma) and (lean eco-sustainability) are used as search strings. This methodical research and selection strategy is essential to procure inclusiveness of the literature review. A point of obstruction was reached when the same manuscript occurs continuously. To avoid this problem, search strings criteria were incorporated in 'Manual Check' concept for all the manuscripts depending on the abstracts of the article. This resulted in eradicating those articles that surely did not convey the concept of GLSS. Other search strings like sustainable lean and sustainability lean were also be evaluated. Search results comprised peer-reviewed manuscripts, published in proceedings of international conferences and academic journals.

In the analysis and synthesis phase, many techniques that comprise thematic synthesis, meta-ethnography, ground theory, etc. are used (Garza-Reyes, 2015). Out of these methods, thematic synthesis is regarded as the most suitable technique for the synthesis of the outcomes from SLR. Thematic synthesis includes the methodical coding of data and causing of expressive and systematic themes (Reddy et al. 2021). Reporting phase of SLR reveals that GLSS has acquired significant interest and acceptance within the community of research since 2012 as 84% (52 articles) of the publications liberated in the span from 1990 to 2020 have been made. This indicates that the GLSS concept is a comparatively new and emerging research area. The trend of GLSS publications may be predicted to continue expanding in the upcoming years.

Based on the SLR, authors selected articles and further investigated the same to find out pertinent gaps in the literature. To answer first research question, which pertains to

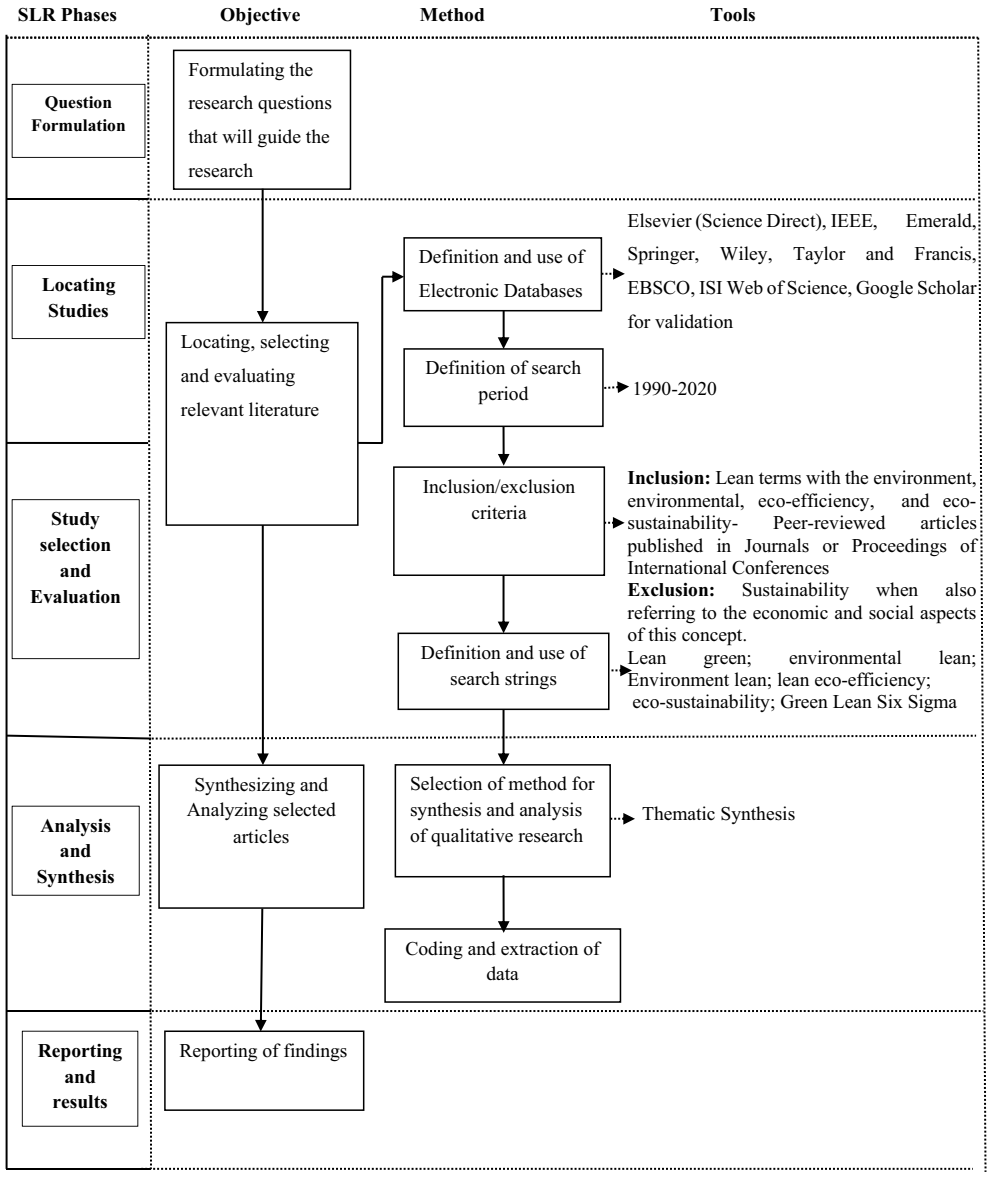

Figure 1. Systematic literature review methodology (adapted from Garza-Reyes, 2015).

integral measures of GLSS, authors identified enablers from literature and formulated theoretical elements (enablers, barriers, tools, etc.)-based model to facilitate the integration of Green technology, Lean and Six Sigma under the head of GLSS. To answer the second research question, authors formulated a five-facet GLSS implementation framework coupled with GLSS tools based on the insight gained from the previous studies. Finally, based on the proposed framework and integral model, theoretical implications and practical implications for potential research and practitioners have been driven.

2.2 Literature pertains to GLSS

Sustainable concerns have progressively acquired significance in the communities and economic discussions over the previous centuries (Chugani et al. 2017). Moreover, in recent years, there is an increasing pressure to enhance the quality, effectiveness and efficiency of products and services (Siegel et al. 2019). Manufacturing sectors contribute nearly one-fifth of carbon emission and it can be mainly attributed to conventional energy methods (Kaswan and Rathi 2021). The Paris agreement acknowledges key requirements to increase collective methods to change the climate effect through the incorporation of sustainable manufacturing operations. So, to remain competitive at the global platform, industrial organisations have to incorporate sustainable operations in their business practices. Green technology is generally employed in operations management to adopt approaches that are conscious of the environmental effects of production and operations (Deif 2011). It is used to enhance environmental performance but it is not able to identify waste and defects associated with process or system (Sony and Naik 2020). Therefore, the answer to this question comes from Lean Six Sigma (LSS), which make the organisation competitive through the reduction of wastes and defects. LSS are two distinct process enhancement approaches (Lean and Six Sigma) that focus on yielding end product profits (Antony 2012; Sreedharan et al., 2018). Lean philosophy makes the

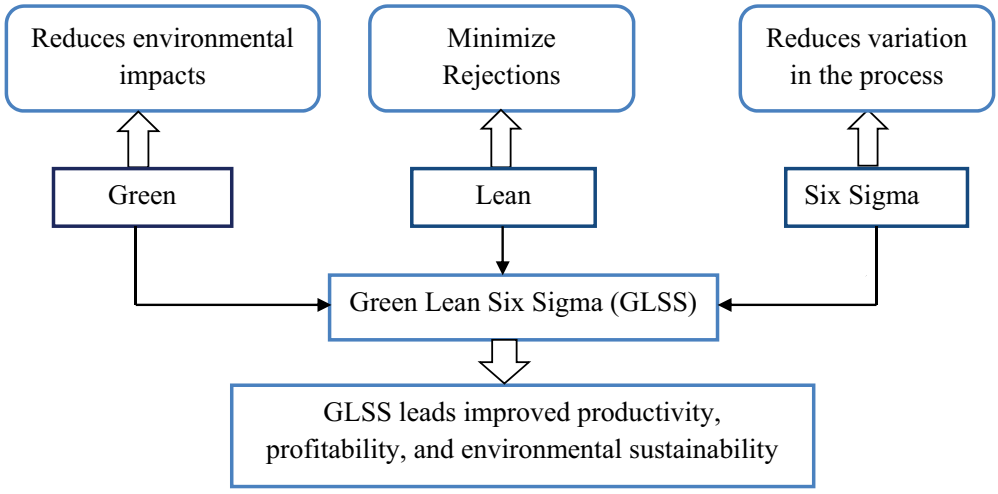

Figure 2. Integrated model of GLSS.

process streamlined and reduces different non-value-added activities (Persis et al. 2020). Six Sigma concept initiates value through compatible process output by recognising and minimising variations in the processes. Effective implementation of LSS approach will facilitate manufacturing sectors to minimise the variation in the process and manufacturing lead time (Albliwi et al. 2014). But LSS strategy is not able to estimate the ecological impacts of the process undertaken. The answer to this question is given by the incorporation of Green technology measures like life cycle assessment. So, it can be deduced from the above discussion that an individual approach is not able to address the modern challenges faced by industries related to sustainability aspects. So answer to this question comes through the integration of Green technology, Lean and Six Sigma under the umbrella of Green Lean Six Sigma. GLSS is a sustainable development approach that mitigates environmental impacts, wastes and defects from the process under consideration (Ershadi, Taghizadeh, and Molana 2021). Figure 2 depicts a simplified model of GLSS.

So, it is imperative to integrate Green technology with LSS pursuits to ensure the sustainability of manufacturing industries. In the literature, no study that prompts integration of Green technology, Lean manufacturing and Six Sigma based on theoretical measures has been reported for the manufacturing sector. Furthermore, as GLSS is a novel prospect of manufacturing, and it has been found that nearly 40% of projects pertain to GLSS have been failed due to a lack of GLSS know-how and framework (Kaswan and Rathi 2020). Although the study pertains to a framework of GLSS in construction, industries have been found in the academic literature (Banawi and Bilec 2014; Zamri et al. 2013). But there is no evidence of a systematic framework of GLSS framework pertains to manufacturing enterprises. Table 1 depicts major research pertains to GLSS that forms the basis for the identification of potential gaps in the research.

2.3 Research gaps

The literature advocates that LSS execution leads to constructive outcomes on the ecological and financial performance of the organisations (Ben Ruben, Vinodh, and Asokan 2017). However, the inclusion and implementation of Green technology with LSS are not deprived of challenges. Lack of finance for clean technologies, poor organisation support system, and unavailability of integral measures along with tools, further hinder effective execution of sustainability-oriented projects. In the literature, few studies exist regarding the framework of GLSS, but they are limited to the construction, jute and mining industries (Zamri et al. 2013; Hussain et al. 2019). There is no evidence of the GLSS framework that can exclusively be applied to the manufacturing industry along with the required toolset at each phase of execution. Moreover, there is no dedicated framework that guides industrial managers and practitioners to execute GLSS along with knowledge of different green metrics and associated toolsets. Furthermore, the study pertains to the integration of Lean with Green technology and Lean with Six Sigma exists but literature lack enough evidence related to the integration of Green technology, Lean and Six Sigma based on commonalities features. So, inclination towards sustainability practices, lack of dedicated execution method, and lack of knowledge base on green technologies measures, provides motivation and avenue for this research work.

3. Methods

In this research work to integrate Green technology, Lean and Six Sigma under the umbrella of Green Lean Six Sigma (GLSS) authors have used theoretical constructs found in the academic literature. For this, author's used enablers or success factors, tools, frameworks modern challenges to the manufacturing as commonalities features to foster integration. To make

Table 1. Major research work pertains to GLSS.

Sr. No.	Author	Year	Description
1	Zamari et al.	2013	Presented a model to analyse the correlation between GLSS and managerial innovation for automobile sectors. The major limitation associated with this study was that the GLSS framework and integration are not presented.
2	Banwai and Bilec	2014	Proposed a framework that integrates GLSS for enhancing the quality and environmental effects in the construction sector. The limitation of this framework was that it did not include manufacturing industries and takes more time for the implementation process.
3	Garza-Reyes	2015	The proposed integration of the green concept with Six Sigma initiative. The drawback was that it has a scarcity of application computation tools in distinct phases.
4	Cherrafi et al.	2016	Carried out the comprehensive review on LSS and sustainability perceptions and explored the prospect of combining GLSS into one approach for dispensing functional excellence. The main drawback of this review was that it is not valid for the manufacturing domain.
5	Sagnak and Kozancoglu	2016	Recommended Six Sigma integration to prevail over the drawbacks of green lean strategy. The proposed framework included measurement system analysis and gauge control-based methodology to assess variation of the process. The limitation of this framework was that it did not propose for GLSS implementation.
6	Cheraffi et al.	2017	Proposed a framework that efficiently assists the industries during the five-stage and sixteen-step process to successfully combine and execute GLSS to enhance environmental sustainability. The drawback of the framework was that empathetic operations may be complicated to execute the GLSS methodology.
7	Sreedharan and Raju	2018	Proposed a GLSS model in the public sector to explore the systematic aspects and hurdles in this sector. This framework lacks the comprehension and evaluation of many green lean wastes.
8	Pandey et al.	2019	Proposed GLSS approach to identify and rank performance improvement enablers in a business organisation. The drawback of this study was that enablers identified only for a specific sector and did not propose a framework.
9	Kaswan and Rathi	2019	Identified GLSS implementation enablers utilising Interpretive Structural Modelling. This model was evolved depends on the judgement of industrial personnel. This model is not certified with the help of other techniques.
10	Hussian et al.	2019	GLSS performance improvement barriers were recognised in the Pakistan construction industry. Modelling and outline were not presented.
11	Kaswan and Rathi	2020	Proposed execution model and framework of GLSS applicable to all industries. But, the application model for the realisation of GLSS in manufacturing at different stages of DMAIC methodology has not been reported.

manufacturing industries more sustainable, authors have proposed a five-step framework of GLSS and embedded different tools of Lean manufacturing, Green technology and Six Sigma. Subsequent sub-sections depict integration measures of GLSS and developed framework that will boost sustainability pursuits of manufacturing organisations.

3.1 Integration perspective of green lean six sigma

GLSS has emerged as a compatible strategy to ensure sustainable development due to its capability to improve productivity and reduces ecological effects (Sony and Naik 2020). Green Lean Six Sigma are three different strategies, but these are collaborative as, these mutually emphasise on mitigation of wastes and optimum resource utilisation (Kumar, Kumar, and Haleem 2015). Therefore, the general ideology and toolsets of these individual strategies can be combined under the umbrella of GLSS. Integration of GLSS can be perceived as the latest prospect to manufacturing sectors for enhancement in sustainable performance. It has been observed that industries that have incorporated GLSS have attained greater performance than those executed independent strategies (Kaswan and Rathi 2020). In the previous studies, there is no evidence of an ordered and congenital practice for the integration of GLSS. For this, the current study presents a conceptual integration model of GLSS based on factual aspects (Enablers, toolset, etc.). Figure 3 illustrates the integration model of GLSS. In this model at the input side are different challenge pertains to the modern manufacturing industries. Operational excellence techniques (Lean, Six Sigma, Lean Six Sigma) have been devised over time horizons to undertake these challenges to ensure organisational competitiveness. As new challenges pertain to social, environmental, uncertain information, and volatile demand comes to fore, organisation have to embed different strategies to realise the advantage of each approach (Ershadi et al. 2020). So, associated challenges with industries foster the integration of different approaches under a single aspect. Furthermore, enablers are the measures that make an organisation ready for the execution of a novel approach and ensure its success. The enablers perform as crucial input which encourages the combination of GLSS, whereas the performances in trade-off supply as output.

It has been found that most of the enablers of the individual approach of Lean, Six Sigma, and Green technology are similar (Cherrafi et al. 2017). In the previous studies, pertains to GLSS, top management support, organisation readiness and effective training have been identified as the most prominent enablers to execute GLSS (Kaswan and Rathi 2020). The same enablers that have been reported in the studies pertain to the individual approach (Aboelmaged, 2011). Therefore, enablers foster the integration of individual Green, Lean, and Six Sigma approaches under the canopy of GLSS. Different tools of Green technology, Lean, and Six Sigma are used concurrently (depicted in framework) and supplement organisational sustainability. For instance, green technology tool, life cycle assessment (LCA), is used to identify potential hot spots, where high emission occurs due to faulty process metrics. LCA provides a solution that leads to saving in a material by altering process parameters and using eco-friendly measures. This will lead to the saving of material and result in the reduction of waste of overprocessing and overproduction that is related to Lean manufacturing. Therefore, the tools of each approach supplement the function aspect from other individual approaches. GLSS tools/techniques will facilitate the organisations to address the challenges on the shop floor and managerial levels. Table 2 depicts production challenges and GLSS tools/techniques associated to overcome the same. This model exhibits the

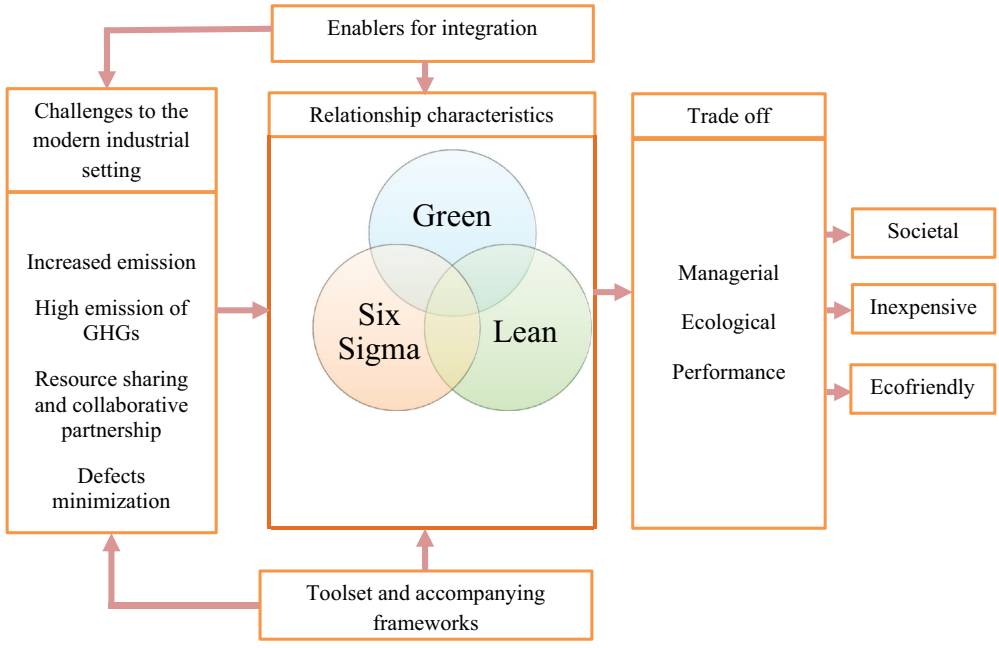

Figure 3. Integration of green lean and six sigma.

Table 2. Production challenges and GLSS tools.

Production Challenge/Problem	GLSS tool/Technique that can help
Batch Tracing	Kanban
Inventory and Equipment	VSM, Poka-yoke, SIPOC
High Emission of GHGs	LCA, VSM
Over Production	Kanban, Capacity Analysis
Defects Minimisation	Poka-yoke, LCA
Training to industrial Personnel	Kaizen, Standardisation
Imperfect by-product	Autonomation
Resource sharing and collaborative partnership	Standardisation
Perspective Plan	Policy Deployment, Hypothesis testing
Quality Control	Automation, Poka-yoke, JIT
Levelled exploitation	Heijunka
Automated Purchase	Kaizen
Materials controlling	5S
Estimating and understanding the relationship between variables	Regression Analysis

theoretical relationship linking these three synergetic strategies. The tools and related GLSS framework work as the assisting mechanism to support GLSS implementation and integration.

3.2. Proposed green lean six sigma framework

The manufacturing sector has employed Lean and Six Sigma strategies in their processes to minimise wastes and process variations. But, due to increasing concerns about sustainability and rigorous policies of the government, organisations have to shift operations dynamics towards eco-friendly methods. So, there is a great need for the inclusion of Green concepts in the LSS that leads to the development of an advanced strategy: GLSS. But to implement this comprehensive GLSS strategy, there is a requirement for a generic framework that dispenses step-by-step directions to attain sustainability. The proposed framework in this study includes a GLSS strategy into DMAIC methodology to attain both functional and environmental benefits (Figure 4). The objective of each step is to monitor and reduce harmful impacts on the environment. The proposed framework of GLSS is executed through the following steps:

Step 1: Selection of suitable sustainability-centred project

The purpose of this step is to choose a suitable project that depends on emission level, the voice of business and customers. GLSS is a project-based strategy and implemented in a step-by-step manner by encompassing every compartment or unit separately (Sony and Naik 2020). The project is categorised as a specific part that is chosen for the commencement of this approach. The GLSS implementation requires significant expenditure and systemic modification in the firm. Therefore, it is essential to choose a suitable project of GLSS that reveals the substantial scope for improvement in sustainability.

For this, an inclusive study of different departments of the industry is carried out. The explicit study of whole industry dispenses wastes, imperfections and related ecological emission levels prevails to distinct sections of manufacturing sectors. The models are prepared for rejection level, imperfections and distinct emissions after many segments. The prioritisation of independent models is accomplished in the succeeding stage to choose a project that reveals substantial capability for enhancement in environmental performance. Also, a high-level SIPOC (Supplier Input Process Output Customer) is to be elevated to dispense transparency on customers, suppliers and input materials required. Tools like Eco QFD and critical to quality (CTQ) are used here to transform sustainably directed customer demand in technical and ecological aspects. Based on the customer demands, simultaneously with business and ecological aspects, a proper project is selected. After recognition of an appropriate project, a charter is developed depending on the scope, program and team of the recognised project. It dispenses a description of roles and responsibilities, objectives of the project, outlines major stakeholders incorporated, and defines a complete control plan of the project.

Table 3. Toolset for GLSS realisation in a manufacturing environment.

GLSS tools	Step 1	Step 2	Step 3	Step 4	Step 5
	Selection of suitable sustainability centred project	Estimation for mapping of the current state of the project	Find out the prominent reason for emission and inefficiencies	Select and implement the best solution	Sustain with an adopted solution and make it mistake-proof

Performance improvement tool					√

Step 2: Estimation for mapping of the current state of the project

The purpose of this phase is to estimate the present state of the system or project undertaken. Now the performance of the adopted project has been estimated on various indices of GLSS. Based on collected data, sigma level, standard deviation" and C_{pk} of the project are evaluated with help of statistical tools. Further, assessment of carbon dioxide consumption, green energy coefficient, material consumption, etc. tools like life cycle assessment (LCA) environmental value stream mapping (EVSM) are used. To estimate the present stage of wastes, EVSM is treated as a beneficial tool of the lean concept. It dispenses an estimation of 'cycle' time and material consumption covering distinct phases and furnishes effective utilisation of time and funds. EVSM also estimates water, power and material consumption and environmental effects in conjunction with conventional value stream specifications like cycle time, changeover time, uptime, and lead time for all projects. Elaborating an Environmental Current State Map assists in predicting authentic manufacturing circumstances and dispenses awareness about resource consumption from point of view of the environment. Moreover, mapping is also employed in this step to gather details concerning the project to point out crucial input and output variables. Furthermore, LCA has been employed in the assessment process to estimate the ecological effects of every sub-process in distinct ecological influence classes. The integrated LCA and EVSM aid in the analysis of several green and lean measures that dispenses identification of possible hot spots for further improvements.

Step 3: Find out the prominent reason for emission and inefficiencies

The purpose of this step is to identify the major causes associated with wastes, emissions and imperfections in the adopted project. In this phase, firstly, value-added, and non-value-added actions have been recognised from the opinions of both customer and business. After this, the process cycle efficiency is directed to equate outstanding standards to detect how much enhancement is required. At the same time, a project is investigated to recognise the bottlenecks points and restraints in an adopted project. After investigation of the project under concern, the causes for emissions, defects and variations are identified. Here tools, like brainstorming, cause and effect diagram (C&E), five why analysis, life cycle impact assessment, failure mode effect analysis (FMEA), etc. are used. The project team here may use brainstorming sessions to recognise possible reasons for the development of these defects. Life cycle impact assessment has been carried out in this stage to measure the possible ecological effects of every process to identify possible sources for high emission levels. Once the potential causes have been investigated, then the study is constricted to find few pre-eminent causes. Tools like Pareto chart, principal component analysis (PCA), hypothesis, brainstorming and regression analysis are also been employed to unearth crucial root causes. Thus, these steps lead to the identification of main reasons for inefficiencies that require to addressed to improve sustainability measures of the project undertaken.

Step 4: Select and implement the best solution

After identifying major reasons for rejections and inefficiencies, then inherent solutions are suggested, explored and the best solution is implemented to handle pre-eminent causes. Here, assured cause and effect relationships are employed to detect a broad range of possible solutions. The solutions dispensed at the present juncture can be refused derived fuel (RDF), upcycling, anaerobic digestion (AD), and recirculation of water. In this phase, high innovation is required from the personnel of the organisation. Relevant training to the

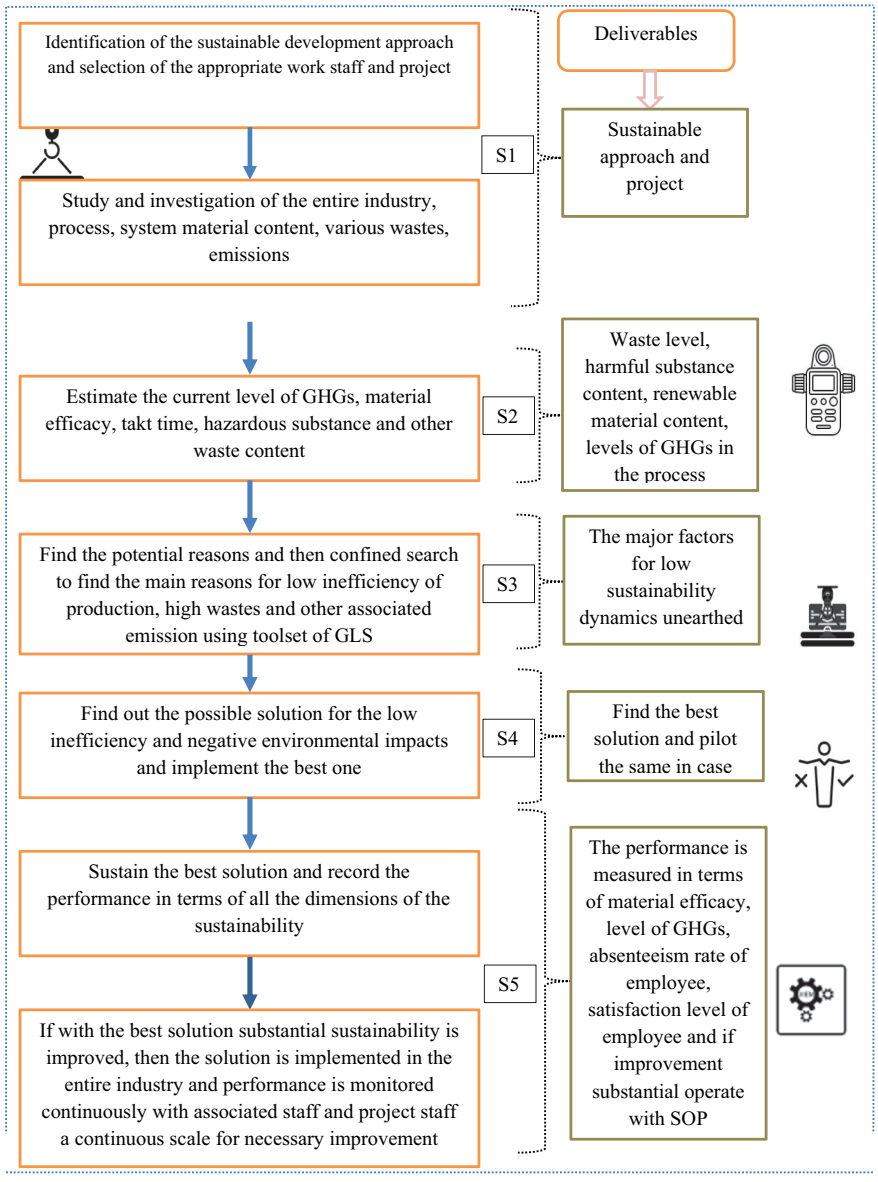

Figure 4. Green lean six sigma framework pertain to manufacturing.

industrial personnel and employees engaged in accomplishing the enhancement activities must be furnished to corroborate the effective execution of the GLSS framework. The feasible solutions are elaborated, standards are established, and elucidations are assessed to find out the best solution. Every origin of particulars like the customer, project sponsors, stakeholders and employed are utilised to propel assessment measures. CTQs, the business concerned, regulatory norms, are the crucial criteria that are used at this stage. Tools like solution matrix, Pugh matrix, Kaizen, and design of experiments (DOE), LCA, etc. are being employed to assess the best possible solutions against criteria.

DOE is carried out in this phase to identify the incredible settings for a merger of factors. Kaizen activities were suggested to improve those activities that do not outline any value based on rejection assortment. These were devised such that both functional and ecological requirements are fulfilled and all-inclusive efficiency gets improved. The Pugh matrix decides robustness and deficiencies of possible solutions so that robustness can be sustained and weakness can be removed. Here, the professionals should be open to adopt or integrate solutions for the determination of the pre-eminent solutions. After choosing the best potential solution, the existing VSM is rephrased to exhibit what practice will seem after changes are devised. The chosen best solution is implemented in the concerned project as a pilot project.

Step 5: Sustain with an adopted solution and make it mistake-proof

The purpose of this step is to sustain or control the best solution if significant enhancement is noticed in the project. This phase confirms that the benefits attained after executing enhancement measures are preserved after the accomplishment of the project. The outcomes acquired after executing enhancements measures must be conveyed to every employee who was engaged in the project. Moreover, a flowchart is prepared to distinctly express the responsibility and jobs of

each person to sustain the improvements. Performance actions must be outlined to assess the performance of the project after enhancements. The outlined typical initiatives which enhance functional and ecological efficiencies are certified with the help of an appropriate control plan. Appropriate training is planned for persons included in the practice to handle modifications made and assist the best solution. Tools like standard operating procedures (SOP), visual management, and Poke Yoke are used to sustain project success. Here, the process is re-explored with the help of EVSM and LCA' to detect the level of rejection and emission metrics. Moreover, control chart, data metrics and control charts are also used to re-evaluate sigma level, $C_{pk'}$, water, power and raw material consumption. If re-evaluated performance specifications are better than in the measuring phase, then adopted solution is retained. Once the success of the pilot solution is sustained, the same can be implemented throughout the industry for improvement in the sustainability of the industry to a greater extent. Therefore, inclusive execution of GLSS provides impetus to sustainability improvement pursuits of the manufacturing industry and enhances competitive advantage at the global platform through the production of sustainable products.

4. Results and discussion

Green Lean strategy has been broadly employed in manufacturing sectors; corresponding, limited work has been done pertains to the execution of GLSS (Hussain et al. 2019; Kumar et al. 2016). It is in its development stage, and manufacturing sectors are resistant to validate this strategy because of cultural differences and repulsion of practical shifts in the work process (Kumar et al. 2016). Once the integration of GLSS has been validated, one can simply communicate the distinct performances of the latest technologies. Enablers are the readiness bases for the manufacturing sectors to execute a novel approach (Laureani and Antony 2012). The industrial managers have taken into the consideration the changeover methods that assist in the effective execution of the new approach (Näslund, 2013). Table 4 represents the enablers for the adoption of GLSS. It is observed that management dedication and participation, team effort and organisational willingness are the key enablers for the effective execution of this strategy. The management dedication, knowledge base of GLSS tools, and assimilation of real-time dataset leads to the sublime success of the GLSS program. The authors have proposed theoretical integration of GLSS that motivates executives to embrace GLSS philosophy in their respective organisations. The study also reveals that the accomplishment of the project in distinct organisations will lead to an improved sigma level of organisation through the reduction in defects. The proposed framework will boost the organisation Green Lean initiative, consequently leads to improved environmental performance in business operations. Moreover, successful execution of the said framework will result in the reduction of material consumption, water usage, and energy utilisation that will enhance environmental efficiency. Besides, parameters that pertain to Lean like, cycle time, lead time, and work in process will significantly reduce through the adoption of the proposed GLSS framework.

The GLSS toolsets also boost the integration and execution of the GLSS strategy. GLSS tools explore hot spots, eliminate rejections, and assists in the best exploitation of resources (Kaswan and Rathi 2021a). Table 3 depcits GLSS toolser for manufacturing industry. The SIPOC chart and EVSM have been found as the most broadly employed tools. Moreover, the most generally employed tools found to be: cause and effect diagram (C&E), process capability and reverse logistics. After the assessment of 18 research manuscripts relates to GLSS, it is observed that most of the research manuscripts used 'lean tools' to obtain lean and green goals. So, manufacturing sectors are inclined towards Lean tools to satisfy environmental measures. The importance of GLSS is enhancing continuously due to its pragmatic impacts on sustainability dynamics. The current work dispenses an integration of GLSS employed on conceptual points and proposed a comprehensive DMAIC-based framework. The developed framework performs as a pilot frame for GLSS execution in a single unit or division of the manufacturing industry. This framework can be expanded in the entire firm after its effective implementation of a pilot project. The proposed framework exhibits the integration of Green and Lean matrices at each step that has been excluded in the prior studies related to Green Lean. Green and Lean actions perform as potential areas for the selection of the project in the first step of the framework of GLSS. To estimate the present situation of the system, in the second step of GLSS execution tools such that EVSM, LCA are employed. The inherent measures for rejections are detected in the third step of 'framework with the help of tools such as LCA and traditional statistical tools. To find probable solutions in the subsequent step of framework' tools like life 'cycle interpretation, EVSM, 5S, Kaizen, etc. are employed. The adopted GLSS framework is sustained for a 'longer span if gains made are significant than the preceding situation of 'project 'under consideration. The proposed framework of GLSS will ensure organisation sustainability through optimum resource utilisation, reduction of wastes, defects, and mitigation of environmental emissions.

5. Implications

The present research work exhibits both theoretical and practical implications. The subsequent subsection depicts the theoretical and practical implications of this research work.

5.1 Theoretical implications

There is a need to scale up the worldwide response to mitigate GHGs emissions through the incorporation of sustainable business practices. GLSS approach mitigates environmental footprint by systematically identifying and mitigating possible hot spots that improves the performance of triple bottom line (social, economic, and environmental). This study develops a thorough knowledge for potential researchers and academia by providing deep insights into integral measures and frameworks. Measures of integration (enablers, barriers, tools, etc) foster the success rate of the GLSS project as they serve as basic know-how before the execution of any sustainability

Table 4. Enablers for adoption GLSS.

Sr. No.	Enablers	Description	References
1	Management dedication and commitment	The participation, support, and vision of the management perform a crucial role in executing the GLSS approach in manufacturing sectors. Management dedication performs a crucial role in the firm's environmental retaliation adequate human, technological and economic resources for executing this strategy.	Bhuiyan and Baghel 2005; Yadav and Desai 2016
2	Allocation of Funds	Funds allocation commences with suitable planning which the manufacturing sectors ready for its objectives and visions for the future. Once the objectives are prepared, the manufacturing sectors require allocating sufficient funds.	Snee 2010
3	Quality of raw material	Quality of raw material is the basis to ensure topmost quality products. A topmost quality product assists the satisfaction of the customers. It will result in improved functional performances, profitability, and the production of high specification products.	
4	Team effort	To attain the objectives of GLSS, every employee of the firm must perform as a group.	Sreedharan et al. 2018; Ben Ruben, Vinodh, and Asokan 2017
5	Prudent interconnection with the retailers	Faithful retailers are necessary with the purpose that raw materials and other components have been provided for some time.	Siegel et al. 2019
6	Proficient training and education programmes	Proficient training and education programs are the most vital needs for executing the GLSS strategy in manufacturing sectors successfully. A rigorously planned training program induced the essential knowledge, skills, and approaches in its employees that are essential for accomplishing the task.	Ravi and Shankar 2005
7	Relating GLSS to business approach	Relating the GLSS concept to business approaches assist the firms to attain prudent business objectives through the utilisation of policy decisions by the management care.	Antony, Gijo, and Childe 2012
8	Culture with effectual correspondence	Change in the culture is crucial for the progress of the manufacturing sectors. The workers associating with any firm should have the liberty of sharing their views to arise with inventive solutions to provide benefits to the organisations.	Hu et al. 2008; Zu, Robbins, and Fredendall 2010
9	Effective Scheduling	Waiting time is a vital problem in manufacturing operations. An effective scheduling system assists in minimising time guiding to curb cost surges, time-preserving, and better performance of the manufacturing sectors.	Maleyeff, Arnheiter, and Venkateswaran (2012)
10	Organizational know-how	Each worker of an organisation must be self-assured with the whole system such that the individual can lay down his or her perceptive attempts for the progress of the organisation.	Kaswan and Rathi 2021
11	Organizational willingness	The business must be in a situation to initiate GLSS in their processes as it needs again transition.	Cherrafi et al. 2017
12	Selection of appropriate tools	Tool selection and technical expertise is key to the execution of the GLSS program	Sony and Naik 2020; Sreedharan et al., 2020
13	Collection of data and performance measures	Collection of data and performance measures is essential for the achievement of the GLSS initiative as 'they dispense support for comparisons.	Habidin and Yusof 2012; Yadav, Seth, and Desai 2018
14	Incorporation beyond the phases of a 'product development 'cycle'	Concurrent engineering conception and incorporation at several phases of product development is necessary to instigate genuine products.	Luthra et al. 2011; Kaswan and Rathi 2020
15	Involvement of suppliers	The involvement of suppliers with the manufacturer is vital for the execution of the GLSS concept. Suppliers are the origin of renovation in the firm. Better involvement of suppliers results in the best quality products.	Kushwaha 2010; Luthra et al. 2011
16	Use of appropriate technology	Advanced technology facilitates organisations to improve the quality of products and enhances the overall environmental performance. It helps the organisation to improve communication, proper utilisation of resources, and minimising paperwork which would result in significant functional performances.	Ravi and Shankar 2005
17	Effective visual system	Visual control helps the organisations to identify those areas where improvements are required to be undertaken.	Shen and Tam 2002
18	Manufacturing facilities with good quality	An accurate, precise, and good quality manufacturing facility assists in the production of high quality and cost-effective products.	Antony, Gijo, and Childe 2012
19	Customer engagement	The customer engagement approach assists the organisations to consummate the business with minimum overheads on human resources. It also minimises the need for middlemen.	Albliwi et al. 2014
20	Green design actions	Green design implies eco-design which targets mitigating the environmental effects yielded by-product at several phases of product chain commencing from taking out of materials to the utilisation of the product.	Vinodh et al., 2011; Yadav et al. 2017

improvement project. Enablers are the promptness measures that make an organisation ready to execute a novel approach. Barriers knowledge base enables researchers to find out the avenues that mitigate the intensity of barriers. Systematic phase-wise toolset provided in this study augment researchers and academicians to adjudge which tool to be implemented at different stages of execution of the GLSS project. The proposed GLSS framework will methodologically facilitate researchers to implement GLSS in manufacturing industries. This will enrich insights on assessment of different metrics, reasons for inefficiencies, identification and implementation of sustainable solutions during the execution of projects related to GLSS and sustainability.

5.2 Practical implications

The proposed framework of GLSS will methodologically facilitate manufacturing industries to implement sustainability improvement initiatives. The developed framework is designed in such a way that each phase contributes to the reduction of wastes and emissions, leads to enhancement in

revenue, making this initiative a worthwhile proposition in the long run. Moreover, this work also furnishes guidelines to industrial personnel for managing the GLSS approach conductive, to secure more flexible, vigorous and methodical processes. The implementation of the GLSS strategy facilitates industrial organisations to achieve organisational and environmental benefits. Further, this study encourages industrial managers and practitioners to recognise possible hot spots that require immediate attention to increase organisational sustainability. This study facilitates the entrepreneurs and ecologists to start sustainable industrial practices like GLSS that leads to reduced ecological damage by promoting: reduce, reuse, recycle, recover and residual management (5'R). Altogether, humanity will be promoted from this study in terms of mitigated emissions and other non-value-added activities through the sequential execution of a sustainable GLSS approach.

6. Conclusions

GLSS has been perceived as a comprehensive strategy that mitigates harmful environmental impacts and provides top-quality environmentally sound products. The purpose of this approach is to enhance metrics like quality, profitability, customer satisfaction, process efficiency and responsiveness. In this research work, GLSS integration has been proposed centred on intangible features like enablers, toolsets, etc. The enablers encourage the integration of the GLSS strategy and related tools and execution techniques to augment GLSS integration. Management commitment and team efforts have been recognised as the most remarkable enablers to execute GLSS strategy in manufacturing industries. The components and the elements of this framework have been presented in such a way that it would fetch high specification eco-friendly products more conveniently when applied in the manufacturing organisations. The proposed GLSS framework dispenses a prospect for the manufacturing enterprises to set up the best practices for defect minimisation and mitigation of environmental impacts.

6.1 Limitations and future scope

Despite several contributions, the present study has a few limitations. Firstly, the proposed GLSS implementation framework takes considerable time during implementation as different tools evolved at different stages of execution. Therefore, the generalisation of outcomes should be taken into consideration just after further studies in distinct manufacturing units. Secondly, limitations associated with this research work is that framework of GLSS has not been tested practically. This drawback imparts motivation for future research directions to implement GLSS in various manufacturing industries. The developed framework must be tested in multi-cultural environments to prospect the contingent and societal impacts on the developed framework. In offing, the proposed framework can be extended by incorporating more sustainability drivers and other associated tools of social sustainability. Further study can also expand GLSS applicability for sustainability improvement by integrating aspects of industry 4.0 and circular economy.

Disclosure statement

No potential conflict of interest was reported by the author(s).

Notes on contributors

Vishwas Yadav is pursuing Ph.D. in Mechanical Engineering from University Institute of Engineering and Technology, Maharishi Dayanand University, Rohtak, Haryana, India. His areas of research are: Green Lean Six Sigma, Total Productive Maintenance, Life cycle assessment, Sustainability and Green Manufacturing. He completed his master's in Mechanical Engineering with specialization in Industrial and Production from National Institute of Technology, Kurukshetra. He completed his bachelor's in Mechanical Engineering from UIET, Maharishi Dayanand University, Rohtak. He has a teaching experience more than 6 years. He is adept in optimization and decision making techniques like: ISM, GRA, AHP, BWM, Decision-Making Trial and Evaluation Laboratory.

Dr. Pardeep Gahlot is working as an Assistant Professor in University Institute of Engineering and Technology, Maharishi Dayanand University, Rohtak, Haryana, India. He completed his PhD from University Institute of Engineering and Technology, Maharishi Dayanand University, Rohtak, Haryana, India. He has been associated with teaching over last 12 years. His areas of research are: Production Engineering, Friction Stir welding, engineering materials. He has presented many papers in national and international conferences and published articles in reputed journals. He is adept in optimization and decision making techniques like: Design of Experiments, Taguchi Method, Experimental Analysis, Response surface methodology.

Dr. Rajeev Rathi is working as an Associate Professor in the School of Mechanical Engineering Lovely Professional University, Punjab, India. His areas of research are: Six Sigma, Lean Six Sigma, Green Lean Six Sigma, LCA, Sustainability and Green Manufacturing. As inspired researcher, he has presented many papers in national and international conferences and published articles in various reputed journals. He is adept in optimization and decision making techniques like: ISM, Preference Ranking Organization Method for Enrichment of Evaluations, Best worst method, Decision-Making Trial and Evaluation Laboratory. His research interests include lean six sigma, green manufacturing, life cycle assessment, circular economy, industry 4.0, clean technologies measures, and Sustainable supply chain.

Dr. Gunjan Yadav is currently working as Associate Professor and Head in Mechanical Engineering Department at Swarnim Startup & Innovation University (SSIU), Gandhinagar (India). He is having more than 12 years of Teaching, Training, Consultancy, Research experience. He has had his education and training in Mechanical and Industrial Engineering at B.E. and M.E. He has completed his Ph.D. from Sardar Vallabhbhai National Institute of Technology (SVNIT), Surat. He has obtained MHRD sponsored funding of □ 1.5 Lacs to pursue International Projects. He is serving as reviewer to renowned International Journals such as Journal of Cleaner Production (Elsevier), Production Planning and Control (Taylor & Francis), Transportation Research: Part A (Elsevier), International Journal of Production Research (Taylor & Francis) and many more. Presently his h-index is 15 and i-10 index is 17. He has contributed 60+ research papers at National/International level at various journals (SCI/Scopus indexed), seminars and conferences. He is presently guiding 12 M.Tech and 3 Ph.D. students. He has chaired sessions at International/National conferences and delivered invited talks in various NITs and government funded institutions. He is presently associated with various societies which include Institution of Engineers (India), Indian Institution of Industrial Engineering (IIIE), Indian Society of Technical Education (ISTE), Operation Research Society of India (ORSI). He regularly conducts training programs and guides research scholars on areas such as Sustainable Manufacturing, Lean Six Sigma, QMS, GT, Renewable

Energy Management, Quality and Productivity Improvement etc. He has been in association with organization of several conferences and open as well as in-house training programs. He can be contacted at gunjanyadav86@gmail.com

Dr. Anil Kumar is a Senior Lecturer (Associate Professor) at Guildhall School of Business and Law, London Metropolitan University (LMU), London, U.K. For the last ten years, he has been associated with teaching and research. Before joining LMU, he was Post-Doctoral Research Fellow in area of Decision Sciences at Centre for Supply Chain Improvement, University of Derby, United Kingdom (UK). He earned his Ph.D. in Management Science from ABV-Indian Institute of Information Technology and Management, Gwalior, India. He did his graduation in Mathematics (Hons) and MSc (Mathematics) from Kurukshetra University, India. He earned his Master of Business Administration (MBA) and qualified National Eligibility Test (NET), June 2011. He has contributed over 100+ research papers in international referred & national journals, and conferences at the international and national level. He has sound analytical capabilities to handle commercial consultancy projects and to deliver business improvement projects. He has skills and expertise of Advance Statistics Models, Multivariate Analysis, Multi-Criteria Decision Making, Fuzzy Theory, Fuzzy Optimisation, Fuzzy Multi-Criteria Decision Making, Grey Theory and Analysis, Machine Learning, Application of Soft-Computing, Econometrics Models etc. His areas of research are sustainability science, green/sustainable supply chain management, customer retention, green purchasing behaviour, sustainable procurement, sustainable development, circular economy, Industry 4.0, performance measurement, human capital in supply chain and operations; decision modelling for sustainable business, and integration of operation area with others areas.

Dr. Mahender Singh Kaswan is an Assistant Professor in the School of Mechanical Engineering Lovely Professional University, Punjab, India. He holds a Ph.D. in Mechanical Engineering from Lovely Professional University, Punjab, M.Tech. in Industrial and Production Engineering from National Institute of Technology Kurkshetra India, and B.E. in Mechanical Engineering from former Career Institute of Technology and Management, India (Manav Rachna International University). He has published a number of articles in leading international journals and conferences. His research interests include lean six sigma, green manufacturing, life cycle assessment, circular economy, industry 4.0, clean technologies measures, and Sustainable supply chain.

Abstract- Mental stress is one of the major contributors to a variety of health issues. Various measures have been created by scientists and medics to determine the intensity of mental stress in its early phases. To assess mental stress in the workplace, several neuroimaging methods have been developed. One key candidate is the electroencephalogram (EEG) signal, which offers a wealth of information regarding mental states and conditions. We analyse trustworthy heart rate variability (HRV) metrics in order to detect stress in this study.We refer WESAD dataset, an experiment protocol was established including two different sensors which correspond to a range of everyday life conditions.We present our work on the development of a stress detection system based on heart rate by calculating and comparing HRV features from time and frequency domain analysis and classifying these features with the machine learning and deep learning algorithms.

Keywords-Mental Stress,Heart Rate Variability, Machine Learning, Deep learmoing, LSTM, WESAD

I. INTRODUCTION

In the current scenario, mental stress has become a social problem. It affects the daily routine work and economy ofan individual and a nation as well. Stressfulin the working style of human age from twenty-five to forty has the effectiveness of stress in their life. Stress has become the common part of daily life which most people struggle in different stages of life. Mental stress has grown to be a social difficulty and could turn out to be a cause of practical incapacity during hobbies work. Mental stress or pressure has been recognized as one of the major contributing variables that prompt different illnesses. The term pressure is characterized into two sections, for example, positive or negative.

Positive pressure consistently searches for a chance, development like improvement in execution, while negative pressure developes more serious conditions. Mental stress is one of the contributing factors to health problems. It is defined as the human body's response to mental, physical, and emotional stimuli, as controlled by the sympathetic nervous system (SNS) and the hypothalamus–pituitary–adrenocortical axis (HPA axis) [1].

This expression can be applied to both internal (personality structure) and external (problem solving) issues, resulting in a variety of physiological and negative emotional alterations [2]. Acute stress, episodic stress, and chronic stress are the three types of stress identified in the literature [3]. Acute stress is caused by a brief period of exposure and is not damaging. When a stimulus is more frequent for a short period of time, it is called episodic stress [4]. Chronic stress, on the other hand, is the most harmful, as it is caused by long-term stressors [5]. Mental stress has been linked to a variety of disorders, including stroke, cardiovascular disease, cognitive issues, speech abnormalities, and depression, according to various studies [6,7].

1.Wareable Sensor Description

WESAD provides data from two kinds of sensors: chest-worn (RespiBAN) and wrist-worn devices (Empatica E4). For the data collection, we used both a chest- and a wrist-worn devices: a RespiBAN Professional and an Empatica E4, respectively. The RespiBAN itself is equipped with sensors to measure ACC and RESP, and can function as a hub for up to four additional modalities. Using the four analog ports, ECG, EDA, EMG, and TEMP were recorded. All signals were sampled at 700 Hz. The RespiBan was placed around the subject's chest (see Figure 1). The RESP is recorded via a respiration inductive plethysmograph sensor.

The ECG data was recorded via a standard three point ECG. In order to allow the subject to move as freely as possible, the EDA signal was recorded on the rectus abdominis (the abdomen has a high density of sweat glands [8], hence suitable for EDA measurement) and the TEMP sensor was placed on the sternum. The EMG data was recorded on the upper trapezius muscle on both sides of the spine. In order to avoid wireless packet loss, the recorded data was stored locally and transferred to a computer for further processing after the experiment. All subjects wore the Empatica E4 on their non-dominant

© 2021 IJSRET

hand. The E4 records BVP (64 Hz), EDA (4 Hz), TEMP (4 Hz), and ACC (32 Hz) are specidfied in Table 1. [9]

Table 1: Empatica E4 data modalities

Data	Sampling	Description
ACC	32Hz	Accelerometer data consists of 3 axis channels
BVP	64Hz	Data from a photoplethysmograph (PPG).
EDA	4Hz	Consists of a tonic (referred to as skin conductance level (SCL)) and a phasic (skin conductance response (SCR)) component.
TEMP	4Hz	Temperature in ˚C

Figure 1 Respi BAN.

2. Application of Stress Detection System

Stress is related to every aspect of human life but is applicable more for people with disabilities. Here are some examples, a stressful situation for a blind person can be as simple as requiring a decision while walking as to whether to change direction, when to cross a street, and how to avoid a sudden obstacle.Firefighters and smoke divers are constantly exposed to stressful situations as they engaged in rescue activities involving fire and poisonous smoke. Any stress in such situations may occur mainly due to lack of knowledge about the affected place, fast-changing conditions, time restrictions, exhaustion, disturbing sights, elevated level of heat, or smoke. This exposure to high-risk environments while performing their jobs, leads to various mental and health problems due to constant physical and psychological stress. A person who has attempted to carry out an attack previously. Such attacks can be avoided by measuring the levels of physiological stress of the suspected person using stress detection systems.

3. Section Organization

These remaining sections of the paper are organized as follows. In the next section, the relation between stress and diseases is presented. Related terminologies are shown in section 3. The proposed methodology for stress management is given in section 4. The obtained result analysis is shown in section 5. Finally, conclude this research article in section 6.

II.STRESS VS DISEASES

Stress will vary vastly from person to person and differs in line with our social and economic circumstances, the surroundings we tend to sleep in, and our genetic makeup.There area unit several things which will result in stress. The death of a beloved, divorce/separation, losing employment, and sudden cash issues area unit among the highest 10 causes of stress in line with one recent survey.But not all life events area unit negative and even positive life changes, like moving to an even bigger house, gaining employment promotion, or occurring vacation are sources of stress. The most significant health problems related to stress are:

1. Depression and anxiety
2. Pain of any kind- Headaches, Stomachache etc.
3. Sleep problems
4. Autoimmune diseases
5. Diabetes
6. Digestive problems, Gastrointestinal problems
6. Skin conditions, such as eczema
7. Heart disease
8. Asthma
9. Weight problems
10. Reproductive issues
11. Thinking and memory problems
12. Alzheimer's
13. Accelerated Aging
14. Premature Death etc.

Hence it is pertinent to be aware of the common warning signs and symptoms of stress overload. Table 2 lists the signs and symptoms of stress overload. Overload of stress can lead to major depression in susceptible people and health problems as mentioned above.

Table 2 Stress Symptoms and Signs

Symptoms	Signs
Cognitive symptoms	Inability to concentrate,Constant worrying,Seeing only the negative, Poor judgment, Memory problems, Anxious or racing thoughts,
Emotional symptoms	Loneliness and isolation, Anxiety and agitation, Moodiness, irritability, or anger, Depression or general unhappiness, Feeling overwhelmed, Other mental or emotional health problems
Physical symptoms	Diarrhea or constipation, Aches and pains, Nausea, Frequent colds or flu, dizziness, Chest pain, rapid heart rate, Loss of sex drive

© 2021 IJSRET

Behavioral symptoms	Withdrawing from others, Eating more or less, Sleeping too much or too little, Using alcohol, cigarettes, or drugs to relax, Procrastinating or neglecting responsibilities, Nervous habits (e.g. nail biting), pacing.

III.RELATED WORK

An algorithmic rule for stress level recognition from the graphical record is planned. To validate the algorithmic rule, an associate degree experiment is intended and disbursed, increasingly, people are collecting detailed personal activity data from commercial trackers. Such data should be able to give important awareness about their activity levels. Millions of people track their physical activity and this data is usefull for analysis of stress detection for daily life of human [10]. [11] provides an effective method for the detection of cognitive stress levels using data provided from a physical activity tracker device developed by FITBIT. The major goal of this system was to use sensor technology to identify stress using a machine learning method.

The effect of each stressor was tested separately using logistic regression, and then a combination model was developed and analysed using ordinal logistic regression models such as logit, probit, and complementary log-log. The novelty of this work lies in the fact that a stress detection system should be as non-invasive as possible for the user.In [12] author proposed a system using Internet of Things architecture where we adopted an activity tracker as our sensing device to reduce cumbersome for daily use.Among the total of 17 features extracted from activity tracker, five features belong tosleep data and six features belong to heart rate data that were proposed to develop the stress recognition model.

In the evaluation of our system, we achieved the accuracy as high as 81.70\% on the cross validation and 78.95\% when tested on the test set. In [13] the authors objective is to investigated the mediating role of work and family activity conflicts (WFC) and family and work activity conflict (FWC) on the effects of workload and life style of the family.Using AMOS 20 through bootstrap analysis for indirect effect, this study assessed the above mentioned relationships based on data collected from 258 respondents in the hospitality industry in Quebec. By highlighting the cross-domain effects, the present research contributes to the existing knowledge by testing the mediating role of WFC and FWC in the effects of workload and various resources of social support on job stress social support in job stress.

IV. METHODOLOGY

In the proposed methodology is divided into different levels like dataset description, analysis of various Machine Learning algorithms and Figure 2 illustrates a flow chart of proposed methodology.

1. Dataset Description

WESAD is a publicly accessible dataset for detecting wearable stress and affect. This multimodal dataset contains physiological and motion data collected from 17 people during a lab research using both a wrist- and a chest-worn device. Blood volume pulse, electrocardiogram, electrodermal activity, electromyogram, respiration, body temperature, and three-axis acceleration are among the sensor modalities provided. Furthermore, by covering three separate affective states (neutral, stress, amusement), the dataset bridges the gap between past lab investigations on stress and emotions. In addition, the dataset contains the individuals' self-reports, which were acquired using a variety of standard questionnaires. Details can be found in the readme file for the dataset, as well as in [29]

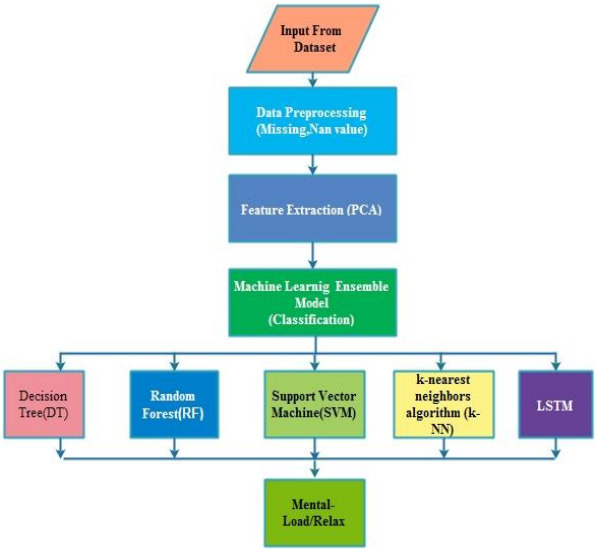

Figure 2 Proposed Flow Chart

Table 3 Dataset Description

Dataset Description	
Data set Characteristics	Multivariate, Time Series
Number of Instances	63000000
Attribute Characteristics	Real
Number of Attributes	12
Missing Values?	In 2 subject, exempted
Number of Subjects	17

2. Machine Learning Algorithm

The Machine Learning (ML) has prompted a new concepts and technologies, including supervised, unsupervised and reinforcement learning, new algorithms for robots, the Internet of Things, analytics tools and many more. The Figure 2 shows the machine learning algorithms based on

© 2021 IJSRET

the learning; supervised and unsupervised and problems; classification, regression and clutering. The paper specifies classification problem for stress detection using WESAD dataset. SVM offers high accuracy compared to other classifiers such as logistic regression, and decision trees. It is known for its kernel (linear , polynomial, radial basis function) trick to handle nonlinear input spaces. It is used in a variety of applications such as face detection, intrusion detection, classification of emails, news articles and web pages, classification of genes, and handwriting recognition [14]. SVM is considered to be a machine learning approach, which can be employed in both types of classification and regression problems. It can easily handle multiple, continuous and categorical variables.

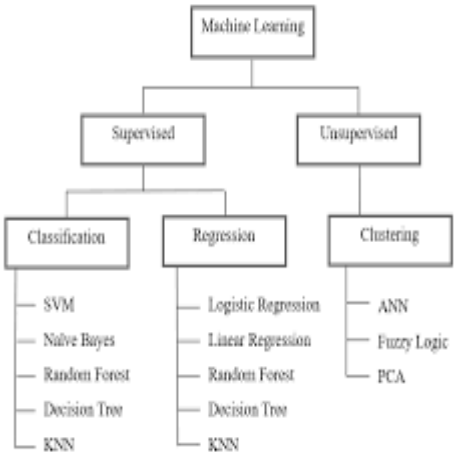

Figure 3 Machine Learning Algorithms

Decision trees are individual learners that are combined. They are one of the most popular learning methods commonly used for data exploration [15]. One type of decision tree is called CART, classification and regression tree.

Random forests is a supervised classification learning algorithm. It is also the flexible and easy to use algorithm. Random forest (or random forests) is an ensemble classifier that consists of many decision trees and outputs the class that is the mode of the class's output by individual decision trees [16]. K Nearest Neighbor(KNN) is a very simple, easy to understand, versatile and one of the topmost machine learning algorithms. KNN is used in a variety of applications such as healthcare, image recognition, finance, political science, handwriting detection and video recognition [17]. KNN is a non-parametric and lazy learning algorithm. Non-parametric means there is no assumption for underlying data distribution. That is, the model structure is determined from the dataset.Lazy algorithm means it does not need any training data points for model generation.

V.CONCLUSION

Machine Learning has been broadened an excessive number of zones of diseases through the outstanding headway of Machine Learning. Heaps of data mining and Machine studying techniques have been applied tothe WESAD dataset for push and loosen up state forecast. In this paper,WESAD dataset was used.The information was recorded from 17subjects, excepted 2 subjects data due to loss of record. Our next step will be to build ML models, we will apply four celebrated AI calculations specifically, Random Forest, K Nearest Neighbor, Support vector machine, and Extra tree classification. Accuracy, precision, recall and F1 socre will be the compairing parameters based on confusion matrix. Our ultimate objective in this study would be to develop a high-accuracy model based on real-time data by overcoming unresolved challenges to alleviate the stress of the users.

LSTM Based Mental Stress Level Detection using Wearable Sensor Devices

Yashvant Dev, Mayank Namdev, Dr Ritu Shrivastava, Dr Rajiv Srivastava
Department of Computer Science and Engineering
Sagar Institute of Research and Technology, Bhopal
yashvantdev.d@gmail.com

Abstract- Nowadays, mental stress is a severe problem, particularly among teenagers. The age group that was previously thought to be the most carefree is now under much strain. Nowadays, increased stress causes many new issues, including depression, suicide, heart attack, and stroke. Many physical health issues related to stress can be avoided if mental stress is detected beforehand. When a person is stressed, there are noticeable changes in several bio-signals such as thermal, electrical, impedance, acoustic, optical, and others, and stress levels may be determined using these bio-signals. The paper proposes various machine learning and deep learning algorithms for stress detection on persons using wearable sensing devices, which can help people avoid various stress-related health problems. The data are taken from the WESAD dataset. The paper uses classification algorithms, SVM, DT, kNN and deep learning models; Long Short-Term Memory (LSTM) is applied, and confusion metrics parameters are used to measure performance in terms of accuracy, precision, recall, f1-score.

Keywords- Mental Stress, WESAD, Machine Learning, Deep Learning, LSTM

Introduction

Mental stress is one of the significant contributors to various health issues. Scientists and medics have created various measures to determine the intensity of mental stress in its early phases. Many neuroimaging methods for assessing mental stress in the workplace have been presented in the literature. One key candidate is the electroencephalogram (EEG) signal, which offers a wealth of mental states and circumstances. It is described as the human body's response to mental, physical, and emotional stimuli, as governed by the sympathetic nervous system (SNS) and the hypothalamus-pituitary–adrenocortical axis (HPA axis) [1]. This expression may be applied to both internal (personality structure) and external (problem-solving) issues, resulting in a variety of physiological and negative emotional alterations [2]. The three forms of stress are identified in the literature [3]. Acute stress is caused by a brief exposure period and is not damaging. When a stimulus is more frequent for a short period, it is called episodic stress [4].

On the other hand, chronic stress is the most harmful, caused by long-term stressors [5]. According to various studies, mental stress has been linked to various disorders, including stroke, cardiovascular disease, cognitive issues, speech abnormalities, and depression [6, 7]. Furthermore, stress indirectly affects the human body at several levels, including skin diseases, food habits, insufficient sleep, and decision-making [8–10]. As a result, researchers have devised several ways to assess stress levels early on to avert harmful health and performance repercussions. Subjective measures have traditionally been used to assess stress. Self-report questionnaires [12], such as the perceived stress scale [13, 14], are the most often used technique. The questionnaire score and self-report rating or interview have been established as ground truth in many research to evaluate mental stress levels.

On the other hand, questionnaires are subjective and need the user's undivided attention. As a result, people are often unaware of their actual stress levels. In the technological era, several physiological measurements have been discovered as stress indicators, including heart rate variability (HRV), electro-dermal activity (EDA), electroencephalogram (EEG) [11], electromyogram (EMG), blood pressure, pupil diameter, salivary cortisol, and salivary alpha-amylase [2]. It is necessary that the stress level detected by any indicators be accurate so that the proper measures to overcome the effect on the human lifestyle.

Related Work

This section describes literature related to the study about stress detection by various authors on employing various machine learning models. Ciabattoni et al. [15] proposed a real-time mental stress detection during cognitive tasks performed by an individual. The dataset contains features such as body temperature, GSR, RR intervals, gathered using a smartwatch, applied kNN classification approach and acquired accuracy of 89.8%. Yekta et al. [16] acquired data from Smartphones and wearable sensors, conducted a study on the daily life routine of the subjects and detected stress. The authors studied SVM and kNN machine learning models and PCA feature selection algorithm. Anderson et al. [17] collected data in EEG, ECG, GSR, PPG, EOG questionnaires, collecting data from physiological signals collected across three stimulus types – music, videos, and games. The authors applied kNN and SVM classification techniques and categorized Stimulus Classification and Arousal Classification with 80.6% and 88.9% accuracy, respectively. Sun et al. [18]

gathered data from 20 subjects across various basic activities such as sitting, standing, walking using various sensors. The authors collected data in the form of ECG, GSR, applied decision tree, SVM, naive Bayes classification algorithm and obtained an accuracy of 92.4%. Castaldo et al. [19] proposed a method to explore the extent to which HRV excerpts can be shortened without losing their ability to automatically detect mental stress employing the SVM classification data-driven approach and obtained an accuracy of 88%. Schmidt et al. [22] aimed to improve human-computer interaction (HCI) by detecting a person's affective state based on observables. The authors introduced a new publicly available dataset, WESAD, for wearable stress and affected detection. A multimodal dataset features physiological and motion data, recorded from both a wrist- and a chest-worn device, of 15 subjects during a lab study. Bajpai et al. [20] evaluated the performance of the WESAD dataset by employing the kNN model. The authors' evaluation is based on changing the K-fold cross-validation parameter and the total number of nearest neighbours while classifying data. Hence, the tradeoff between optimum performance and computational cost is achieved by limiting the number of neighbours and controlling the model's complexity. Lai et al. [21] proposed a prototype of intelligent Stress Monitoring Assistant (SMA) for first responders and professionals coping with exposure to extreme physical and psychological stressors such as firefighters, emergency medical technicians and many more; it is the next generation stress detector. SMA is designed using a residual-temporal convolution network to learn data from sensors and detect stress features. In both modes, stress recognition and stress detection, the SMA achieves 86% and 98% accuracy for the WESAD dataset.

Algorithm 1: Proposed algorithm for Mental Stress prediction

Results:	*Mental Stress Recognition using Precision, F1-score, Recall, Sensitivity, Specificity, classification accuracy and Conversion curve;*
Input:	*WESAD Dataset*
Output:	*Classify Stress level*
Procedure:	
Step 1:	*Extract the features from input data:*
	1.1 Clean unnecessary data;
	1.2 Missing Values;
	1.3 Scaling the data(if required)
Step 2:	*Apply Feature selection method;*
Step 3:	*Apply Machine Learning and LSTM Model and compare with the existing model;*
Step 4:	*Generate and store obtained classification accuracy, precision, recall, f1-score, Sensitivity, Specificity and classification accuracy and ROC curve;*
Step 5:	*Repeat Step 3 and Step 4.*

The WESAD

WESAD (Wearable Stress and Affect Detection) dataset [22] is collected from 15 subjects, consisting of 13 male and two female participants. Each subject participates in two hours of data collection protocol with four types of conditions: baseline, amusement, stress, and meditation condition. We used these four conditions data as the classes for the classification task. WESAD provides data from two kinds of sensors: chest-worn (RespiBAN) and wrist-worn device (Empatica E4). In this research work, we use only wrist-worn device data because it is not as intrusive as a chest-worn device, and they state that wrist-worn device data is quite promising to use for the classification process [22].

Proposed Work

The paper proposed Long short-term memory (LSTM), an artificial recurrent neural network (RNN) architecture used in deep learning. Unlike standard feedforward neural networks, LSTM has feedback connections. It can process single data points (images) and entire data sequences (such as speech or video). It is capable of learning long term dependencies in data. This is achieved because the recurring module of the model has a combination of four layers interacting with each other. Algorithm 1 proposes the procedure to predict the individual's stress using the WESAD dataset.

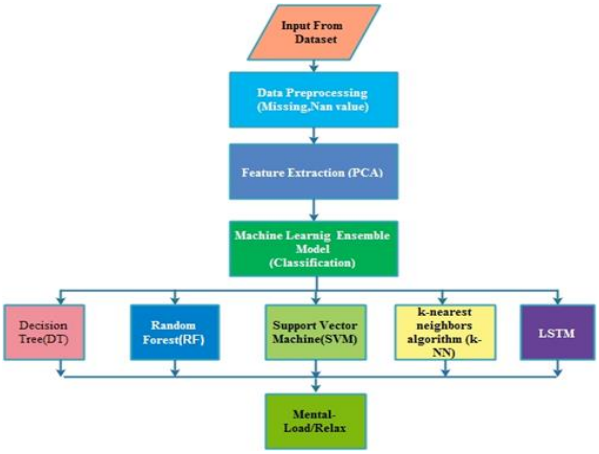

Figure 1: Flow Chart of the Proposed Model

Empirical Results

Different metrics have been used to evaluate the performance of proposed deep learning models on test sets, such as precision, recall, f1-score, and accuracy. The comparison of different models concerning performance metrics by all the applied machine learning algorithms and deep learning model LSTM is depicted in Table 1. Compared to other models, our proposed deep learning model LSTM achieved better accuracy than other machine learning algorithms such as DT, SVM and kNN. The accuracy obtained by LSTM models is 98%.

Table 1: Comparison of different ML models and Proposed Model

Model	Precision	Recall	F1-Score	Accuracy
DT	96	96	96	96
SVM	81	75	77	79
KNN	88	92	90	90.49
PLSTM	97	97	97	98
DT-> Decision tree, **SVM**->Support Vector Machine				
kNN-> k-nearest neighbors, **PLSTM->** Proposed LSTM				
All measurements are in %				

Figure 2 shows the graphical comparison of accuracy after generating confusion matrix on applying Decision Tree (DT), k Nearest Neighbors (KNN), Support Vector Machine (SVM) and LSTM models on the WESAD dataset.

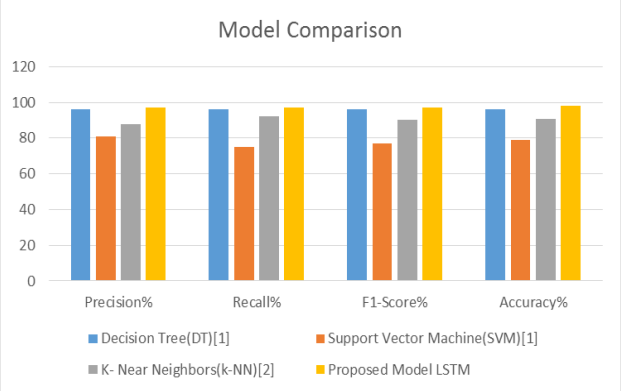

Figure 2: Model Comparison

Conclusion and Future work

Stress is a significant problem in today's society, with social and economic consequences. It is one of the variables that contribute to health issues. It is described as the human body's response to mental, physical, and emotional stimuli, governed by the sympathetic nervous system (SNS) and hypothalamic-pituitary-adrenocortical axis (HPA axis). The research began in a controlled laboratory setting, and the results show a high degree of accuracy in recognizing stress. Our suggested LSTM model attained a 98% accuracy compared to other models. There are still open research difficulties for detecting stress in everyday life, and there is space for development in this field. We will continue to work on the Internet of Things employing high-quality sensing devices and more precise data categorization approaches in the future.

Abstract

We know that the classical Mittag-Leffler function play an important role as solution of fractional order differential and integral equations. We introduce the j-generalized p - k Mittag-leffler function. We evaluate the second order differential recurrence relation and four different integral representations and introduce a homogeneous linear differential equation whose one of the solution is the j-generalized p-k Mittag-Leffler function.
Also we evaluate the certain relations that exist between j-generalized p - k Mittag-leffler function and Riemann-Liouville fractional integrals and derivatives.
We evaluate Mellin-Barnes integral representation of j-generalized p-k Mittag-Leffler Function. The relationship of j-generalized p-k Mittag-Leffler Function with Fox H-Function and Wright hypergeometric function is also establish. we obtained its Euler transform, Laplace Transform and Mellin transform.
Finally we derive some particular cases.

MSC(2011): 33E12, 33B10, 26A33.

Keywords: The j-generalized p - k Mittag-Leffler Function, The p - k Mittag-Leffler Function, Generalized k-Mittag-Leffler Function, Two parameter pochhammer symbol, Two parameter Gamma function.

1 Introduction

The two parameter pochhammer symbol is recently introduce by [9], equation 2.1, in the form,

1.1 Definition

Let $x \in C; k, p \in R^+ - \{0\}$ and $Re(x) > 0, n \in N$, the p - k Pochhammer Symbol (i.e. Two Parameter Pochhammer Symbol), ${}_p(x)_{n,k}$ is given by

$$ {}_p(x)_{n,k} = (\frac{xp}{k})(\frac{xp}{k} + p)(\frac{xp}{k} + 2p).....(\frac{xp}{k} + (n-1)p). \tag{1.1}$$

And the Two Parameter Gamma Function is given by [9], some of it's result are,

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 5 May 2020 doi:10.20944/preprints202005.0054.v1

1.2 Definition

For $x \in C/kZ^-; k, p \in R^+ - \{0\}$ and $Re(x) > 0, n \in N$, the p - k Gamma Function (i.e. Two Parameter Gamma Function), ${}_p\Gamma_k(x)$ as

$$ {}_p\Gamma_k(x) = \frac{1}{k} \lim_{n\to\infty} \frac{n! p^{n+1} (np)^{\frac{x}{k}}}{{}_p(x)_{n+1,k}}. \tag{1.2}$$

or

$$ {}_p\Gamma_k(x) = \frac{1}{k} \lim_{n\to\infty} \frac{n! p^{n+1} (np)^{\frac{x}{k}-1}}{{}_p(x)_{n,k}}. \tag{1.3}$$

The integral representation of p - k Gamma Function is given by

$$ {}_p\Gamma_k(x) = \int_0^\infty e^{-\frac{t^k}{p}} t^{x-1} dt. \tag{1.4}$$

$$ {}_p\Gamma_k(x) = (\frac{p}{k})^{\frac{x}{k}} \Gamma_k(x) = \frac{p^{\frac{x}{k}}}{k} \Gamma(\frac{x}{k}). \tag{1.5}$$

$$ {}_p(x)_{n,k} = (\frac{p}{k})^n (x)_{n,k} = (p)^n (\frac{x}{k})_n. \tag{1.6}$$

Also for Generalized p - k Pochhammer Symbol, we have

$$ {}_p(x)_{nq,k} = (\frac{p}{k})^{nq} (x)_{nq,k} = (p)^{nq} (\frac{x}{k})_{nq} = (pq)^{nq} \prod_{r=1}^{q} (\frac{\frac{x}{k} + r - 1}{q})_n. \tag{1.7}$$

$$ {}_p(x)_{n,k} = \frac{{}_p\Gamma_k(x + nk)}{{}_p\Gamma_k(x)}. \tag{1.8}$$

$$ {}_p\Gamma_k(x + k) = \frac{xp}{k} {}_p\Gamma_k(x). \tag{1.9}$$

$$ np\ {}_p(x)_{n-1,k} = {}_p(x)_{n,k} - {}_p(x - k)_{n,k}. \tag{1.10}$$

And

$$ {}_p(x)_{n+j,k} = {}_p(x)_{j,k} \times {}_p(x + jk)_{n,k}. \tag{1.11}$$

The Mittag-Leffler function $E_\alpha(z)$ introduced by Gosta Mittag-Leffler [4] in 1903, defined as

$$ E_\alpha(z) = \sum_{n=0}^{\infty} \frac{z^n}{\Gamma(\alpha n + 1)}. \tag{1.12}$$

Here $z \in C, \alpha \geqslant 0$.

Wiman [2] generalized $E_\alpha(z)$ in 1905 and gave $E_{\alpha,\beta}(z)$ known as Wiman function, defined as

$$ E_{\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{z^n}{\Gamma(\alpha n + \beta)}. \tag{1.13}$$

Here $z, \alpha, \beta \in C; Re(\alpha) > 0, Re(\beta) > 0$.

Prabhakar [17] in 1971, gave next generalization of Mittag-Leffler function and denoted as $E^\gamma_{\alpha,\beta}(z)$ and defined as

$$ E^\gamma_{\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{(\gamma)_n}{\Gamma(\alpha n + \beta)} \frac{z^n}{n!}. \tag{1.14}$$

Here $z, \alpha, \beta, \gamma \in C; Re(\alpha) > 0, Re(\beta) > 0, Re(\gamma) > 0$.

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 5 May 2020 doi:10.20944/preprints202005.0054.v1

Shukla and Prajapati [1] in 2007, gave second generalization of Mittag-Leffler function and denoted it as $E^{\gamma,q}_{\alpha,\beta}(z)$ and defined as,

$$E^{\gamma,q}_{\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{(\gamma)_{nq}}{\Gamma(\alpha n+\beta)} \frac{z^n}{n!}. \tag{1.15}$$

Here $z, \alpha, \beta, \gamma \in C; Re(\alpha) > 0, Re(\beta) > 0, Re(\gamma) > 0$ and $q \in (0,1) \cup N$.
The function $E^{\gamma,q}_{\alpha,\beta}(z)$ converges absolutely for all z if $q < Re(\alpha) + 1$ and for $|z| < 1$ if $q = Re(\alpha) + 1$. It is entire function of order $\frac{1}{Re(\alpha)}$.

Gehlot K.S.[8] introduce Generalized k- Mittag-Leffler function in 2012, denoted as $GE^{\gamma,q}_{k,\alpha,\beta}(z)$ and defined for $k \in R; z, \alpha, \beta, \gamma \in C; Re(\alpha) > 0, Re(\beta) > 0, Re(\gamma) > 0$ and $q \in (0,1) \cup N$, as,

$$GE^{\gamma,q}_{k,\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{(\gamma)_{nq,k}\, z^n}{\Gamma_k(n\alpha+\beta)(n!)}, \tag{1.16}$$

where$(\gamma)_{nq,k}$ is the k- pochhammer symbol and $\Gamma_k(x)$ is the k-gamma function given by [15]. The generalized Pochhammer symbol is given as,

$$(\gamma)_{nq} = \frac{\Gamma(\gamma+nq)}{\Gamma(\gamma)} = q^{qn} \prod_{r=1}^{q} (\frac{\gamma+r-1}{q})_n,\ if\ q \in N. \tag{1.17}$$

Gehlot K.S.[9], Introduce The p- k Mittag-Leffler function in 2018, denoted by ${}_pE^{\gamma,q}_{k,\alpha,\beta}(z)$ and defined for $k, p \in R^+ - \{0\}; \alpha, \beta, \gamma \in C/kZ^-; Re(\alpha) > 0, Re(\beta) > 0, Re(\gamma) > 0$ and $q \in (0,1) \cup N$.

$${}_pE^{\gamma,q}_{k,\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{{}_p(\gamma)_{nq,k}}{{}_p\Gamma_k(n\alpha+\beta)} \frac{z^n}{n!}. \tag{1.18}$$

Where ${}_p(\gamma)_{nq,k}$ is two parameter Pochhammer symbol given by equation (1.1) and ${}_p\Gamma_k(x)$ is the two parameter Gamma function given by equation (1.3).

L.L.Luque [14]in the year 2019, introduce the L-mittag-Leffler function defined for $\alpha, \beta, \gamma \in C; Re(\alpha) > 0, Re(\beta) > 0, Re(\gamma) > 0, j \in N_0$ by the series

$$L^{\gamma,j}_{\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{(\gamma)_{n+j}}{\Gamma(n\alpha+\beta)} \frac{z^n}{(n+j)!}, \qquad (z \in C). \tag{1.19}$$

The Fractional Integral operators ([16], Definition 2.1, Page 33) are defined as,

$$(I^{\vartheta}_{0+}f)(z) = \frac{1}{\Gamma(\vartheta)} \int_0^z \frac{f(t)}{(z-t)^{1-\vartheta}} dt, (z > 0), \tag{1.20}$$

and

$$(I^{\vartheta}_{-}f)(z) = \frac{1}{\Gamma(\vartheta)} \int_z^{\infty} \frac{f(t)}{(t-z)^{1-\vartheta}} dt, (z > 0), \tag{1.21}$$

The Fractional Derivative ([16], Definition 2.2, Page 35) are defined as,

$$(D^{\vartheta}_{0+}f)(z) = (\frac{d}{dz})^{[Re(\vartheta)]+1} (I^{1-\vartheta+[Re(\vartheta)]}_{0+}f)(z)$$

$$= \frac{1}{\Gamma(1-\vartheta+[Re(\vartheta)])} (\frac{d}{dz})^{[Re(\vartheta)]+1} \int_0^z \frac{f(t)}{(z-t)^{\vartheta-[Re(\vartheta)]}} dt, (z > 0), \tag{1.22}$$

and

$$(D^{\vartheta}_{-}f)(z) = (-\frac{d}{dz})^{[Re(\vartheta)]+1} (I^{1-\vartheta+[Re(\vartheta)]}_{-}f)(z)$$

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 5 May 2020 doi:10.20944/preprints202005.0054.v1

$$= \frac{1}{\Gamma(1-\vartheta+[Re(\vartheta)])}(-\frac{d}{dz})^{[Re(\vartheta)]+1}\int_z^\infty \frac{f(t)}{(t-z)^{\vartheta-[Re(\vartheta)]}}dt, (z>0). \tag{1.23}$$

Where $\vartheta \in C(Re(\vartheta)>0)$.

Wright generalized hypergeometric function [15];

$${}_p\psi_q\left[\begin{array}{c}(\alpha_1,A_1),\ldots,(\alpha_p,A_p);\\ \\ (\beta_1,B_1),\ldots,(\beta_q,B_q);\end{array} z\right] = \sum_{n=0}^{\infty}\frac{\prod_{i=1}^{p}\Gamma(\alpha_i+A_in)z^n}{\prod_{j=1}^{q}\Gamma(\beta_i+B_in)n!}. \tag{1.24}$$

$${}_p\psi_q\left[\begin{array}{c}(\alpha_1,A_1),\ldots,(\alpha_p,A_p);\\ \\ (\beta_1,B_1),\ldots,(\beta_q,B_q);\end{array} z\right] = H^{1,p}_{p,q+1}\left[-z\,\middle|\,\begin{array}{c}(1-\alpha_1,A_1),\ldots,(1-\alpha_p,A_p);\\ \\ (0,1),(1-\beta_1,B_1),\ldots,(1-\beta_q,B_q);\end{array}\right]. \tag{1.25}$$

Where $H^{m,n}_{p,q}[.]$ denotes the Fox H-function.
Euler Beta transform,[6],

$$B[f(z):a,b] = \int_0^1 z^{a-1}(1-z)^{b-1}f(z)dz. \tag{1.26}$$

Laplace transform,([7],equation3.1.1),

$$L[f(z):s] = \int_0^\infty e^{-sz}f(z)dz. \tag{1.27}$$

Mellin transform,([7],equation 4.1.1),

$$M[f(z):s] = \int_0^\infty z^{s-1}f(z)dz = f^*(s), Re(s)>0, \tag{1.28}$$

then

$$f(z) = M^{-1}[f^*(s):x] = \int f^*(s)x^{-s}ds, \tag{1.29}$$

Throughout this paper Let $C, R^+, Re(), Z^-, N_0$ and N be the sets of complex numbers, positive real numbers, real part of complex number, negative integer, whole number and natural numbers respectively.

2 The j-generelized p - k Mittag-Leffler function

In this section we introduce the j-generelized p - k Mittag-Leffler function and prove some of its properties.

2.1 Definition

Let $k,p \in R^+ - \{0\}; \alpha,\beta,\gamma \in C/kZ^-; Re(\alpha)>0, Re(\beta)>0, Re(\gamma)>0$, $j \in N_0$ and $q \in (0,1)\cup N$. The j-generelized p - k Mittag-Leffler function denoted by ${}^j_pE^{\gamma,q}_{k,\alpha,\beta}(z)$ and defined as

$${}^j_pE^{\gamma,q}_{k,\alpha,\beta}(z) = \sum_{n=0}^{\infty}\frac{{}_p(\gamma)_{(n+j)q,k}}{{}_p\Gamma_k(n\alpha+\beta)}\frac{z^n}{(n+j)!}, \qquad z\in C. \tag{2.1}$$

Where ${}_p(\gamma)_{nq,k}$ is two parameter Pochhammer symbol given by equation (1.1) and ${}_p\Gamma_k(x)$ is the two parameter Gamma function given by equation (1.3).

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 5 May 2020 doi:10.20944/preprints202005.0054.v1

Particular cases : For some particular values of the parameters $j, p, q, k, \alpha, \beta, \gamma$ we can obtain certain defined and undefined Mittag-Leffler functions:

(a) For $j = 0$ equation (2.1), reduces in the p-k Mittag-Leffler functions defined by [10],

$$ {}^{0}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{{}_{p}(\gamma)_{nq,k}}{{}_{p}\Gamma_{k}(n\alpha+\beta)} \frac{z^n}{n!}, \qquad z \in C. \tag{2.2} $$

(b) For $q = 1$ equation (2.1), reduces in j form of p-k Mittag-Leffler functions defined as,

$$ {}^{j}_{p}E^{\gamma,1}_{k,\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{{}_{p}(\gamma)_{(n+j),k}}{{}_{p}\Gamma_{k}(n\alpha+\beta)} \frac{z^n}{(n+j)!}, \qquad z \in C. \tag{2.3} $$

(c) For $q = 1, p = k$ equation (2.1), reduces in j form of k- Mittag-Leffler functions defined as,

$$ {}^{j}_{k}E^{\gamma,1}_{k,\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{(\gamma)_{(n+j),k}}{\Gamma_{k}(n\alpha+\beta)} \frac{z^n}{(n+j)!}, \qquad z \in C. \tag{2.4} $$

(d) For $q = 1, j = 0$ equation (2.1), reduces in generalized form of k- Mittag-Leffler functions defined as.

$$ {}_{p}E^{\gamma,1}_{k,\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{{}_{p}(\gamma)_{n,k}\, z^n}{{}_{p}\Gamma_{k}(n\alpha+\beta)(n!)}. \tag{2.5} $$

(e) For $p = k, j = 0$ equation (2.1), reduces in Generalized k- Mittag-Leffler functions defined by [8].

$$ {}_{k}E^{\gamma,q}_{k,\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{{}_{k}(\gamma)_{nq,k}\, z^n}{{}_{k}\Gamma_{k}(n\alpha+\beta)(n!)} = GE^{\gamma,q}_{k,\alpha,\beta}(z). \tag{2.6} $$

(f) For $p = k, q = 1, j = 0$ equation (2.1), reduces in k - Mittag-Leffler functions defined by [3].

$$ {}_{k}E^{\gamma,1}_{k,\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{(\gamma)_{n,k}\, z^n}{\Gamma_{k}(n\alpha+\beta)(n!)} = E^{\gamma}_{k,\alpha,\beta}(z). \tag{2.7} $$

(g) For $p = k$ and $k = 1, j = 0$ equation (2.1), reduces in Mittag-Leffler functions defined by [1].

$$ {}_{1}E^{\gamma,q}_{1,\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{(\gamma)_{nq}\, z^n}{\Gamma(n\alpha+\beta)(n!)} = E^{\gamma,q}_{\alpha,\beta}(z). \tag{2.8} $$

(h) For $p = k = q = 1$ equation (2.1), reduces in L-Mittag-Leffler functions defined by [14].

$$ {}_{1}E^{\gamma,1}_{1,\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{(\gamma)_{n+j}\, z^n}{\Gamma(n\alpha+\beta)(n+j)!} = L^{\gamma,j}_{\alpha,\beta}(z). \tag{2.9} $$

(i) For $p = k, q = 1, j = 0$ and $k = 1$ equation (2.1), reduces in Mittag-Leffler functions defined by [17].

$$ {}_{1}E^{\gamma,1}_{1,\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{(\gamma)_{n}\, z^n}{\Gamma(n\alpha+\beta)(n!)} = E^{\gamma}_{\alpha,\beta}(z), \tag{2.10} $$

(j) For $p = k, q = 1, k = 1, j = 0$ and $\gamma = 1$ equation (2.1), reduces in Mittag-Leffler functions defined by [3].

$$ {}_{1}E^{1,1}_{1,\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{z^n}{\Gamma(n\alpha+\beta)} = E_{\alpha,\beta}(z), \tag{2.11} $$

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 5 May 2020 doi:10.20944/preprints202005.0054.v1

(k) For $p = k, q = 1, k = 1, \gamma = 1, j = 0$ and $\beta = 1$ equation (2.1), reduces in Mittag-Leffler functions defined by [4].

$$ {}_1E^{1,1}_{1,\alpha,1}(z) = \sum_{n=0}^{\infty} \frac{z^n}{\Gamma(n\alpha + 1)} = E_\alpha(z). \tag{2.12}$$

Theorem 2.1: The j-generelized p - k Mittag-Leffler function defined by equation (2.1) is an entire function of order

$$ \frac{1}{\rho} = Re(\frac{\alpha}{k}) - q + 1. \tag{2.13}$$

Proof: Let R is the radius of convergence of the j-generelized p - k Mittag-Leffler function. The asymptotic Striling formula for Gamma function and factorial are given by,[5]

$$ \Gamma(az + b) = \sqrt{2\pi} e^{-az} (az)^{az+b-\frac{1}{2}} \Big[1 + o(\frac{1}{z})\Big], (arg(az + b) < \pi; \imath\, z \imath\!\rightarrow \infty). \tag{2.14}$$

and

$$ n! = \sqrt{2\pi} e^{-n} (n)^{n+\frac{1}{2}} \Big[1 + o(\frac{1}{n})\Big], (n \in N; n \rightarrow \infty). \tag{2.15}$$

From equation (2.1), we have

$$ {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{{}_p(\gamma)_{(n+j)q,k}}{{}_p\Gamma_k(n\alpha + \beta)} \frac{z^n}{(n + j)!} = \sum_{n=0}^{\infty} C_n z^n,$$

since

$$ R = \limsup_{n\rightarrow\infty} \Big|\frac{C_n}{C_{n+1}}\Big|,$$

$$ \Big|\frac{C_n}{C_{n+1}}\Big| = \Big|\frac{{}_p(\gamma)_{(n+j)q,k}}{{}_p\Gamma_k(n\alpha + \beta)} \frac{1}{(n + j)!} \times \frac{{}_p\Gamma_k(n\alpha + \alpha + \beta)(n + 1 + j)!}{{}_p(\gamma)_{(n+1+j)q,k}}\Big|$$

using equations (2.19) and (2.20) of [9], we have

$$ \Big|\frac{C_n}{C_{n+1}}\Big| = (n + 1 + j)\Big|p^{\frac{\alpha-qk}{k}}\Big|\Big|\frac{\Gamma(nq + jq + \frac{\gamma}{k})}{\Gamma(nq + jq + q + \frac{\gamma}{k})}\Big|\Big|\frac{\Gamma(\frac{n\alpha+\alpha+\beta}{k})}{\Gamma(\frac{n\alpha+\beta}{k})}\Big|,$$

using equation (2.15), we have

$$ \simeq \Big|p^{\frac{\alpha}{k}-q}\Big|\Big|q^{-q}\Big|\Big|(\frac{\alpha}{k})^{\frac{\alpha}{k}}\Big|\Big|n^{\frac{\alpha}{k}+1-q}\Big| \rightarrow \infty$$

when,

$$ Re(\frac{\alpha}{k} + 1 - q) > 0,$$

Thus, the j-generelized p - k Mittag-Leffler function is an entire function for $q < Re(\frac{\alpha}{k}) + 1$
To determine the order ρ,

$$ \rho = \limsup_{n\rightarrow\infty} \frac{n \ln n}{\ln(\frac{1}{|C_n|})}, \tag{2.16}$$

$$ \Big|\frac{1}{C_n}\Big| = \Big|\frac{{}_p\Gamma_k(n\alpha + \beta)(n + j)!}{{}_p(\gamma)_{(n+j)q,k}}\Big|,$$

using theorem 2.19 and 2.20 of [9], we have

$$ \Big|\frac{1}{C_n}\Big| = \frac{(n + j)!}{k}\Big|p^{\frac{\gamma}{k}+\frac{n\alpha+\beta}{k}-\frac{\gamma+(n+j)qk}{k}}\Big|\Big|\frac{\Gamma(\frac{\gamma}{k})\Gamma(\frac{n\alpha+\beta}{k})}{\Gamma(\frac{\gamma}{k} + (n + j)q)}\Big|,$$

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 5 May 2020 doi:10.20944/preprints202005.0054.v1

By using equation (2.12) and (2.13), we get

$$\left|\frac{1}{C_n}\right| = k^{-1}(2\pi)^{\frac{1}{2}}\left|p^{(\frac{\alpha-qk}{k})n+\frac{\beta}{k}-jq}\right|\left|(\frac{\alpha}{k})^{\frac{n\alpha}{k}+\frac{\beta}{k}-\frac{1}{2}}\right|\left|n^{\frac{n\alpha}{k}+\frac{\beta}{k}-\frac{\gamma}{k}-nq-jq+n+j+\frac{1}{2}}\right|\left|e^{-nRe(\frac{\alpha}{k}+1-q)}\right|$$

taking ln of above equation and put in equation (2.13), we have the order of j-generelized p - k Mittag-Leffler function is given by

$$\rho = \frac{k}{Re(\alpha) - qk + k}.$$

Hence.

Theorem 2.2: The functional relation between the j-generelized p - k Mittag-Leffler function given by equation (2.1) with p - k Mittag-Leffler function defined by [10] and generelized Mittag-Leffler function defined by [1] are given by

$${}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z) = \left(kp^{jq-\frac{\beta}{k}}\right){}^{j}E^{\frac{\gamma}{k},q}_{\frac{\alpha}{k},\frac{\beta}{k}}(zp^{q-\frac{\alpha}{k}}). \tag{2.17}$$

$$(\frac{d}{dz})^{l}\left[z^{j} \times {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z)\right] = {}_{p}(\gamma)_{lq,k}\ z^{j-l}\ {}^{j-l}_{p}E^{\gamma+lqk,q}_{k,\alpha,\beta}(z),\ for\ l<j. \tag{2.18}$$

$$(\frac{d}{dz})^{l}\left[z^{j} \times {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z)\right] = {}_{p}(\gamma)_{lq,k}\ {}_{p}E^{\gamma+lqk,q}_{k,\alpha,\beta}(z),\ for\ l=j. \tag{2.19}$$

$$(\frac{d}{dz})^{l}\left[z^{j} \times {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z)\right] = {}_{p}(\gamma)_{lq,k}\ {}_{p}E^{\gamma+lqk,q}_{k,\alpha,\beta+l\alpha-j\alpha}(z),\ for\ l>j. \tag{2.20}$$

Proof of equation (2.16)
Using equation (1.5) and (1.6), we get the desired result.
Proof of equation (2.17), (2.18) and (2.19)
Using the equation (2.1), in right hand side of (2.17), we have

$$\frac{d^{l}}{dz^{l}}\left[z^{j} \times {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z)\right] = \sum_{n=0}^{\infty}\frac{{}_{p}(\gamma)_{(n+j)q,k}}{{}_{p}\Gamma_{k}(n\alpha+\beta)}\frac{z^{n+j-l}}{(n+j-l)!},$$

using equation (1.11), we have

$$\frac{d^{l}}{dz^{l}}\left[z^{j} \times {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z)\right] = \sum_{n=0}^{\infty}\frac{{}_{p}(\gamma)_{lq,k}\ {}_{p}(\gamma+lqk)_{(n+j-l)q,k}}{{}_{p}\Gamma_{k}(n\alpha+\beta)}\frac{z^{n+j-l}}{(n+j-l)!},$$

hence we have,

$$= {}_{p}(\gamma)_{lq,k}\ z^{j-l}\ {}^{j-l}_{p}E^{\gamma+lqk,q}_{k,\alpha,\beta}(z),\ for\ l<j.$$

$$= {}_{p}(\gamma)_{jq,k}\ {}_{p}E^{\gamma+lqk,q}_{k,\alpha,\beta}(z),\ for\ l=j.$$

$$= {}_{p}(\gamma)_{lq,k}\ {}_{p}E^{\gamma+lqk,q}_{k,\alpha,\beta+l\alpha-j\alpha}(z),\ for\ l>j.$$

Theorem 2.3: The following elementary properties are satisfied by the j-generelized p - k Mittag-Leffler function defined by equation (2.1),

$$k\ {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z) = p\beta\ {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta+k}(z) + zp\alpha\frac{d}{dz}\ {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta+k}(z). \tag{2.21}$$

$$pq\ {}_{p}(\gamma)_{q-1,k}\ {}^{j-1}_{p}E^{\gamma+kq-k,q}_{k,\alpha,\beta}(z) = {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z) - {}^{j}_{p}E^{\gamma-k,q}_{k,\alpha,\beta}(z). \tag{2.22}$$

$$\sum_{n=0}^{\infty}(x+y)^{n}\ {}^{j}_{p}E^{nqk+k,q}_{k,0,nk+jk+k}(xy) = \sum_{r=0}^{\infty}\frac{{}_{p}\Gamma_{k}(rqk+k)(xyp)^{r}}{{}_{p}\Gamma_{k}(rk+jk+k)} \times {}^{j}_{p}E^{rqk+k,q}_{k,qk,k}(\frac{x+y}{p}). \tag{2.23}$$

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 5 May 2020 doi:10.20944/preprints202005.0054.v1

Proof of equation (2.20)
Consider the right hand side of equation (2.20),

$$A \equiv p\beta\ {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta+k}(z) + zp\alpha\frac{d}{dz}\ {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta+k}(z),$$

using equation (2.1),

$$A \equiv p\beta \sum_{n=0}^{\infty} \frac{{}_{p}(\gamma)_{(n+j)q,k}}{{}_{p}\Gamma_k(n\alpha+\beta+k)}\frac{z^n}{(n+j)!} + zp\alpha\sum_{n=0}^{\infty}\frac{{}_{p}(\gamma)_{(n+j)q,k}}{{}_{p}\Gamma_k(n\alpha+\beta+k)}\frac{nz^{n-1}}{(n+j)!},$$

$$A \equiv p\sum_{n=0}^{\infty}\frac{{}_{p}(\gamma)_{(n+j)q,k}(n\alpha+\beta)}{{}_{p}\Gamma_k(n\alpha+\beta+k)}\frac{z^n}{(n+j)!},$$

using the equation (1.9), we have

$$A \equiv k\ {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z).$$

Proof of equation (2.21)
Consider the right hand side of (2.21),

$$A \equiv\ {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z) -\ {}^{j}_{p}E^{\gamma-k,q}_{k,\alpha,\beta}(z),$$

using equation (2.1), we have

$$A \equiv \sum_{n=0}^{\infty}\frac{z^n}{{}_{p}\Gamma_k(n\alpha+\beta)(n+j)!}\Big[{}_{p}(\gamma)_{(n+j)q,k} -\ {}_{p}(\gamma-k)_{(n+j)q,k}\Big],$$

using equations (1.10) and (1.11), we have

$$A \equiv pq\ {}_{p}(\gamma)_{q-1,k}\ {}^{j-1}_{p}E^{\gamma+kq-k,q}_{k,\alpha,\beta}(z).$$

Proof of equation (2.22)
Consider the Left hand side of equation (2.22),

$$A \equiv \sum_{n=0}^{\infty}(x+y)^n\ {}^{j}_{p}E^{nqk+k,q}_{k,0,(n+j+1)k}(xy),$$

using equation (2.1), we have

$$A \equiv \sum_{n=0}^{\infty}(x+y)^n\sum_{r=0}^{\infty}\frac{{}_{p}(nqk+k)_{(r+j)q,k}}{{}_{p}\Gamma_k(nk+jk+k)}\frac{(xy)^r}{(r+j)!}, \tag{2.24}$$

now simplifying, by using equation (1.5) and (1.6), we have

$$\begin{aligned}
{}_{p}(nqk+k)_{(r+j)q,k} &= p^{(r+j)q}(nq+1)_{(r+j)q},\\
&= p^{(r+j)q}\frac{\Gamma(nq+(r+j)q+1)}{\Gamma(nq+1))},\\
&= p^{(r+j)q}\frac{\Gamma((r+j)q+1+nq)}{\Gamma((r+j)q+1)}\frac{\Gamma((r+j)q+1)}{\Gamma(nq+1)},\\
&= {}_{p}\Gamma_k(rqk+k)\frac{{}_{p}(rqk+k)_{(r+j)q,k}}{{}_{p}\Gamma_k(nqk+k)},
\end{aligned}$$

then equation (2.23) becomes by rearranging the terms, we have

$$A \equiv \sum_{r=0}^{\infty}\frac{{}_{p}\Gamma_k(rqk+k)(xyp)^r}{{}_{p}\Gamma_k(rk+jk+k)}\sum_{n=0}^{\infty}\frac{{}_{p}(rqk+k)_{(n+j)q,k}}{{}_{p}\Gamma_k(qkn+k)(n+j)!}\Big(\frac{x+y}{p}\Big)^n.$$

This completes the proof.

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 5 May 2020 doi:10.20944/preprints202005.0054.v1

3 Fractional Integral and Differentiation of the j-generalized p - k Mittag-Leffler Function

In this section we evaluate certain relations that exist between the j-generalized p - k Mittag-Leffler Function and Riemann-Liouville fractional integrals and derivatives. It has been shown that the fractional integration and differentiation operators of j-generalized p - k Mittag-Leffler Function with power multipliers into the function of the same form. Also point out some special cases.

Theorem 3.1 The left-side Riemann-Liouville Fractional Integral Operator $I_{0^+}^{\vartheta}$ of the j-generalized p - k Mittag-Leffler Function is given by,

$$(I_{0^+}^{\vartheta}[t^{\frac{\beta}{k}-1}\,{}_p^j E_{k,\alpha,\beta}^{\gamma,q}(t^{\frac{\alpha}{k}})])(z) = p^{\vartheta} z^{\frac{\beta}{k}+\vartheta-1}\,{}_p^j E_{k,\alpha,\beta+k\vartheta}^{\gamma,q}(z^{\frac{\alpha}{k}}). \tag{3.1}$$

Where

$k, p \in R^+ - \{0\}; \alpha, \beta, \gamma \in C/kZ^-; Re(\alpha) > 0, Re(\beta) > 0, Re(\gamma) > 0, j \in N_0,\ q \in (0,1) \cup N$ *and* $Re(\vartheta) > 0$.

Proof: Consider left hand side,

$$A \equiv (I_{0^+}^{\vartheta}[t^{\frac{\beta}{k}-1}\,{}_p^j E_{k,\alpha,\beta}^{\gamma,q}(t^{\frac{\alpha}{k}})])(z),$$

by virtue of equation (1.20) and (2.1), we have

$$A \equiv \frac{1}{\Gamma(\vartheta)} \int_0^z \frac{t^{\frac{\beta}{k}-1}}{(z-t)^{1-\vartheta}} \sum_{n=0}^{\infty} \frac{{}_p(\gamma)_{(n+j)q,k}}{{}_p\Gamma_k(n\alpha+\beta)} \frac{t^{\frac{n\alpha}{k}}}{(n+j)} dt,$$

interchanging the order of integration and summation and evaluate the inner integral by substitute $t = zu$ and using the beta function formula, it gives

$$A \equiv \frac{z^{\frac{\beta}{k}+\vartheta-1}}{\Gamma(\vartheta)} \sum_{n=0}^{\infty} \frac{{}_p(\gamma)_{(n+j)q,k}}{{}_p\Gamma_k(n\alpha+\beta)} \frac{z^{\frac{n\alpha}{k}}}{(n+j)!} \frac{\Gamma(\frac{n\alpha+\beta}{k})\Gamma(\vartheta)}{\Gamma(\frac{n\alpha+\beta+k\vartheta}{k})},$$

using the equation (1.5), we have

$$A \equiv p^{\vartheta} z^{\frac{\beta}{k}+\vartheta-1}\,{}_p^j E_{k,\alpha,\beta+k\vartheta}^{\gamma,q}(z^{\frac{\alpha}{k}}).$$

Hence, we get the desired result.

Theorem 3.2 The right-side Riemann-Liouville Fractional Integral Operator I_{-}^{ϑ} of the j-generalized p - k Mittag-Leffler Function is given by,

$$(I_{-}^{\vartheta}[t^{-\frac{\beta}{k}-\vartheta}\,{}_p^j E_{k,\alpha,\beta}^{\gamma,q}(t^{-\frac{\alpha}{k}})])(z) = p^{\vartheta} z^{-\frac{\beta}{k}}\,{}_p^j E_{k,\alpha,\beta+k\vartheta}^{\gamma,q}(z^{-\frac{\alpha}{k}}). \tag{3.2}$$

Where

$k, p \in R^+ - \{0\}; \alpha, \beta, \gamma \in C/kZ^-; Re(\alpha) > 0, Re(\beta) > 0, Re(\gamma) > 0, j \in N_0,\ q \in (0,1) \cup N$ *and* $Re(\vartheta) > 0$.

Proof: Consider left hand side,

$$A \equiv (I_{-}^{\vartheta}[t^{-\frac{\beta}{k}-\vartheta}\,{}_p^j E_{k,\alpha,\beta}^{\gamma,q}(t^{-\frac{\alpha}{k}})])(z),$$

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 5 May 2020 doi:10.20944/preprints202005.0054.v1

by virtue of equation (1.21) and (2.1), we have

$$A \equiv \frac{1}{\Gamma(\vartheta)} \int_z^\infty \frac{t^{-\frac{\beta}{k}-\vartheta}}{(t-z)^{1-\vartheta}} \sum_{n=0}^{\infty} \frac{p(\gamma)_{(n+j)q,k}}{{}_p\Gamma_k(n\alpha+\beta)} \frac{t^{-\frac{n\alpha}{k}}}{(n+j)!} dt,$$

interchanging the order of integration and summation and evaluate the inner integral by substitute $t = \frac{z}{u}$ and using the beta function formula, it gives

$$A \equiv \frac{z^{-\frac{\beta}{k}}}{\Gamma(\vartheta)} \sum_{n=0}^{\infty} \frac{p(\gamma)_{(n+j)q,k}}{{}_p\Gamma_k(n\alpha+\beta)} \frac{z^{-\frac{n\alpha}{k}}}{(n+j)!} \frac{\Gamma(\frac{n\alpha+\beta}{k})\Gamma(\vartheta)}{\Gamma(\frac{n\alpha+\beta+k\vartheta}{k})},$$

using the equation (1.5), we have

$$A \equiv p^{\vartheta} z^{-\frac{\beta}{k}} {}_p^j E_{k,\alpha,\beta+k\vartheta}^{\gamma,q}(z^{-\frac{\alpha}{k}}).$$

Hence, we get the desired result.

Theorem 3.3 The left-side Riemann-Liouville Fractional Derivative Operator D_{0+}^{ϑ} of the j-generalized p - k Mittag-Leffler Function is given by,

$$(D_{0+}^{\vartheta}[t^{\frac{\beta}{k}-1} {}_p^j E_{k,\alpha,\beta}^{\gamma,q}(t^{\frac{\alpha}{k}})])(z) = p^{-\vartheta} z^{\frac{\beta}{k}-\vartheta-1} {}_p^j E_{k,\alpha,\beta-k\vartheta}^{\gamma,q}(z^{\frac{\alpha}{k}}). \tag{3.3}$$

Where

$k, p \in R^+ - \{0\}; \alpha, \beta, \gamma \in C/kZ^-; Re(\alpha) > 0, Re(\beta) > 0, Re(\gamma) > 0, j \in N_0,\ q \in (0,1) \cup N$ *and* $Re(\vartheta) > 0.$

Proof: Consider left hand side,

$$A \equiv (D_{0+}^{\vartheta}[t^{\frac{\beta}{k}-1} {}_p^j E_{k,\alpha,\beta}^{\gamma,q}(t^{\frac{\alpha}{k}})])(z),$$

by virtue of equation (1.22) and (2.1), we have

$$A \equiv \frac{1}{\Gamma(1-\vartheta+[Re(\vartheta)])} (\frac{d}{dz})^{[Re(\vartheta)]+1} \int_0^z \frac{t^{\frac{\beta}{k}-1}}{(z-t)^{\vartheta-Re(\vartheta)}} \sum_{n=0}^{\infty} \frac{p(\gamma)_{(n+j)q,k}}{{}_p\Gamma_k(n\alpha+\beta)} \frac{t^{\frac{n\alpha}{k}}}{(n+j)!} dt,$$

interchanging the order of integration and summation and evaluate the inner integral by substitute $t = zu$ and using the beta function formula, it gives

$$A \equiv \frac{z^{\frac{\beta}{k}-\vartheta-1}}{\Gamma(\vartheta)} \sum_{n=0}^{\infty} \frac{p(\gamma)_{(n+j)q,k}}{{}_p\Gamma_k(n\alpha+\beta)} \frac{z^{\frac{n\alpha}{k}}}{(n+j)!} \frac{\Gamma(\frac{n\alpha+\beta}{k})\Gamma(\vartheta)}{\Gamma(\frac{n\alpha+\beta-k\vartheta}{k})},$$

using the equation (1.5), we have

$$A \equiv p^{-\vartheta} z^{\frac{\beta}{k}-\vartheta-1} {}_p^j E_{k,\alpha,\beta-k\vartheta}^{\gamma,q}(z^{\frac{\alpha}{k}}).$$

Hence, we get the desired result.

Theorem 3.4 The right-side Riemann-Liouville Fractional Derivative Operator D_{-}^{ϑ} of the j-generalized p - k Mittag-Leffler Function is given by,

$$(D_{-}^{\vartheta}[t^{-\frac{\beta}{k}+\vartheta} {}_p^j E_{k,\alpha,\beta}^{\gamma,q}(t^{-\frac{\alpha}{k}})])(z) = p^{-\vartheta} z^{-\frac{\beta}{k}} {}_p^j E_{k,\alpha,\beta-k\vartheta}^{\gamma,q}(z^{-\frac{\alpha}{k}}). \tag{3.4}$$

Where

$k, p \in R^+ - \{0\}; \alpha, \beta, \gamma \in C/kZ^-; Re(\alpha) > 0, Re(\beta) > 0, Re(\gamma) > 0, j \in N_0,\ q \in (0,1) \cup N$ *and* $Re(\vartheta) > 0.$

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 5 May 2020 doi:10.20944/preprints202005.0054.v1

Proof: Consider left hand side,

$$A \equiv (D_{-}^{\vartheta}[t^{-\frac{\beta}{k}+\vartheta}\ {}_{p}^{j}E_{k,\alpha,\beta}^{\gamma,q}(t^{-\frac{\alpha}{k}})])(z),$$

by virtue of equation (1.23) and (2.1), we have

$$A \equiv \frac{1}{\Gamma(1-\vartheta+[Re(\vartheta)])}(-\frac{d}{dz})^{[Re(\vartheta)]+1}\int_{z}^{\infty}\frac{z^{-\frac{\beta}{k}+\vartheta}}{(t-z)^{\vartheta-[Re(\vartheta)]}}\sum_{n=0}^{\infty}\frac{{}_{p}(\gamma)_{(n+j)q,k}}{{}_{p}\Gamma_{k}(n\alpha+\beta)}\frac{t^{-\frac{n\alpha}{k}}}{(n+j)!}dt,$$

interchanging the order of integration and summation and evaluate the inner integral by substitute $t=\frac{z}{u}$ and using the beta function formula, it gives

$$A \equiv \frac{z^{-\frac{\beta}{k}}}{\Gamma(\vartheta)}\sum_{n=0}^{\infty}\frac{{}_{p}(\gamma)_{(n+j)q,k}}{{}_{p}\Gamma_{k}(n\alpha+\beta)}\frac{z^{-\frac{n\alpha}{k}}}{(n+j)!}\frac{\Gamma(\frac{n\alpha+\beta}{k})\Gamma(\vartheta)}{\Gamma(\frac{n\alpha+\beta-k\vartheta}{k})},$$

using the equation (1.5), we have

$$A \equiv p^{-\vartheta}z^{-\frac{\beta}{k}}\ {}_{p}^{j}E_{k,\alpha,\beta-k\vartheta}^{\gamma,q}(z^{-\frac{\alpha}{k}}).$$

Hence, we get the desired result.

4 Recurrence Relation and Integral Representation of the j-generalized p - k Mittag-Leffler Function

In this section we evaluate the recurrence relations and integral representations of the j-generalized p - k Mittag-Leffler function.

Theorem 4.1 For $k,p\in R^{+}-\{0\};\ \alpha+r,\beta+s+k,\gamma\in C/kZ^{-};\ R(\alpha+r)>0, R(\beta+s+k)>0, R(\gamma)>0, q\in(0,1)\cup N, j\in N_{0}$, we get

$$\begin{aligned}{}_{p}^{j}E_{k,\alpha+r,\beta+s+k}^{\gamma,q}(z)-p\ {}_{p}^{j}E_{k,\alpha+r,\beta+s+2k}^{\gamma,q}(z)=\frac{p^{2}}{k^{2}}\Big[&(\alpha+r)^{2}z^{2}\ {}_{p}^{j}\ddot{E}_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z)\\&+\Big\{(\alpha+r)^{2}+(\alpha+r)(2\beta+2s+2k)z\Big\}\ {}_{p}^{j}\dot{E}_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z)\\&+(\beta+s)(\beta+s+2k)\ {}_{p}^{j}E_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z)\Big],\end{aligned}\tag{4.1}$$

where ${}_{p}^{j}\dot{E}_{k,\alpha,\beta}^{\gamma,q}(z)=\frac{d}{dz}\ {}_{p}^{j}E_{k,\alpha,\beta}^{\gamma,q}(z)$ and ${}_{p}^{j}\ddot{E}_{k,\alpha,\beta}^{\gamma,q}(z)=\frac{d^{2}}{dz^{2}}\ {}_{p}^{j}E_{k,\alpha,\beta}^{\gamma,q}(z)$.

Proof: The j-generalized p-k Mittag-Leffler function, from equation (2.1),

$${}_{p}^{j}E_{k,\alpha+r,\beta+s+k}^{\gamma,q}(z)=\sum_{n=0}^{\infty}\frac{{}_{p}(\gamma)_{(n+j)q,k}\ z^{n}}{{}_{p}\Gamma_{k}(n(\alpha+r)+\beta+s+k)((n+j)!)},$$

using equation (1.9), we have

$${}_{p}^{j}E_{k,\alpha+r,\beta+s+k}^{\gamma,q}(z)=\sum_{n=0}^{\infty}\frac{k}{p}\frac{{}_{p}(\gamma)_{(n+j)q,k}\ z^{n}}{{}_{p}\Gamma_{k}(n(\alpha+r)+\beta+s)\{n(\alpha+r)+\beta+s)\}((n+j)!)},\tag{4.2}$$

and

$${}_{p}^{j}E_{k,\alpha+r,\beta+s+2k}^{\gamma,q}(z)=\sum_{n=0}^{\infty}\frac{{}_{p}(\gamma)_{(n+j)q,k}\ z^{n}}{{}_{p}\Gamma_{k}(n(\alpha+r)+\beta+s+2k)((n+j)!)},\tag{4.3}$$

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 5 May 2020 doi:10.20944/preprints202005.0054.v1

using equation (1.9), we have

$$ {}_{p}^{j}E_{k,\alpha+r,\beta+s+2k}^{\gamma,q}(z) = \sum_{n=0}^{\infty} \frac{{}_{p}(\gamma)_{(n+j)q,k}\, z^n}{{}_{p}\Gamma_k(n(\alpha+r)+\beta+s)((n+j)!)} $$

$$ \times \frac{k^2}{p^2} \frac{1}{\{n(\alpha+r)+\beta+s)\}\{n(\alpha+r)+\beta+s+k)\}}, $$

$$ {}_{p}^{j}E_{k,\alpha+r,\beta+s+2k}^{\gamma,q}(z) = \sum_{n=0}^{\infty} \frac{k}{p^2}[\frac{1}{(n(\alpha+r)+\beta+s)} - \frac{1}{(n(\alpha+r)+\beta+s+k)}] $$

$$ \times \frac{{}_{p}(\gamma)_{(n+j)q,k}\, z^n}{{}_{p}\Gamma_k(n(\alpha+r)+\beta+s)((n+j)!)}, $$

$$ {}_{p}^{j}E_{k,\alpha+r,\beta+s+2k}^{\gamma,q}(z) = \frac{k}{p^2}[\frac{p}{k}\, {}_{p}^{j}E_{k,\alpha+r,\beta+s+k}^{\gamma,q}(z) - S], $$

$$ S = \frac{p}{k}\, {}_{p}^{j}E_{k,\alpha+r,\beta+s+k}^{\gamma,q}(z) - \frac{p^2}{k}\, {}_{p}^{j}E_{k,\alpha+r,\beta+s+2k}^{\gamma,q}(z), \tag{4.4} $$

where

$$ S = \sum_{n=0}^{\infty} \frac{{}_{p}(\gamma)_{(n+j)q,k}\, z^n}{{}_{p}\Gamma_k(n(\alpha+r)+\beta+s)\{n(\alpha+r)+\beta+s+k)\}((n+j)!)}, \tag{4.5} $$

applying the simple identity $\frac{1}{u} = \frac{k}{u(u+k)} + \frac{1}{u+k}$; for $u = n(\alpha+r)+\beta+s+k$ to (4.5),we obtain,

$$ S = \sum_{n=0}^{\infty} \frac{k\, {}_{p}(\gamma)_{(n+j)q,k}\, z^n}{{}_{p}\Gamma_k(n(\alpha+r)+\beta+s)((n+j)!)} \times \frac{1}{\{n(\alpha+r)+\beta+s+k\}\{n(\alpha+r)+\beta+s+2k\}} $$

$$ + \sum_{n=0}^{\infty} \frac{{}_{p}(\gamma)_{(n+j)q,k}\, z^n}{{}_{p}\Gamma_k(n(\alpha+r)+\beta+s)\{n(\alpha+r)+\beta+s+2k)\}((n+j)!)}, $$

$$ S = \sum_{n=0}^{\infty} \frac{k\{n(\alpha+r)+\beta+s\}_{p}(\gamma)_{(n+j)q,k}\, z^n}{{}_{p}\Gamma_k(n(\alpha+r)+\beta+s)((n+j)!)} $$

$$ \times \frac{1}{\{n(\alpha+r)+\beta+s\}\{n(\alpha+r)+\beta+s+k\}\{n(\alpha+r)+\beta+s+2k\}} $$

$$ + \sum_{n=0}^{\infty} \frac{\{n(\alpha+r)+\beta+s\}\{n(\alpha+r)+\beta+s+k\}_{p}(\gamma)_{(n+j)q,k}\, z^n}{{}_{p}\Gamma_k(n(\alpha+r)+\beta+s)((n+j)!)} $$

$$ \times \frac{1}{\{n(\alpha+r)+\beta+s\}\{n(\alpha+r)+\beta+s+k\}\{n(\alpha+r)+\beta+s+2k\}}, $$

using equation (1.9), we obtain

$$ S = \sum_{n=0}^{\infty} \frac{k\{n(\alpha+r)+\beta+s\}_{p}(\gamma)_{(n+j)q,k}\, z^n}{\frac{k^3}{p^3}\, {}_{p}\Gamma_k(n(\alpha+r)+\beta+s+3k)((n+j)!)} $$

$$ + \sum_{n=0}^{\infty} \frac{\{n(\alpha+r)+\beta+s\}\{n(\alpha+r)+\beta+s+k\}_{p}(\gamma)_{(n+j)q,k}\, z^n}{\frac{k^3}{p^3}\, {}_{p}\Gamma_k(n(\alpha+r)+\beta+s+3k)((n+j)!)}, $$

$$ S\frac{k^3}{p^3} = \sum_{n=0}^{\infty} \frac{{}_{p}(\gamma)_{(n+j)q,k}\, z^n}{{}_{p}\Gamma_k(n(\alpha+p)+\beta+s+3k)((n+j)!)} $$

$$ \times [n^2(\alpha+r)^2 + 2n(\alpha+r)(\beta+s+k) + (\beta+s)(\beta+s+2k)]. \tag{4.6} $$

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 5 May 2020 doi:10.20944/preprints202005.0054.v1

We now express each summation in the right hand side of (4.6) as follows:

$$\frac{d}{dz}[z\,{}_p^j E_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z)] = \sum_{n=0}^{\infty} \frac{(n+1)\,{}_p(\gamma)_{(n+j)q,k}\,z^n}{{}_p\Gamma_k(n(\alpha+r)+\beta+s+3k)((n+j)!)},$$

$$z\,{}_p^j \dot{E}_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z) + {}_p^j E_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z) = \sum_{n=0}^{\infty} \frac{(n+1)\,{}_p(\gamma)_{(n+j)q,k}\,z^n}{{}_p\Gamma_k(n(\alpha+r)+\beta+s+3k)((n+j)!)},$$

$$z\,{}_p^j \dot{E}_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z) = \sum_{n=0}^{\infty} \frac{n\,{}_p(\gamma)_{(n+j)q,k}\,z^n}{{}_p\Gamma_k(n(\alpha+r)+\beta+s+3k)((n+j)!)}. \tag{4.7}$$

Again

$$\frac{d^2}{dz^2}[z^2\,{}_p^j E_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z)] = \sum_{n=0}^{\infty} \frac{(n+1)(n+2)\,{}_p(\gamma)_{(n+j)q,k}\,z^n}{{}_p\Gamma_k(n(\alpha+r)+\beta+s+3k)((n+j)!)}, \tag{4.8}$$

and

$$\frac{d^2}{dz^2}[z^2\,{}_p^j E_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z)]$$

$$= z^2\,{}_p^j \ddot{E}_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z) + 4z\,{}_p^j \dot{E}_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z) + 2\,{}_p^j E_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z), \tag{4.9}$$

from equation (4.8) and (4.9) we have

$$\sum_{n=0}^{\infty} \frac{\{n^2\}_p(\gamma)_{(n+j)q,k}\,z^n}{{}_p\Gamma_k(n(\alpha+r)+\beta+s+3k)((n+j)!)} = z^2\,{}_p^j \ddot{E}_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z)$$

$$+ 4z\,{}_p^j \dot{E}_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z) - 3\sum_{n=0}^{\infty} \frac{\{n\}_p(\gamma)_{(n+j)q,k}\,z^n}{{}_p\Gamma_k(n(\alpha+r)+\beta+s+3k)((n+j)!)},$$

using equation (4.7), we have

$$\sum_{n=0}^{\infty} \frac{\{n^2\}_p(\gamma)_{(n+j)q,k}\,z^n}{{}_p\Gamma_k(n(\alpha+r)+\beta+s+3k)((n+j)!)}$$

$$= z^2\,{}_p^j \ddot{E}_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z) + z\,{}_p^j \dot{E}_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z), \tag{4.10}$$

applying equation (4.4), (4.7) and (4.10) to (4.6), we get

$$\frac{k^3}{p^3}S = (\alpha+r)^2 z^2\,{}_p^j \ddot{E}_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z) + \Big[(\alpha+r)^2 + (\alpha+r)(2\beta+2s+2k)\Big]z$$

$$\times\,{}_p^j \dot{E}_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z) + (\beta+s)(\beta+s+2k)\,{}_p^j E_{k,\alpha+r,\beta+s+3k}^{\gamma,q}(z),$$

Hence.

Theorem 4.2 For $k,p \in R^+ - \{0\}$; $\alpha+r, \beta+s+k, \gamma \in C/kZ^-$; $R(\alpha+r) > 0, R(\beta+s+k) > 0, R(\gamma) > 0, q \in (0,1) \cup N, j \in N_0$, we get

$$\int_0^1 t^{\beta+s+k-1}\,{}_p^j E_{k,\alpha+r,\beta+s}^{\gamma,q}(t^{\alpha+r})dt = \frac{p}{k}\,{}_p^j E_{k,\alpha+r,\beta+s+k}^{\gamma,q}(1) - \frac{p^2}{k}\,{}_p^j E_{k,\alpha+r,\beta+s+2k}^{\gamma,q}(1). \tag{4.11}$$

Proof: Put $z = 1$ in equation (4.4) and (4.5), we have

$$S = \frac{p}{k}\,{}_p^j E_{k,\alpha+r,\beta+s+k}^{\gamma,q}(1) - \frac{p^2}{k}\,{}_p^j E_{k,\alpha+r,\beta+s+2k}^{\gamma,q}(1)$$

$$= \sum_{n=0}^{\infty} \frac{{}_p(\gamma)_{(n+j)q,k}}{{}_p\Gamma_k(n(\alpha+r)+\beta+s)\{n(\alpha+r)+\beta+s+k)\}((n+j)!)}, \tag{4.12}$$

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 5 May 2020 doi:10.20944/preprints202005.0054.v1

now consider the integral,

$$A \equiv \int_0^1 t^{\beta+s+k-1}\, {}_p^j E_{k,\alpha+r,\beta+s}^{\gamma,q}(t^{\alpha+r})dt,$$

using the equation (2.1), we have

$$A \equiv \sum_{n=0}^{\infty} \frac{{}_p(\gamma)_{(n+j)q,k}}{{}_p\Gamma_k(n(\alpha+r)+\beta+s)((n+j)!)} \int_0^1 t^{n(\alpha+r)+\beta+s+k-1}dt,$$

$$A \equiv \sum_{n=0}^{\infty} \frac{{}_p(\gamma)_{(n+j)q,k}}{{}_p\Gamma_k(n(\alpha+r)+\beta+s)\{n(\alpha+r)+\beta+s+k)\}((n+j)!)},$$

from equation (4.12), we have the desired result.

Theorem 4.3 For $k,p \in R^+ - \{0\}; \alpha,\beta,\gamma,\delta \in C; R(\alpha) > 0, R(\beta) > 0, R(\gamma) > 0, R(\delta) > 0$ *and* $q \in (0,1) \cup N, j \in N_0$ then

$$p^{\delta}\, {}_p^j E_{k,\alpha,\beta+\delta k}^{\gamma,q}(z) = \frac{1}{\Gamma(\delta)} \int_0^1 u^{\frac{\beta}{k}-1}(1-u)^{\delta-1}\, {}_p^j E_{k,\alpha,\beta}^{\gamma,q}(z\, u^{\frac{\alpha}{k}})du. \tag{4.13}$$

Proof : Consider the right side integral and using equation (2.1), we have

$$A \equiv \frac{1}{\Gamma(\delta)} \int_0^1 u^{\frac{\beta}{k}-1}(1-u)^{\delta-1}\, {}_p^j E_{k,\alpha,\beta}^{\gamma,q}(z\, u^{\frac{\alpha}{k}})du,$$

$$A \equiv \frac{1}{\Gamma(\delta)} \sum_{n=0}^{\infty} \frac{{}_p(\gamma)_{(n+j)q,k}\, z^n}{{}_p\Gamma_k(n\alpha+\beta)((n+j)!)} \int_0^1 u^{\frac{\alpha n+\beta}{k}-1}(1-u)^{\delta-1}du,$$

using the definition of Beta function, we have

$$A \equiv \frac{1}{\Gamma(\delta)} \sum_{n=0}^{\infty} \frac{{}_p(\gamma)_{(n+j)q,k}\, z^n}{{}_p\Gamma_k(n\alpha+\beta)((n+j)!)} \frac{\Gamma(\frac{\alpha n+\beta}{k})\Gamma(\delta)}{\Gamma(\frac{\alpha n+\beta}{k}+\delta)},$$

applying equation (1.5), we have

$$A \equiv \sum_{n=0}^{\infty} \frac{p^{\delta}\, {}_p(\gamma)_{(n+j)q,k}\, z^n}{{}_p\Gamma_k(n\alpha+\beta+\delta k)((n+j)!)} = p^{\delta}\, {}_p^j E_{k,\alpha,\beta+\delta k}^{\gamma,q}(z),$$

Hence.

Theorem 4.4 For $k,p \in R^+ - \{0\}; \beta,\gamma \in C; R(\beta) > 0, R(\gamma) > 0$ *and* $\alpha,q \in N, j \in N_0$, then

$${}_p^j E_{k,k\alpha,\beta}^{\gamma,q}(z) = \frac{{}_p(\gamma)_{jq,k}}{{}_p\Gamma_k(\beta)} \prod_{i=1}^{q} \prod_{l=1}^{\alpha} \frac{\Gamma(b_l)}{\Gamma(a_i)\Gamma(b_l-a_i)} \int_0^1 u^{a_i-1}(1-u)^{b_l-a_i-1} E_{1,j+1}\Big(uz\frac{p^{q-\alpha}q^q}{\alpha^{\alpha}}\Big)du. \tag{4.14}$$

Where $a_i = \dfrac{\frac{\gamma}{k}+qj+i-1}{q}$ and $b_l = \dfrac{\frac{\beta}{k}+l-1}{\alpha}$.

Proof : Using definition of j-generalized p-k Mittag- Leffler function, from equation (2.1),

$$A \equiv {}_p^j E_{k,k\alpha,\beta}^{\gamma,q}(z) = \sum_{n=0}^{\infty} \frac{{}_p(\gamma)_{(n+j)q,k}\, z^n}{{}_p\Gamma_k(nk\alpha+\beta)((n+j)!)},$$

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 5 May 2020 doi:10.20944/preprints202005.0054.v1

using relation (1.11),we have

$$A \equiv \sum_{n=0}^{\infty} \frac{{}_p(\gamma)_{jq,k}\, {}_p(\gamma + jqk)_{nq,k}\, z^n}{{}_p(\beta)_{n\alpha,k}\, {}_p\Gamma_k(\beta)((n+j)!)} = \sum_{n=0}^{\infty} D \frac{{}_p(\gamma)_{jq,k}\, z^n}{{}_p\Gamma_k(\beta)((n+j)!)}. \tag{4.15}$$

Where $D \equiv \frac{{}_p(\gamma + jqk)_{nq,k}}{{}_p(\beta)_{n\alpha,k}}$,
using equation (1.6), we have

$$D \equiv \frac{{}_p(\gamma + jqk)_{nq,k}}{{}_p(\beta)_{n\alpha,k}} = \frac{p^{n(q-\alpha)}(\frac{\gamma+jqk}{k})_{qn}}{(\frac{\beta}{k})_{n\alpha}},$$

using the relation given by equation (1.7), we have

$$D \equiv \frac{p^{(q-\alpha)n} q^{qn} \prod_{i=1}^{q} (\frac{\frac{\gamma}{k}+jq+i-1}{q})_n}{\alpha^{\alpha n} \prod_{l=1}^{\alpha} (\frac{\frac{\beta}{k}+l-1}{\alpha})_n},$$

$$let\ a_i = \frac{\frac{\gamma}{k} + jq + i - 1}{q}\ and\ b_l = \frac{\frac{\beta}{k} + l - 1}{\alpha},$$

$$D \equiv (\frac{p^{(q-\alpha)} q^q}{\alpha^\alpha})^n \prod_{i=1}^{q} \prod_{l=1}^{\alpha} \frac{(a_i)_n}{(b_l)_n},$$

$$D \equiv (\frac{p^{(q-\alpha)} q^q}{\alpha^\alpha})^n \prod_{i=1}^{q} \prod_{l=1}^{\alpha} \frac{\Gamma(a_i+n)\Gamma(b_l)}{\Gamma(b_l+n)\Gamma(a_i)},$$

$$D \equiv (\frac{p^{(q-\alpha)} q^q}{\alpha^\alpha})^n \prod_{i=1}^{q} \prod_{l=1}^{\alpha} \frac{\Gamma(b_l)}{\Gamma(b_l-a_i)\Gamma(a_i)} \frac{\Gamma(a_i+n)\Gamma(b_l-a_i)}{\Gamma(b_l-a_i+a_i+n)},$$

using the definition of Beta function, we have

$$D \equiv (\frac{p^{(q-\alpha)} q^q}{\alpha^\alpha})^n \prod_{i=1}^{q} \prod_{l=1}^{\alpha} \frac{\Gamma(b_l)}{\Gamma(b_l-a_i)\Gamma(a_i)} \int_0^1 u^{a_i+n-1}(1-u)^{b_l-a_i-1} du, \tag{4.16}$$

from equation (4.15) and (4.16), we have

$$A \equiv \frac{{}_p(\gamma)_{jq,k}}{{}_p\Gamma_k(\beta)} \prod_{i=1}^{q} \prod_{l=1}^{\alpha} \frac{\Gamma(b_l)}{\Gamma(b_j-a_i)\Gamma(a_i)} \int_0^1 u^{a_i-1}(1-u)^{b_j-a_i-1} \sum_{n=0}^{\infty} \frac{(uz)^n}{(n+j)!} (\frac{p^{(q-\alpha)} q^q}{\alpha^\alpha})^n du,$$

Hence.

Theorem 4.5 For $k, p \in R^+ - \{0\}; \alpha, \beta, \gamma \in C; R(\alpha) > 0, R(\beta) > 0, R(\gamma) > 0$ and $q \in (0,1) \cup N, j \in N_0$ then

$${}^j_p E^{\gamma,q}_{k,\alpha,\beta}(z) = \frac{p^{jq}}{\Gamma(\frac{\gamma}{k})} \int_0^\infty e^{-t}\, t^{(\frac{\gamma}{k}+jq-1)}\, {}^j_p E^{1,0}_{k,\alpha,\beta}(zt^q p^q) dt. \tag{4.17}$$

Proof: Using definition of j-generalized p-k Mittag-Leffler function, equation (2.1), we have

$${}^j_p E^{\gamma,q}_{k,\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{{}_p(\gamma)_{(n+j)q,k}\, z^n}{{}_p\Gamma_k(n\alpha+\beta)((n+j)!)},$$

using equation (1.5) and (1.6), we have

$${}^j_p E^{\gamma,q}_{k,\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{z^n}{{}_p\Gamma_k(n\alpha+\beta)((n+j)!)} \frac{p^{(n+j)q}\Gamma(\frac{\gamma}{k}+q(n+j))}{\Gamma(\frac{\gamma}{k})},$$

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 5 May 2020 doi:10.20944/preprints202005.0054.v1

$$ {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{z^n}{{}_p\Gamma_k(n\alpha+\beta)((n+j)!)} \frac{p^{q(n+j)}}{\Gamma(\frac{\gamma}{k})} \int_0^{\infty} e^{-t}\, t^{(\frac{\gamma}{k}+q(n+j)-1)} dt, $$

$$ {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z) = \frac{p^{jq}}{\Gamma(\frac{\gamma}{k})} \int_0^{\infty} e^{-t}\, t^{(\frac{\gamma}{k}+jq-1)} \sum_{n=0}^{\infty} \frac{z^n\, p^{qn}\, t^{qn}}{{}_p\Gamma_k(n\alpha+\beta)((n+j)!)} dt, $$

$$ {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z) = \frac{p^{jq}}{\Gamma(\frac{\gamma}{k})} \int_0^{\infty} e^{-t}\, t^{(\frac{\gamma}{k}+jq-1)}\, {}^{j}_{p}E^{1,0}_{k,\alpha,\beta}(zt^q p^q) dt. $$

Hence.

5 Integral Transform of the j-generalized P-K Mittag-Leffler Function

In this section we evaluate Mellin-Barnes integral representation of j-generalized p-k Mittag-Leffler function, relationship with Fox H-function and Wright hypergeometric function. Also evaluate Euler Beta Transform, Laplace Transform and Mellin Transform of j-generalized p-k Mittag-Leffler function.

Mellin-Barnes integral representation of the j-generalized p-k Mittag-Leffler function.

Theorem 5.1 Let $k, p \in R^+ - \{0\}; Re(\alpha) > 0, Re(\beta) > 0, Re(\gamma) > 0, and\, q \in (0,1) \cup N, j \in N_0$, then the j-generalized p-k Mittag-Leffler function is represented by the Mellin-Barnes integral as,

$$ {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z) = \frac{kp^{jq-\frac{\beta}{k}}}{2\pi i\Gamma(\frac{\gamma}{k})} \int_L \frac{\Gamma(s)\Gamma(1-s)\Gamma(\frac{\gamma}{k}+jq-qs)}{\Gamma(\frac{\beta}{k}-\frac{\alpha s}{k})\Gamma(1+j-s)} (-zp^{q-\frac{\alpha}{k}})^{-s} ds. \tag{5.1} $$

Where $|\, argz\, | < \pi$; the contour integration beginning at $-i\infty$ and ending at $+i\infty$, and indented to separate the poles of the integrand as $s = -n$ for every $n \in N_0$(to the left) from those at $s = \frac{\frac{\gamma}{k}+n}{q}$ for every $n \in N_0$ (to the right).

Proof Consider the integral on right side of equation(5.1) and use the theorem of calculus of residues,

$$ A \equiv \frac{kp^{jq-\frac{\beta}{k}}}{2\pi i\Gamma(\frac{\gamma}{k})} \int_L \frac{\Gamma(s)\Gamma(1-s)\Gamma(\frac{\gamma}{k}+jq-qs)}{\Gamma(\frac{\beta}{k}-\frac{\alpha s}{k})\Gamma(1+j-s)} (-zp^{q-\frac{\alpha}{k}})^{-s} ds $$

$= 2\pi i$[sum of the residues at the poles $s = 0, -1, -2, ...$]

$$ A \equiv \frac{kp^{jq-\frac{\beta}{k}}}{\Gamma(\frac{\gamma}{k})} \sum_{n=0}^{\infty} \underset{s=-n}{Re} \quad (s+n)\Big[\frac{\Gamma(s)\Gamma(1-s)\Gamma(\frac{\gamma}{k}+jq-qs)}{\Gamma(\frac{\beta}{k}-\frac{\alpha s}{k})\Gamma(1+j-s)}\Big](-zp^{q-\frac{\alpha}{k}})^{-s} $$

$$ A \equiv \frac{kp^{jq-\frac{\beta}{k}}}{\Gamma(\frac{\gamma}{k})} \sum_{n=0}^{\infty} \lim_{s\to -n} \Big[\frac{\pi(s+n)}{sin\pi s} \frac{\Gamma(\frac{\gamma}{k}+jq-qs)}{\Gamma(1+j-s)\Gamma(\frac{\beta}{k}-\frac{\alpha s}{k})}\Big](-zp^{q-\frac{\alpha}{k}})^{-s} $$

$$ A \equiv \frac{kp^{jq-\frac{\beta}{k}}}{\Gamma(\frac{\gamma}{k})} \sum_{n=0}^{\infty} \Big[\frac{\Gamma(\frac{\gamma}{k}+jq+qn)}{\Gamma(1+j+s)\Gamma(\frac{\beta}{k}+\frac{\alpha n}{k})}\Big](zp^{q-\frac{\alpha}{k}})^{n} $$

using equations (1.5) and (1.6), we have,

$$ A \equiv {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z). $$

Hence.

Relationship with Fox H-function

Theorem 5.2 Let $k, p \in R^+ - \{0\}; Re(\alpha) > 0, Re(\beta) > 0, Re(\gamma) > 0, and\, q \in (0,1) \cup N, j \in N_0$

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 5 May 2020 doi:10.20944/preprints202005.0054.v1

then the j-generalized p-k Mittag-Leffler function is given in the form of Fox H-function, as.

$$ {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z) = \frac{kp^{jq-\frac{\beta}{k}}}{\Gamma(\frac{\gamma}{k})} H^{1,2}_{2,3}\left[-zp^{q-\frac{\alpha}{k}} \middle| \begin{matrix} (0,1),(1-\frac{\gamma}{k}-jq,q); \\ (0,1),(1-\frac{\beta}{k},\frac{\alpha}{k}),(-j,1); \end{matrix} \right]. \tag{5.2} $$

Proof. Using the equations (5.1) and (1.25), we get the desired result.

Relationship with Wright hypergeometric function

Theorem 5.3 Let $k,p \in R^{+}-\{0\}; Re(\alpha)>0, Re(\beta)>0, Re(\gamma)>0, and\, q \in (0,1)\cup N, j \in N_0$, then the j-generalized p-k Mittag-Leffler function is given in the form of Wright hypergeometric function, as.

$$ {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(z) = \frac{kp^{jq-\frac{\beta}{k}}}{\Gamma(\frac{\gamma}{k})}\, {}_2\Psi_2\left[\begin{matrix} (1,1)\ (\frac{\gamma}{k}+jq,q); \\ (\frac{\beta}{k},\frac{\alpha}{k})(1+j,1); \end{matrix} zp^{q-\frac{\alpha}{k}} \right]. \tag{5.3} $$

Proof. Using the equations (5.1) and (1.24), we get the desired result.

Euler Beta Transform, Laplace Transform and Mellin Transform of j-generalized p-k Mittag-Leffler function

Theorem 5.4 Let $k,p \in R^{+}-\{0\}; a,b,\sigma \in C; Re(\alpha)>0, Re(\beta)>0, Re(\gamma)>0, Re(\sigma)>0$ and $q \in (0,1)\cup N, j \in N_0$, then Euler Beta Transform of j-generalized p-k Mittag-Leffler function, is given by,

$$ \int_0^1 z^{a-1}(1-z)^{b-1}\, {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(xz^{\sigma})dz = \frac{kp^{jq-\frac{\beta}{k}}\Gamma(b)}{\Gamma(\frac{\gamma}{k})}\, {}_3\psi_3\left[\begin{matrix} (1,1),(\frac{\gamma}{k}+qj,q),(a,\sigma); \\ (\frac{\beta}{k},\frac{\alpha}{k}),(1+j,1),(a+b,\sigma); \end{matrix} xp^{q-\frac{\alpha}{k}} \right] \tag{5.4} $$

Proof Consider the left side integral and using equation (5.4), we have

$$ A \equiv \int_0^1 z^{a-1}(1-z)^{b-1}\, {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(xz^{\sigma})dz $$

$$ A \equiv \sum_{n=0}^{\infty} \frac{{}_p(\gamma)_{(n+j)q,k}\, x^n}{{}_p\Gamma_k(n\alpha+\beta)\,(n+j)!} \int_0^1 z^{\sigma n+a-1}(1-z)^{b-1}dz, $$

using definition of Beta function, we have

$$ A \equiv \sum_{n=0}^{\infty} \frac{{}_p(\gamma)_{(n+j)q,k}\, x^n}{{}_p\Gamma_k(n\alpha+\beta)\,(n+j)!} B(\sigma n+a,b) $$

using equation (1.5),(1.6) and (1.24), we have

$$ A \equiv \frac{kp^{jq-\frac{\beta}{k}}\Gamma(b)}{\Gamma(\frac{\gamma}{k})}\, {}_3\psi_3\left[\begin{matrix} (1,1),(\frac{\gamma}{k}+qj,q),(a,\sigma); \\ (\frac{\beta}{k},\frac{\alpha}{k}),(1+j,1),(a+b,\sigma); \end{matrix} xp^{q-\frac{\alpha}{k}} \right]. $$

Hence.

Theorem 5.5 The Laplace transform of j-generalizedp-k Mittag-Leffler function, is given by,

$$ \int_0^{\infty} z^{a-1}e^{-zs}\, {}^{j}_{p}E^{\gamma,q}_{k,\alpha,\beta}(xz^{\sigma})dz = \frac{kp^{jq-\frac{\beta}{k}}\, s^{-a}}{\Gamma(\frac{\gamma}{k})}\, {}_3\psi_2\left[\begin{matrix} (1,1),(\frac{\gamma}{k}+qj,q),(a,\sigma); \\ (\frac{\beta}{k},\frac{\alpha}{k})(1+j,1); \end{matrix} \frac{xp^{q-\frac{\alpha}{k}}}{s^{\sigma}} \right] \tag{5.5} $$

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 5 May 2020 doi:10.20944/preprints202005.0054.v1

Where $k, p \in R^+ - \{0\}$; $a, \sigma \in C$; $Re(\alpha) > 0, Re(\beta) > 0, Re(\gamma) > 0, Re(\sigma) > 0$ and $q \in (0,1) \cup N, j \in N_0$, and $|\frac{x}{s^\sigma}| < 1$.

Proof Consider the right side integral and using equation(2.1), we have

$$A \equiv \int_0^\infty z^{a-1} e^{-zs}\, {}_p^j E_{k,\alpha,\beta}^{\gamma,q}(xz^\sigma) dz$$

$$A \equiv \sum_{n=0}^{\infty} \frac{{}_p(\gamma)_{(n+j)q,k}}{{}_p\Gamma_k(n\alpha+\beta)} \frac{x^n}{(n+j)!} \int_0^\infty z^{n\sigma+a-1}\, e^{-zs} dz,$$

using definition of gamma function, we have

$$A \equiv s^{-a} \quad \sum_{n=0}^{\infty} \frac{{}_p(\gamma)_{(n+j)q,k}}{{}_p\Gamma_k(n\alpha+\beta)\,(n+j)!} \Gamma(\sigma n + a)(\frac{x}{s^\sigma})^n$$

using equation (1.5),(1.6) and (1.24), we have

$$A \equiv \frac{k p^{jq-\frac{\beta}{k}}\, s^{-a}}{\Gamma(\frac{\gamma}{k})}\; {}_3\psi_2 \left[\begin{matrix} (1,1), (\frac{\gamma}{k}+qj, q), (a,\sigma); \\ \\ (\frac{\beta}{k}, \frac{\alpha}{k})(1+j,1); \end{matrix} \begin{matrix} \\ \frac{x p^{q-\frac{\alpha}{k}}}{s^\sigma} \\ \\ \end{matrix} \right].$$

Hence.

Theorem 5.6 The Mellin transform of j-generalized p-k Mittag-Leffler function, is given by,

$$\int_0^\infty t^{s-1}\, {}_p^j E_{k,\alpha,\beta}^{\gamma,q}(-wt) dt = \frac{k p^{qj-\frac{\beta}{k}} \Gamma(s)\,\Gamma(1-s)\,\Gamma(\frac{\gamma}{k}+qj-qs)}{\Gamma(\frac{\beta}{k}-\frac{\alpha s}{k})\Gamma(\frac{\gamma}{k})\Gamma(1+j-s)} (\frac{p^{\frac{\alpha}{k}-q}}{w})^s \tag{5.6}$$

Where $k, p \in R^+ - \{0\}$; $a, \sigma \in C$; $Re(\alpha) > 0, Re(\beta) > 0, Re(\gamma) > 0, Re(s) > 0$ and $q \in (0,1) \cup N, j \in N_0$.

Proof Putting z = -wt in equation (5.1), we have

$${}_p^j E_{k,\alpha,\beta}^{\gamma,q}(-wt) = \frac{k p^{jq-\frac{\beta}{k}}}{2\pi i \Gamma(\frac{\gamma}{k})} \int_L \frac{\Gamma(s)\Gamma(1-s)\Gamma(\frac{\gamma}{k}+jq-qs)}{\Gamma(\frac{\beta}{k}-\frac{\alpha s}{k})\Gamma(1+j-s)} (-wtp^{q-\frac{\alpha}{k}})^{-s} ds.$$

$${}_p^j E_{k,\alpha,\beta}^{\gamma,q}(-wt) = \frac{k p^{jq-\frac{\beta}{k}}}{2\pi i \Gamma(\frac{\gamma}{k})} \int_L f^*(s)(t)^{-s} ds. \tag{5.7}$$

where

$$f^*(s) = \frac{\Gamma(s)\Gamma(1-s)\,\Gamma(\frac{\gamma}{k}+jq-qs)}{\Gamma(\frac{\gamma}{k})\Gamma(\frac{\beta}{k}-\frac{\alpha s}{k})\Gamma(1+j-s)} (-wp^{q-\frac{\alpha}{k}})^{-s}$$

using equation (1.28),(1.29) and (5.7), which immediately leads to (3.9).

Particular cases: Putting some particular values of $j, p, q, k, \alpha, \beta, \gamma$ we obtain all the results given by [1], [3],[8],[9],[10],[11],[12],[13]and [14].

Abstract. *Here, XFEM is used to model structural discontinuities like cracks and holes in order to forecast the strength and dependability of the structure under service conditions. By contrasting the numerical outcomes of several issues with the analytical and experimental findings, the method's resilience has been shown. Additionally, XFEM is coupled with a stochastic method to predict the sensitivity of a structure with discontinuities (cracks and holes) under tensile loading conditions in terms of output COVs and fracture strength in terms of mean values of stress intensity factors (SIFs) using input individual and combined randomness in various system parameters. The second order perturbation technique has been utilized in stochastic / perturbation theory to forecast how constructions would fracture. The perturbation technique is also utilized as Taylor series expansion method and yields accurate results if the input randomness is less than twenty percentage.*

Keywords. XFEM, COV, MMSIF, Stochastic, Perturbation

1. Introduction

We are aware that randomness always exists in reality and affects every aspect of a construction, including its geometry, strength, lifespan, susceptibility to damage, and fracture parameters. Even with the finest quality control procedures, randomness in system attributes has a major impact on how the mechanical

component responds to fracture. Therefore, randomness, external loads, material qualities, crack parameters, and geometry must all be taken into account when performing a fracture analysis on a structure. The stochastic fracture analysis increases the safety of structures by offering a reliable prediction of the fracture behaviour of the structure. The reliability evaluation methodologies can aid in the creation of preliminary recommendations for reliable designs. Many scholars have successfully analysed the stochastic fracture behaviour of the structure. Through the use of several numerical examples and the scaled boundary finite element method (SBFEM), Chowdhury et al. [1] completed the shape sensitivity analysis (Rahman and Chen [2]; Reddy and Rao [3]) of stress intensity variables to the crack size and direction. They performed the reliability assessment by Monte Carlo simulations (Chakraborty and Rahman [4, 5]; Choi et al. [6]; Evangelatos and Spanos [7]; Haldar and Mahadevan [8]; Khasin [9]; Lal and Palekar [10]). Some academics have talked about their work using the perturbation technique to forecast the material's stochastic reaction. In this regard, Rahman and Rao [11] introduced a stochastic meshless technique for resolving random material property boundary-value issues in linear elasticity. For the purpose of forecasting stochastic structure response, they created a meshless formulation. Classical perturbation expansions were produced in conjunction with the meshless equations to forecast the response's second-moment characteristics.

The XFEM has been further improved or enhanced by many researchers through coupling the XFEM with another technique to overcome the difficulties faced by the general XFEM. In the direction, a new set of enrichment functions was proposed for solving the Poisson equation in 1D and 2D spaces and was reduced the analysis error by Paweł [12]. The XFEM was coupled with a constitutive law with embedded discontinuity (CLED) approach for modelling of mixed mode cracking in concrete structure for simplifying the numerical implementation (Pietruszczak and Haghighat, [13]). Improved XFEM was developed for 3D and demonstrated better accuracy, convergence and efficiency. It overcomes the linear dependency problem by utilizing an extra degree of freedom free partition of unity approximation which is based on local least-squares fitting with a one-point interpolation constraint (Tian et al., [14]).

Using XFEM and various independent, combined uncorrelated and correlated input random Gaussian variables using SOPT and MCS, Lal and Markad [15] presented mixed mode SIFs and crack propagation analysis of the symmetric angle-ply laminated composite plate with through-thickness arbitrary curve cracks subjected to tensile and shear stress. The stochastic finite element technique is an extension of the MCS with uncertainty in the system parameters, such as materials, geometry, etc. given by Arregui-Mena et al. [16]. The spectral stochastic finite element approach and the perturbation technique (SSFEM). Lal and Markad [10] utilised a C^0 FEM based on higher order shear deformation plate theory was used to evaluate the second order statistics of MMSIFs of single edge V-notched angle-ply laminated composite plates under in-plane tensile load with uncertainty in material parameters, crack opening, and fracture length (HSDT). With the help of FOPT, SOPT, and MCS, the probabilistic evaluation was carried out.

The few researchers predicted how an infinite plate with a separate circular hole and a crack would fracture under tensile force. To the author's knowledge, XFEM with SOPT has not been used to investigate the stochastic fracture behaviour in terms of normalised MMSIFs and corresponding COVs of the infinite plate with various positions of a separate circular hole and a crack with various crack angles under tensile loading with input random parameters such as crack length, normalised radius of the hole, crack angle, and the central distance between separate hole and crack.

By incorporating the individual and combined randomness in the normalised crack length, crack angle, and normalised radius of the hole in an isotropic plate with a hole emanating cracks using SOPT, the stochastic fracture response through the normalised MMSIFs is calculated. Some results are validated with MCS. Present work is also focuesed on effect of combined loading over stochastic fracture response of the structural plate in terms of normalized MMSIFs.

2. Mathematical formulation

The XFEM is useful for modelling discontinuities like fractures, holes or voids, inclusions, interfaces, etc. while including discontinuous functions in the FE mesh. The level set method (LSM) has been successfully

used in conjunction with the XFEM to address these problems by providing further enrichment functions like crack faces and crack tips. Here, the XFEM software is built upon the 2D MATLAB code by Pais [18].

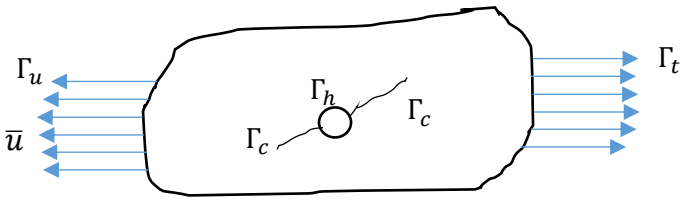

Fig. 1 Area under consideration with cracks, holes, and boundary condition

2.1 Equilibrium equation

The surfaces of cracks Γ_c and holes Γ_h are assumed traction free as are mentioned by Daux et al. [20], and shown in figure 1. The equilibrium equation in the domain Ω is:

$$\tilde{\nabla} \cdot \boldsymbol{\sigma}_t + \mathbf{f}_b = 0 \tag{1}$$

Small strains and displacements are taken into consideration in the current work. Thus, the relationship between strain and displacement illustrates the kinematics equations:

$$\boldsymbol{\varepsilon} = \boldsymbol{\varepsilon}(\mathbf{u}) = \tilde{\nabla}_s \cdot \mathbf{u} \tag{2}$$

Here, $\tilde{\nabla}_s$ is the symmetric part of the gradient operator and $\mathbf{u}$ is a displacement field vector. The boundary conditions for the displacements on the boundary Γ_u are:

$$\mathbf{u} = \bar{\mathbf{u}} . \tag{3}$$

The constitutive relation for elastic material can be shown by Hooke's law as:

$$\boldsymbol{\sigma}_t = \boldsymbol{D} \cdot \boldsymbol{\varepsilon}(\mathbf{u}) \tag{4}$$

where $\boldsymbol{D}$ is Hooke tensor or constitutive matrix for isotropic materials for plane stress and strain conditions in 2D.

The equilibrium equations' weak form is provided by:

$$\int_{\Omega} \boldsymbol{\varepsilon}(\mathbf{u}) : \boldsymbol{D} : \boldsymbol{\varepsilon}(\mathbf{v}) d\Omega = \int_{\Omega} \bar{\mathbf{b}} \cdot \mathbf{v} d\Omega + \int_{\Gamma_t} \bar{\mathbf{t}} \cdot \mathbf{v} d\Gamma \quad \forall \mathbf{v} \in \gamma_0 \tag{5}$$

The linear, FF and bilinear, SS forms of the equation (5) are:

$$FF(\mathbf{v}) = \int_{\Gamma} \bar{\mathbf{b}} \cdot \mathbf{v} d\Omega + \int_{\Gamma_t} \bar{\mathbf{t}} \cdot \mathbf{v} d\Omega \tag{6}$$

$$SS(\mathbf{u}, \mathbf{v}) = \int_{\Omega} \boldsymbol{\varepsilon}(\mathbf{u}) : \boldsymbol{D} : \boldsymbol{\varepsilon}(\mathbf{v}) d\Omega \tag{7}$$

Potential energy (Π) of an elastic body is $\Pi = \frac{1}{2} SS(\mathbf{u}, \mathbf{u}) - FF(\mathbf{u})$ (8)

By applying a variant of the previous equation and substituting $\frac{\partial \Pi}{\partial \mathbf{u}} = 0$, the minimization of the elastic body's potential energy may be solved, and the following set of discrete equations is produced as a result.

$$[\mathbf{K}]\{\mathbf{d}\} = \{\mathbf{f}\} \tag{9}$$

where, $[\mathbf{K}]$ is the global stiffness matrix, $\{\mathbf{d}\}$ are the global degrees of freedom and $\{\mathbf{f}\}$ are the applied loading or force.

$$\mathbf{K}_{ij}^{e} = \begin{bmatrix} \mathbf{K}_{ij}^{uu} & \mathbf{K}_{ij}^{ua} & \mathbf{K}_{ij}^{ub} & \mathbf{K}_{ij}^{ug} \\ \mathbf{K}_{ij}^{au} & \mathbf{K}_{ij}^{aa} & \mathbf{K}_{ij}^{ab} & \mathbf{K}_{ij}^{ag} \\ \mathbf{K}_{ij}^{bu} & \mathbf{K}_{ij}^{ba} & \mathbf{K}_{ij}^{bb} & \mathbf{K}_{ij}^{bg} \\ \mathbf{K}_{ij}^{gu} & \mathbf{K}_{ij}^{ga} & \mathbf{K}_{ij}^{gb} & \mathbf{K}_{ij}^{gg} \end{bmatrix} \tag{10}$$

$$\mathbf{f}_i^e = \left\{ \mathbf{f}_i^u \;\; \mathbf{f}_i^a \;\; \mathbf{f}_i^{b_1} \;\; \mathbf{f}_i^{b_2} \;\; \mathbf{f}_i^{b_3} \;\; \mathbf{f}_i^{b_4} \;\; \mathbf{f}_i^g \right\}^{\mathbf{T}} \tag{11}$$

$$\mathbf{d} = \left\{ \mathbf{u} \;\; \mathbf{a} \;\; \mathbf{b}_1 \;\; \mathbf{b}_1 \;\; \mathbf{b}_1 \;\; \mathbf{b}_1 \;\; \mathbf{g} \right\}^{\mathbf{T}} \tag{12}$$

2.2 XFEM Approximation

XFEM Approximation for Cracks and voids are defined as,

$$\mathbf{u}^{fi}(\mathbf{x}) = \mathbf{u}^{\mathbf{FEM}} + \mathbf{u}^{\mathbf{ENR}} = \sum_{i=1}^{n} \mathcal{N}_i(\mathbf{x}) \left\{ \bar{\mathbf{u}}_i + \sum_{j=1}^{m} \mathbf{F}^j(\mathbf{x}) \mathbf{a}_i^j \right\} \tag{13}$$

Heaviside function for a discontinuous function for the crack and voids defined as,

$$\mathcal{H}_1(\mathbf{x}) = \begin{cases} 1 \text{ for } \boldsymbol{\varphi}(\mathbf{x}) > 0 \\ 0 \text{ for } \boldsymbol{\varphi}(\mathbf{x}) = 0 \\ -1 \text{ for } \boldsymbol{\varphi}(\mathbf{x}) < 0 \end{cases} \quad \text{and} \quad \mathcal{H}_2(\mathbf{x}) = \begin{cases} 1 \text{ for } \chi(\mathbf{x}) > 0 \\ 0 \text{ for } \chi(\mathbf{x}) \le 0 \end{cases} \tag{14}$$

2.3 Level Set Method

For crack, level set method implemented by eq. (15), and for voids by eq. (16). The sign distance function $\phi(\mathbf{x}, \mathrm{t})$ to the curve Γ_c

$$\phi(\mathbf{x}) = \begin{cases} \min\limits_{\mathbf{x}_c \in \Gamma} \left\| \mathbf{x} - \mathbf{x}_c \right\| = d\left(\mathbf{x}, \mathbf{x}_i\right) & \forall \left(\mathbf{x} - \mathbf{x}_c\right) \cdot e_2 \ge 0 \\ \min\limits_{\mathbf{x}_c \in \Gamma} \left\| \mathbf{x} - \mathbf{x}_c \right\| = -d\left(\mathbf{x}, \mathbf{x}_i\right) & \text{otherwise} \end{cases} \tag{15}$$

$$\chi(\mathbf{x},0) = \min_{\mathbf{x}_c^i \in \Omega_c^i} \left\{ \left\| \mathbf{x} - \mathbf{x}_c^i \right\| - \mathrm{r}_c^i \right\} \qquad \text{where, } i = 1, 2, ..., n_c \tag{16}$$

where, d is the absolute distance, $\mathbf{x}_i$ is the point on crack closest to a point x with any point $\mathbf{x}_c$ on the crack surface Γ_c. r_c^i is the radius of the *i*th hole.

2.4 Evaluation of Stress Intensity Factors (SIFs)

For general mixed-mode problems in two dimensions, SIFs and J-integral can be stated as,

$$J = \frac{K_I^2}{E^*} + \frac{K_{II}^2}{E^*} \tag{17}$$

where, $E^* = \begin{cases} E & \text{for plane stress} \\ \dfrac{E}{1-\nu^2} & \text{for plane strain} \end{cases}$ (18)

The J -integral also follows the path-independence and it is explained

$$J = \int_{\Gamma} \left(W n_j - \mathbf{t}_i \cdot \frac{\partial \mathbf{u}_i}{\partial x} \right) d\Gamma \tag{19}$$

where, W is the strain energy density. For the plate of the elastic material, it can explain that $W = (1/2)\boldsymbol{\sigma}_{ij}\boldsymbol{\varepsilon}_{ij}$.

Now, two equilibrium, independent states of a cracked body are considered. Consider the state1, $\left(\boldsymbol{\sigma}_{ij}^{(1)},\boldsymbol{\varepsilon}_{ij}^{(1)},\mathbf{u}_{j}^{(1)}\right)$, corresponds to the present or actual state and state 2, $\left(\boldsymbol{\sigma}_{ij}^{(2)},\boldsymbol{\varepsilon}_{ij}^{(2)},\mathbf{u}_{j}^{(2)}\right)$, is an auxiliary state. Further, $\boldsymbol{\sigma}_{ij}^{(2)}$, $\boldsymbol{\varepsilon}_{ij}^{(2)}$ and $\mathbf{u}_{j}^{(2)}$ are the auxiliary stress field, auxiliary strain filed and auxiliary displacement field, respectively. Thus, superposition of these two states brings another equilibrium state, say, $\left(\boldsymbol{\sigma}_{ij},\boldsymbol{\varepsilon}_{ij},\mathbf{u}_{j}\right)$. Now, we have:

$$\boldsymbol{\sigma}_{ij}=\boldsymbol{\sigma}_{ij}^{(1)}+\boldsymbol{\sigma}_{ij}^{(2)}\quad \boldsymbol{\varepsilon}_{ij}=\boldsymbol{\varepsilon}_{ij}^{(1)}+\boldsymbol{\varepsilon}_{ij}^{(2)}\qquad \mathbf{u}_{j}=\mathbf{u}_{j}^{(1)}+\mathbf{u}_{j}^{(2)} \tag{20}$$

The strain energy densities are:

$$W=W^{(1)}+W^{(2)}\quad W^{(1)}=\frac{1}{2}\boldsymbol{\sigma}_{ij}^{(1)}\boldsymbol{\varepsilon}_{ij}^{(1)}\qquad W^{(2)}=\frac{1}{2}\boldsymbol{\sigma}_{ij}^{(2)}\boldsymbol{\varepsilon}_{ij}^{(2)} \tag{21}$$

$$W=\frac{1}{2}\boldsymbol{\sigma}_{ij}\boldsymbol{\varepsilon}_{ij}=\frac{1}{2}\left(\boldsymbol{\sigma}_{ij}^{(1)}+\boldsymbol{\sigma}_{ij}^{(2)}\right)\left(\boldsymbol{\varepsilon}_{ij}^{(1)}+\boldsymbol{\varepsilon}_{ij}^{(2)}\right)=\frac{1}{2}\left(W^{(1)}+W^{(2)}\right)-\boldsymbol{\sigma}_{ij}^{(1)}\boldsymbol{\varepsilon}_{ij}^{(2)} \tag{22}$$

2.5 Stress intensity factor (SIF)

The Mode-I and Mode-II SIFs are formulated as,

$$K_{I}=K_{I}^{(1)}+K_{I}^{(2)}\quad K_{II}=K_{II}^{(1)}+K_{II}^{(2)} \tag{23}$$

The Mode-I and Mode-II SIFs for the actual state can be obtained by choosing the auxiliary state (state 2), e.g., if auxiliary state 2 is chosen to be state for Mode-I, then the auxiliary state is Mode-I near tip displacement and stress field, then by putting $K_{I}^{(2)}=1$ and $K_{II}^{(2)}=0$ in the equation (23), we have:

$$K_{I}^{(1)}=\frac{M^{(1,\text{Mode I})}E^{*}}{2} \tag{24}$$

Similarly, if auxiliary state 2 is chosen to be state for Mode-II, then the auxiliary state is Mode-II near tip displacement and stress field, then by putting $K_{I}^{(2)}=0$ and $K_{II}^{(2)}=1$ in equation (23), we have:

$$K_{II}^{(1)}=\frac{M^{(1,\text{Mode II})}E^{*}}{2} \tag{25}$$

where, $M^{(1,\text{Mode I})}$ and $M^{(1,\text{Mode II})}$ are interaction integrals.

3. Results and discussion

By incorporating the individual and combined randomness in the normalised crack length $\left(e_1 = a/W\right)$, crack angle $\left(e_2 = \alpha\right)$, and normalised radius of the hole $\left(e_3 = R/W\right)$ in an isotropic plate with a hole emanating cracks using SOPT, the stochastic fracture response through the normalised MMSIFs is calculated. Some results are validated with MCS. The input random variables are indicated by the parameter { e_i (*i*=1, 2 and 3). Furthermore, it is assumed that the input COV for individual and combined randomness in all the parameters is 15% or 0.15 variation of characteristics from their mean values in order to forecast the stochastic MMSIFs of the plate under tensile, shear, and combination (tensile and shear) loadings. The percentage of the input random parameters has been randomly adopted because in perturbation technique, for input COVs < 0.2 or 20 %, the solution can be obtained up to the acceptable accuracy (Stefanou [20]). The normalized MMSIFs in terms of K_I and K_{II} are expressed as:

For Tensile loading

$$K_I = K_{I,\text{mean}} / \left(\sigma\sqrt{\pi a}\right) \text{ and } K_{II} = K_{II,\text{mean}} / \left(\sigma\sqrt{\pi a}\right) \tag{26}$$

For Shear loading

$$K_I = K_{I,\text{mean}} / \left(\tau\sqrt{\pi a}\right) \text{ and } K_{II} = K_{II,\text{mean}} / \left(\tau\sqrt{\pi a}\right) \tag{27}$$

where K_I , K_{II} , $K_{I,\text{mean}}$, $K_{II,\text{mean}}$, σ , τ and λ are normalized Mode-I and Mode-II SIFs, numerical Mode-I and Mode-II SIFs, tensile, shear and combined stresses, respectively and where, $\lambda = \sigma = \tau$.

3.1 Convergence and validation study

The results of Grasa et al. [21] using a first-order perturbation technique (FOPT) on the basis of analytical and XFEM solution for an isotropic edge cracked plate subjected to tensile loading are available and are compared with the mean value of Mode-I SIF using the current perturbation-based SOPT combined with XFEM, and they are in good agreement as shown in Table 1.

Table 1 Validation of SIFs of an isotropic edge cracked plate subjected to tensile loading

Analytical Solution [21]	XFEM with FOPT [21]	% Error	XFEM with SOPT	% Error	XFEM with MCS	% Error
99.8182	98.951	0.87	100.4834	0.67	100.1276	0.31

Rarely are the SOPT findings for the stochastic fracture analysis of the investigated model under various stress situations available in the literature. To validate the current stochastic fracture analysis for a/W= 0.4 with $\alpha = 30^0$, as indicated in Table 2, the current mean and corresponding COV $\{e_i(i=1, 2 \text{ and } 3) = 0.15\}$ of MMSIFs K_I and K_{II} acquired by SOPT are compared with those obtained by MCS.

Table 2 Behaviour of the analyzed model under different loading conditions for normalized crack length (a/W= 0.4) with crack angles ($\alpha = 30^\circ$) through individual randomness in a/W by MCS with different numbers of samples

Total no. of samples	Tensile loading				Shear loading			
	K_I		K_{II}		K_I		K_{II}	
	Mean	COV	Mean	COV	Mean	COV	Mean	COV
9000	0.809	0.121	0.354	0.223	2.527	0.059	1.296	0.125
9500	0.822	0.084	0.342	0.197	2.536	0.051	1.193	0.097
10000	0.828	0.056	0.334	0.167	2.540	0.047	1.128	0.081
10500	0.828	0.056	0.334	0.167	2.540	0.047	1.128	0.081
11000	0.828	0.056	0.334	0.167	2.540	0.047	1.128	0.081

The results obtained by both SOPT and MCS are in very good agreement. In the direct MCS method, the different sets of random samples of random system properties are generated first by direct use of the computer by using Gaussian random number generation. These sets of random samples are substituted in the response equation of MMSIFs and again generated the random samples of MMSIFs. The mean of these random samples gives the mean value of MMSIFs, while the variance of random samples gives the variance of MMSIFs. The optimum numbers of samples are decided on the basis of convergence of mean results. In the present analysis, 10,000 samples are used for satisfactory convergence of the results. Therefore, the 10,000 random samples are used for further computation of results using MCS. In the present study, MCS is used only for validation purpose due to higher consumption of computational time, particularly for fracture problem with very high mesh density.

Fig. 2(a) and 2(b) show the line diagram of an isotropic rectangular plate with the analyzed model with dimensions of length $(2L)$, width $(2W)$, crack length $(2a)$, and hole radius (R) and a central cracked plate without hole with required above-mentioned dimensions, under shear (τ) stress.

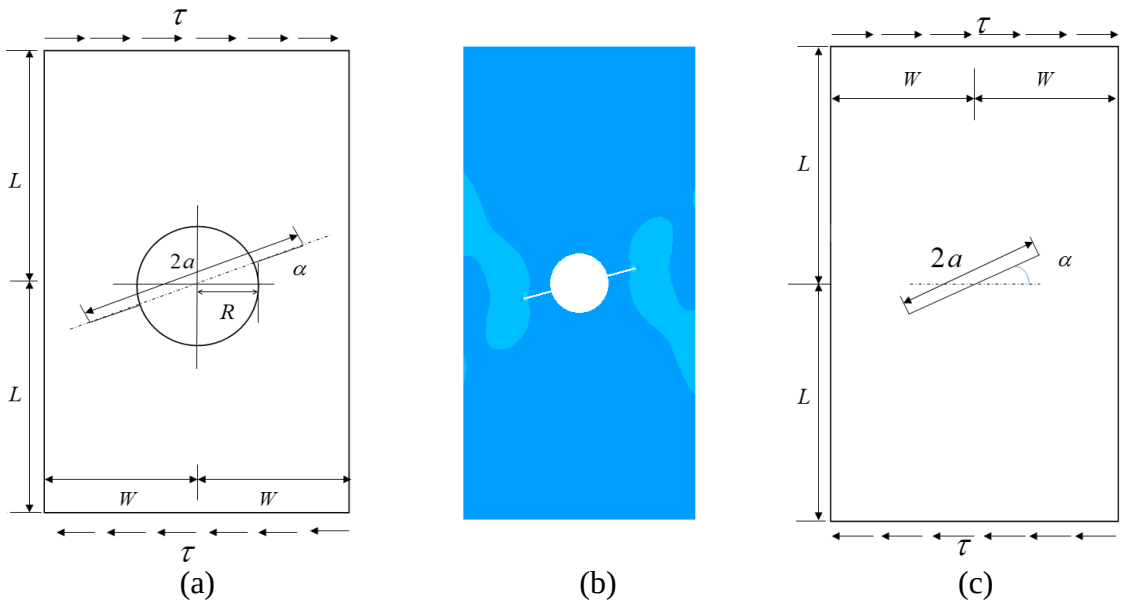

Fig. 2 (a) A line diagram and (b) the stress contour (general) of a plate with radial cracks on a hole and (c) a line diagram of central crack under shear loading

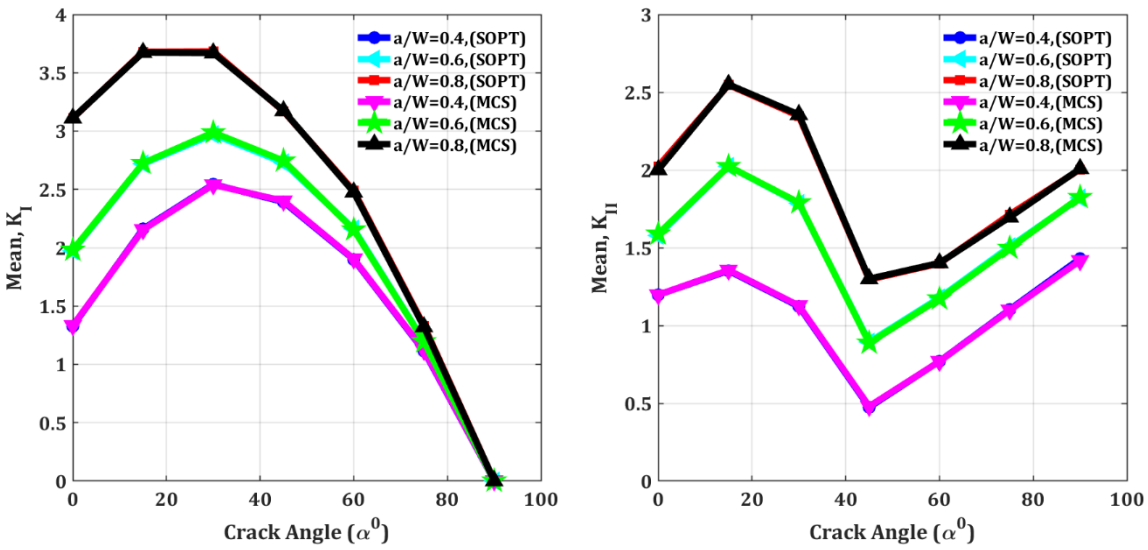
The behaviour of mean values of normalized MMSIFs of the analyzed model under uniform shear loading w.r.t. different crack angles is presented in Fig. 3(a) and 3(b). It is again clear that the SOPT results are in good agreement with those of MCS.

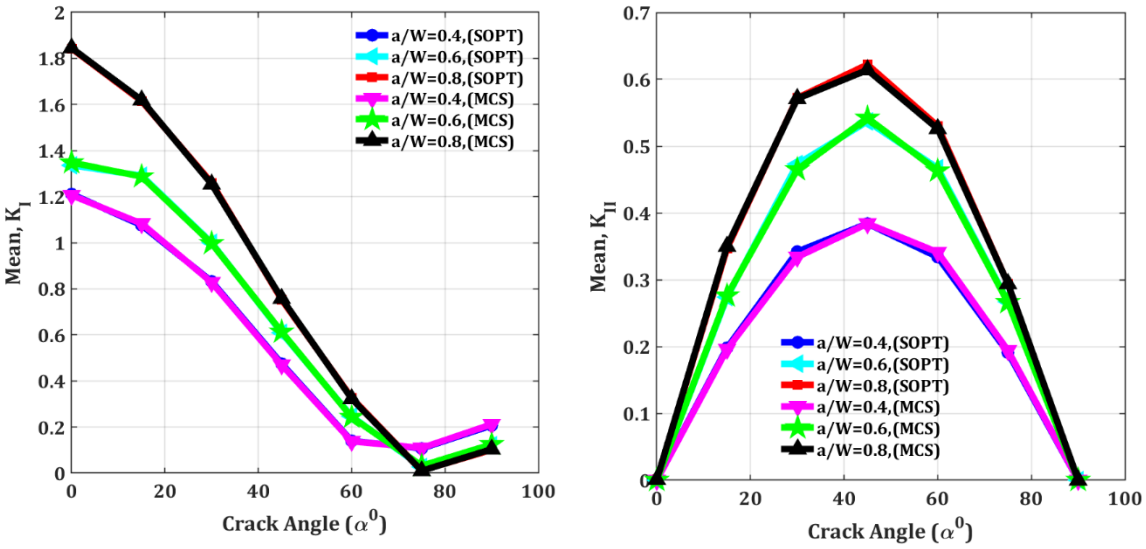


(a) (b)

Fig. 3 The mean values of normalized MMSIFs (a) K_I and (b) K_{II} of a plate under shear loading with individual randomness in e_1, e_2 and e_3

It can be seen that the mean values of K_I are largest at a crack angle α = 30°, and due to the increment in *a/W*, the mean values of K_I starts to dominate at α= 15°. As the crack angle (α) increases from 0° to 30°, the mean values of K_I are increased. Then, these values are continuously decreased to zero at 90° crack angle. Now, the mean values of normalized Mode-II SIFs K_{II} of the analyzed model are maximum at 15° crack angle and are minimum at 45° crack angle. At α = 0° and 90°, the mean values of K_{II} are nearly equal as the normalized crack length increases (*a/W*= 0.8). From crack angle 45° to 90°, the mean values of K_I and K_{II} continuously decrease and increase, respectively.

Fig. 4(a) and 4(b) show the behaviour of the mean values of normalized MMSIFs K_I and K_{II} of the analyzed model under uniform tensile loading with individual randomness { e_i (*i*=1, 2 and 3)} with respect to different crack angles using SOPT and MCS.



(a) (b)

Fig. 4 The mean values of normalized MMSIFs (a) K_I and (b) K_{II} of plate under tensile loading with individual or combined randomness in e_1, e_2 and e_3

It is clear that the SOPT results are in good agreement with those obtained using MCS. It can be seen that the mean values of normalized Mode-I SIFs K_I of the analyzed model are the largest at a crack angle α = 0°, and the SIFs K_I are decreased with increment in the crack angle till 75°. At 90° crack angle, the SIFs K_I for the shorter crack lengths *a/W* are further increased and it is so because the compressive stresses dominant and so the tips of longer crack will get less influence of the buckling, as compared to the shorter ones and the results is the higher SIFs in shorter cracks and the lower SIFs for longer cracks. The mean values of normalized Mode-II SIFs K_{II} of the analyzed model are largest at a crack angle α = 45° and are minimum (zero) at α = 0° and 90°. For the crack angles α and (90◦ -α), the mean values of K_{II} are almost equal if the normalized crack length (a/W = 0.4 and 0.6) is shorter. For the longer cracks (a/W = 0.8), the mean values of K_{II} are not the same.

Fig. 5(a) and 5(b) show the line diagram of the analyzed model with dimensions of length $(2L)$, width $(2W)$, crack length $(2a)$, and hole radius (R) and a central cracked plate without hole with required above-mentioned dimensions, under combined tensile (σ) and shear (τ) stresses.

The behaviour of the mean values of normalized MMSIFs K_I and K_{II} of the analyzed model w.r.t. different crack angles using SOPT is predicted and compared with the deterministic values of normalized MMSIFs K_I and K_{II} of the plate with a central crack without any hole with the same geometrical properties subjected to combined loading, as shown in Fig. 6(a) and 6(b).

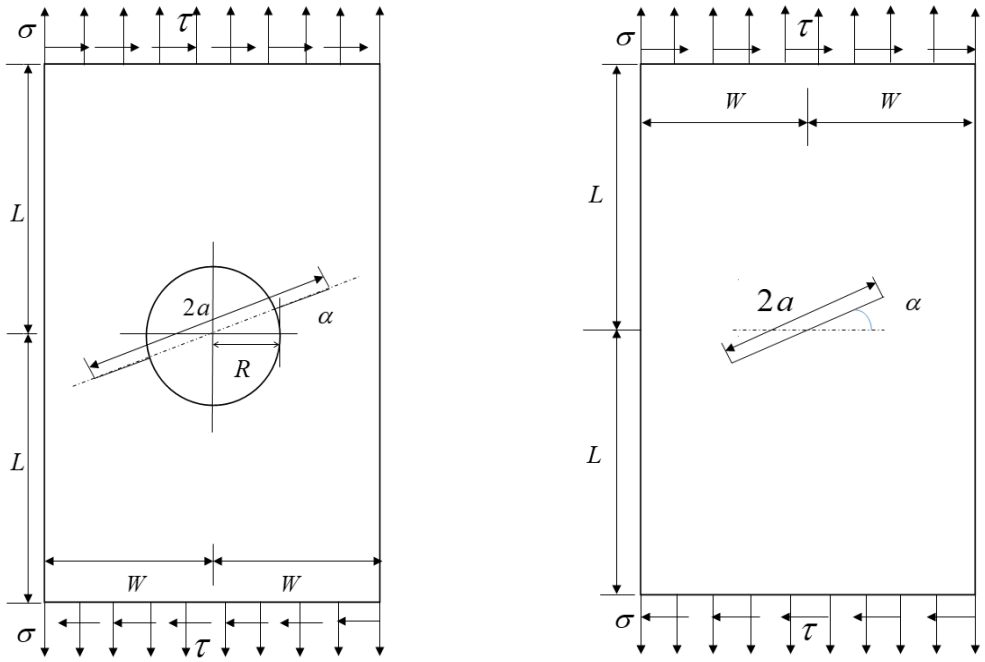


Fig. 5 Line diagrams of the plates with (a) hole emanating radial cracks and (b) a central crack subjected to combined loadings

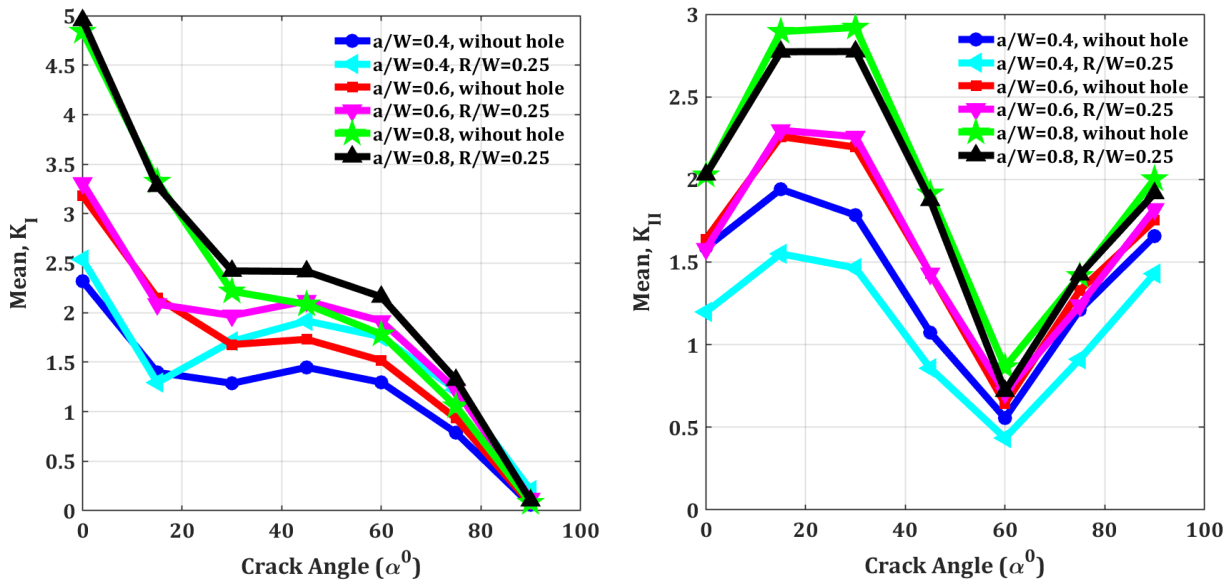
It can be seen that the mean values of normalized Mode-I SIFs K_I are highest at crack angle α = 0°. Also, as the crack angle (α) is increased, the mean values of K_I are decreased from 0° to 90° crack angle. At 90° crack angle, the mean values of K_I are zero. For the crack angle 15°, the mean values of K_I are increased for shorter crack length (a/W = 0.4) because due to combined loading the stress concentration on the periphery of the hole, from where the cracks are emanating, will be maximum and the stress concentration zone will be upper and lower parts of the sides of the hole and crack. As the crack makes an angle of 30°, the tip of the crack will be much nearer to the stress concentration zone and more stresses will be on a crack tip, therefore, the mean values of K_I are continuously increased till angle 45° and remain

critical. After 45° angle, the crack tips gradually leave the stress concentration zone till angle 90°. But, for longer crack, the crack tip remains somewhat away from the periphery of the hole. That is why the stress concentration zone becomes unable to produce much effect on the crack tip. If the length of the emanating cracks is very large, then the hole becomes the part of crack only.

The mean values of normalized Mode-II SIFs K_{II} are highest at a crack angle α = 15° but as a/W increases, the values of K_{II} start to dominate at α = 30°. From crack angles 30° to 60° and 60° to 90°, the mean values of K_{II} decreased and increased, respectively. Now, the mean values of normalized Mode-II SIFs K_{II} of an isotropic plate with a hole emanating radial cracks are the largest at 15° crack angle and are minimum at 60° crack angle.

At 90° crack angle, the mean value of K_I is zero because here, the effect of K_I is completely ineffective under the shear and combined loading. The mean values of normalized MMSIFs K_I and K_{II} of an isotropic plate with a hole emanating radial cracks subjected to combined and shear loadings are much higher as compared to those are under tensile loading. So, it can be concluded that the combined loading is much critical as compared to tensile and shear loading for the present problem.

Under all types of loading conditions, the gaps between the graphs, for the mean values of normalized MMSIFs K_I and K_{II} and the deterministic values of MMSIFs $K_{I,\text{det}}$ and $K_{II,\text{det}}$, are decreased as (a/W) is increased. It is so because the smaller crack with the hole has the influence on stress concentration as well as it works as a small edge crack on the periphery of the hole, whereas for the larger crack, the hole works as a part of the crack only or the role of the hole is just like a crack. Also, the mean values of normalized MMSIFs K_I and K_{II} are increased with increment in a/W.



(a) (b)

Fig. 6 Comparison of the behavior of the mean and deterministic values of normalized MMSIFs (a) K_I and (b) K_{II} of the plate with a hole and without hole with central cracks of different lengths subjected to combined loading

At the crack angles α = 0° and 90°, the mean values of K_{II} for a plate emanating radial cracks are nearly equal to the deterministic values of $K_{II,\det}$ for the cracked plate without hole with the increment in normalized crack length (a/W = 0.8). At 60° crack angle, the mean values of K_{II} are nearly equal to the deterministic values of normalized Mode-II SIFs $K_{II,\det}$ of an isotropic cracked plate without a hole.

4. Conclusions

The fracture behaviour of the plate with discontinuities subjected to shear and combined loading conditions are much more critical as compared to tensile loading. Hence, proper control of these types of loading will increase the reliability of structures. The input random variables such as normalized crack length, crack angle, and normalized radius of the hole show much influence on the stochastic fracture behavior of the plate with discontinuities. So, the reliability and safety in a structure can be enhanced by controlling the input random variables properly.

Under tensile loadings, the plate is the least critical and sensitive when the geometry (hole emanating cracks) at the centre position and is the most critical and sensitive when the geometry is either side of the central part of the plate. Under shear and combined loadings, the plate is the least critical and sensitive when the geometry is below the central part of the plate and is the most critical and sensitive when the geometry is above the central part of the plate.

Abstract. *Here, XFEM is used to model structural discontinuities like cracks and holes in order to forecast the strength and dependability of the structure under service conditions. By contrasting the numerical outcomes of several issues with the analytical and experimental findings, the method's resilience has been shown. Additionally, XFEM is coupled with a stochastic method to predict the sensitivity of a structure with discontinuities (cracks and holes) under tensile loading conditions in terms of output COVs and fracture strength in terms of mean values of stress intensity factors (SIFs) using input individual and combined randomness in various system parameters. The second order perturbation technique has been utilized in stochastic / perturbation theory to forecast how constructions would fracture. The perturbation technique is also utilized as Taylor series expansion method and yields accurate results if the input randomness is less than twenty percentage.*

Keywords. XFEM, COV, MMSIF, Stochastic, Perturbation

1. Introduction

We are aware that randomness always exists in reality and affects every aspect of a construction, including its geometry, strength, lifespan, susceptibility to damage, and fracture parameters. Even with the finest quality control procedures, randomness in system attributes has a major impact on how the mechanical

component responds to fracture. Therefore, randomness, external loads, material qualities, crack parameters, and geometry must all be taken into account when performing a fracture analysis on a structure. The stochastic fracture analysis increases the safety of structures by offering a reliable prediction of the fracture behaviour of the structure. The reliability evaluation methodologies can aid in the creation of preliminary recommendations for reliable designs. Many scholars have successfully analysed the stochastic fracture behaviour of the structure. Through the use of several numerical examples and the scaled boundary finite element method (SBFEM), Chowdhury et al. [1] completed the shape sensitivity analysis (Rahman and Chen [2]; Reddy and Rao [3]) of stress intensity variables to the crack size and direction. They performed the reliability assessment by Monte Carlo simulations (Chakraborty and Rahman [4, 5]; Choi et al. [6]; Evangelatos and Spanos [7]; Haldar and Mahadevan [8]; Khasin [9]; Lal and Palekar [10]). Some academics have talked about their work using the perturbation technique to forecast the material's stochastic reaction. In this regard, Rahman and Rao [11] introduced a stochastic meshless technique for resolving random material property boundary-value issues in linear elasticity. For the purpose of forecasting stochastic structure response, they created a meshless formulation. Classical perturbation expansions were produced in conjunction with the meshless equations to forecast the response's second-moment characteristics.

The XFEM has been further improved or enhanced by many researchers through coupling the XFEM with another technique to overcome the difficulties faced by the general XFEM. In the direction, a new set of enrichment functions was proposed for solving the Poisson equation in 1D and 2D spaces and was reduced the analysis error by Paweł [12]. The XFEM was coupled with a constitutive law with embedded discontinuity (CLED) approach for modelling of mixed mode cracking in concrete structure for simplifying the numerical implementation (Pietruszczak and Haghighat, [13]). Improved XFEM was developed for 3D and demonstrated better accuracy, convergence and efficiency. It overcomes the linear dependency problem by utilizing an extra degree of freedom free partition of unity approximation which is based on local least-squares fitting with a one-point interpolation constraint (Tian et al., [14]).

Using XFEM and various independent, combined uncorrelated and correlated input random Gaussian variables using SOPT and MCS, Lal and Markad [15] presented mixed mode SIFs and crack propagation analysis of the symmetric angle-ply laminated composite plate with through-thickness arbitrary curve cracks subjected to tensile and shear stress. The stochastic finite element technique is an extension of the MCS with uncertainty in the system parameters, such as materials, geometry, etc. given by Arregui-Mena et al. [16]. The spectral stochastic finite element approach and the perturbation technique (SSFEM). Lal and Markad [10] utilised a C^0 FEM based on higher order shear deformation plate theory was used to evaluate the second order statistics of MMSIFs of single edge V-notched angle-ply laminated composite plates under in-plane tensile load with uncertainty in material parameters, crack opening, and fracture length (HSDT). With the help of FOPT, SOPT, and MCS, the probabilistic evaluation was carried out.

The few researchers predicted how an infinite plate with a separate circular hole and a crack would fracture under tensile force. To the author's knowledge, XFEM with SOPT has not been used to investigate the stochastic fracture behaviour in terms of normalised MMSIFs and corresponding COVs of the infinite plate with various positions of a separate circular hole and a crack with various crack angles under tensile loading with input random parameters such as crack length, normalised radius of the hole, crack angle, and the central distance between separate hole and crack.

By incorporating the individual and combined randomness in the normalised crack length, crack angle, and normalised radius of the hole in an isotropic plate with a hole emanating cracks using SOPT, the stochastic fracture response through the normalised MMSIFs is calculated. Some results are validated with MCS. Present work is also focuesed on effect of combined loading over stochastic fracture response of the structural plate in terms of normalized MMSIFs.

2. Mathematical formulation

The XFEM is useful for modelling discontinuities like fractures, holes or voids, inclusions, interfaces, etc. while including discontinuous functions in the FE mesh. The level set method (LSM) has been successfully

used in conjunction with the XFEM to address these problems by providing further enrichment functions like crack faces and crack tips. Here, the XFEM software is built upon the 2D MATLAB code by Pais [18].

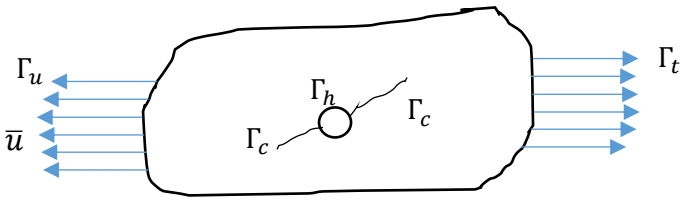

Fig. 1 Area under consideration with cracks, holes, and boundary condition

2.1 Equilibrium equation

The surfaces of cracks Γ_c and holes Γ_h are assumed traction free as are mentioned by Daux et al. [20], and shown in figure 1. The equilibrium equation in the domain Ω is:

$$\tilde{\nabla} \cdot \boldsymbol{\sigma}_t + \mathbf{f}_b = 0 \tag{1}$$

Small strains and displacements are taken into consideration in the current work. Thus, the relationship between strain and displacement illustrates the kinematics equations:

$$\boldsymbol{\varepsilon} = \boldsymbol{\varepsilon}(\mathbf{u}) = \tilde{\nabla}_s \cdot \mathbf{u} \tag{2}$$

Here, $\tilde{\nabla}_s$ is the symmetric part of the gradient operator and $\mathbf{u}$ is a displacement field vector. The boundary conditions for the displacements on the boundary Γ_u are:

$$\mathbf{u} = \bar{\mathbf{u}} . \tag{3}$$

The constitutive relation for elastic material can be shown by Hooke's law as:

$$\boldsymbol{\sigma}_t = \boldsymbol{D} \cdot \boldsymbol{\varepsilon}(\mathbf{u}) \tag{4}$$

where $\boldsymbol{D}$ is Hooke tensor or constitutive matrix for isotropic materials for plane stress and strain conditions in 2D.

The equilibrium equations' weak form is provided by:

$$\int_{\Omega} \boldsymbol{\varepsilon}(\mathbf{u}) : \boldsymbol{D} : \boldsymbol{\varepsilon}(\mathbf{v}) d\Omega = \int_{\Omega} \bar{\mathbf{b}} \cdot \mathbf{v} d\Omega + \int_{\Gamma_t} \bar{\mathbf{t}} \cdot \mathbf{v} d\Gamma \quad \forall \mathbf{v} \in \gamma_0 \tag{5}$$

The linear, FF and bilinear, SS forms of the equation (5) are:

$$FF(\mathbf{v}) = \int_{\Gamma} \bar{\mathbf{b}} \cdot \mathbf{v} d\Omega + \int_{\Gamma_t} \bar{\mathbf{t}} \cdot \mathbf{v} d\Omega \tag{6}$$

$$SS(\mathbf{u}, \mathbf{v}) = \int_{\Omega} \boldsymbol{\varepsilon}(\mathbf{u}) : \boldsymbol{D} : \boldsymbol{\varepsilon}(\mathbf{v}) d\Omega \tag{7}$$

Potential energy (Π) of an elastic body is $\Pi = \frac{1}{2} SS(\mathbf{u}, \mathbf{u}) - FF(\mathbf{u})$ (8)

By applying a variant of the previous equation and substituting $\frac{\partial \Pi}{\partial \mathbf{u}} = 0$, the minimization of the elastic body's potential energy may be solved, and the following set of discrete equations is produced as a result.

$$[\mathbf{K}]\{\mathbf{d}\} = \{\mathbf{f}\} \tag{9}$$

where, $[\mathbf{K}]$ is the global stiffness matrix, $\{\mathbf{d}\}$ are the global degrees of freedom and $\{\mathbf{f}\}$ are the applied loading or force.

$$\mathbf{K}_{ij}^{e} = \begin{bmatrix} \mathbf{K}_{ij}^{uu} & \mathbf{K}_{ij}^{ua} & \mathbf{K}_{ij}^{ub} & \mathbf{K}_{ij}^{ug} \\ \mathbf{K}_{ij}^{au} & \mathbf{K}_{ij}^{aa} & \mathbf{K}_{ij}^{ab} & \mathbf{K}_{ij}^{ag} \\ \mathbf{K}_{ij}^{bu} & \mathbf{K}_{ij}^{ba} & \mathbf{K}_{ij}^{bb} & \mathbf{K}_{ij}^{bg} \\ \mathbf{K}_{ij}^{gu} & \mathbf{K}_{ij}^{ga} & \mathbf{K}_{ij}^{gb} & \mathbf{K}_{ij}^{gg} \end{bmatrix} \tag{10}$$

$$\mathbf{f}_i^e = \left\{ \mathbf{f}_i^u \;\; \mathbf{f}_i^a \;\; \mathbf{f}_i^{b_1} \;\; \mathbf{f}_i^{b_2} \;\; \mathbf{f}_i^{b_3} \;\; \mathbf{f}_i^{b_4} \;\; \mathbf{f}_i^g \right\}^{\mathbf{T}} \tag{11}$$

$$\mathbf{d} = \left\{ \mathbf{u} \;\; \mathbf{a} \;\; \mathbf{b}_1 \;\; \mathbf{b}_1 \;\; \mathbf{b}_1 \;\; \mathbf{b}_1 \;\; \mathbf{g} \right\}^{\mathbf{T}} \tag{12}$$

2.2 XFEM Approximation

XFEM Approximation for Cracks and voids are defined as,

$$\mathbf{u}^{fi}(\mathbf{x}) = \mathbf{u}^{\mathbf{FEM}} + \mathbf{u}^{\mathbf{ENR}} = \sum_{i=1}^{n} \mathcal{N}_i(\mathbf{x}) \left\{ \bar{\mathbf{u}}_i + \sum_{j=1}^{m} \mathbf{F}^j(\mathbf{x}) \mathbf{a}_i^j \right\} \tag{13}$$

Heaviside function for a discontinuous function for the crack and voids defined as,

$$\mathcal{H}_1(\mathbf{x}) = \begin{cases} 1 \text{ for } \boldsymbol{\varphi}(\mathbf{x}) > 0 \\ 0 \text{ for } \boldsymbol{\varphi}(\mathbf{x}) = 0 \\ -1 \text{ for } \boldsymbol{\varphi}(\mathbf{x}) < 0 \end{cases} \quad \text{and} \quad \mathcal{H}_2(\mathbf{x}) = \begin{cases} 1 \text{ for } \chi(\mathbf{x}) > 0 \\ 0 \text{ for } \chi(\mathbf{x}) \le 0 \end{cases} \tag{14}$$

2.3 Level Set Method

For crack, level set method implemented by eq. (15), and for voids by eq. (16). The sign distance function $\phi(\mathbf{x}, \mathrm{t})$ to the curve Γ_c

$$\phi(\mathbf{x}) = \begin{cases} \min\limits_{\mathbf{x}_c \in \Gamma} \left\| \mathbf{x} - \mathbf{x}_c \right\| = d\left(\mathbf{x}, \mathbf{x}_i\right) & \forall \left(\mathbf{x} - \mathbf{x}_c\right) \cdot e_2 \ge 0 \\ \min\limits_{\mathbf{x}_c \in \Gamma} \left\| \mathbf{x} - \mathbf{x}_c \right\| = -d\left(\mathbf{x}, \mathbf{x}_i\right) & \text{otherwise} \end{cases} \tag{15}$$

$$\chi(\mathbf{x},0) = \min_{\mathbf{x}_c^i \in \Omega_c^i} \left\{ \left\| \mathbf{x} - \mathbf{x}_c^i \right\| - \mathrm{r}_c^i \right\} \qquad \text{where, } i = 1, 2, ..., n_c \tag{16}$$

where, d is the absolute distance, $\mathbf{x}_i$ is the point on crack closest to a point x with any point $\mathbf{x}_c$ on the crack surface Γ_c. r_c^i is the radius of the *i*th hole.

2.4 Evaluation of Stress Intensity Factors (SIFs)

For general mixed-mode problems in two dimensions, SIFs and J-integral can be stated as,

$$J = \frac{K_I^2}{E^*} + \frac{K_{II}^2}{E^*} \tag{17}$$

where, $E^* = \begin{cases} E & \text{for plane stress} \\ \dfrac{E}{1-\nu^2} & \text{for plane strain} \end{cases}$ (18)

The J -integral also follows the path-independence and it is explained

$$J = \int_{\Gamma} \left(W n_j - \mathbf{t}_i \cdot \frac{\partial \mathbf{u}_i}{\partial x} \right) d\Gamma \tag{19}$$

where, W is the strain energy density. For the plate of the elastic material, it can explain that $W = (1/2)\boldsymbol{\sigma}_{ij}\boldsymbol{\varepsilon}_{ij}$.

Now, two equilibrium, independent states of a cracked body are considered. Consider the state1, $\left(\boldsymbol{\sigma}_{ij}^{(1)},\boldsymbol{\varepsilon}_{ij}^{(1)},\mathbf{u}_{j}^{(1)}\right)$, corresponds to the present or actual state and state 2, $\left(\boldsymbol{\sigma}_{ij}^{(2)},\boldsymbol{\varepsilon}_{ij}^{(2)},\mathbf{u}_{j}^{(2)}\right)$, is an auxiliary state. Further, $\boldsymbol{\sigma}_{ij}^{(2)}$, $\boldsymbol{\varepsilon}_{ij}^{(2)}$ and $\mathbf{u}_{j}^{(2)}$ are the auxiliary stress field, auxiliary strain filed and auxiliary displacement field, respectively. Thus, superposition of these two states brings another equilibrium state, say, $\left(\boldsymbol{\sigma}_{ij},\boldsymbol{\varepsilon}_{ij},\mathbf{u}_{j}\right)$. Now, we have:

$$\boldsymbol{\sigma}_{ij}=\boldsymbol{\sigma}_{ij}^{(1)}+\boldsymbol{\sigma}_{ij}^{(2)}\quad \boldsymbol{\varepsilon}_{ij}=\boldsymbol{\varepsilon}_{ij}^{(1)}+\boldsymbol{\varepsilon}_{ij}^{(2)}\qquad \mathbf{u}_{j}=\mathbf{u}_{j}^{(1)}+\mathbf{u}_{j}^{(2)} \tag{20}$$

The strain energy densities are:

$$W=W^{(1)}+W^{(2)}\quad W^{(1)}=\frac{1}{2}\boldsymbol{\sigma}_{ij}^{(1)}\boldsymbol{\varepsilon}_{ij}^{(1)}\qquad W^{(2)}=\frac{1}{2}\boldsymbol{\sigma}_{ij}^{(2)}\boldsymbol{\varepsilon}_{ij}^{(2)} \tag{21}$$

$$W=\frac{1}{2}\boldsymbol{\sigma}_{ij}\boldsymbol{\varepsilon}_{ij}=\frac{1}{2}\left(\boldsymbol{\sigma}_{ij}^{(1)}+\boldsymbol{\sigma}_{ij}^{(2)}\right)\left(\boldsymbol{\varepsilon}_{ij}^{(1)}+\boldsymbol{\varepsilon}_{ij}^{(2)}\right)=\frac{1}{2}\left(W^{(1)}+W^{(2)}\right)-\boldsymbol{\sigma}_{ij}^{(1)}\boldsymbol{\varepsilon}_{ij}^{(2)} \tag{22}$$

2.5 Stress intensity factor (SIF)

The Mode-I and Mode-II SIFs are formulated as,

$$K_{I}=K_{I}^{(1)}+K_{I}^{(2)}\quad K_{II}=K_{II}^{(1)}+K_{II}^{(2)} \tag{23}$$

The Mode-I and Mode-II SIFs for the actual state can be obtained by choosing the auxiliary state (state 2), e.g., if auxiliary state 2 is chosen to be state for Mode-I, then the auxiliary state is Mode-I near tip displacement and stress field, then by putting $K_{I}^{(2)}=1$ and $K_{II}^{(2)}=0$ in the equation (23), we have:

$$K_{I}^{(1)}=\frac{M^{(1,\text{Mode I})}E^{*}}{2} \tag{24}$$

Similarly, if auxiliary state 2 is chosen to be state for Mode-II, then the auxiliary state is Mode-II near tip displacement and stress field, then by putting $K_{I}^{(2)}=0$ and $K_{II}^{(2)}=1$ in equation (23), we have:

$$K_{II}^{(1)}=\frac{M^{(1,\text{Mode II})}E^{*}}{2} \tag{25}$$

where, $M^{(1,\text{Mode I})}$ and $M^{(1,\text{Mode II})}$ are interaction integrals.

3. Results and discussion

By incorporating the individual and combined randomness in the normalised crack length $\left(e_1 = a/W\right)$, crack angle $\left(e_2 = \alpha\right)$, and normalised radius of the hole $\left(e_3 = R/W\right)$ in an isotropic plate with a hole emanating cracks using SOPT, the stochastic fracture response through the normalised MMSIFs is calculated. Some results are validated with MCS. The input random variables are indicated by the parameter { e_i (*i*=1, 2 and 3). Furthermore, it is assumed that the input COV for individual and combined randomness in all the parameters is 15% or 0.15 variation of characteristics from their mean values in order to forecast the stochastic MMSIFs of the plate under tensile, shear, and combination (tensile and shear) loadings. The percentage of the input random parameters has been randomly adopted because in perturbation technique, for input COVs < 0.2 or 20 %, the solution can be obtained up to the acceptable accuracy (Stefanou [20]). The normalized MMSIFs in terms of K_I and K_{II} are expressed as:

For Tensile loading

$$K_I = K_{I,\text{mean}} / \left(\sigma\sqrt{\pi a}\right) \text{ and } K_{II} = K_{II,\text{mean}} / \left(\sigma\sqrt{\pi a}\right) \tag{26}$$

For Shear loading

$$K_I = K_{I,\text{mean}} / \left(\tau\sqrt{\pi a}\right) \text{ and } K_{II} = K_{II,\text{mean}} / \left(\tau\sqrt{\pi a}\right) \tag{27}$$

where K_I , K_{II} , $K_{I,\text{mean}}$, $K_{II,\text{mean}}$, σ , τ and λ are normalized Mode-I and Mode-II SIFs, numerical Mode-I and Mode-II SIFs, tensile, shear and combined stresses, respectively and where, $\lambda = \sigma = \tau$.

3.1 Convergence and validation study

The results of Grasa et al. [21] using a first-order perturbation technique (FOPT) on the basis of analytical and XFEM solution for an isotropic edge cracked plate subjected to tensile loading are available and are compared with the mean value of Mode-I SIF using the current perturbation-based SOPT combined with XFEM, and they are in good agreement as shown in Table 1.

Table 1 Validation of SIFs of an isotropic edge cracked plate subjected to tensile loading

Analytical Solution [21]	XFEM with FOPT [21]	% Error	XFEM with SOPT	% Error	XFEM with MCS	% Error
99.8182	98.951	0.87	100.4834	0.67	100.1276	0.31

Rarely are the SOPT findings for the stochastic fracture analysis of the investigated model under various stress situations available in the literature. To validate the current stochastic fracture analysis for a/W= 0.4 with $\alpha = 30^0$, as indicated in Table 2, the current mean and corresponding COV $\{e_i(i=1, 2 \text{ and } 3) = 0.15\}$ of MMSIFs K_I and K_{II} acquired by SOPT are compared with those obtained by MCS.

Table 2 Behaviour of the analyzed model under different loading conditions for normalized crack length (a/W= 0.4) with crack angles ($\alpha = 30^\circ$) through individual randomness in a/W by MCS with different numbers of samples

Total no. of samples	Tensile loading				Shear loading			
	K_I		K_{II}		K_I		K_{II}	
	Mean	COV	Mean	COV	Mean	COV	Mean	COV
9000	0.809	0.121	0.354	0.223	2.527	0.059	1.296	0.125
9500	0.822	0.084	0.342	0.197	2.536	0.051	1.193	0.097
10000	0.828	0.056	0.334	0.167	2.540	0.047	1.128	0.081
10500	0.828	0.056	0.334	0.167	2.540	0.047	1.128	0.081
11000	0.828	0.056	0.334	0.167	2.540	0.047	1.128	0.081

The results obtained by both SOPT and MCS are in very good agreement. In the direct MCS method, the different sets of random samples of random system properties are generated first by direct use of the computer by using Gaussian random number generation. These sets of random samples are substituted in the response equation of MMSIFs and again generated the random samples of MMSIFs. The mean of these random samples gives the mean value of MMSIFs, while the variance of random samples gives the variance of MMSIFs. The optimum numbers of samples are decided on the basis of convergence of mean results. In the present analysis, 10,000 samples are used for satisfactory convergence of the results. Therefore, the 10,000 random samples are used for further computation of results using MCS. In the present study, MCS is used only for validation purpose due to higher consumption of computational time, particularly for fracture problem with very high mesh density.

Fig. 2(a) and 2(b) show the line diagram of an isotropic rectangular plate with the analyzed model with dimensions of length $(2L)$, width $(2W)$, crack length $(2a)$, and hole radius (R) and a central cracked plate without hole with required above-mentioned dimensions, under shear (τ) stress.

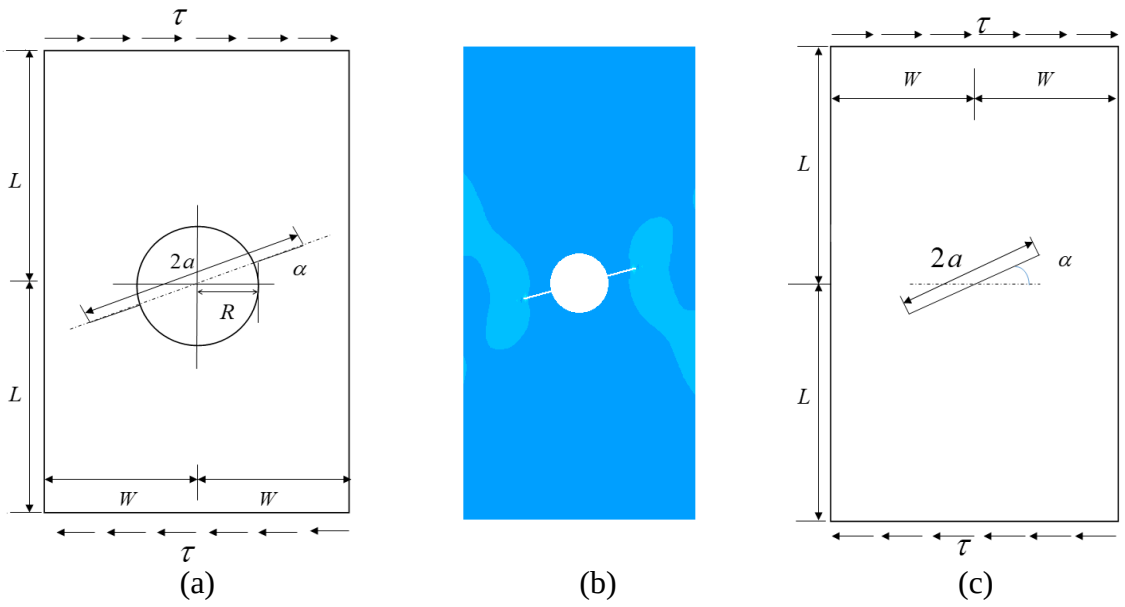

Fig. 2 (a) A line diagram and (b) the stress contour (general) of a plate with radial cracks on a hole and (c) a line diagram of central crack under shear loading

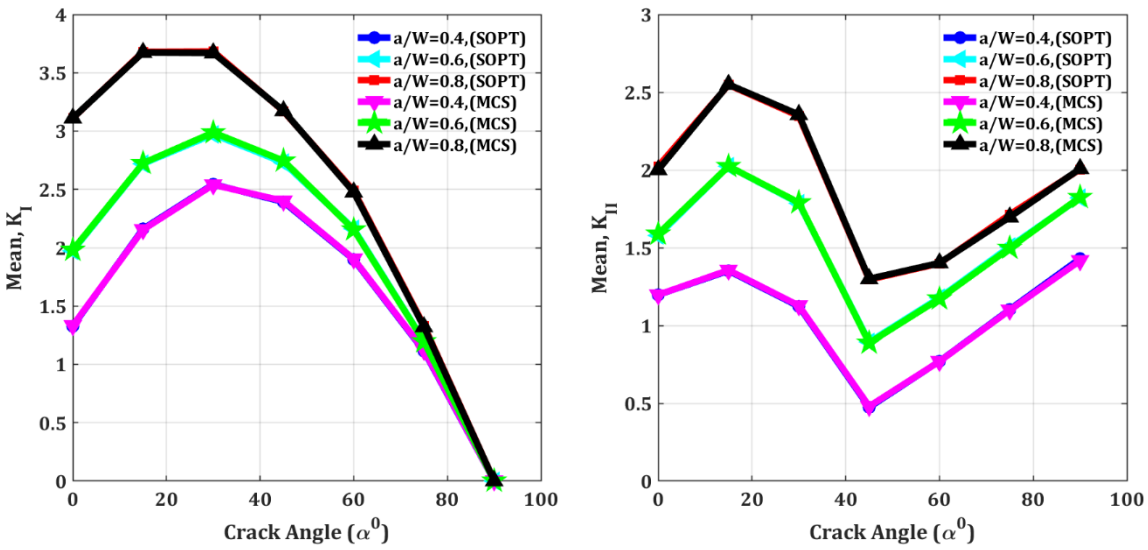
The behaviour of mean values of normalized MMSIFs of the analyzed model under uniform shear loading w.r.t. different crack angles is presented in Fig. 3(a) and 3(b). It is again clear that the SOPT results are in good agreement with those of MCS.

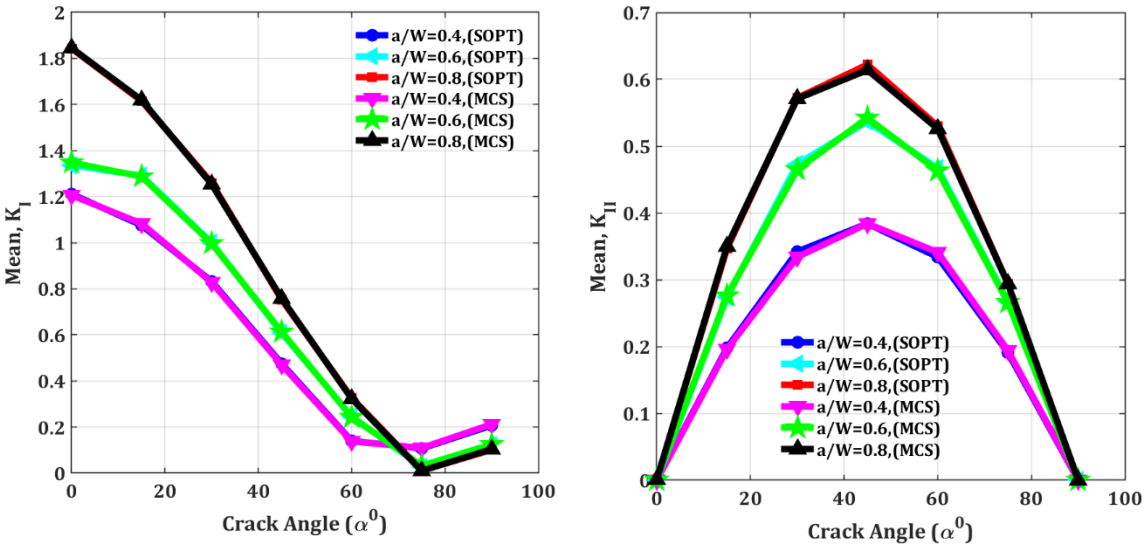


(a) (b)

Fig. 3 The mean values of normalized MMSIFs (a) K_I and (b) K_{II} of a plate under shear loading with individual randomness in e_1, e_2 and e_3

It can be seen that the mean values of K_I are largest at a crack angle α = 30°, and due to the increment in *a/W*, the mean values of K_I starts to dominate at α= 15°. As the crack angle (α) increases from 0° to 30°, the mean values of K_I are increased. Then, these values are continuously decreased to zero at 90° crack angle. Now, the mean values of normalized Mode-II SIFs K_{II} of the analyzed model are maximum at 15° crack angle and are minimum at 45° crack angle. At α = 0° and 90°, the mean values of K_{II} are nearly equal as the normalized crack length increases (*a/W*= 0.8). From crack angle 45° to 90°, the mean values of K_I and K_{II} continuously decrease and increase, respectively.

Fig. 4(a) and 4(b) show the behaviour of the mean values of normalized MMSIFs K_I and K_{II} of the analyzed model under uniform tensile loading with individual randomness { e_i (*i*=1, 2 and 3)} with respect to different crack angles using SOPT and MCS.



(a) (b)

Fig. 4 The mean values of normalized MMSIFs (a) K_I and (b) K_{II} of plate under tensile loading with individual or combined randomness in e_1, e_2 and e_3

It is clear that the SOPT results are in good agreement with those obtained using MCS. It can be seen that the mean values of normalized Mode-I SIFs K_I of the analyzed model are the largest at a crack angle α = 0°, and the SIFs K_I are decreased with increment in the crack angle till 75°. At 90° crack angle, the SIFs K_I for the shorter crack lengths *a/W* are further increased and it is so because the compressive stresses dominant and so the tips of longer crack will get less influence of the buckling, as compared to the shorter ones and the results is the higher SIFs in shorter cracks and the lower SIFs for longer cracks. The mean values of normalized Mode-II SIFs K_{II} of the analyzed model are largest at a crack angle α = 45° and are minimum (zero) at α = 0° and 90°. For the crack angles α and (90◦ -α), the mean values of K_{II} are almost equal if the normalized crack length (a/W = 0.4 and 0.6) is shorter. For the longer cracks (a/W = 0.8), the mean values of K_{II} are not the same.

Fig. 5(a) and 5(b) show the line diagram of the analyzed model with dimensions of length $(2L)$, width $(2W)$, crack length $(2a)$, and hole radius (R) and a central cracked plate without hole with required above-mentioned dimensions, under combined tensile (σ) and shear (τ) stresses.

The behaviour of the mean values of normalized MMSIFs K_I and K_{II} of the analyzed model w.r.t. different crack angles using SOPT is predicted and compared with the deterministic values of normalized MMSIFs K_I and K_{II} of the plate with a central crack without any hole with the same geometrical properties subjected to combined loading, as shown in Fig. 6(a) and 6(b).

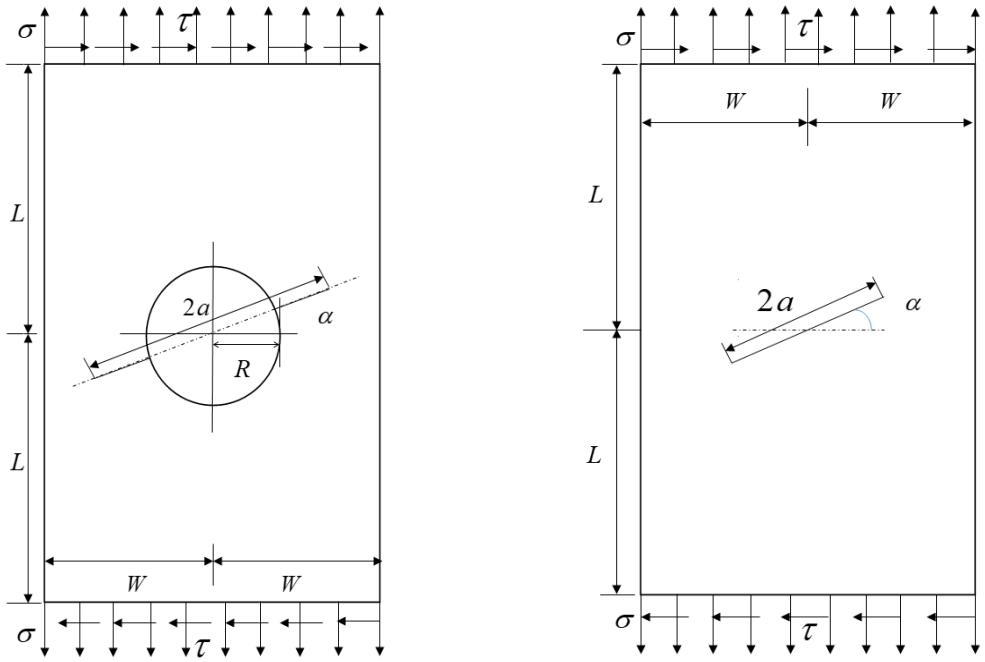


Fig. 5 Line diagrams of the plates with (a) hole emanating radial cracks and (b) a central crack subjected to combined loadings

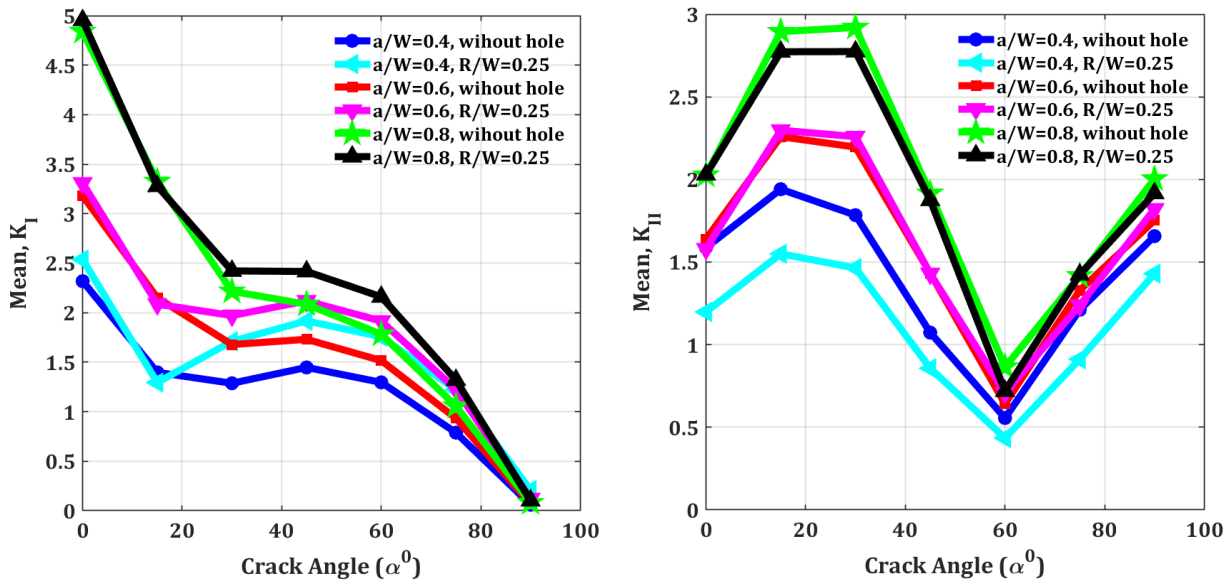
It can be seen that the mean values of normalized Mode-I SIFs K_I are highest at crack angle α = 0°. Also, as the crack angle (α) is increased, the mean values of K_I are decreased from 0° to 90° crack angle. At 90° crack angle, the mean values of K_I are zero. For the crack angle 15°, the mean values of K_I are increased for shorter crack length (a/W = 0.4) because due to combined loading the stress concentration on the periphery of the hole, from where the cracks are emanating, will be maximum and the stress concentration zone will be upper and lower parts of the sides of the hole and crack. As the crack makes an angle of 30°, the tip of the crack will be much nearer to the stress concentration zone and more stresses will be on a crack tip, therefore, the mean values of K_I are continuously increased till angle 45° and remain

critical. After 45° angle, the crack tips gradually leave the stress concentration zone till angle 90°. But, for longer crack, the crack tip remains somewhat away from the periphery of the hole. That is why the stress concentration zone becomes unable to produce much effect on the crack tip. If the length of the emanating cracks is very large, then the hole becomes the part of crack only.

The mean values of normalized Mode-II SIFs K_{II} are highest at a crack angle α = 15° but as a/W increases, the values of K_{II} start to dominate at α = 30°. From crack angles 30° to 60° and 60° to 90°, the mean values of K_{II} decreased and increased, respectively. Now, the mean values of normalized Mode-II SIFs K_{II} of an isotropic plate with a hole emanating radial cracks are the largest at 15° crack angle and are minimum at 60° crack angle.

At 90° crack angle, the mean value of K_I is zero because here, the effect of K_I is completely ineffective under the shear and combined loading. The mean values of normalized MMSIFs K_I and K_{II} of an isotropic plate with a hole emanating radial cracks subjected to combined and shear loadings are much higher as compared to those are under tensile loading. So, it can be concluded that the combined loading is much critical as compared to tensile and shear loading for the present problem.

Under all types of loading conditions, the gaps between the graphs, for the mean values of normalized MMSIFs K_I and K_{II} and the deterministic values of MMSIFs $K_{I,\text{det}}$ and $K_{II,\text{det}}$, are decreased as (a/W) is increased. It is so because the smaller crack with the hole has the influence on stress concentration as well as it works as a small edge crack on the periphery of the hole, whereas for the larger crack, the hole works as a part of the crack only or the role of the hole is just like a crack. Also, the mean values of normalized MMSIFs K_I and K_{II} are increased with increment in a/W.



(a) (b)

Fig. 6 Comparison of the behavior of the mean and deterministic values of normalized MMSIFs (a) K_I and (b) K_{II} of the plate with a hole and without hole with central cracks of different lengths subjected to combined loading

At the crack angles α = 0° and 90°, the mean values of K_{II} for a plate emanating radial cracks are nearly equal to the deterministic values of $K_{II,\det}$ for the cracked plate without hole with the increment in normalized crack length (a/W = 0.8). At 60° crack angle, the mean values of K_{II} are nearly equal to the deterministic values of normalized Mode-II SIFs $K_{II,\det}$ of an isotropic cracked plate without a hole.

4. Conclusions

The fracture behaviour of the plate with discontinuities subjected to shear and combined loading conditions are much more critical as compared to tensile loading. Hence, proper control of these types of loading will increase the reliability of structures. The input random variables such as normalized crack length, crack angle, and normalized radius of the hole show much influence on the stochastic fracture behavior of the plate with discontinuities. So, the reliability and safety in a structure can be enhanced by controlling the input random variables properly.

Under tensile loadings, the plate is the least critical and sensitive when the geometry (hole emanating cracks) at the centre position and is the most critical and sensitive when the geometry is either side of the central part of the plate. Under shear and combined loadings, the plate is the least critical and sensitive when the geometry is below the central part of the plate and is the most critical and sensitive when the geometry is above the central part of the plate.

An Experimental Study On Ultra High Performance Concrete Using Micro Fine And GGBS

Zeel Rabari[1], Hitesh Makad[2], Mansi Prajapati[3]
[2, 3]Assistant Professor
[1, 2, 3] Swarnim of Technology, Gandhinagar

Abstract- *The researchers and scientists have been constantly working on the development of the concrete. As per today's requirement of industry, it is essential to have good performance and durability of concrete for RCC structures. Two decades ago, the scientist has developed the ultra-high-performance concrete. The research and development have been into the progress on how to improve the durability, performance of concrete and make it more environment friendly. In the present study, the aim is to develop concrete mix incorporating ground granulated blast furnace slag and microfine. Ultra high-performance concrete usually provides the compressive strength more than 60 Mpa with good performance during service life of concrete. We have incorporated waste material like GGBS and microfine in the concrete so that impact of waste material on the environment can be reduced.*

Keywords- Compressive Strength, Durability, GGBS, Microfine, Performance etc.

I. INTRODUCTION

Concrete is the essential material in Construction industry. Concrete is the highest consumed material in the world after water. The use of concreting per day is on very high. As the population of the world is increasing, the smart material is required to fulfil the requirement of infrastructure with great durability. The rapid development on Ultra High-performance concrete has been going from last 20 years rigorously. The frequent use of UHPC (ultra high-performance concrete) is limited because it has very high cost and skilled labor is required for using it. One more material which has been used in this process is microfine. These are the material which is found as a byproduct of steel and iron manufacturing industry. These materials having cementitious property that is why these materials are used as a replacement of cement.

As per the past studies done on this topic, these materials are capable to provide bonding and strength in between all the ingredients of the concrete. Still there are many pros and cons in using it.

While we adding these materials, the good performance can be seen in the dance concrete. Construction industry requires both the thing Higher strength and good performance as well.

Ultra high-performance concrete having high modulus of Elasticity and reduces deflection in the concrete. There are many disadvantages of Ultra High performance Concrete. Due to inadequate research in this field, it is very difficult to identify proportion of material in the mix design as per UHPC requirement. Material selection is the also having the main factor on which performance of concrete depends.

Along with the GGBS and microfine, the scientists have used various admixtures different type of fibres various industrial waste to improve the mechanical and chemical properties of concrete material.

While designing the ultra-performance concrete we must keep into our mind the impact of sulphate and chloride attack on the concrete.

II. EXPERIMENTAL STUDY

The waste material used in this study isGround Granulated Blast Furnace Slag (GGBS) and Microfine. These are the waste materials by product of steel industry. Both material having some cementitious property that attracts researchers to incorporate these materials into the concrete mix. Effective outcome could be achieved by proper selection of materials, inspection, quality control and required proportion of all ingredient of concrete. The Ordinary Portland Cement is used having 53 Grade to meet the optimum requirement. The Typical Chemical Composition of GGBS is mentioned below:

Compound	Quantity Present (%)
Calcium Oxide	40-45 %
Silica	35-40 %
Magnesia	8-10 %
Alumina	10-15 %

The Typical Physical composition of GGBS are mentioned below:
Color: Off White
Specific Gravity: 2.85
Bulk Density: 1060-1160 kg/m3 (Loose)
1275-1375 kg/m3 (vibrated)
Fineness: >360 m2/kg

Typical Physical Composition of Microfine:
Fineness: >560 m2/kg
Compressive Strength: >18 (in N/mm2 at 28 Days)
Initial Setting: 140 minutes
Final Setting: 190 minutes Grain Density: 2.75 kg/m3

Table 5.1 Experimental Result Obtained for OPC 53 Grade

Property of Cement	Result Obtained	Value Specified by IS 12269:2013
Fineness	1.60 %	< 10 %
Standard Consistency	35 %	Range 25-35 %

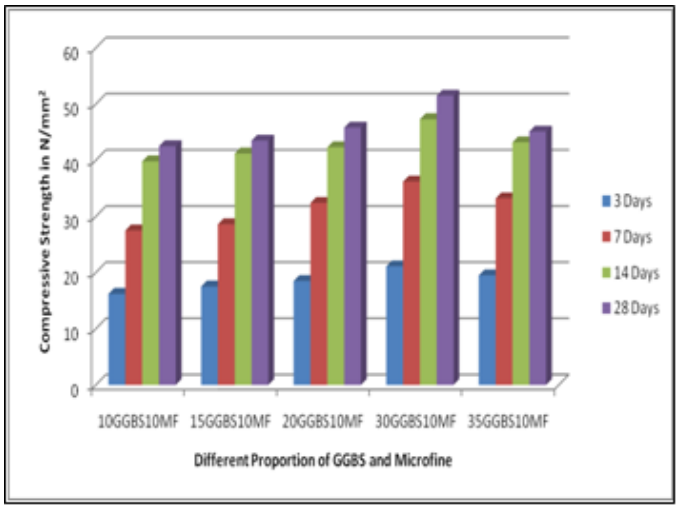

Graph 1 Compressive Strength results comparison for M40 Grade of Concrete

IV. CONCLUSIONS

The Following conclusion can be given as an outcome of this study:

1. GGBS and Microfine both are very good cementitious material and have ability to improve compressive strength and durability of concrete.
2. The Best outcome found when we add 30% GGBS and 10% Microfine as a replacement of Cement. Further, the results go down if we increase the amount of waste material.
3. The Split and Flexural Strength result found maximum at replacement of cement by 30% GGBS and 10% Microfine.
4. NDT Test (Rebound Hammer and Ultrasonic Pulse Velocity Test) results show that dispersion of ingredient of concrete and mixing bond with GGBS and microfine was very good.
5. This study shows that if we continue doing research on this material, would have great results in future. This would have direct benefit not only in construction industry but also for environmental protection also.

***Abstract*—**
India, one of the economies with the fastest growth rates in the world, is expanding at a rate of 7% annually. The nation is striving hard to alter itself over the next few decades, with a population that is also expanding. The Indian government has public transit improvement high on its priority list. Even though private vehicle ownership in India is rising and producing significant traffic issues in big areas like Navi-Mumbai, there are numerous initiatives to upgrade and modernize transport systems. At least 1.42 billion people, or around 35.87% of the population of the country, are estimated to live in urban areas, according to the World Bank's collection of Development Indicators 2022. Even while the amount of urbanization may appear to be low in percentage terms, there are a huge number of people living in cities. India's urban population currently outnumbers the populations of Brazil and the United States combined. India's level of urbanization is predicted to rise even more, and by 2030, there should be around 600 million people living in cities. Sadly, there is a rising quantity of traffic on the streets of our cities nowadays, which is increasing the time it takes for goods to be transported as well. This traffic is also a big factor in problems like air and noise pollution, traffic accidents, and serious health hazards for locals. Technology will be crucial in identifying mobility gaps and altering current transport systems in order to create an inclusive, safer, and more sustainable city of the future. we are solving the transportation problem with the help of dual simplex and two-phase methods. Here we are solving this problem with the help of the Branch and Bound Method of Integer Programming Problem by using R software and we are comparing the obtained optimal solution with the Vogel Approximation Method.

Keywords— Congestion, collision, Pollution, Transportation, Urbanization, R, VAM

I. INTRODUCTION:

Navi Mumbai is also known as the twin city of Mumbai. This city was designed by renowned urban planner and architect Charles Correa, structural engineer Pravina Mehta, and engineer Shirish Patel. It is situated in the western suburbs of Mumbai. A freshly constructed township called Navi Mumbai is a well-planned metropolis with a robust infrastructure for its time.

In early 1964, Navi Mumbai was designed as a diversion from the unending traffic congestion in Mumbai and the city's rapidly expanding population. A 343.70 square km area from Thane to Raigad was included in the development plan for Navi Mumbai created by CIDCO. In addition, the idea received official approval from the Maharashtra government in August 1979. The site was chosen because it would be simpler to relocate the population because it was across the harbour from Bombay Island. Making livable spaces and a mass transit system was crucial.

The following were the primary drivers of the relocation:

1. Bombay's deterioration of older buildings
2. Better and more affordable housing amenities in Navi Mumbai.
3. More employment opportunities are available in Navi Mumbai.
4. Shorter distances for commuting

One cannot dispute the fact that most of Navi-Mumbai's population relies on public services when discussing the transportation infrastructure of a large and well-known city in India like Navi-Mumbai. However, given the current traffic jams on the roads, the time it takes for products to be transported is now also a problem. Apart from a few sections during the morning and evening rush hours, Navi Mumbai is a planned city and does not experience significant traffic congestion in some areas. Additionally, the Sion-Panvel Highway experiences heavy traffic during any hour of the day as a result of the significant increase in vehicle traffic.

India's Navi-Mumbai has traditionally had a strong transit infrastructure. In order to fulfill the rising demand for transport services, both rail and buses have greatly expanded but still for goods transport is by road only. Although the present administration is working to meet the minimum requirements for public transportation as well as for trucks, tempos and other means of goods transport but land restrictions are the main problem impeding further development programs and concepts in this particular sector. Cause of transport system:

IJFANS International Journal of Food And Nutritional Sciences

Research Paper **© 2012 IJFANS. All Rights Reserved**

The main causes of traffic bottlenecks in Navi Mumbai are several. Among the most frequent causes are:

1. Heavy traffic on main thoroughfares and highways as a result of dense population and rising vehicle ownership.
2. Insufficient infrastructure for alternate means of transportation and a lack of public transit choices.
3. Roadwork and construction that causes lane closures and detours.
4. Ineffective local government agency coordination and traffic management.
5. Inadequate land use planning and unplanned urban growth.

It is crucial to remember that several additional factors, such as weather conditions, accidents, and special events, can also contribute to traffic bottlenecks. The time of day and day of the week can also affect traffic patterns and congestion levels.

II. OBJECTIVE:

The main objective is to minimize expenses and maximize profit. The starting site is where transportation issues originate, and the destination is where they are conveyed to move the goods at the lowest possible cost without compromising supply and demand.

III. LITERATURE REVIEW COST MINIMIZING TRANSPORTATION PROBLEM:

A better VAM approach was put out by Korukoglu and Balli (2011) for the transportation issue. Phase-II of the simplex technique was employed by Sharma et al. (2011) to address the transportation issue. solving the transportation issue using the integer programming problem that Gaurav Sharma et al. (2012) described. Sudhakar et al. (2012) suggested a novel method for identifying the best solution to the transportation challenge. For TP of Three Variables, Rekha (2013) suggested optimisation approaches. An algorithm was created by Mollah Mesbahuddin Ahmed et al. (2014) to identify an initial basic workable solution for both the balanced and unbalanced TP.Rekha et al. developed a max min penalty solution to the transportation cost minimization problem in 2014.A solution to the transport problem's degeneracy was put out by Sarbjit Singh in 2015.

To calculate the shortest travel time, Sharif Uddin (2012) used a transportation algorithm. The time-minimizing TP with fractional bottleneck objective function was discussed by Jain and Saksena in 2012. Pavel Kolman (2015) put forth a fresh approach to cut down on the amount of time required to move materials from collection points to processing facilities.

For the purpose of solving a MOTP with fuzzy coefficients, Surapati and Roy (2008) investigated a fuzzy goal programming approach based on priorities. Fuzzy logic-guided non-dominated sorting genetic algorithm was used by Lau et al. (2009) to resolve the MOTP, which is concerned with the optimisation of vehicle routing when numerous items, multiple consumers, and different depots are considered. To identify the ideal compromise solution of a problem, Lohgaonkar and Bajaj (2010) used the fuzzy programming technique with linear and non-linear membership functions. The time-minimizing TP with fractional bottleneck objective function was discussed by Jain and Saksena in 2012. Pavel Kolman (2015) put forth a fresh approach to cut down on the amount of time required to move materials from collection points to processing facilities.

For the purpose of solving a MOTP with fuzzy coefficients, Surapati and Roy (2008) investigated a fuzzy goal programming approach based on priorities. Fuzzy logic-guided non-dominated sorting genetic algorithm was used by Lau et al. (2009) to resolve the MOTP, which is concerned with the optimisation of vehicle routing when numerous items, multiple consumers, and different depots are considered. To discover the ideal compromise solution of a multi-objective capacitated TP, Lohgaonkar and Bajaj (2010) used the fuzzy programming technique using linear and non-linear membership functions. For the purpose of addressing multi-objective transportation problems, assignment, and transshipment difficulties, TP. Sayed et al. (2012) employed a genetic algorithm. Fuzzy programming was utilised by Osuji et al. (2014) to solve a multi-objective transportation problem. A non-dominated point for the multi-objective transportation problem was provided by Abbas et al. (2015).

IV. FORMULATION TRANSPORTATION PROBLEM:

Given p origins and q destinations, the transportation problem can be formulated as the following linear programming problem model:

Minimize: $\sum_{r=1}^{p}\sum_{k=1}^{q} crkxrk$

Subject to constraint:

$$\sum_{k=1}^{q} xrk \leq ar \quad \text{r= 1, 2,…, p}$$

$$\sum_{r=1}^{p} xrk \leq bk \quad \text{k= 1,2,…,q}$$

$xrk \geq 0$ for all r and k

Where xij is the number of units shipped from origin r to destination k and crk is the cost of shipping one unit from origin r to destination k. The amount of supply at origin r is ar and the amount of destination k is bk. The objective is to determine the unknown xrk that will be the total transportation cost while satisfying all the supply and demand constraints

V. NUMERICAL EXAMPLES:

IJFANS INTERNATIONAL JOURNAL OF FOOD AND NUTRITIONAL SCIENCES
ISSN PRINT 2319 1775 Online 2320 7876
Research Paper **© 2012 IJFANS. All Rights Reserved** UGC CARE Listed (Group -I) Journal Volume 11, Iss 10, 2022

From Navi-Mumbai, specifics of the numerical problem have been gathered. Since the contributor wanted to keep the company's details private, we have not included them here.

Tables: Both table details were gathered for a month

Table :1

Plants	Supply [Heavy Vehicles]
A	20
B	50
C	50
TOTAL	120

Table 1 represents the quantity available in these plants

Table:2

Warehouses	Demand
X	10
Y	6
Z	14
TOTAL	30

Table 2 represents the demand for warehouses in various places.

VI. FORMULATION AND TABLES:

We create a transportation issue for XYZ Company since it is the primary resource. To find the best option and reduce the cost of transportation, we use the transportation model as shown below.

Table:3

TO/FROM	X	Y	Z	SUPPLY
A	8	10	20	20
B	40	30	55	50
C	20	25	35	50
DEMAND	10	6	14	30/120

If we can see the problem, Σ ar= 120, Σ bk = 30. Since Σar ≠ Σbk the problem is a type of unbalanced. Firstly, will balance the problem by adding a dummy warehouse "D". So will add 90 quantities with zero cost as a dummy.

Table:4

TO/FROM	X	Y	Z	D	SUPPLY
A	8	10 **6**	20 **14**	0	20
B	40	30	55	0 **50**	50
C	20 **10**	25	35	0 **40**	50
DEMAND	10	6	14	90	120

From Vogel's Approximation method [VAM], we find several occupied cells is 6 which is equal to m+n-1. Then we get the initial feasible solution as X12 =06, X13=14, X24 =50, X31=10, X34=40

The Optimistic transportation cost is Rs 540,000

VII. LINEAR PROGRAMMING PROBLEM FORMULATION OF TP:

Now we are converting the transportation problem into a Linear programming problem by using table 4

Minimize:

Z=8X11+10X12+20X13+40X21+30X22+55X23+20X31+ 25X32+35X33

Subject to constraint:

X11 + X12 + X13 ≤ 20 ……(I)
X21 + X22+ X23 ≤ 50 ……(II)
X31 + X32 + X33 ≤ 50……(III)
X11 + X21 + X31 ≥ 10……(IV)
X12 + X22 + X32 ≥ 6……...(V)
X13 + X23+ X33 ≥14 ……(VI)
X11, X12, X13, X21, X22, X23, X31, X32, X33 ≥ 0

Firstly, we change the problem in integer programming and using r Software on Integer Programming Formulation of Transportation Problem we are getting the optimal solution of our transportation problem which solving for Albert David Company to reduce transportation cost Rs 540,000 at X12 = 6, X13 = 14, X31 = 10

VIII. CONCLUSION:

We have proven the exclusivity and existence of the best possible solution to the transportation issue for the XYZ Company. This has been demonstrated through the development of the transportation problem into an integer programming problem, the application of the discussed methods in the paper, which produces the same optimal

Research Paper **© 2012 IJFANS. All Rights Reserved**

solution, and the articulation of the problem's optimality requirements. Additionally, the Branch and Bound approach yields the same outcome as VAM.

C	20 **10**	25	35	0 **40**	50
DEMAND	10	6	14	90	120

From Vogel's Approximation method [VAM], we find several occupied cells is 6 which is equal to m+n-1. Then we get the initial feasible solution as X12 =06, X13=14, X24 =50, X31=10, X34=40

The Optimistic transportation cost is Rs 540,000

VII. LINEAR PROGRAMMING PROBLEM FORMULATION OF TP:

Now we are converting the transportation problem into a Linear programming problem by using table 4

Minimize:

Z=8X11+10X12+20X13+40X21+30X22+55X23+20X31+ 25X32+35X33

Subject to constraint:

X11 + X12 + X13 ≤ 20 ……(I)
X21 + X22+ X23 ≤ 50 ……(II)
X31 + X32 + X33 ≤ 50……(III)
X11 + X21 + X31 ≥ 10……(IV)
X12 + X22 + X32 ≥ 6……...(V)
X13 + X23+ X33 ≥14 ……(VI)
X11, X12, X13, X21, X22, X23, X31, X32, X33 ≥ 0

Firstly, we change the problem in integer programming and using r Software on Integer Programming Formulation of Transportation Problem we are getting the optimal solution of our transportation problem which solving for Albert David Company to reduce transportation cost Rs 540,000 at X12 = 6, X13 = 14, X31 = 10

VIII. CONCLUSION:

We have proven the exclusivity and existence of the best possible solution to the transportation issue for the XYZ Company. This has been demonstrated through the development of the transportation problem into an integer programming problem, the application of the discussed methods in the paper, which produces the same optimal

Research Paper **© 2012 IJFANS. All Rights Reserved**

solution, and the articulation of the problem's optimality requirements. Additionally, the Branch and Bound approach yields the same outcome as VAM.

Green Lean Six Sigma for sustainability improvement: a systematic review and future research agenda

Abstract

Design/ Methodology/ Approach: To do a systematic analysis of the literature, a systematic literature review methodology has been used in this research work. 140 articles from the reputed databases were identified to explore hidden aspects of GLSS. Exploration of articles in different continents, year-wise, approach-wise, and journal-wise, were also done to find the execution status of GLSS.

Purpose: The main purpose of this article is to explore different aspects of the Green Lean Six Sigma approach, application status, and potential benefits from a comprehensive review of the literature and provides an avenue for future research work. The study also provides a conceptual framework for GLSS.

Findings: The study depicts that GLSS implementation is increasing year by year, and it leads to considerable improvement in all dimensions of sustainability. Enablers, barriers, tools, and potential benefits that foster the execution of GLSS in industrial organizations are also identified based on a systematic review of the literature.

Originality: The study's uniqueness lies in that study is the first of its kind that depicts the execution status of GLSS, and its different facets, explores different available frameworks and provides avenues for potential research in this area for potential researchers and practitioners.

Keywords: Lean Six Sigma; Green Lean Six Sigma; Sustainability; Enablers; Barriers; Framework

1. Introduction

Over the last few decades, economic change, sustainable product demands, governmental policy toward climate change, and market influence have led to a surge in the level of competition. The human-driven actions and fast industrial development have raised the temperature of the earth's surface by 1.5 °C in many world regions (IPCC, 2014). The industrial sectors contribute about 35% of the worldwide emissions of greenhouse gases (GHGs) (Thirupathi et al., 2019). This can be credited to the conventional approaches to production acquired by manufacturing sectors in most countries (Wang et al., 2019). The increase in global emission of GHGs has led to severe health problems in different parts of the world (Kwon, 2020; Jacobson, 2008). Therefore, emissions related to industry and other

International Journal of Lean Six Sigma

man-made actions and their health impacts have compelled the manufacturing sectors to implement sustainable production methods. Furthermore, because of the pressure of strict government policies on climate change and the motive of the Paris pact, industrial sectors have to implement sustainable practices. Therefore, the manufacturing sectors are expanding massive investments in research and development to evolve other ways of manufacturing high-specification eco-friendly products (Sharma et al., 2016). In several manufacturing areas, various ideas and strategies have been fostered during the previous decades like green manufacturing, value engineering, Six Sigma, lean six sigma (LSS), and green lean Six sigma (GLSS) to attain functional excellence in the organization (Pandey et al., 2018).

Organizations employ the lean concept to create value by improving the process through the identification and removal of different wastes (Garza-Reyes et al., 2016). However, the Lean approach reduces waste but cannot address process variations and ecological effects. Thus, the requirement of Six Sigma and Green technology was observed to manufacture high-quality eco-friendly products at a lower cost. The green concept was more associated with thinking about protecting natural resources through manufacturing and significantly related to sustainability (Zhu et al., 2018; Huo et al., 2019). It is a novel approach that minimizes harmful environmental impacts and focuses on the cost-effectiveness of an organization by producing high-specification eco-friendly products (Haapala et al., 2013; Yadav and Gahlot, 2022). However, this approach conveys the ecological problems but does not minimize variations in the process. Therefore, the requirement of Six Sigma was felt to manufacture a process with a lesser variation. The six sigma concept generates value through reliable process output by recognizing and minimizing variations (Kazancoglu et al., 2018; Shokri, 2017; Silich et al., 2012). This approach minimizes process variation but does not reduce negative environmental impacts and related wastes in the process (Sun et al., 2017). Lean and Six Sigma are two widely adopted methods that lead to the improved sustainable performance of an organization (Arnheiter and Maleyeff, 2005; Antony et al., 2019). In recent years, there has been a vivid development in LSS. Success stories of LSS execution and consequent enhancements in industrial sectors throughout the globe have been exhibited in academic journals (Shah et al., 2008; Pepper and Spedding, 2010). But LSS is also not able to address societal and ecological issues associated with the process and industrial organizations. The integrated GLSS approach focuses on enhancing resource efficiency and mitigating harmful environmental effects and aims to improve the customer's overall satisfaction level (Chaudhary & Mudimela, 2022).

International Journal of Lean Six Sigma

As GLSS is much devoted to enhancing the green performance of the industries, so, this approach will be helpful to attain two targets of the COP 26 conference (Deif, 2011). As GLSS is a novel methodology, it is essential to consider different theoretical elements related to this approach like readiness measures, barriers, potential benefits, and a review of available GLSS frameworks/methods. In the literature, there is no evidence on the study occurs that dispense a thorough exploration of GLSS literature, in conjunction with different theoretical elements related to this approach. The current study's objective is to opt for GLSS approach implementation in manufacturing sectors by discerning the research gaps and methods utilized by distinct researchers and practitioners. This study answers the following research questions:

RQ1: What are the different facets (enablers, barriers, tools, benefits) of GLSS that foster to promote, and adopt this sustainable approach?

RQ2: What are the current status of the implementation of GLSS, gaps in the studies, and possible avenues for future research?

This manuscript is categorized into seven sections. Section 1 represents the introduction part of the current work. Section 2 depicts SLR, a literature survey concerning Lean, Six Sigma, Green, LSS, and GLSS, and different theoretical elements related to this approach. Section 3 reports the adopted research methodology in the current study. Section 4 presents a descriptive analysis of the chosen manuscript in detail. Section 5 highlights outcomes from the existing literature gaps recognized and the future direction of the current research. Section 6 presents the purposed GLSS framework, and section 7 presents the conclusion, implications, and limitations of the recent research.

2. Literature Review

This section first outlines the literature research methodology. Then the literature was surveyed according to the points of view of Lean, Green, Lean-Green, Six Sigma, LSS, and GLSS approach, respectively.

2.1 Literature Search Methodology

To do a literature review, the authors have followed the systematic literature review (SLR) methodology. SLR provides an explicit view of the literature review and the uniqueness of the study. There are three different phases to realizing the SLR. In the first phase of SLR, the study's objectives are identified. The main objective of the present research work is to find out the current status of the implementation of GLSS and suggest future research dimensions. Based on the research objective, in the second step of locating the relevant studies, different

International Journal of Lean Six Sigma

electronic databases (EDB) Springer, Elsevier, Taylor and Francis, Emerald, Inderscience, Scopus, and Google Scholar databases were searched. After that, the search strings or keywords were used. In this study research papers were identified using the keywords Lean, Six Sigma, Lean-Green, Lean Six Sigma, Green Lean Six Sigma, Sustainability, barriers, framework, manufacturing, etc. To select pertinent articles related to the study, firstly, the authors used the chosen keywords in the reputed database to identify all the articles. The exclusion criteria of the study directly related to the theoretical concept of Lean, Six Sigma, and LSS were neglected. Further, all articles related to conferences, book chapters, and unpublished data were neglected. This leads to the final selection of the 140 articles pertinent to the research work. By using search strings, we identified 140 articles. Once the 140 articles have been identified, the authors critically investigate all the articles to identify different facets related to the Green Lean Six Sigma implementation and other hidden areas that are not explored to date. Figure 1 depicts the systematic literature review methodology.

2.2 Lean manufacturing

This concept was acquainted with Toyota Production System and acquired recognition after the book titled "The Machine That Changed the World" was published (Womack et al., 1990). It is a systematized approach to identify and remove wastes of all non-value-added actions by consistent enhancement that high-performance manufacturing sectors have executed to obtain extraordinary outcomes (Chugani et al., 2017; Antony et al., 2016). The mitigation or minimization of any waste will boost efficiency, decrease costs, and initiate the organization's more unassuming on the global market (Kaswan and Rathi, 2021b; Galeazzo et al., 2014). In manufacturing sectors as well as for the service sectors, lean strategy has been demonstrated a significant methodology for the development of an organization (Raci & Shankar, 2005). Rathi et al. (2021) proposed an integrated framework model for the GLSS approach. They recommended that the green concept must be connected with the lean concept to minimize the harmful effects of lean. The pragmatic applications of lean are employed on the participation of employees through utilizing tools and methods like Kaizen, Kanban, 5S, poka-yoke, and value stream mapping (VSM) (M. Singh et al., 2021; Jurado and Fuentes, 2014).

International Journal of Lean Six Sigma

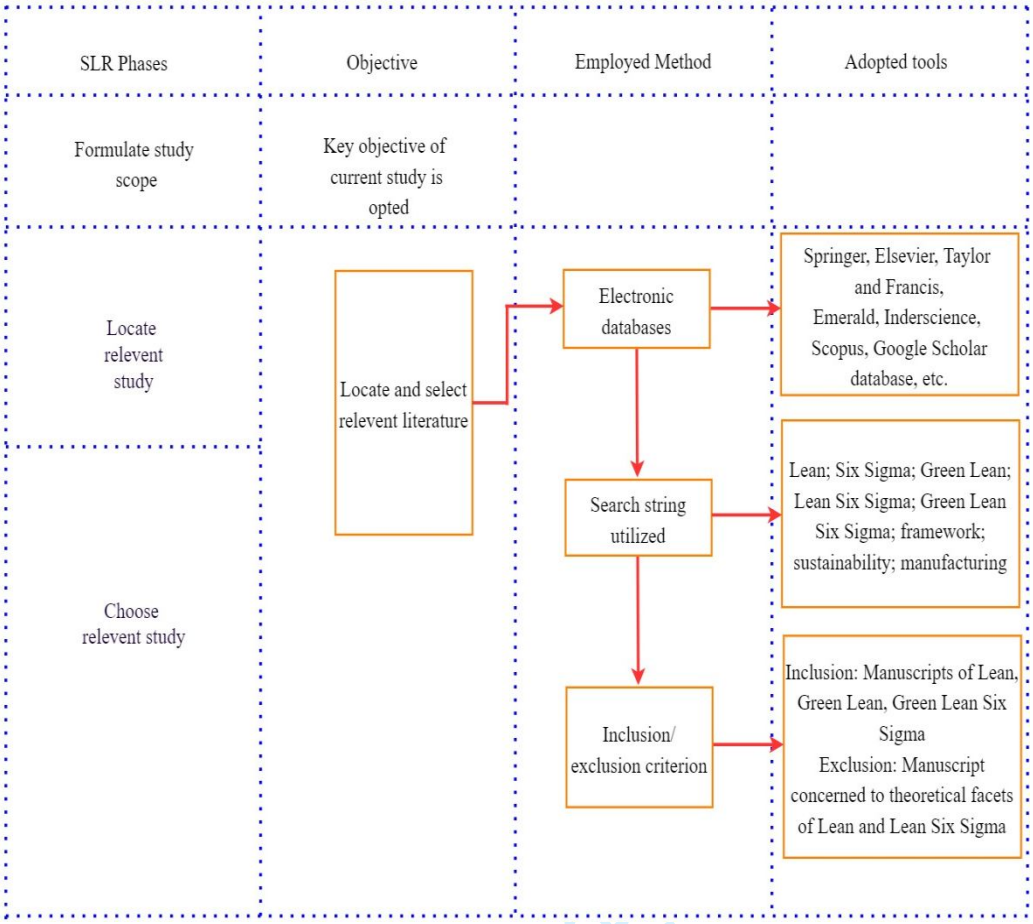

Fig. 1. Systematic literature review methodology

2.3 Green technology

Green technology is employed to minimize pollution and waste by reducing natural resource use. This concept also uses the 3'R technique (reduce, reuse, recycle) to mitigate waste and emissions. Most companies have launched the "Go Green" mission statement to mitigate the harmful environmental impacts of their operations (Gaikwad and Sunnapwar, 2020). Llorach and Roncero (2020) recommended that this concept is a vital innovation to upgrade eco-business and sustainable growth. The waste generation rate, energy consumption levels, and contamination levels are continuously increasing in organizations (Gandhi et al., 2018). That is why the government initiates strict rules and regulations on the industries to adopt green technology in their operations. The pragmatic application of green manufacturing is employed on discipline and appropriate training to the employees by utilizing various practices such as waste recycling, life cycle assessment (LCA), green designing and packing, etc. (Rehman and Shrivastava, 2013; Vinodh et al., 2011).

According to Garza-Reyes (2015), green manufacturing as an ideology determines, measures, evaluates and controls ecological waste by solving product and process problems. Digalwar

et al. (2017) identified and developed the structural interrelationship between distinct variables for the effective execution of GM. The study reveals that top management commitment has the most significant driving power for executing this strategy. According to Kazancoglu et al. 2018), green manufacturing includes several environmental strategies in the form of, green purchasing, green packaging, and green design. According to Prasad et al. (Prasad et al., 2016) ecological strategies in the form of eco-labeling, environmental management system (EMS), and ecological regulations have created a huge demand for green manufacturing in industrial sectors. Karuppiah et al. (2020) identified twenty-five barriers to the execution of GM in Indian SMEs through a comprehensive literature review and expert opinions. The recognized barriers are further ranked using DEMATEL, ANP, and TOPSIS techniques. Gedam et al. (2021) identified eleven barriers to the execution of GM through the literature review and consultation with industrial personnel. Further, the identified barriers are ranked by using the ISM-DEMATEL methodology.

2.4 Green Lean

The difference between lean and green wastes is that first is about non-value-added activities, and the second is about needless utilization of water, electricity, and natural assets (Mollenkopf et al., 2010; Ferreira et al., 2020). Gadekar, A. and Gadekar (2014) introduced an incorporated framework for these practices for attaining both financial and ecological sustainable performance in an organization. Pampanelli et al. (2014) believed that the green and lean concept could decrease resource utilization from 40 to 60 percent on a normal and could diminish the total expense of energy needed for manufacturing. Garza-Reyes (2015) carried out a systematic review of the existing literature on green and lean. This review aims to contribute by stimulating researchers to study further this field in-depth, which will assist in a better understanding of the compatibility and impact on organizational performance of lean and green strategies. Lu et al. (2019) presented a framework in the construction sector to assess greenhouse gas emissions. Yadav et al. (2021) developed a framework for visualizing and evaluating the manufacturing process performance. This framework will facilitate the industrial sectors to overcome challenges related to integrating and executing green and lean approaches.

2.5 Six Sigma

Six Sigma emphasizes continuous and breakthrough enhancements to minimize the cost of production, improve the satisfaction level of customers, and predictably produce high-quality products and services (Noone et al., 2010; Thomas et al., 2009). It is a closely controlled approach that minimizes variation in the process so that defects are minimized to less than

International Journal of Lean Six Sigma

3.4/M opportunities (Rathi et al., 2022b; Kumaravadivel and Natarajan, 2013). SS methodologies were not confined to enhancement impacts on the shop floor, but they also affected distinct aspects of manufacturing sectors (Haikonen et al., 2004; Fatemi and Franchetti, 2016). Schroeder et al. (2008) dictated that SS group members employ advanced root cause analysis methods and acquire outstandingly more control and investigation concerning an issue compared to any other quality enhancement strategy. Mehrjerdi (2011) determined SS DMAIC methodology application that included describing the problem to the control of the method to improve output. The key objective of SS is to attain the quality of products by enhancing the process and mitigating source causes of defects (P. Kumar et al., 2017). Antony et al. (2005) presented an analysis on the status of SS execution in SMEs of United Kingdom. This method tries to estimate prevailing execution measurements and explores how the needed and optimal concert level could be accomplished (Mudimela and Chaudhary, 2020).

2.6 Lean Six Sigma

The term "LSS" was first utilized in the beginning phase of the 2000s. Several authentications accessible in the existing literature have upheld the probability of incorporating LSS and their significant effects on the performance of the manufacturing sectors (Drohomeretski et al., 2014; Chaudhary et al., 2020). Arnheiter and Maleyeff (2005) tried to eradicate Six Sigma and Lean drawbacks by incorporating them that encouraged incorporation. Shahin and Alinavaz (2008) attempted to exhibit the different and relative methodologies of LSS. The unified effect of Six Sigma and lean tools dispenses the best solution for the industrial sector at reasonable costs. Sunder (2016) proposed an LSS model for shareholder management in the Banking and economic sector and also employed the LSS philosophy in service areas like retail banks and acquired a profit of INR 1.6m.

Snee (2010) momentarily clarified the survey of 16 years of LSS and discovered eight significant attributes, which were the functioning component for effective execution. Antony Antony (2011) emphasized the crucial transformation between Six Sigma and Lean for process excellence execution in manufacturing sectors by accompanying the views of academicians and experts throughout the world. Drohomeretski et al. (2014) studied the execution of Lean, Six Sigma, and LSS to investigate the explanations that encouraged the industrial sectors to embrace such enhancement strategies and recognized that cost minimization was the critical cause for industries to execute these approaches. Albliwi et al. (2015) carried out a systematic literature review (SLR) on this concept for industrial sectors and depicts distinct issues like profits, encouraging factors, approaching aspects, and

International Journal of Lean Six Sigma

drawbacks. Case study-based research can be carried out to recognize the prospects for LSS projects and major performance pointers of higher-education sectors (Sunder, 2016). Antony et al. (2017) illuminated the execution of LSS from the previous fifteen years and recognized the basic elements of the same like the involvement of top leaders, dedicated management leadership, cooperative organizations, dedicated management leadership, and a complete strategy to enhancement incorporating the area of utilization and techniques employed.

Prashar and Antony (2018) carried out an SLR on LSS in the food industry. The study reveals that human factors and food industry characteristics were recognized as the key barriers to implementing the LSS strategy. Singh and Rathi (2019) carried out a study to exhibit a comprehensive review of the benefits and critical challenges of the execution of LSS in business organizations and disperse literature in terms of many organizations wise, research methodology wise, and journal-wise. Gupta et al. (2020) carried out a study exploring the existing literature concerning the LSS concept. Big Data Analysis (BDA) has been employed in each phase of LSS. Shokri and Li (2020) represent a synthesis of present literature published in 2010 to dispense a general comprehension of the sustainable execution of LSS projects as far as task approaches instead of results. The study reveals that geographically and methodically comprehensive research works have been carried out on the integration of green manufacturing and LSS.

2.7 Green Lean Six Sigma

Every tool of GLSS can reduce the drawbacks of other tools; it implies it corresponds to one another that influences value addition because of its capacity to distinguish the wastage and assess its ecological effect (Shokri and Li 2020; Rathi et al., 2021). Banawi and Bilec (2014) proposed a framework that integrates GLSS to enhance the quality and ecological effects in the construction sector. They accomplished excellent outcomes as diminished waste in the quantity cover measure by executing the presented framework. Kumar et al. (2015) dissected the combining philosophy taken on by the manufacturing sectors through interviews, questionnaires, sustainably employed overviews, and workshops. This study also presented a framework for recognizing barriers, drivers, and key execution measures of the GLSS approach.

Cherrafi et al. (2016) evaluated the existing literature on LSS and sustainability and recommended future investigation directions and possibilities for academic scholars and practitioners. They recognized the advantages of incorporating the LSS and sustainability. Cherrafi et al. (2017) reviewed 450 organizations (which incorporated SMEs and global companies) for recognizing the crucial elements of GLSS. The researchers proposed that

International Journal of Lean Six Sigma

more research can be leaned toward discovering the main components that affect the GLSS. Kumar et al. (2016) recognized Twenty-One GLS barriers in the automobile sector of India through the literature review. Further, they were modeled by the ISM technique. Cherrafi et al. (2017) proposed a theoretical framework and equated results in four distinct sectors, which directed case organizations in executing the GLSS strategy. Ben Ruben et al. (2017) developed a framework for assessing the concert of Lean sustainable systems established on aspects recognized by adaptive neuro-fuzzy interface systems. Erdil and Arani (2019) presented a model, inspecting each of the three components of sustainability and embedded sustainability objectives in LSS projects.

Siegel et al. (2019) suggested a generic framework for the execution of Green and Lean in the context of Indian SMEs. This research focused on success factors, challenges, tools and techniques, sustainability measures, frameworks, and advantages of Green Lean in SMEs. Kaswan and Rathi (2020b) proposed the integration and framework of GLSS. The integration of GLSS was developed dependent on hypothetical fundamentals and the framework was developed dependent on the DMAIC methodology. Sony and Naik (2020) suggested that GLSS integration will develop a robust approach and assist the manufacturing sectors to be sustainable. They also proposed a generic implementation framework, and this is the first study in which it has been tested practically. Kaswan et al. (2021) carried out a study on the review of GLSS strategy along with readiness aspects, failure factors, integration, and execution framework. This study investigates grey areas of GLSS and dispenses a methodical path to integrate Green, Lean, and Six Sigma under the umbrella of GLSS.

2.7.1 Critical success factors for executing GLSS strategy

Critical success factors are imperative for implementing any type of strategy in the manufacturing sector (Rungasamy et al., 2002).

Habidin and Yusof (2013) recognized the following critical success factors to execute LSS:

(1) Leadership
(2) Structured improvement process
(3) Quality information and analysis
(4) Supplier relationship
(5) Customer focus
(6) Focus on metric

Cherrafi et al. (2017) recognized the following critical success factors to execute the GLSS strategy effectively:

(1) Organizational Readiness to execute GLSS approach

International Journal of Lean Six Sigma

(2) The project is chosen, and prioritization

(3) A commitment of higher management and Employees

(4) Communication

(5) Resource and skills to facilitate execution

M. Singh & Rathi (2019) identified 16 success factors to implement LSS strategy in MSMEs (Micro-small and medium enterprises). Out of 16 critical success factors, 10 CFs are prioritized using BWM (Best Worst Method). Raval et al. (2021) identified 10 CFs for effective implementation of LSS strategy in manufacturing sectors. The study reveals that top management is the most critical success factor and should execute in a step-wise methodology under the drawbacks of available resources.

2.7.2 Barriers and drivers for integration of GLSS strategy

GLSS approaches are influenced by the assortment of drivers and barriers to their execution; thus, it is important to find out the significant drivers and barriers of this incorporation. Due to increasing demand and scarcity of resources, the cost of raw materials, energy, and resources continuously enhances day by day in organizations (Diaz-Elsayed et al., 2013; Kaswan et al., 2019). Wong & Wong (2014) believed that this is intricate to predict manufacturing costs therefore industrial organizations require higher material proficiency to achieve improved functional performance. As per Luo (2013), each one of the manufacturing sectors is forced by consumers, controllers, contestants, and shareholders to assess and adjust their methods to enhance societal and ecological development.

To implement the GLSS approach in the organization, it is imperative to identify the performance improvement GLSS barriers. Outcomes from the literature reveal that only a few works had been done regarding the identification of GLS barriers. Kumar et al. (2016) recognized Twenty-One GLS barriers in the automobile sector of India through the literature review. Further, they were modeled by the ISM technique. Cherrafi et al. (2017) identified fifteen GLS barriers from systematic literature review (SLR). Then, they were validated through ISM and MICMAC analysis. Hussain et al. (2019) recognized twenty-four barriers in the construction sector. Then, the ISM technique was employed to establish the relationship between these barriers. C. Singh et al. (2021) identified twelve barriers by reviewing the literature. Using the DEMATEL technique, a cause-and-effect diagram was developed to identify the critical barriers. Singh et al. (2021) identified 16 barriers to implementing LSS strategy in MSMEs through opinion and experts and authenticated through statistical reliability theory. Further, they are modeled by using the ISM technique.

International Journal of Lean Six Sigma

The study reveals that concerning management barriers are the most critical barriers. Furthermore, obtained results were validated through structural equation modeling (SEM).

2.7.3 Benefits of Green, Lean, and Six Sigma Integration

GLSS is commercial methodologies and processes that might help the industrial sectors. Different researchers intimated that executing these methodologies might successfully impact the company's performance (Dües et al., 2013). As per Miller et al. (2010), GLSS can have a more significant, positive effect on central concern performance (financial, societal, and ecological) when carried out together as opposed to independently. The significance of this integration will be in industrial organizations where exclusively GLSS methodologies have been carried out to acquire sustainable advantages for industrial organizations.

2.7.4 Tools, techniques, and methods

Several researchers propose numerous tools that help manufacturing sectors to eliminate waste (Langenwalter, 2006; G. Yadav and Desai, 2017). These tools and techniques of LSS include LCA, JIT, TPM, Kaizen, VSM, 5S, C&E diagram, QFD, etc. These tools have been modified and expanded to gain more ecological and societal development (Kaswan and Rathi, 2020a). But these tools and techniques should be painstakingly chosen and should be fitted with the manufacturing sector's set-up (EPA, 2003). Table 1 depicts the effect of distinct LSS tools on the environment.

Table 1. Effect of distinct LSS tools on environment concern

LSS Tools	Obtained Environmental Benefits	References
Life Cycle Assessment	LCA technique will facilitate the organizations to search for the most accessible life cycles which are helpful for mitigation of harmful impacts	Paolotti et al. (2016); Kamei et al. (2013); Kaswan and Rathi (2021b)
Kaizen	Kaizen is a continuous improvement process that has a positive environmental impact as the enhancement activities protect to minimize the scarps that also directly mitigate resource consumption.	Vinodh et al. (2011); Chiarini and Vagnoni (2015); Torielli et al. (2010)
Value Stream Mapping	This technique has a pragmatic impact on the ecological concert. Its objective is to recognize waste in the value stream so that wasteful activities can be minimized. Its future map is used to eliminate environmental impacts	Kaswan et al. (2021a); Yadav et al. (2022)
5S	5S activities provide a safer working environment and eliminate all-inclusive resource consumption	Bae et al. (2007); Wilson (2010); Costa et al. (2018)

International Journal of Lean Six Sigma

	as systematization has been retained in the industries.	
Cause and Effect Diagram	This diagram is used to recognize possible root causes of the problem or condition to improve the environmental performance of the organization.	Loon et al. (2014); Kennet (2008); Rios et al. (2019)
Quality Function Deployment (QFD)	Customer needs can be incorporated with environmental necessities to convert them into practical needs.	Garibay et al. (2010); Klochkov et al. (2016); Erdil and Arani (2019)

2.7.5 Review of existing frameworks, models, and methods

Researchers have developed several frameworks, models, and methods to integrate Green, Lean, and Six Sigma. Table 2 depicts the interpretation of framework, models, and methods and Table 3 depicts prominent research regarding Green Lean Six Sigma in different industries.

Table 2. Interpretation of frameworks, models, and methods

Authors	Research Stream	Framework/Model/Method	Major Contribution	Drawbacks
Duarte and Cruz-Machado (2013)	Green and Lean	Projected and implemented model	Developed a model for executing lean and sustainability strategies. This presents how and when green and lean approaches can be synergetic and companionable with the help of the tools and principles of these two approaches.	The major limitation of this model was that it was not corroborated in a real-life environment.
Zhang and Awasthi (2014)	Six Sigma and Sustainability	Development of framework	Presented a framework that integrates Six Sigma and sustainability. It completely describes imperative steps to attain exactly sustainable development.	The main drawback of this framework was that it did not emphasize economic development.
Caiado et al. (2018)	Green, Lean, and Six Sigma	Proposed and integrated framework	This article provides a comprehensive GLSS framework seeking to assist practitioners in standardizing it in several types of services by identifying nine critical factors for its execution.	This study's major drawback was that the developed framework was not tested practically and restricted only to service sectors.
Subrata Talapatra (2019)	Green, Lean, and Six Sigma	Proposed and implemented framework	Presented and executed GLSS framework for jute industry to reduce defects, carbon footprints, and energy utilization.	The proposed framework completely emphasized jute industry and did not include societal aspects.
Kaswan and Rathi (2020b)	Green, Lean and Six Sigma	Proposed and implemented framework	The purpose of this manuscript is to incorporate and prosper DMAIC dependent GLSS framework. This developed framework provides a path for GLSS implementation by an appropriate preference for the task.	The major drawback of the current study was that the framework of GLS has not been tested practically.

International Journal of Lean Six Sigma

			The research work exhibits that several sustainability actions had been assessed with the assistance of exclusive GLSS indices and a toolset.	
Shokri and Li (2020)	Green, Lean and Six Sigma	Exploring the Green effect on LSS	The objective of this article is to implement a green strategy in LSS ventures in industrial organizations. This manuscript also distinguishes under which situations the yield of LSS developments with reasonable advantages is more ecologically sound.	The main limitation of this work was that the present model is extremely distracted to describe the decision in LSS.
Gholami et al. (2021)	Green, Lean and Six Sigma	Proposed and implemented framework	Presented and executed GLSS framework to improve organizational sustainability dependent on DMAIC methodology	The major drawback associated with this study was that the proposed framework had not considered the application of lean.

Table 3. depicts prominent research regarding Green Lean Six Sigma in different industries

Authors, Year	Sector	Major contribution	Limitations
Izzaida et al. (2013)	Automotive Industry	Established the interrelationship between Green Lean Six Sigma (GLS) and Management Innovation (MI). It also explores how GLS can be encouraged and have a practical effect on establishing MI to obtain better performances in the automotive sector. This outcome minimizes waste generation, process variation, and environmental impacts in this sector.	GLSS framework and integration have not been presented.
Banawi and Bilec (2014)	Construction Industry	Presented a framework and integrates Green, Lean, and Six Sigma in a commonsense strategy to improve the quality and ecological impacts of the construction process. This framework provides a comprehensive, multi-phase approach for the improvement in-process and minimization of the life cycle ecological effects in the construction process.	This framework did not incorporate manufacturing industries and takes more time for the execution process.
Garza-Reyes (2015)	Manufacturing Industry	Presented the DMAIC methodology of the Six Sigma strategy to display that the Systematic Literature Review (SLR) stipulates that integration of Green Lean may have expected similar drawbacks as the independent green and lean strategies, but these may be enhanced with the help of this strategy.	This methodology has a scarcity of application computation tools in various phases.
Cherrafi et al. (2016)	Manufacturing Industry	Proposed a framework that methodically leads manufacturing sectors by a five-phase and sixteen steps processes to integrate and implement this strategy effectively to improve sustainability performance. The study reveals that average resource consumption and cost of energy or mass stream reduce from 20 to 40% and 7-12%, respectively, after executing this approach.	This framework was that sensitive operations may be elaborated to enhance by this methodology.

International Journal of Lean Six Sigma

Mangla et al. (2017)	Automobile Industry	Recognized barriers in GLS product development (GLSPD) from consultation with industrial personnel and an all-embracing literature review. Twenty-one barriers are recognized and authenticated by the brainstorming sessions. Then, Interpretive Structural Modeling (ISM) was employed to initiate a hierarchical model of these barriers in implementing the GLSPD process in the automobile sector.	GLS framework was that it did not analyze properly.
Ruben et al. (2018)	Manufacturing Industry	Represented the effective execution of the LSS framework with environmental considerations to pledge the minimization in defects and ecological impacts. The study exposes that internal defects have been reduced from 16000 PPM to 5000 PPM. Environmental impacts were also reduced from 42Pt to 33 Pt.	The LSS framework could be employed only automotive component organizations and definite manufacturing sectors working with analogous manufacturing operations.
Powell et al. (2017)	Food Industry	Climaxed the application of LSS and evaluates the impacts of LSS on environmental sustainability in food processing industries. This outcome minimizes process variation, rejections, and ecological effects.	Only one case company had been considered to carry out the research work.
Zhu et al. (2018)	Health care Industry	Proposed a systematic framework dependent on an outdated DEF meta modal that recommends specific measures and synergies between Lean and Green approaches. These outcomes in reducing the waste generation in the hospital operations and successfully related greening to lean abilities may reduce environmental impacts within the hospitals.	The presented frameworked had not been tested practically.
Sreedharan et al. (2018)	Public sector	Dispensed the GLS modal for public sectors. This modal improves the efficient brilliance of public sector assistance like telecommunication, construction, and health care. GLS is integrated with supply chain management to eliminate obstacles resist by public sectors, leading to process enhancement.	This framework lacks the comprehension and evaluation of many green lean wastes.
Kaswan and Rathi (2019)	Manufacturing Industry	Recognized GLS enablers and modeling is done with the help of Interpretive Structural Modelling (ISM) and methodically determines the relationship between these enablers. Further, Impact Matrix Cross-Reference Multiplication Applied to a Classification (MICMAC) analysis has been utilized to classify these enablers for better interpretation. The study exposes that twelve GLS enablers hindering the implementation of this approach are recognized and modeled.	The application model for the realisation of GLSS in manufacturing at distinct phases of DMAIC methodology has not been reported.
Sony and Naik (2020)	Mine Industry	Presented a framework for implementing this strategy within the organization to attain the green goal through the DMAIC process of the five aspects of the environmental exhibition. In this paper, a case study approach is employed to implement the GLS framework to reduce the level of graphite and dust pollution in cast mines.	The key limitation related with this study was that a single case study was predicted as being an execution framework. It grasps a substantial time for execution and analysis, taking into consideration various variables.
Siegel et al. (2019)	Manufacturing SMEs	Proposed a conceptual framework for a collective green lean approach and sustainability for small-medium enterprises. The result requires that the most general incitement to green lean implementation is a shortage of matrices and evaluation.	Six Sigma concepts were not incorporated for the minimization of variations in the manufacturing operations.

International Journal of Lean Six Sigma

Hussain et al. (2019)	Construction Industry	Identified barriers to the GLS construction process through the literature survey and the opinion of the experts. Further, these barriers were authenticated by brainstorming sessions. The study reveals that there will be a reduction in wastage generation process variation and environmental impacts after implementing this strategy in the construction industry.	The implications of this work may not be appropriate for other industries that may have other valid issues.
Kaswan and Rathi (2020)	Manufacturing Industry	Proposed integrated and progress DMAIC dependent GLSS framework. The proposed framework provides a pathway for GLSS implementation by a suitable preference for the project. The study exposes that many sustainability measures have been assessed with the help of unique GLS indices and toolsets.	The framework of GLS has not been tested practically.
Shokri and Li (2020)	Manufacturing Industry	Implemented green strategy into lean six sigma approach projects in manufacturing sectors. It also recognized under which circumstances the output of LSS projects with prudent benefits are more environmentally sound. This results in achieving greener, customized, and economic–oriented outcomes.	The present model is extremely distracted to describe the decision in LSS.
Prashar (2020)	Pharmaceutical Industry	Minimization in electricity utilization, minimization in the emission of tons of CO2 per kilowatt-hour of energy	The presented framework is probed by research actions within a single commercial element of a large multinational industry majority drugs.
Yadav et al. (2021)	Manufacturing Industry	Presented integrated and developing the GLSS framework in the manufacturing environment. Integration of the GLSS approach has been presented on intangible features like enablers, toolsets, etc. This article also presents a five-facet GLSS framework for an industrial organization to increase organizational sustainability. The major drawback of this study was that the GLSS framework had not been authenticated with the help of a case study.	GLSS framework had not been authenticated with the help of a case study.
Kaswan and Rathi (2020)	Manufacturing Industry	Critically reviewed the GLSS strategy simultaneously with readiness measures, failure factors, integration, and implementation of the framework. This study also presents a methodical GLSS framework with the related toolsets to encourage industrial managers and practitioners to execute this sustainable strategy.	GLSS framework had not been probed practically.
Gholami et al. (2021)	Chemical Industry	Minimized consumption of chemicals and energy in the operations by 28 and 21%, cost saving in operations.	The proposed framework had not considered the application of lean.
Rathi et al. (2022a)	Manufacturing Industry	Developed a framework for GLSS for capacity waste reduction in the fastening component industry.	The framework formed from the literature and to consult with the industrial personnel. Furthermore no techniques and actions were dispensed to modify defects level, societal sustainability of considered industry.

2.8 The significance of digitization regarding Lean and Green

International Journal of Lean Six Sigma

Lean and Green technologies are augmented by the incorporation of digital technologies like Industry 4.0 (I4.0). Dalenogare et al. (2018) integrated Lean with digital technologies and found that digital technologies can overcome the limitations of Lean especially when the product are differs in terms of variety. They also suggested that I4.0 must be incorporated after Lean is implemented, as Lean creates the process baseline, and then this process baseline can be automated and digitized. The same has been supported by Wang et al. (2019) who proposed that it is easier for the industry to incorporate digital technologies measures after they have already incorporated Lean measures. Although the integration of Lean and digital technologies is still in its infancy, initial evidence suggests integration of the two approaches leads to improvement in metrics related to waste, costs, and productivity of the organizations. Also, it has been found that digital technologies moderates the effect of Lean practices on the operational efficacy of the industry (Huo et al., 2019).

Integration of Lean aspects with Green technology also comes with many difficulties. As stated by Powell et al. (2017) and Ershadi et al. (2021), it tends to focus primarily on economic aspects of sustainability and overlook environmental ones due to a large number of environmental metrics. The inclusion of green metrics also involves many stakeholders such as the customer, organization, government, NGOs, etc. The wide spectra of constituents have different interests and sometimes conflicting ones that lead to difficulty in data gathering and further investigation. Thus, there is a need for big data and further examination of the same is required to make effective judgments on green measures of sustainability. Lean integration with digital technologies like Big data and the Internet of things (IoT) will make the workplace “smarter”, enhance decision capability, and ensure improved environmental sustainability of the industry. IoT-based systems can be used to make the workplace more responsive and reduce hazards, as they provide quick information exchange and communication to achieve smart recognition, position, and tracing (Patel & Keyur, 2016). Green technology coupled with digital technologies is further augmented by the adoption of artificial intelligence (AI), contributing to reduced workplace accidents and less human intervention in the system (Cheng et al., 2020; Kaswan et al., 2022). The adoption of other smart technologies, such as 3D printing, further supplements GLSS's pursuits to realize a product with reduced environmental damage (Spears & Gold, 2016). GLSS is further augmented by other digital technologies, such as collaborative and autonomous mobile robots (COBOT and AMR), augmented reality (AR), and digital automation with sensors, making systems more responsive, reducing lead time, and supporting adaptation to self-decision-making in a complex environment (Djuric et al., 2016).

International Journal of Lean Six Sigma

3. Research Methodology

In the current study, a comprehensive literature review regarding the GLSS approach has been carried out. To select pertinent research articles, the authors have used the systematic literature review (SLR) technique. SLR is a process for recognizing, assessing, and correlating the existing body of concluded and registered studies carried out by researchers, scholars, and practitioners (M. Singh & Rathi, 2019; Rathi et al., 2022b). After developing the SLR, the theoretical background of Lean, Green, Lean-Green, Six Sigma, LSS, and GLSS have been discussed. After that, different theoretical elements related to GLSS like CSFs, barriers, potential benefits, and a review of available GLSS frameworks/methods have been explained in this methodology. Thereafter, a descriptive analysis of published articles has been carried out. It presents the year-wise analysis of articles, journal-wise analysis of articles, continent-wise distribution of articles, and approach-wise distribution of articles to explore different facets of the GLSS approach. From the comprehensive review of the articles, potential research gaps have been identified for fostering the research plan. The analysis carried out provides several directions for future scope in the GLSS field. The current research presents both theoretical and practical implications for practitioners and researchers. Figure 3 depicts the adopted research methodology.

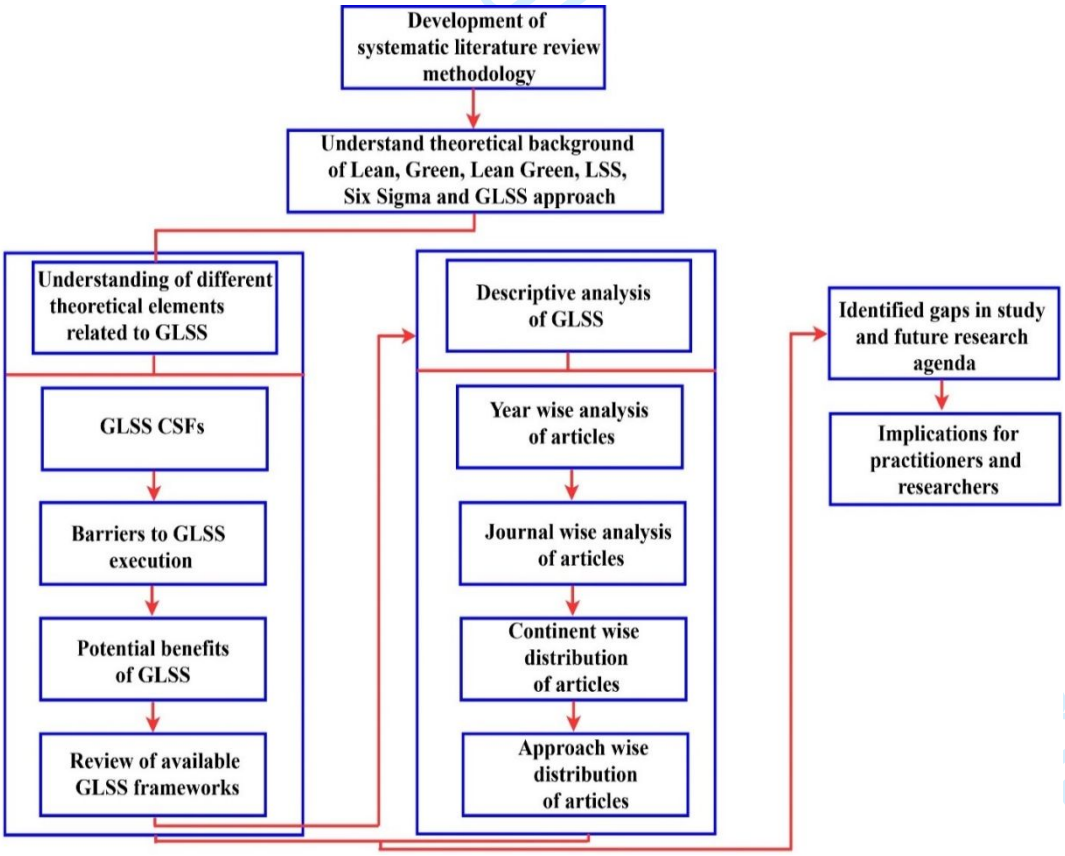

Fig. 3. Adopted research methodology

4. Descriptive Analysis

4.1 Categorization of manuscripts according to the year of publication

Figure 4 exhibits the categorization of manuscripts according to the year of publication over the period from 2005 to 2021 in which 140 articles were studied. This was reorganized from the studies of (Parmar & Desai, 2020) and (Gaikwad & Sunnapwar, 2020), where the manuscripts selected were plotted by the year, they were published. This indicates how the manuscripts were published and if the research is for sure depending on the current data. It shows the growing tendency of research manuscripts published throughout the previous span of the period. The manuscripts on Green, Lean, and Six Sigma continuously increased after 2015. It is apparent from the graph that the greatest number of manuscripts were published in 2021, dispensing better evidence of research developed on current information. Then more manuscripts were published in 2020 and after that, more manuscripts were published in the year 2018 and 2019 on GLSS, respectively. A relatively less number of manuscripts were published in the year 2007 and 2012. Furthermore, the distribution of manuscripts of GLSS was found on seven continents of our world. Out of 270 research articles, 119 were contributed by Asia, followed by Europe and North America. Figure 5 outlines the continent-wise distribution of publications.

4.2 Categorization of manuscripts journal wise

Figure 6 shows the categorization of several manuscripts in the journal publications. It is observable that the *Journal of Cleaner Production* contributed to a large portion of the manuscripts (24) published in this field. This is maybe because of the way that most research papers talk about ecological issues in this journal and as such, hold a lot of pertinence towards this research study. International Journal of Lean Six Sigma (11) likewise dispenses a lot of manuscripts in this field. Then after that, research papers (9) were published in each international journal of Six Sigma and competitive advantage, *International Journal of Quality and Reliability Engineering*, and *International Journal of Production Economics* respectively. It can be assumed that research on the integration of GLSS is expected to be published in a variety of well-reputed journals.

International Journal of Lean Six Sigma

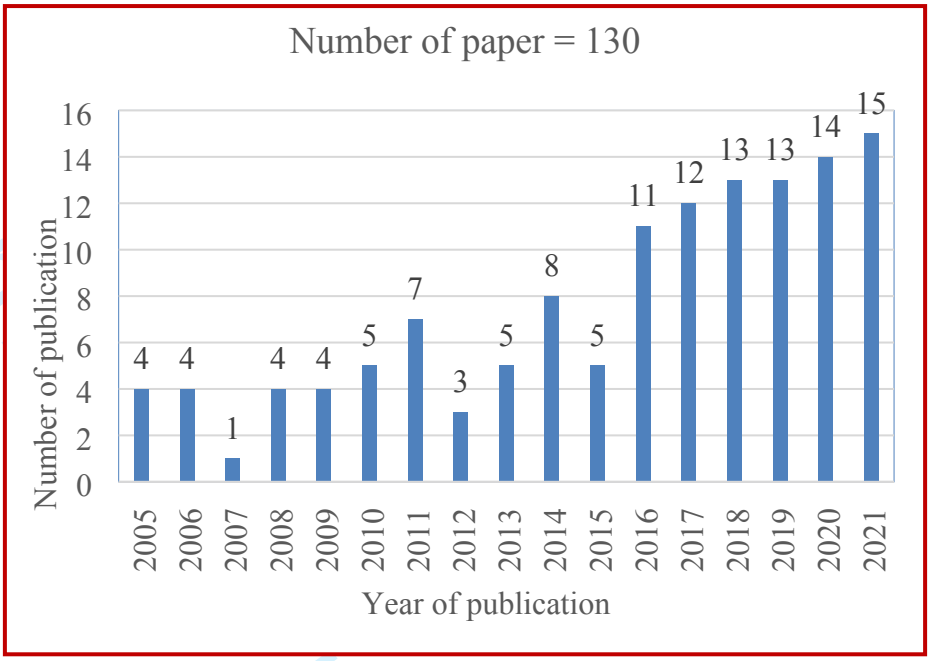

Fig. 4. Distribution of publications per year across the period studied

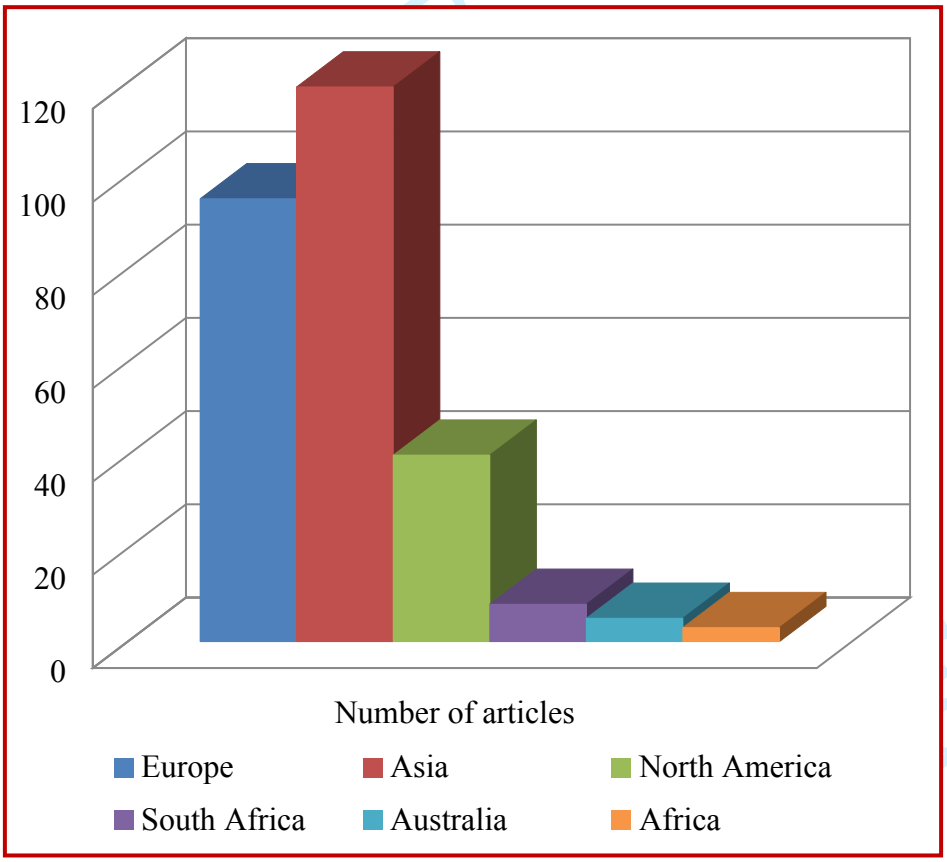

Fig. 5. Continent wise distribution of publications

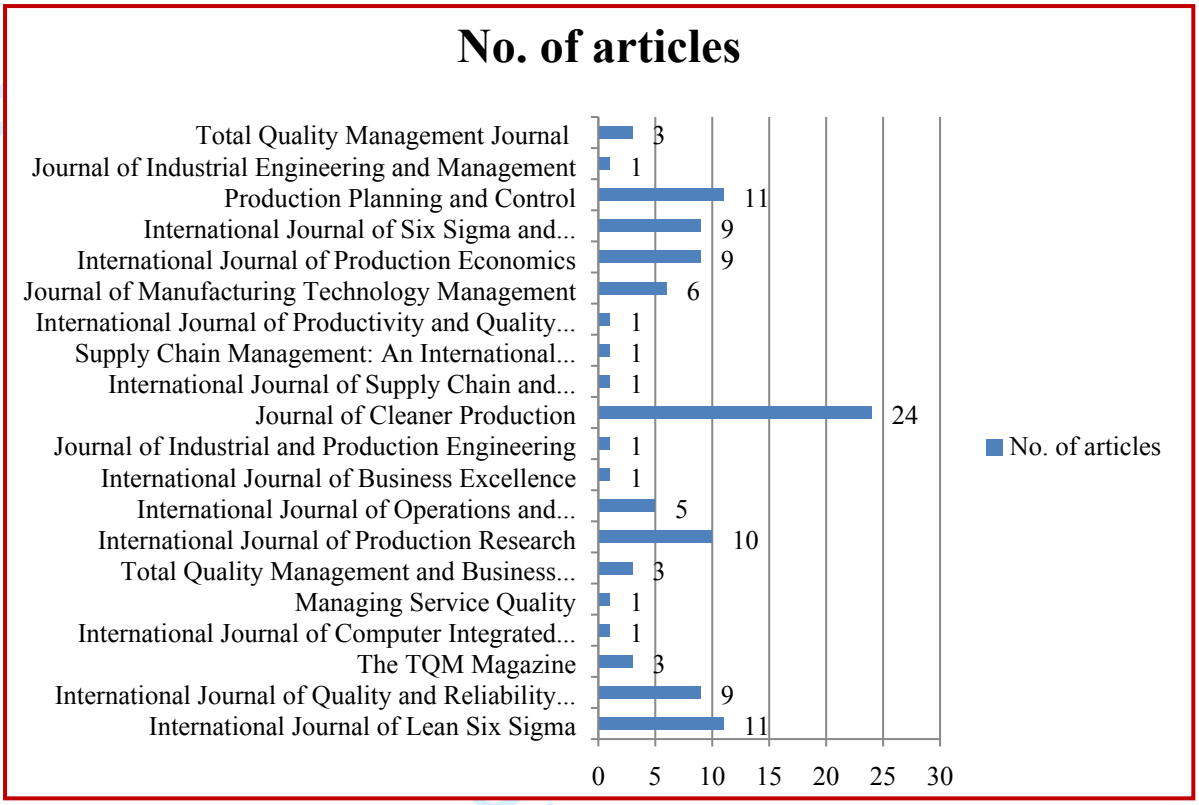

Fig. 6. Categorization of manuscripts journal wise

4.3 Approach-wise categorization of articles

Figure 7 illustrates the distribution of published papers for Green, Lean and Six Sigma separately and incorporated strategies of LSS, Green-Lean, and GLSS.

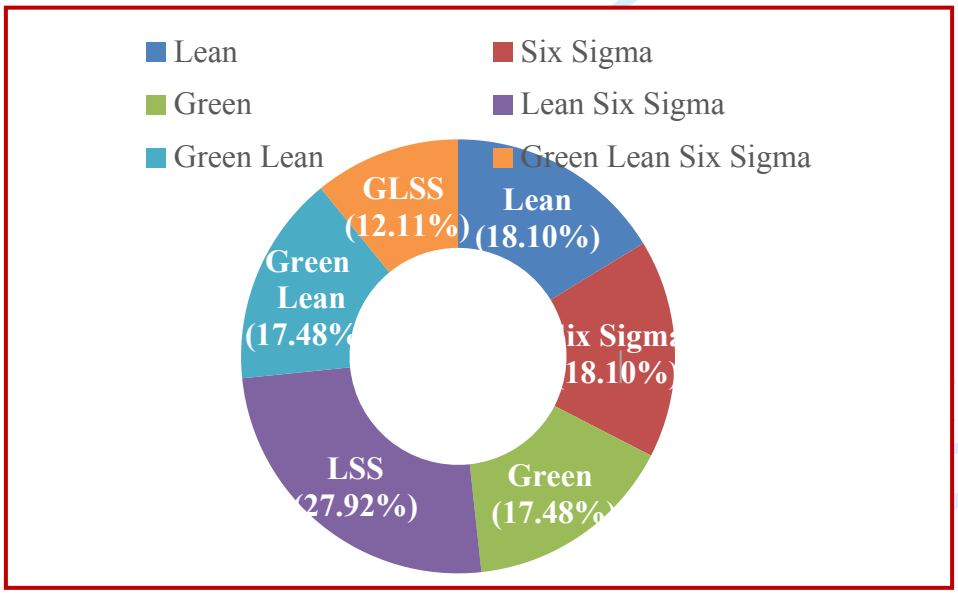

Fig. 7. Approach-wise categorization of articles

The study reveals that 29.92 percent of manuscripts are published on LSS, 18.10% of research papers are published on Lean and Six Sigma separately, 17.48% of manuscripts are published on integrated Green-Lean strategy and 12.11% of the manuscripts are published on the integration of GLSS strategy. Referring to Figure 4, it is perceived that most of the research has been done in the field of LSS (27.92%) when contrasted with Green-Lean (17.48%). So, limited research has been carried out on integrating the GLSS (12.11%) approach, which requires the future direction and importance of the research work.

5. Identified research gaps and future scope of the research

In this review, the existing literature on GLSS published during the time of 2005 to 2021 is assessed to separate hypothetical components from fostering an integrated framework. The encouraging or adverse results on the environment because of GLSS execution cannot seem to be investigated in all industrial organizations. Hence, there is a requirement for the integration of similar approaches. The study reveals that research in the area of GLSS is in the increasing phase. To motivate researchers in the area of GLSS and provide appropriate directions, we feature the gaps in the existing literature for fostering the research plan. The analysis carried out gives numerous directions for future scope in the GLSS field.

5.1 Performance measurement system

In this review, this is tracked down that few kinds of research examined performance measurement, yet the performance measurement in Green, Lean, and Six Sigma was analyzed separately. According to the sustainability perspective, there is an unavailability of a unified measurement and metrics system to evaluate the incorporated performance of these three approaches.

5.2 Integrated framework, model, and methods

The corroborative interrelationship among GLSS has encouraged organizations to utilize three kinds of approaches to enhance their functional performance (EPA, 2003). Banawi and Bilec (2014) proposed a framework for incorporating three strategies for the construction sector to mitigate environmental effects. Cluzel et al. (2010) proposed an eco-plan strategy that intends to incorporate the GLSS approach for ecological evaluation and enhancement. The encouraging or adverse results on climate because of GLSS execution presently cannot seem to be investigated in all industrial organizations. According to Park and Linich (2008) “LSS can be a significant part of Green that assist any organization with boosting sustainable performance”. The study reveals that there is a lack of research in the area of integration of

International Journal of Lean Six Sigma

three approaches just as various issues that are general to the vast majority of business models. These frameworks allude to the requirement of robust leadership, support of higher management, and involvement of every worker for continuous enhancement exertion to provide top-quality performance (Pampanelli et al., 2014). Everyone's methods/framework depend on the organizational culture of TQM.

5.3 Application of GLSS in SMEs

Small and Medium Enterprises (SMEs) are considered the backbone of any nation's economy. In general, this sector accounts for the most significant portion of established enterprises (Saleh and Ndubisi, 2006). India is one of the developing nations whose economy majorly depends on the SME sector (Siegel et al., 2019). Despite its great role in economic growth, it faces dynamic environmental, competitiveness, and continuous improvement (Gandhi et al., 2018). SMEs are incredibly accountable for carbon emissions (M. Singh et al., 2021). This sector is responsible for 70 percent of industrial pollution resulting in $32 billion in environmental costs (NPC, 2013; MoEF, 2012). It also consumes 6 percent of total energy consumption (Haeri & Rezaei, 2019). SMEs are the primary source of CO_2 emission (117.98 million tons/year) in India (Ministry of the Environment, 2020; Krolczyk et al., 2020).

5.4 Service Sector

The potential of GLSS has not been explored to its full potential in the service sector. As per Vargo and Lusch (2008), the service sector is a critical portion of our economy that could be observed as a significant under-investigated influent.

5.5 Societal aspect

Integration of GLSS methodologies results from societal change that should include the shareholders. The review recognizes that the interrelationship between these three approaches and societal performance is not completely examined in academic research. Also, social performance (safety, health, staff assurance, expertise, etc.) appears to be obscure. Consequently, there is a requirement to concentrate on the human side more extensively and take a look at the administrative difficulties of dispatching, driving, and making persons for GLSS exertion.

6. Proposed framework for GLSS execution

Figure 8 depicts the GLSS execution framework proposed by the authors for minimizing defects and environmental impacts for the considered manufacturing organization. The GLSS framework evolved dependent on three design dimensions. The first design dimension comprised the activity of studying the characteristics, the main cause for development, and appropriateness of the several GLSS execution frameworks pointed up in the last section.

International Journal of Lean Six Sigma

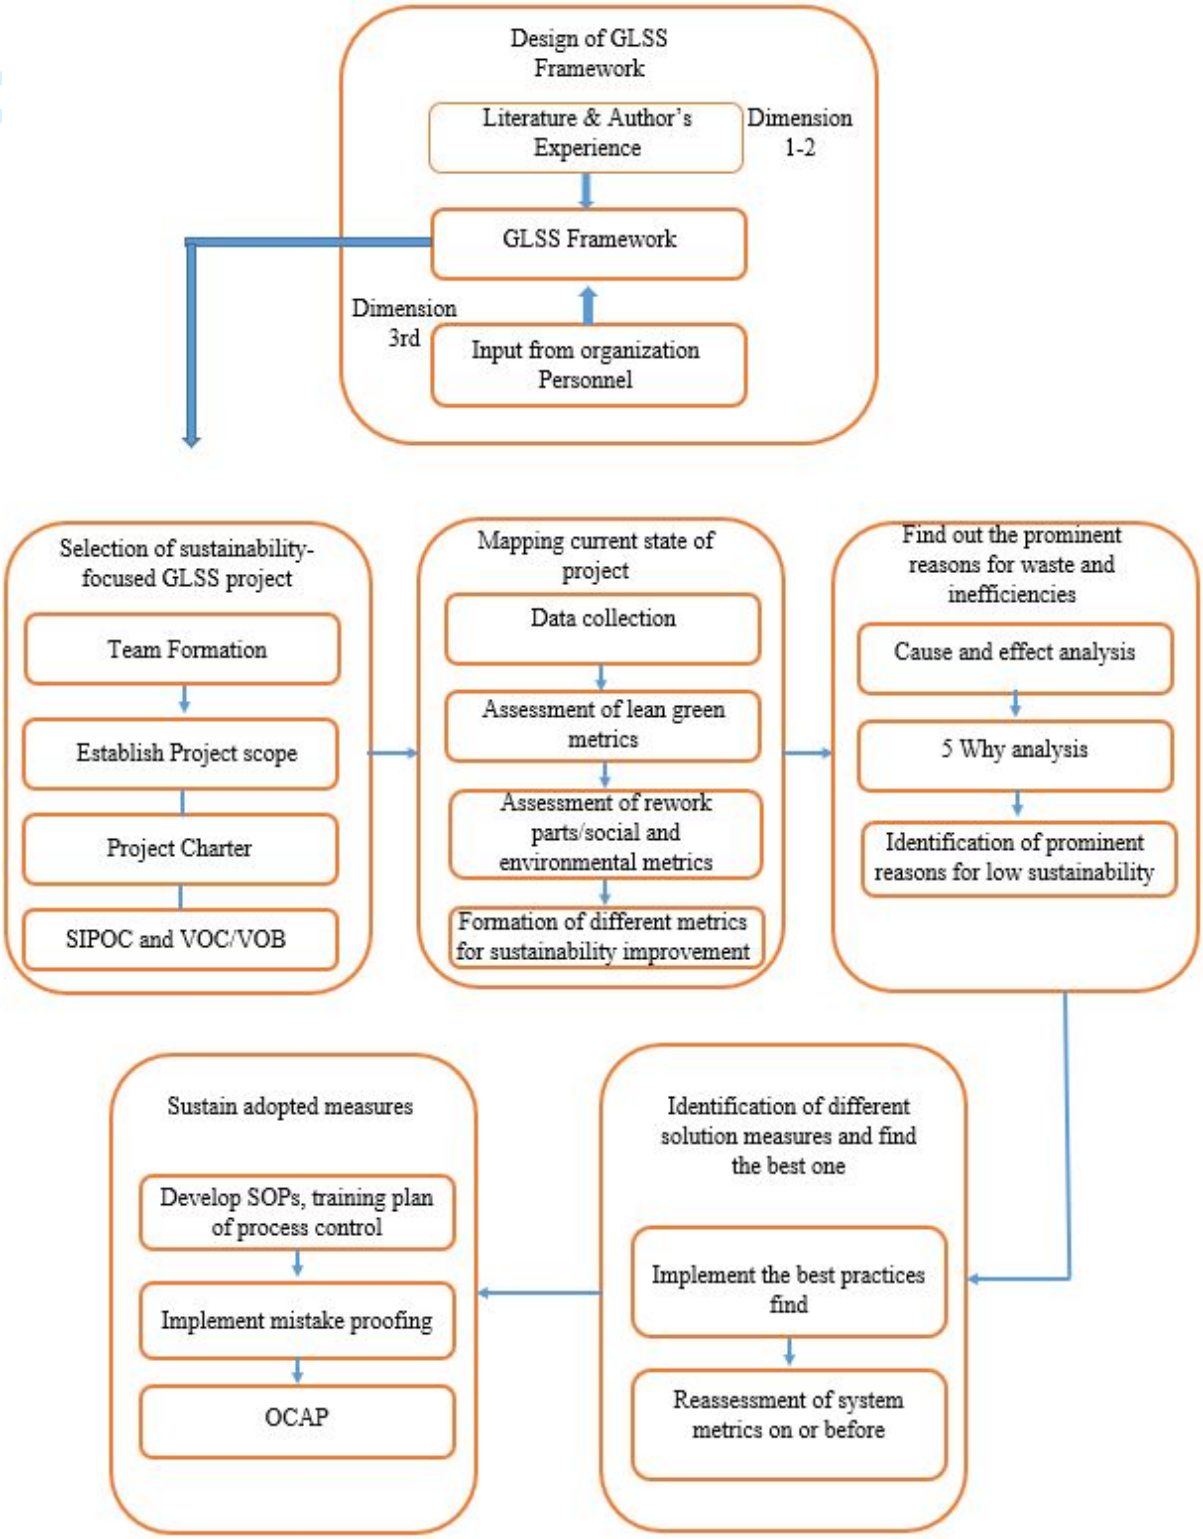

Fig.8: Proposed framework and adopted methodology

This secured the incorporation of the most current and specific conceptual knowledge into the developed GLSS framework. The second design dimension incorporated using the substantial theoretical and industrial revel of the authors as specialists, industrial practitioners, and academic researchers to help the development of the proposed framework.

Garza-Reyes et al. (2016) recommend that experience of practitioners performs a crucial role while developing conceptual frameworks which are needed to be implemented in the industry.

Lastly, the third design dimension incorporated the consideration of appropriate inputs from the industry. Thus, the authors discussed this with a team of experts. Consequently, 40 experts were recognized from several departments of the selected industry, other industries, and academicians. From this group, 18 industrial experts agreed to dispense their feedback about the GLSS framework. The expert panel comprised general managers, senior managers, master black belts, project leaders from the selected industry, and experts from an academic background. Each expert that was included in the panel had more than eighteen years of industrial and academic experience. The experts dispensed valuable feedback and criticism to improve the applicability and maturity of the GLSS framework. Afterward, the developed framework was probed in a leading manufacturing industry. The purpose was to gather appropriate observations, evaluate weaknesses, and regulate the framework.

The proposed framework was developed to inscribe problems associated with ecological and quality measures of projects and enhance the functional dynamics of industrial sectors. Every step of the attainment of the GLSS framework has several activities that minimize waste and related ecological impacts. So, the current study's unique contribution lies in supporting industrial sectors to compute several functional, environmental, and societal measures and dispense ways to enhance and sustain the same for improved organization competitiveness. The conceptual facets of the developed GLSS framework are discussed below:

Step 1: This step of the developed framework is concerned with recognizing and delineating the adopted project. The scope of the project is considered to explore ecological, social, and quality implications. The requirements, preferences, and presumptions of the business and customers are clearly stated in terms of VOB and VOC to recognize the expectations from the product being manufactured. This has been recognized from VOB and VOC analysis that the firm needed high-level customer satisfaction, capacity usage, and worker engagement while customers want high specification eco-friendly products at a reasonable cost. In this step, the subsequent process of manufacturing, SIPOC diagram, and project charter dispenses a complete understanding of several aspects of the adopted GLSS project.

Step 2: In this step, data collection was carried out to represent the current state of the system and data corresponding to defects and inefficiencies. Moreover, EVSM analysis was employed to evaluate the current state of the project concerned to lead time, raw material consumption, water consumption, etc. LCA was also utilized in this phase of the GLSS

International Journal of Lean Six Sigma

framework to estimate the current environmental impacts of the process. The data prevails to rework was also gathered to find out shop's critical to rework problems.

Step 3: This phase focuses on recognizing the root causes of waste and inspecting the problems and process inefficiencies. Based on the measure phase, reasons for inefficient material handling, rework, low environmental performance, and enhancement in societal sustainability are recognized. When the potential causes are recognized, then the search is dispersed to obtain crucial contributors to waste and inefficiencies.

Step 4: In this phase, several solutions are recommended and the best solutions are recognized and implemented to mitigate the root causes of waste and inefficiencies. Each suggested solution has been executed in such a way that an appropriate recording can be done to compare with previous results. The training has been provided to employees and managers of the organization from time to time for the effective execution of the GLSS approach.

Step 5: In this step of GLSS implementation, enhancements obtained are registered to sustain the improvement actions. Now, the enhanced process is handed over to the process owner along with the whole procedure for sustaining the gains. This step confirms that gains attained from the enhancements made are sustained after the accomplishment of the GLSS project. In the beginning, it is imperative to document and regulate the process to represent a perfect image of the improvements made and how to maintain these improvements.

Summary of the review

The objective of this review is to explore different aspects of the Green Lean Six Sigma approach, application status, and potential benefits from a comprehensive review of the literature and provides an avenue for future research work. This review proposes a five-facet GLSS framework to minimize overall defects and environmental impacts simultaneously to enhance the functional and environmental performance of the organization. The study depicts that GLSS implementation is increasing yearly, leading to considerable improvement in all dimensions of sustainability. Enablers, barriers, tools, and potential benefits that foster the execution of GLSS in industrial organizations are also identified based on a systematic review of the literature. The study's uniqueness lies in that study is the first of its kind that depicts the execution status of GLSS, and its different facets explore different available frameworks and provide avenues for potential research in this area for possible researchers and practitioners. The implementation of the proposed framework assisted in enhancing the sigma level of the case industry and also minimized the overall environmental impacts. The contribution of the present review pretends two-fold, first, the GLSS framework has been suggested to direct in conducting the activities of implementation of this program. The

International Journal of Lean Six Sigma

presented framework dispenses a prospect to the industrial sectors to enhance ecological wastes, improved capacity usage, and handling of items, along with enhancement in social subtleties by the deployment of tools like LCA, SLCA, EVSM, Kaizen, etc. Second, this work exhibits the empirical benefits of using the projected GLSS by its effective execution framework in an industrial environment by methodical insertion of Green technology, Lean, and Six Sigma tools. The present review accommodated the organization to understand its present level of environmental effects and aided it to detect further minimizing CO_2 emissions by the integration of more green technology measures. This framework also had a constructive impact on societal significance as enhancements were perceived to relate to the health of humans (as an outcome of minimized ecological effects) and shopfloor safety (after the deportment of the 7S). The industrial sectors were also encouraged to share their profit in Corporate Social Responsibility (CSR) activities.

7. Conclusions and limitations of the research

Ecological and societal facets have become tactical needs for companies and customary preferences of productivity and profitability to sustain in this competitive market. GLSS has been demonstrated to be one of those incorporated strategies that need additional investigation and further exploration. The current manuscripts dispense a similar effort of investigating different perceptions of the GLSS area. The several philosophies used by academic researchers and experts have been clarified, and gaps for future research are distinguished. In all, 140 research papers from the period from 2005 to 2021 were taken into consideration for literature review.

In the current study, the study of manuscripts was done dependent on: critical success factors for the implementation of the GLSS approach, performance improvement barriers, frameworks/models/methods of GLSS. Year of journals and publication journals were also taken into consideration for the analysis of the paper. The analysis of these distinct classifications gives a better comprehension of the GLSS field and upgrades the knowledge base. The study reveals that 29.92% of manuscripts are published on LSS, 18.10 % of research papers are published on Lean and Six Sigma separately, 17.48% of manuscripts are published on the integrated Green-Lean strategy and 12.11% of the manuscripts are published on the integration of GLSS strategy. It is perceived that most of the research has been carried out in the field of LSS (27.92%) when contrasted with Green-Lean (17.48%). So, limited research has been done on the integration of the GLSS (12.11%) approach, which requires the future direction and application of the research work. The categorization of chosen

International Journal of Lean Six Sigma

manuscripts also investigates several future research directions for academic researchers and practitioners. This shows that research in the area of GLSS is in the increasing phase.

The present study is the first of its kind that provides a better understanding of different theoretical elements related to the GLSS approach. This study provides different theoretical elements like GLSS critical success factors (CSFs), barriers to GLSS implementation, potential benefits of this approach, and a review of available GLSS frameworks. The existing literature lacks any evidence about the different theoretical elements related to this approach for effective implementation. Thereafter, a descriptive analysis of published articles has been carried out. From the comprehensive review of the articles, potential research gaps have been identified for fostering the research plan. The analysis carried out provides several directions for future scope in the GLSS field. The current research presents both theoretical and practical implications for practitioners and researchers. More research should be started in developing countries like India these nations to recognize GLSS barriers for the developing nations and outline to eliminate these barriers.

The present study might have some drawbacks because of the scarcity of accessibility of pertinent and adequate literature on the subject matter. Although, restricted data is accessible about linking GLSS techniques in industrial sectors. The research is based on a survey analysis that may not provide accurate results. In this study, there are some leading journals were considered for analysis. In the literature, only papers, papers in the press, review papers, and quality papers like international conference papers and conference review papers are taken into consideration to maintain the quality of the manuscript. Online reports, thesis, and books are excluded during the choice of research papers; appropriately, it is well might be probable that some of the research manuscripts might have been left remaining to cover in this literature review.

Theoretical and practical Implications

To assist the industrial practitioners to employ three approaches instantaneously in an environment when linking among GLSS methods in manufacturing sectors has not been instituted. Thus, instantaneously employment of these three approaches encourages the manufacturing industries to improve their functional and environmental performance. This review also encourages ecologists and entrepreneurs to initiate sustainable industrial methods like GLSS that reduce ecological damage by recommending the 5'R technique. Furthermore, the academic audience can employ these bits of knowledge to grow their comprehension of the ideas and might be urged to explore to apportion a specific and explicit hypothesis on the

International Journal of Lean Six Sigma

GLSS approach. Finally, insights on GLSS grey areas will enable project managers and practitioners to develop a GLSS framework for improved operational and environmental efficacy. Society will also be benefitted from the current study by getting eco-friendly products at reasonable costs.

Abstract: Green Lean Six Sigma (GLSS) is an all-inclusive methodology that assists the optimal utilisation of resources, minimises waste, and imparts the pathway for sustainable development. This study proposes a novel five facet GLSS framework for the manufacturing industry to improve performance in terms of different sustainability dimensions. The framework has been designed based on three key dimensions: insights from literature, the experience of authors, and inputs from the case organisation members. The framework is validated in an Indian automotive component manufacturing organisation. From the effective implementation of the proposed GLSS framework, defects were minimised from 18,000 ppm to 7,000 ppm and environmental impacts were brought down from 44.70 Pt to 32.70 Pt. This study facilitates industrial managers and practitioners to adopt the GLSS approach to improve sustainability dynamics in the manufacturing industries.

Keywords: Lean; Six Sigma; green manufacturing; Green Lean Six Sigma; GLSS; framework; sustainability.

Reference to this paper should be made as follows: Yadav, V., Gahlot, P., Duhan, R.K., Kaswan, M.S., Rathi, R., Yadav, G., Kumar, P. and Kumar, V. (2023) 'A framework for the systematic implementation of Green Lean Six Sigma to improve performance in the manufacturing industry', *Int. J. Internet Manufacturing and Services*, Vol. 9, Nos. 2/3, pp.341–372.

Biographical notes: Vishwas Yadav is pursuing his PhD in Mechanical Engineering from University Institute of Engineering and Technology, Maharishi Dayanand University, Rohtak, Haryana, India. His areas of research are Green Lean Six Sigma, total productive maintenance, life cycle assessment, sustainability and green manufacturing. He completed his Master's in Mechanical Engineering with specialisation in industrial and production from National Institute of Technology, Kurukshetra. He has a teaching experience more than six years. He is adept in optimisation and decision-making techniques like ISM, AHP, and BWM.

Pardeep Gahlot is working as an Assistant Professor in University Institute of Engineering and Technology, Maharishi Dayanand University, Rohtak, Haryana, India. He completed his PhD from University Institute of Engineering and Technology, Maharishi Dayanand University, Rohtak, Haryana, India. He has been associated with teaching over last 12 years. His areas of research are: production engineering, friction stir welding, engineering materials. He has presented many papers in national and international conferences and published articles in reputed journals.

Raj Kumar Duhan is working as an Assistant Professor in University Institute of Engineering and Technology, Maharishi Dayanand University, Rohtak, Haryana, India. He completed his PhD from University Institute of Engineering and Technology, Maharishi Dayanand University, Rohtak, Haryana, India. He has been associated with teaching over last 13 years. His areas of research are industrial engineering and manufacturing, automobile engineering, material science, composite materials. He has presented many papers in national and international conferences and published articles in various reputed journals.

Mahender Singh Kaswan is an Assistant Professor in the School of Mechanical Engineering Lovely Professional University, Punjab, India. He holds a PhD in Mechanical Engineering from Lovely Professional University, Punjab, MTech in Mechanical Engineering from National Institute of Technology Kurkshetra India. His research interests include Lean Six Sigma, life cycle assessment, Industry 4.0, and sustainable supply chain.

Rajeev Rathi is working as an Assistant Professor in the Department of Production and Industrial, National Institute of Technology, Kurkshetra, India. His areas of research are Six Sigma, Lean Six Sigma, Green Lean Six Sigma, LCA, sustainability and green manufacturing. As inspired researcher, he has presented many papers in national and international conferences and published articles in various reputed journals. He is adept in optimisation and decision-making techniques like ISM, preference ranking organisation method for enrichment of evaluations, best worst method, decision-making trial and evaluation laboratory. His research interests include Lean Six Sigma, green manufacturing, life cycle assessment, circular economy, Industry 4.0, clean technologies measures, and sustainable supply chain.

Gunjan Yadav is currently working as an Associate Professor and Head in Mechanical Engineering Department at Swarnim Startup and Innovation University (SSIU), Gandhinagar (India). He is having more than 12 years of teaching, training, consultancy, and research experience. He has had his education and training in mechanical and industrial engineering at BE and ME. He has completed his PhD from Sardar Vallabhbhai National Institute of Technology (SVNIT), Surat. He has obtained MHRD-sponsored funding of 1.5 Lacs to pursue international projects.

Pawan Kumar completed his PhD in Machine Learning from the School of Computer Applications, Lovely Professional University, India. His research interests include machine learning, data analytics and performance optimisation. He is a life member of the Computer Society of India (CSI). Also, he is a life member of the Indian Science Congress Association (ISCA). He has qualified UGC-NET in computer science and applications. He has also qualified GATE in computer science and information technology. He has acted as a reviewer for several reputed journals including *Decision Support Systems* by Elsevier.

Varun Kumar is an Associate Professor in Lovely Professional University, Punjab, India. He holds a PhD in the Theory of Elasticity (Mathematical Physics) with a research experience of more than ten years. He has Master's degree in the Mathematics and has also qualified CSIR-NET. He has 15 years of university teaching to UG, PG and PhD students. He is a life member of the Indian Science Congress Association (ISCA).

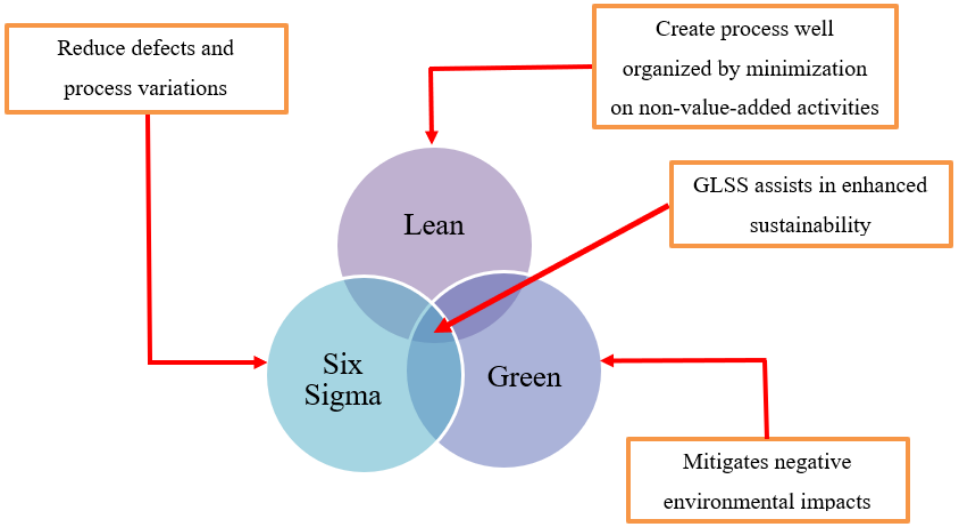
1 Introduction

In an era of high competition to stay in the business, manufacturing organisations have to change their functional dynamics from traditional to eco-friendly. The human being-driven actions and quick industrial development have raised global surface temperatures to 1.5°C in several regions of the globe (Rathi et al., 2022a). Industrial organisations contribute to about 30% of greenhouse gas emissions (GHGs) (Kaswan and Rathi, 2021). This can be attributed to the conventional methods of operations adopted by manufacturing organisations (Kaswan et al., 2021). The enhanced level of GHGs will result in a surge of more than 20,000 deaths annually per °C (Jacobson, 2008). Thus, to persist competitive in the market and obey the environmental pacts the manufacturing sectors have to reduce their present level of emissions by implementing sustainable practices (Yadav and Gahlot, 2022). Therefore, the manufacturing sectors are expanding

massive investment in research and development to evolve other ways of manufacturing high-specification eco-friendly products (Shokri and Li, 2020). In many manufacturing arenas, several methods have been proposed in the past such as green manufacturing, total quality management, value engineering, lean manufacturing, Six Sigma, Lean Six Sigma (LSS), Green Lean Six Sigma (GLSS) to attain functional excellence (Garza-Reyes et al., 2018).

GLSS strategy assists in the success of the organisation by methodical minimisation of wastes, GHGs, and process variation (Gupta et al., 2020). This approach discourses the contemporary problems of the organisation by the methodical implementation of related tools at distinct phases of the product attention (Kaswan and Rathi, 2020). Figure 1 illustrates the integration model of GLSS.

Figure 1 Integration model of GLSS (see online version for colours)



Source: Rathi et al. (2022b)

LSS leads to improvement in the performance related to economical dimensions of the sustainability but do not contribute considerably towards to ecological dimension (Rathi et al., 2022b). Further, LSS also not incorporate social aspects related to the sustainability that is also a pioneer aspect to remain competitive at the global platform (Mohan et al., 2022). Inclusion of green aspects fills this gaps and leads to the sustainable development of the manufacturing enterprises. In addition, there is a demand to incorporate societal facets into GLSS practices to focus on healthy work environment and exceptionally hard work practices. Furthermore, manufacturing sectors in developing countries seek to reduce operating prices and throttle overall in their ability to convert into durable goods. In literature no study related to GLSS that improve production rate environmental metrics and social metrics have been reported. For this research work tends to answer research question: How to construct a comprehensive framework to execute GLSS in the manufacturing environment and test the same for improvement in environmental, social and economical metrics? The proposed framework includes ecological aspects, life cycle assessment (LCA) procedures, social facets, and primary LSS tools in distinct phases. Every step of this framework comprises a set of specified

activities that focus on reducing wastes and related environmental impacts. This framework assists the organisation in obtaining ecological benefits and operational improvement. The unique contribution of the article lies in proposing GLSS framework for a manufacturing industry to enhance performance dynamics. The proposed model was prepared based on three unique dimensions and has capability to improve manufacturing industry performance in terms of reduction of defects level, improve work space utilisation, and also provides measures to ascertain social sustainability.

2 Literature review

The green technology encourages manufacturing sectors to reduce their environmental impacts (Garza-Reyes, 2015). An abundance of literature has focused on the effects of green technologies like LCA, environmental management system (EMS), and design for environmental (DFE), on ecological performance (Al-Sheyadi et al., 2019). These techniques have pragmatic results in satisfying regulatory needs, and fulfilling customers' wants of environmentally-sound products (Prasad et al., 2016). This strategy aims to mitigate harmful ecological effects like hazardous wastes, air emissions, pollution, health prospect to human beings, and environment and power and resource conservation (Kaswan et al., 2022). The lean concept is employed to minimise waste in almost every section of the industry (Thakur and Mangla, 2019). Industries execute this strategy to generate value for consumers by reducing waste and lead time and enhancing process flow (Singh et al., 2021a, 2021b). These tools will facilitate organisations in attaining functional performance along with achieving environmental objectives (Erdil and Arani, 2019). Six Sigma concept is employed to minimise the defects up to 3.4 parts per million opportunities, and the word 'sigma' is utilised to express variations. The primary aim of this approach is to reduce variations and defect mitigation (Andersson et al., 2006). Even though minimising environmental waste is not the prime aim of this strategy, it can attain environmental performance like decreasing air emissions, electricity consumption, and wastewater (Chugani et al., 2017). However, Six Sigma does not directly address issues related to environmental and social sustainability (Rathi et al., 2022c).

An unrequired movement of raw material, work-in-process, and finished products are assessed as waste from both green and lean points of view regarding electricity consumption, gaseous emission, and excessive utilisation of resources (Prashar and Antony, 2018). The correlation between green and lean not only attains the environmental benefits but also minimises cost by waste reduction (Shokri and Li, 2020). Deployed on the common purpose of waste reduction, these have been integrated into a common approach (Campbell and Sigalov, 2022). Moreover, Lean and Six Sigma have been integrated into a joint strategy to achieve environmental benefits by minimising waste (Kaswan and Rathi, 2021). The substantial general features of LSS are waste reduction, continuous enhancement, and satisfaction to the customers (Yadav et al., 2020). The correlation between these three approaches of GLSS can be better realised by their intrinsic features of satisfaction of customers by waste minimisation and value addition (Ershadi et al., 2021). Every approach in GLSS overcomes the drawbacks of another system to impart value by recognising and eliminating wastes that positively impact the organisation's environmental performance (Yadav and Gahlot, 2022). In terms of the ecological impacts of these approaches, the green concept primarily emphasises environmental sustainability and resource conservation as of its key aspects (Gandhi

et al., 2018). Lean preserves resources by minimising waste, so, is identified as an 'eco-friendly technique' (Yadav and Desai, 2017). Identically, Six Sigma describes defects as waste material, area employed, safety matters, and electricity utilised (Gedam et al., 2021).

Table 1 Major studies related to GLSS

Sr. no.	*Author*	*Year*	*Description*	*Limitations*
1	Zhang and Awasthi	2014	Presented a framework that integrates Six Sigma and sustainability. It completely describes imperative steps to attain exactly sustainable development.	The main drawback of this framework was that it did not emphasise economic growth.
2	Ng et al.	2015	Proposed a methodology for executing green and lean manufacturing employed on its metrics.	The major limitation associated with this study was that the tools and techniques that were utilised in this case observation; can not be used for other case research
3	Cherrafi et al.	2016	Proposed a framework that efficiently leads the industries by five-stages and 16-step processes to successfully combine and execute the GLSS strategy to enhance their environmental performance.	The key drawback associated with this model was that delicate operations could be elaborated to enhance by this method.
4	Ben Ruben et al.	2017	Presented an LSS framework with ecological considerations to simultaneously minimise all-inclusive defects and ecological effects to enhance the organisation's functional and environmental performance. This framework is deployed on the DMAIC cycle of the Six Sigma strategy. The LSS framework is authenticated with the help of a case study that is carried out in an Indian automotive component manufacturing industry. The study reveals that internal defects were dropped down from 16,000 ppm to 6,000 ppm, and ecological effects were also minimised from 42 Pt to 32 Pt.	The major limitation of this study was that the LSS framework can be employed only for automotive component organisations and definite industrial sectors working with analogous industrial operations
5	Caiado et al.	2018	This manuscript presents a critical review of LSS approaches and underlines their significance to attain sustainable services. This article also provides a comprehensive GLSS framework seeking to assist practitioners to detect the way of standardising it in several types of services, by identifying nine critical factors for its execution.	The major drawback of this review was that LSS methodology was restricted only to service sectors.

Table 1 Major studies related to GLSS (continued)

Sr. no.	*Author*	*Year*	*Description*	*Limitations*
6	Talapatra and Gaine	2019	Presented and executed GLSS framework for jute industry to reduce defects, carbon footprints and energy utilisation.	The proposed framework completely emphasised jute industry and did not include societal aspects.
7	Kaswan and Rathi	2020	This manuscript is concerned with the integration and development of the GLSS framework. GLSS integration was presented dependent on conceptual factors, and the GLSS framework was presented dependent on DMAIC methodology. The developed framework imparts a way to implement the GLSS approach by a proper selection of the project.	The major drawback of the current study was that the framework of GLS has not been tested practically.
8	Yadav et al.	2021	This article is concerned with integrating and developing the GLSS framework in the manufacturing environment. Integration of the GLSS approach has been presented on intangible features like enablers, toolsets, etc. This article also presents a five facet GLSS framework for an industrial organisation to increase organisational sustainability.	The major drawback associated with this study was that the GLSS framework had not been authenticated with the help of a case study.
9	Kaswan and Rathi	2021	The purpose of this manuscript is to critically review the GLSS strategy simultaneously with readiness measures, failure factors, integration, and implementation of the framework. This study also presents a methodical GLSS framework with the related toolsets to encourage industrial managers and practitioners to execute this sustainable strategy..	The limitation of this study was that the GLSS framework had not been probed practically
10	Rathi et al.	2022b	Develop framework for GLSS for capacity waste reduction in the fastening component industry	The key drawback associated with this study was that the framework formed from the literature and to consult with the industrial personnel. Furthermore no techniques and actions were dispensed to modify defects level, societal sustainability of considered industry.

Previous studies have emphasised theoretical frameworks, but these have required pragmatic validation and experimental substantiation. Ruben et al. (2018) presented 'framework' of LSS with ecological features but could not discourse on how proposed 'framework' can be accepted by small-scale establishments. Furthermore, presented GLSS framework did not take into consideration the social facets of sustainability.

Gholami et al. (2021) employed this approach to enhance the functionality and ecological facets nonetheless presented framework wants practical authenticity in utilising LSS tools and LCA toolsets. Thus, past studies claim the research for the GLSS framework is non-specific, employed in a distinct context, and includes all facets of sustainability. Furthermore, several projects have a high prospect of execution failure of LSS sustainable frameworks (Singh et al., 2021a, 2021b). Thus, contribute to production literature; this study contributes to the restricted body of knowledge in the fields of GLSS and sustainability by developing and executing an GLSS framework that industrial organisations can use to enhance performance dynamics. Table 1 depicts major research work pertaining to GLSS.

2.1 Research gaps

The literature shows that execution of 'LSS' assists to positive results on environmental and economic concert. But, incorporation and execution of Green approach with this concept are not divested of tasks. Scarcity of finance for environmentally sound technology projects, lack of support from top management, shortage of assets, inaccessibility of equipments and practices, and over-focus on profits, further avert powerful execution of sustainability-orientated initiatives. GLSS literature reveals that focuses has been limited to ecological and financial aspects of sustainability but that the social component was not noted. Furthermore, industrial sectors in emerging countries require to open the restrain their ability for minimising functional costs and providing high specification ecological products. In the literature, there is no evidence of a committed GLSS framework that assists in the mitigation of environmental impacts and increased capacity utilisation together with improved social facets. Therefore, the noted literature gaps have dispensed path for the current study.

3 Proposed framework for GLSS execution and adopted methodology

GLSS framework was evolved dependent on three design dimensions. The first design dimension comprised of action of perusing characteristics, the main cause for development, and appropriateness of several GLSS execution frameworks pointed up in last section. This secured merger of utmost recent and specific conceptual knowledge in developed GLSS framework.

Lastly, the third design dimension incorporated the consideration of appropriate inputs from the industry. The professionals dispensed valued feedback and criticism to improve pertinency and adulthood of framework of GLSS. Afterward, the developed framework was probed in an automotive component manufacturing industry.

The GLSS framework was developed to inscribe problems associated with ecological and quality actions of projects and enhance functional subtleties of industrial sectors. Every step of the attainment of the GLSS framework has several activities that minimise waste and related ecological impacts. The conceptual facets of the developed GLSS framework are discussed below:

Step 1 This step of developed framework is concerned with recognising and delineating the adopted project (Section 4.1). The scope of the project is considered to explore ecological, social, and quality implications. The requirements, preferences, and presumptions of the business and customers are clearly stated in terms of VOB and VOC to recognise the expectations from the product being manufactured. This has been recognised from VOB and VOC analysis that the firm needed high-level customer satisfaction, capacity usage, and worker engagement while customers want high specification eco-friendly products at a reasonable cost. In this step, the subsequent process of manufacturing, SIPOC diagram, and project charter dispenses a complete understanding of several aspects of the adopted GLSS project.

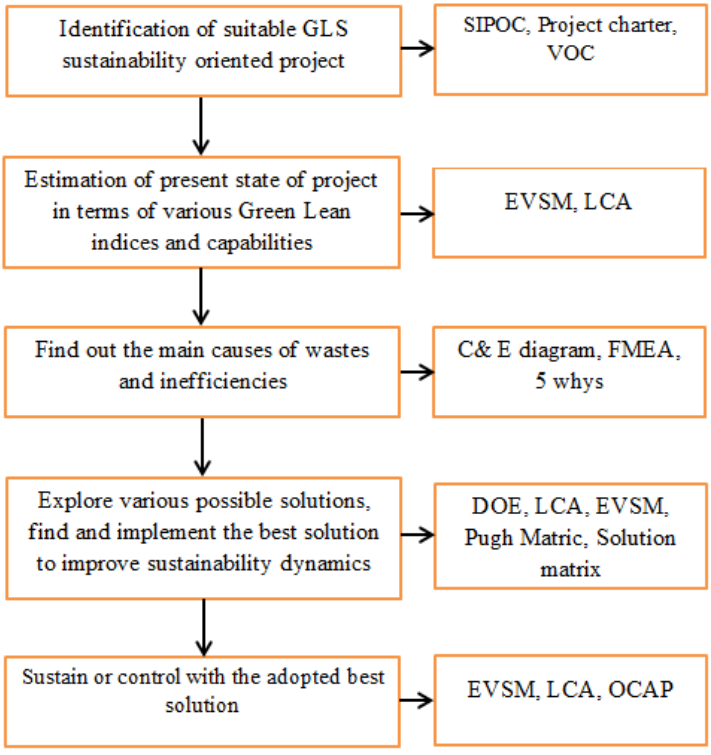
Step 2 In this step, data collection was carried out to represent present state of the system and data corresponding to defects and inefficiencies (Section 4.2). Moreover, EVSM analysis was employed to evaluate the current state of the project concerning lead time, raw material consumption, water consumption, etc. LCA was also utilised in this phase of the GLSS framework to estimate the current environmental impacts of the process. The data prevailing to rework was also gathered to find out shop's critical to rework problems.

Step 3 This phase focuses on recognising the root causes of waste and inspecting the problems and process inefficiencies (Section 4.3). Based on the measure phase, reasons for inefficient material handling, rework, low environmental performance, and enhancement in societal sustainability are recognised. Tools like brainstorming, C&E, 'FMEA and 5 why analysis are' deployed at this stage to determine probable reasons for defects. When the potential reasons are recognised, then the quest is dispersed to obtain crucial contributors for wastes and inefficiencies.

Step 4 In this phase, several solutions are recommended and the best solutions are recognised and implemented to mitigate root causes of waste and inefficiencies (Section 4.4). Each suggested solution has been executed in such a way that an appropriate recording can be done to compare with previous results. The training has been provided to employees and managers of the organisation from time to time for the effective execution of the GLSS approach. Tools such as DOE, Kaisen, and other process enhancement methods are deployed for planning the enhancement activities associated with productivity and quality.

Step 5 In this step of GLSS implementation, enhancements obtained are registered to sustain the improvement actions (Section 4.5). Now, the enhanced process is handed over to the process owner along with the whole procedure for sustaining the gains. This step confirms that gains attained from the enhancements made are sustained after the accomplishment of the GLSS project. In the beginning, it is imperative to document and regulate the process to represent a perfect image of the improvements made and how to maintain these improvements.

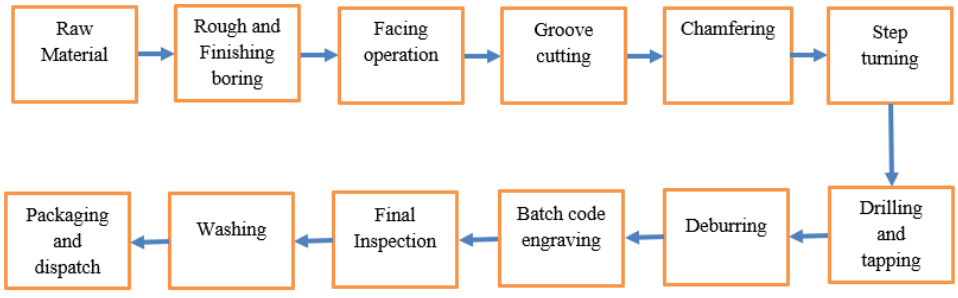
Figure 2 GLSS framework (see online version for colours)



4 Application and validation of the proposed GLSS framework

The work is carried out in a major automotive component manufacturing industry which is situated at Gurugram, Haryana (India). The considered organisation produces about 35 kinds of vehicle axle assembly components. The company is certified with ISO: 9001.2008 and QS 14001 certification. The automotive component banjo-type axle housing are selected to carry out the current study. A banjo-type axle housing comprises a hollow central member with a pair of hollow tubes extending outward. Such axle assemblies comprise several components that are adjusted to transmit power from one engine of the vehicle to the wheels thereof. The banjo-type axle housing is made up of mild steel and weighs about 45 kg as a finished product. The banjo-type axle housing required more quality and rework concerns as compared to other produced components. The concerned organisation was highly motivated to mitigate environmental impacts of this component. The manufacturing sequence of banjo-type axle housing is depicted in Figure 3. As can be seen in Figure 3, the manufacturing process begins with the flange rough and finishing boring operation.

Figure 3 Manufacturing sequence of banjo-type axle housing in the adopted organisation (see online version for colours)



4.1 Selection of sustainability-focused GLSS project

As previously indicated, the implementation of the GLSS project requires a well-committed team having several skills for manufacturing operations. In this current study, the team involved a specialist, a controller from the higher management, and five managerial members. In this step, the subsequent process of manufacturing, SIPOC diagram, and project charter dispenses a complete understanding of several aspects of the adopted GLSS project. A meeting was also arranged by the higher management of the industry to direct the workers about the requirement of the adopted project and its outputs. This assists in imparting appropriate consciousness and understanding about the project to the workers. The management of the selected firm outlined its concern for production waste, minimisation of emission for manufacturing of banjo-type axle housing, and evaluation of the social sustainability of the firm. The company produces 6,000 vehicle assembly components per month and about 72,000 components in a year. The total established capacity of business unit was 150,000 parts per annum. Based on significant data of the previous four years, it is observed that the firm was working at 56.8% of the total capacity that implying that there was about 48% of production waste. The company possessed a considerable level of ecological emission with 28.20 Pt, and there was no initiative to evaluate the social sustainability of the industry.

Crucial parameters for production waste were recognised in this subsection to consult with experts and industrial visits. Then radar chart is constructed to illustrate the percentage contribution of parameters in the production waste of the selected firm (Figure 5).

The radar chart outlines that inefficient material handling (39%), inefficient manpower movements and space usage (27%), ecological issues combined with social issues (18%), and rework (11%) were the significant contributing features for production waste of adopted organisation. The time utilised for material handling activities in several units was evaluated to recognise crucial units concerns to inefficient material handling. Shop-wise material handling time was evaluated in this subsection to detect key shops responsible for poor material handling. The previous 24 months' data refers to the time taken to find items and equipment in several shops that were collected. A Pareto chart is plotted to find out the shops that were incredibly accountable for the production waste of the considered organisation. The horizontal axis of this chart illustrates several shops/sections in the industry. The times adapted in the material have been delineated by the several bars conforming to every shop/section of the concerned organisation.

Figure 4 High-level SIPOC diagram (see online version for colours)

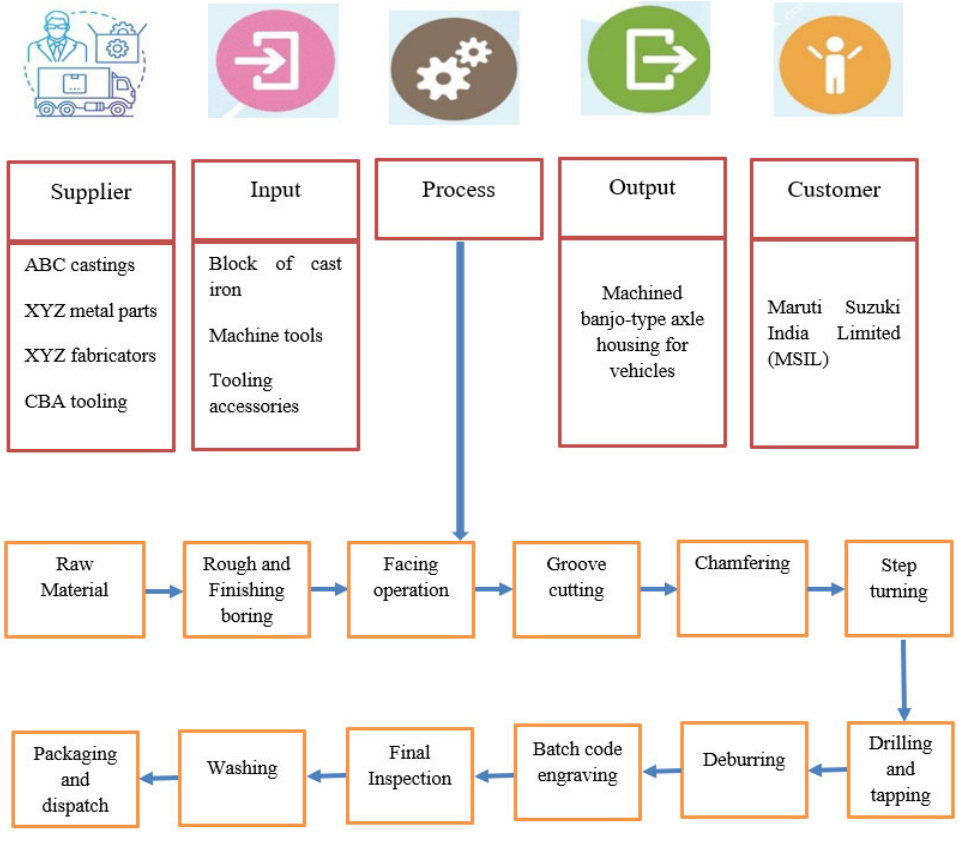


Figure 5 Crucial parameters for production waste (see online version for colours)

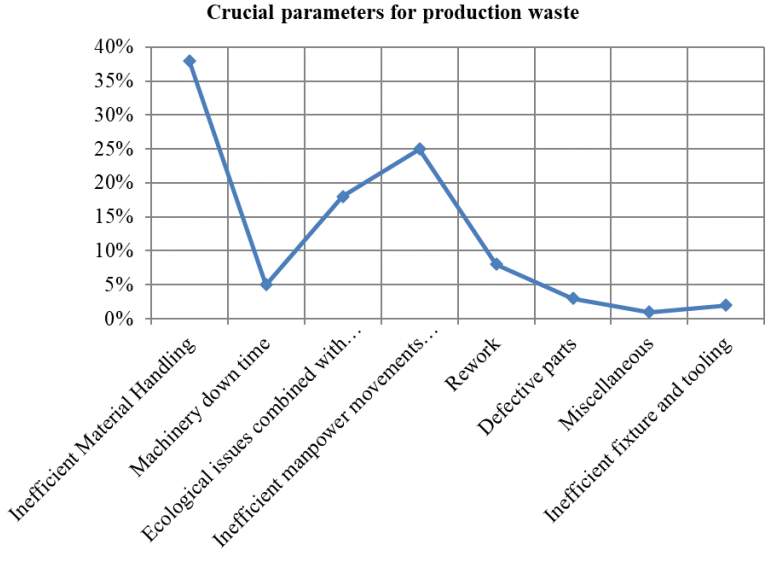

Figure 6 Pareto chart for poor material handling time for several shops/section (see online version for colours)

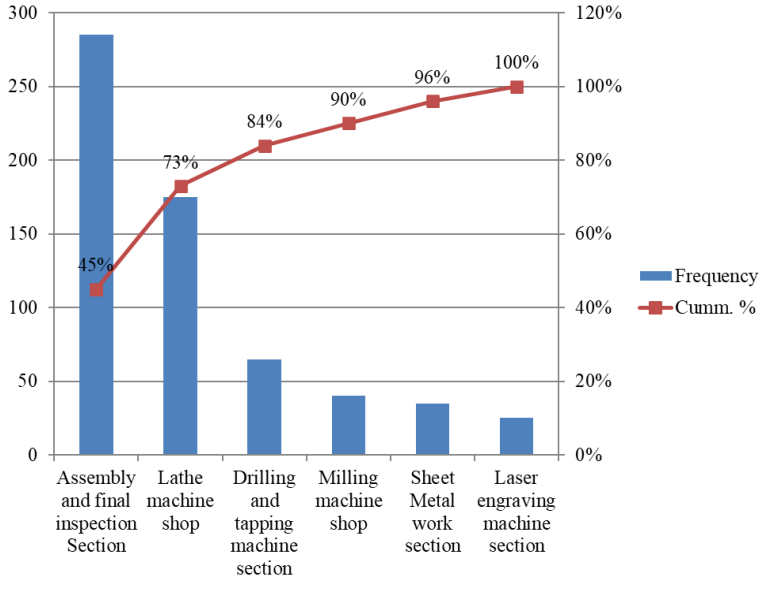

The Pareto chart indicates that the assembly and 'final inspection section and lathe shop are the key contributors to poor material handling and production waste of selected industry'.

4.2 Estimation for mapping of the current state of the project

An environmental current state mapping has been developed to impart higher insight into the current manufacturing operations. Environmental value stream mapping (EVSM) includes details concerning power consumption, water consumption, material consumption, environmental impacts, and conventional value stream criteria, such as cycle time, change over time, uptime, and lead time for every manufacturing process. Formulating an EVSM (Figure 7) assists in predicting the real manufacturing context and dispenses understandings on the resource consumption from the point of view of the environment, and leads to the development of critical process metrics (Table 2).

An open LCA (Figure 8) was carried out to compute current environmental impacts for the manufacturing process under consideration. The environmental impacts of process were estimated dependent on dataset of raw material, power, and water consumption. The environmental impacts were computed in Pt that indicates strength of impacts. These are assessed for entire process as well as independent processes. In EVSM, the estimated environmental impacts for each process are indicated in the boxes below water consumption line. The overall environmental impacts for present industrial processes considering the stakeholder were found to be 44.70 Pt. Stakeholders considered were cast iron, lubricating oil, water, electricity, groove cutting, chamfering process, drilling and tapping process, deburring and boring process.

Figure 7 Environmental current state value stream mapping (see online version for colours)

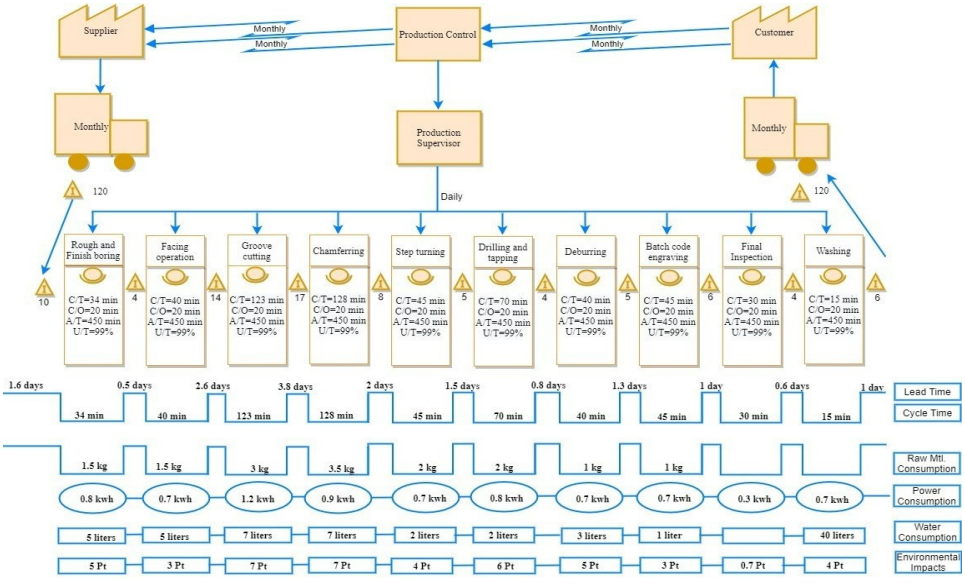

Table 2 Identified EVSM critical process metrics

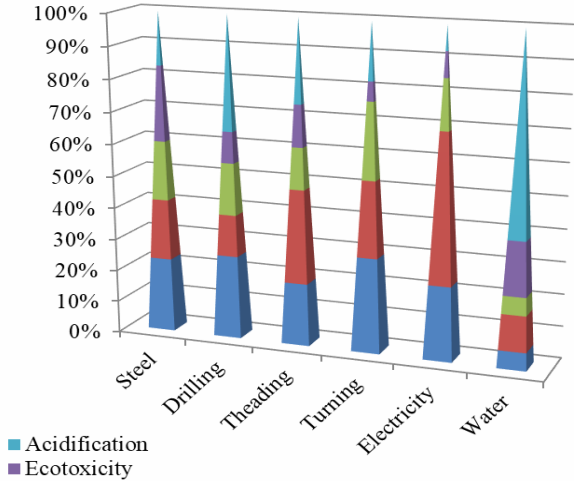
Critical process metric	*Units*
Total cycle time	570 min
Process lead time	16.7 days
Raw material consumption	15.50 kg
Power consumption	7.5 kWh
Water consumption	72 litres
Environmental impacts	44.70 Pt

Figure 8 Current environmental impact using LCA (see online version for colours)



Further, for computing the current sigma level of the manufacturing process, a sample size of 1,000 units was taken into consideration. The number of defects detected was 18 units. For above-indicated number of defects, DPMO were calculated as 18,000 ppm. The current sigma level of the manufacturing process after matching the attained ppm value with the standard process sigma table was obtained as 3.65.

Figure 9 Shops/section-wise number of parts needed rework (see online version for colours)

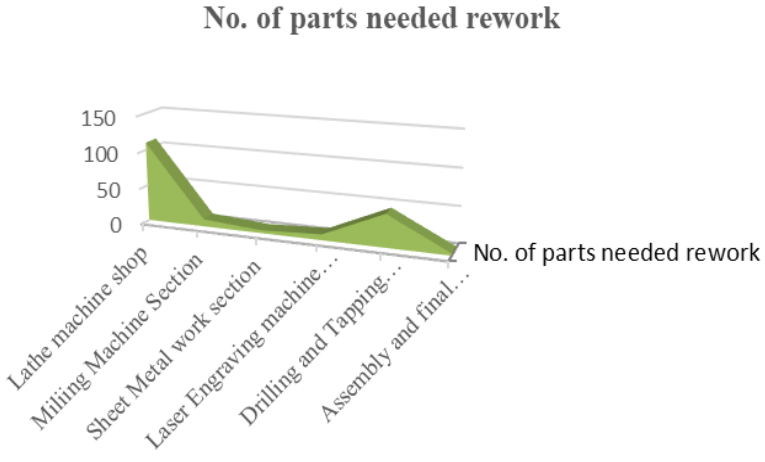


Figure 10 The suggested indicators for social sustainability assessment (see online version for colours)

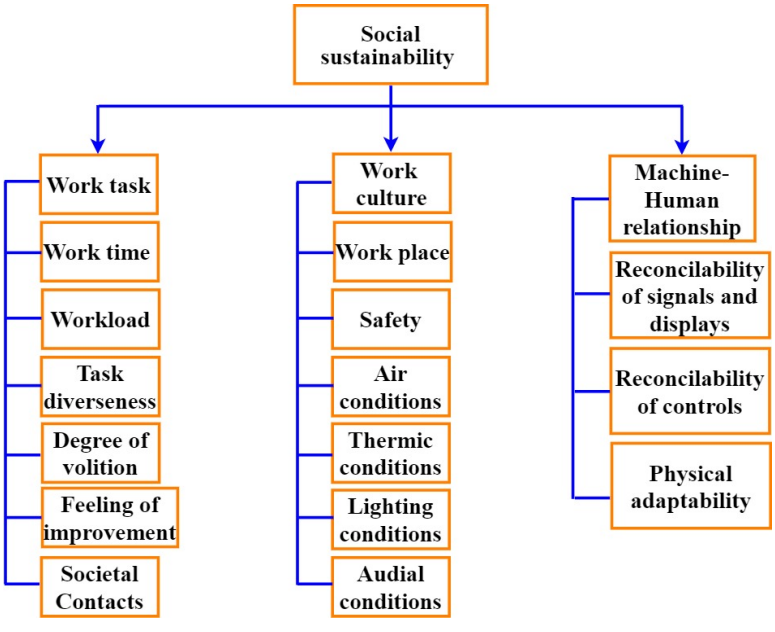


An intensive analysis of distinct shops/sections of concerned organisation had been done by the project team to gather monthly data associated with the number of parts needing rework in distinct shops of industry. Figure 9 illustrates a plot of the section wise number of parts that needed rework. It is clear from Figure 9 that there are mainly two shops/sections that is a lathe machine shop and a drilling and tapping machine section that contributed to reworking in the considered organisation's processes.

To ascertain societal sustainability is crucial concern in worldwide supply chains to defend workers of the organisation from harassment and dispense a better work atmosphere (Venkatesh et al., 2020). Social sustainability estimations have been assumed to be a lesser consideration by industrial organisations, particularly in emerging economies such as India. In the current research work, a societal sustainability assessment model to evaluate the social sustainable performance has been presented (Figure 10).

Social sustainability has been divided into three categories: work task, work culture, and human-machine relationship. The work task aspect of the social sustainability assessment model includes work time, workload, task diverseness, degree of volition, the feeling of improvement, and societal contacts. The work culture aspect of the social sustainability assessment model includes workplace, safety, air conditions, thermic conditions, lighting conditions, and audial conditions. The machine-human relationship aspect of the social sustainability assessment model comprises reconcilability of signals and displays, reconcilability of controls, and physical adaptability.

In the current study, novel inventory societal performance data was collected by a questionnaire-based survey. The samples were obtained from workers, engineers, managers, and local government officers. It was observed that concerned organisations had marginal sustainability and contributes to society. There is a need to improve work task and machine-human relationship aspects of the social sustainability assessment model of considered organisation.

In this step, the gathered data, and the current state map of the project are used to recognise the weak sections where further analysis was needed. These identified areas are given below:

- inefficient material handling: Final assembly and inspection section
- inessential worker movement and space usage: the whole industry
- rework needed: Lathe machine section and drilling and tapping machine section
- environmental footprints: the whole industry
- societal sustainability: societal and confined community.

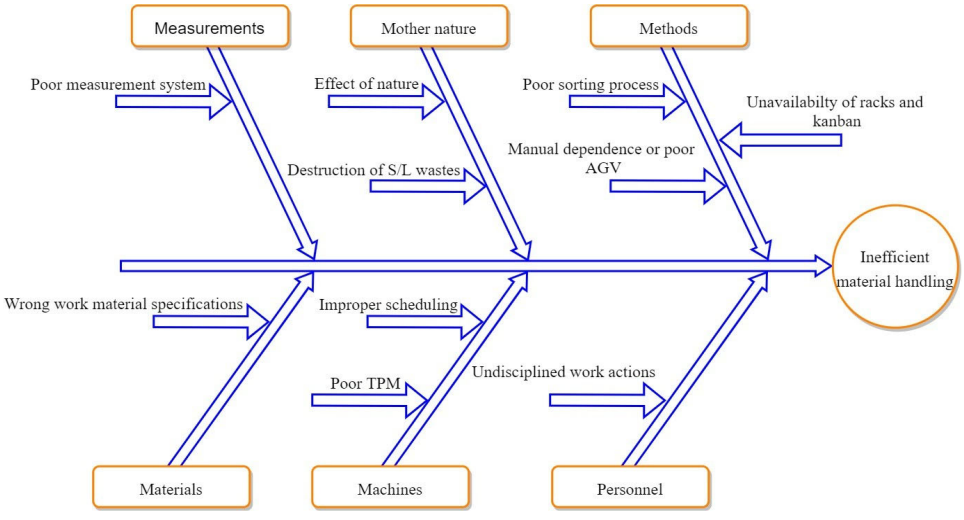
The priortised areas incorporating critical quality characteristics were further assessed to recognise possible causes in the succeeding steps.

4.3 Find out the prominent reason for waste and inefficiencies

The cause-and-effect diagram was instituted focused on inefficient material handling in final inspection and assembly section in selected industry (refer to Figure 11). Personnel, machines, methods, materials, mother nature, and measurements are the key categories that were taken into consideration for further investigation of potential causes. The

brainstorming sessions were also organised with the low, middle, and top managers of concerned organisation.

Figure 11 Cause and effect diagram of inefficient material handling in the assembly section (see online version for colours)



It has been found that there are ten factors that were greatly accountable for inefficient material handling in the considered organisation (Table 3). Further, grey relational analysis (GRA) was employed to find critical causes/factors among the identified factors. Table 4 illustrates the ranks of causes/factors accountable for inefficient or poor material handling. It was observed 'by GRA analysis that unavailability of racks and Kanban system and poor sorting process' were most crucial causes/factors accountable for poor or inefficient material handling and thus actions were required to overcome these.

Table 3 Causes/factors accountable for poor or inefficient material handling

Sr. no.	*Factors accountable for poor or inefficient material handling*	*Labels*
1	Poor sorting process	W1
2	Destruction of S/L wastes	W2
3	Effect of nature	W3
4	Wrong work material specifications	W4
5	Poor TPM	W5
6	Improper scheduling	W6
7	Unavailability of racks and Kanban system	W7
8	Poor measurement system	W8
9	Manual dependence or poor AGV	W9
10	Undisciplined work actions	W10

Table 4 Prioritisation of poor or inefficient material handling factors/causes by GRA

Label	*CR1*	*CR2*	*CR3*	*CR4*	*GRG*	*Rank*
W1	0.982	0.621	0.991	1	0.898	2
W2	0.543	0.432	0.421	1	0.599	5
W3	0.343	0.352	0.664	0.374	0.433	9
W4	0.383	0.524	0.534	0.623	0.516	8
W5	0.374	0.519	0.687	0.512	0.523	7
W6	0.549	0.412	0.424	0.991	0.594	6
W7	0.799	1	0.991	0.872	0.915	1
W8	0.472	0.362	0.343	0.442	0.404	10
W9	0.642	0.762	0.991	0.567	0.74	3
W10	0.372	0.612	1	0.434	0.604	4

Five why was also used for analysis for rework, inessential worker movement, and space usage. This tool dispenses methodical analysis for obtaining root causes of the problem and aims only on the regarding reasons. In the current study, team members of the project discuss with section heads, section supervisors, workers, and machine operators for computing the root causes of rework and inessential worker movement and space usage. Figure 12 depicts the prime root cause for rework issues.

Figure 12 Five why analysis for rework (see online version for colours)

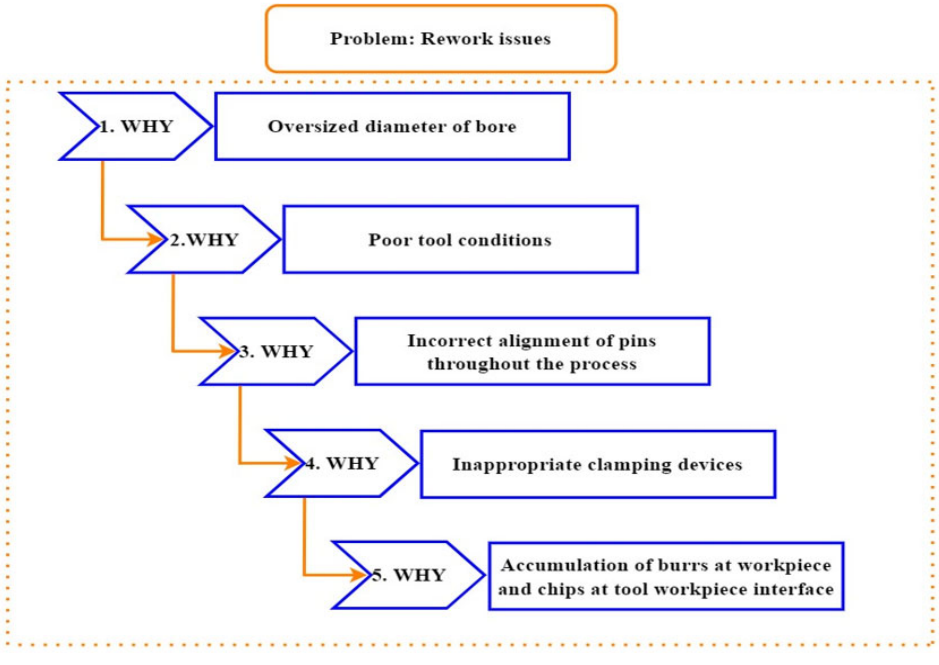


Figure 13 Five why analysis for inessential worker movements and space usage (see online version for colours)

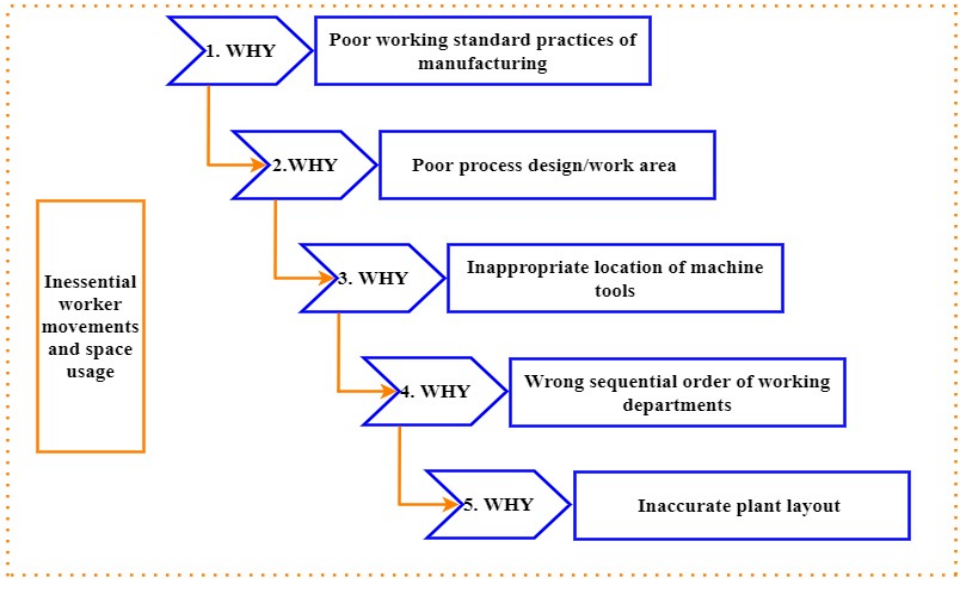

Table 5 Identified prominent reasons for waste and inefficiencies

Sr. no.	*Encountered problem*	*Key areas*	*Prominent reasons for waste and inefficiencies*
1	Inefficient material handling	Final assembly and inspection section	Unavailability of racks and Kanban system, poor sorting process, manual dependence, or poor AGV
2	Inessential worker movement and space usage	whole industry	Inaccurate plant layout
3	Rework needed	Lathe machine section and drilling and tapping machine section	Accumulation of burrs at workpiece and chips at tool-workpiece interface
4	Excessive water, power, and raw material (consumption)	Overall plant	Poor tool conditions, inaccurate machining parameters, lack availability of appropriate cleaning and recirculation system
5	Societal performance	Societal and confined community	Locality investment, new employment in the whole plant, majority of deployment from the local region

The team of the project also carried out a five why analysis for inessential worker movement and space usage. It was observed from the analysis (Figure 13) inaccurate plant layout resulted in inessential worker movement and space usage.

Furthermore, the team of the project crucially inspected several departments of the concerned organisation and organised distinct brainstorming sessions with industrial managers and employees, and recognised that key sources for low ecological performance were water, power, and material consumption. This was recognised that for enhanced societal sustainability, considered organisation must work out on humanity and resident communal facets. With the help of the cause and effect diagram and five why analysis, the list of prominent reasons for waste and inefficiencies at the selected organisation is shown in Table 5. In the next step of the GLSS framework, several actions were executed to enhance the sustainability dynamics of the considered industry.

4.4 Select and implement the best solution

After executing enhancement activities, pilot tests are carried out to register the concert of the improved design, and cost-benefit study is accomplished to assess the complete investments initiated from the project.

Figure 14 Final assembly and inspection section before and after the implementation of 7S technique (see online version for colours)

(a) (b)

A brainstorming sessions was conducted with experts dispense suggestions on how to employ 5S techniques for minimising the inefficient material handling in final assembly and inspection section of considered organisation. In the current study, the 7S tool, (5S + Sustainability + Safety) was adopted to enhance the sustainability dynamics of the company. 7S techniques were also used to create a sorted out, safe, clean, accident-free, and eco-friendly workplace in the concerned organisation. Here 7S stands for Seri, Seiton, Seso, Seiketsu, SeJizoku kanosei, and SeiAnzen which implies sort, simplify, shine, standardise, sustain, sustainability, and safety, respectively. In the Seri step, all the parts and equipment were sorted out as per their operating frequency. After sorting, the replanning of all the parts and equipment was done to streamline the flow of material. The structure of the final assembly and inspection section before and after the implementation of the 7S technique is shown in Figure 14. This technique assists in the daily saving of about 145 minutes in finding the parts/components to assemble one product. Furthermore, the workplace was cleaned appropriately to create a healthy

working environment and reduce air pollution. The assumed work actions were standardised to make a compatible means of executing tasks accomplished daily, incorporating sort, set in order, and shine. Standardise compel methods and process more pragmatical and rigorous to create right things, the right way and right time. The visual process control system was also incorporated to encourage employees and other members of the organisation to retain things at assigned places. The work standards were decided such as regular checking of the first aid kits and reforming the environmental rules and regulations for sustainability.

To certify sustainability and safety in the adopted industry, separately from the 5S technique, probes for mitigation of accidents, also enclosing the areas of machine tools liable to high-temperature chips were accomplished.

Kaizen activities

To minimise various non-value-added activities in the considered organisation, several kaizen activities were suggested and executed. These activities have been mapped out in a manner that can improve the productivity and ecological sustainability of an organisation. These were also mapped out to minimise work issues, setup time, and improve the social sustainability of the considered organisation.

Enhancements concerned with the cutting of raw material and lathe section

Initially, overhead crane systems were used to transport the raw materials bars to a devoted slicing system in the lathe machine shop of considered organisation. The raw material bar was inserted in the devoted fixture and positioned on cutting machine to be cut into small pieces after dispensing appropriate clamping and location. The clamping and setting work takes more time as the size of bar size changes. Therefore, there is great requirement to impart quick change over and minimisation of set up time. For this purpose, exploration and practicability of three possible techniques were carried out. Table 6 outlines the analysis of techniques for set up time minimisation.

Table 6 Exploration of set up techniques

Technique	*Explanation*	*Adopted feasibility*
Modularisation of equipment	Create changes in prevailing fixtures to encounter operational needs	Time minimised for setting up but demands quick moderation
Modification in equipment	Accomplish redesigning of fixtures and substituted existing one with an improved one	This assists in huge reduction in set up time by reshaping and enhancements in the prevailing fixture
Advance part preparedness	Fortified with a batch devoted fixture to minimise changeover time	This could be employed for the short time period when handling and total manufacturing cost is high

Enhancements prevailing to rework issues

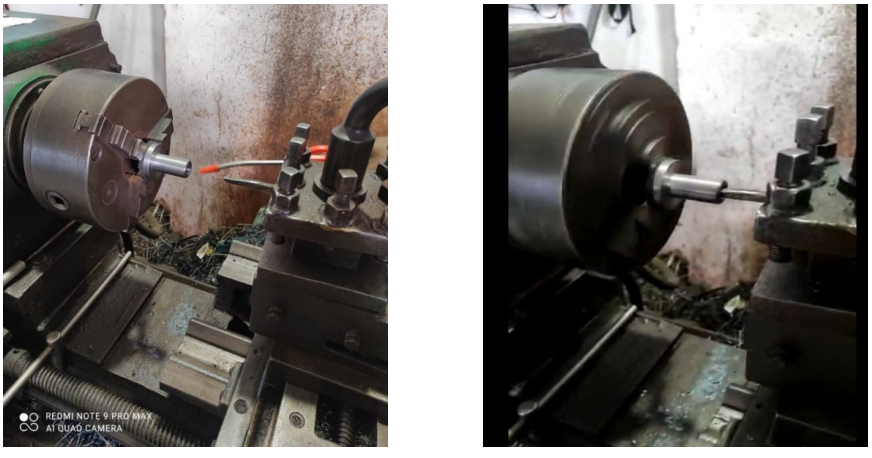
In the previous step, this has been recognised that the accumulation of burrs at the workpiece and chips at the tool-workpiece interface was a crucial aspect behind the

rework concerning problems in the section of the lathe machine. To assist, in appropriate tool conditioning the carbide tool has been substituted and locators have been imparted and pins positioned accurately to minimise the disarticulation of parts. The pressurised air guns have been included to reduce the chips and burrs from the W/P and interface areas. This will assist in improvement in tool life and minimisation of rework problems. Figure 15 shows lathe machine tools before and after the assimilation of an air pressure gun to eradicate burrs at the tool-workpiece interface.

Enhancements to improve social dynamics

Obtaining brilliance in ecological, health, protection, employment, and community engagement should be a part of the value conception plan to sustain the world market. This has been observed from the LCA technique that the considered company was straggling in the constraints of community and employment investment. However, the selected organisation shows a societal sustainability level but to improve the existing one, to a better level, the company must include measures to improve community and employment investment facets. As powerful community performance in lengthy turn forces stakeholder value conception, concerned organisations ought to capitalise more inside the community closer to the non-profit sectors. Enlarging community investment in conjunction with the measurement of final results finished will cause approach enrichment, enhanced social resource engagement, culture constructing, and enterprise technology for the selected company. The selected company ought to include actions for training, education, and skill development as a part of commercial societal responsibility. Such types of actions will improve the manufacturing sector to recruit probable talents from the local community that only improve social sustainability but also assist in enhanced efficiency of the organisation.

Figure 15 Lathe machine tool before and after assimilation of air pressure gun (see online version for colours)



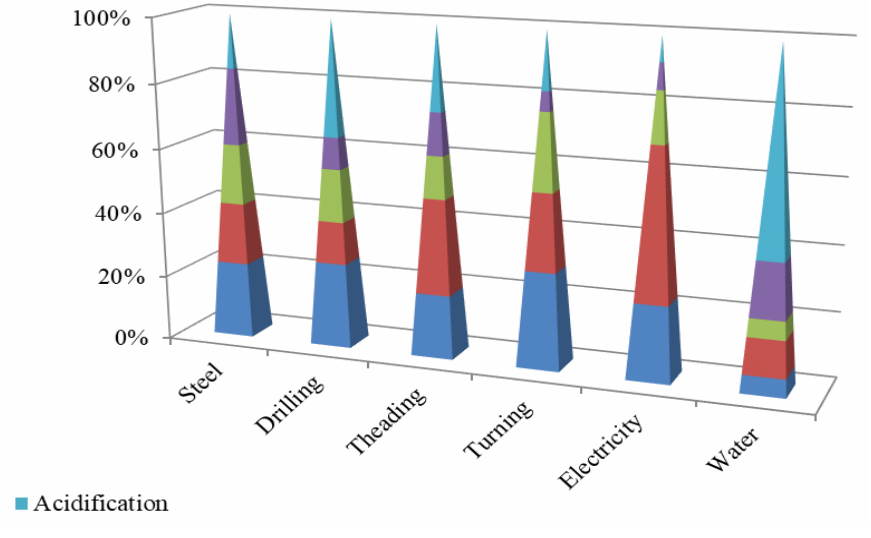
(a) (b)

Table 7 Proposed actions for minimising the overall environmental effects

Aspects	*Executed actions*	*Proposed actions*
Raw material consumption	Excessive scrap was minimised by changing machining parameters	Utilisation of different materials with lesser environmental impacts as related to cast iron
	The weight of input raw material was minimised by altering the product features	
Water consumption	The washing machine is situated with a closed-loop circulating water system to minimise coolant consumption	Adopt normal methods of cleaning with usage of steam to diminish coolant consumption
	The surface of the water tank was bordered through a smooth material to circumvent loss from the condensation	
Power consumption	Experiments and investigations were carried out milling, deburring, and turning machines tools to minimise power consumption by optimising the features of feed rate, spindle speed and authorising electrical units	Electrical power management system (EPMS) has been incorporated to recognise and modify energy waste
	Energy storage and recovery stoppage elements were mounted in the machine tools to attain energy efficacy	

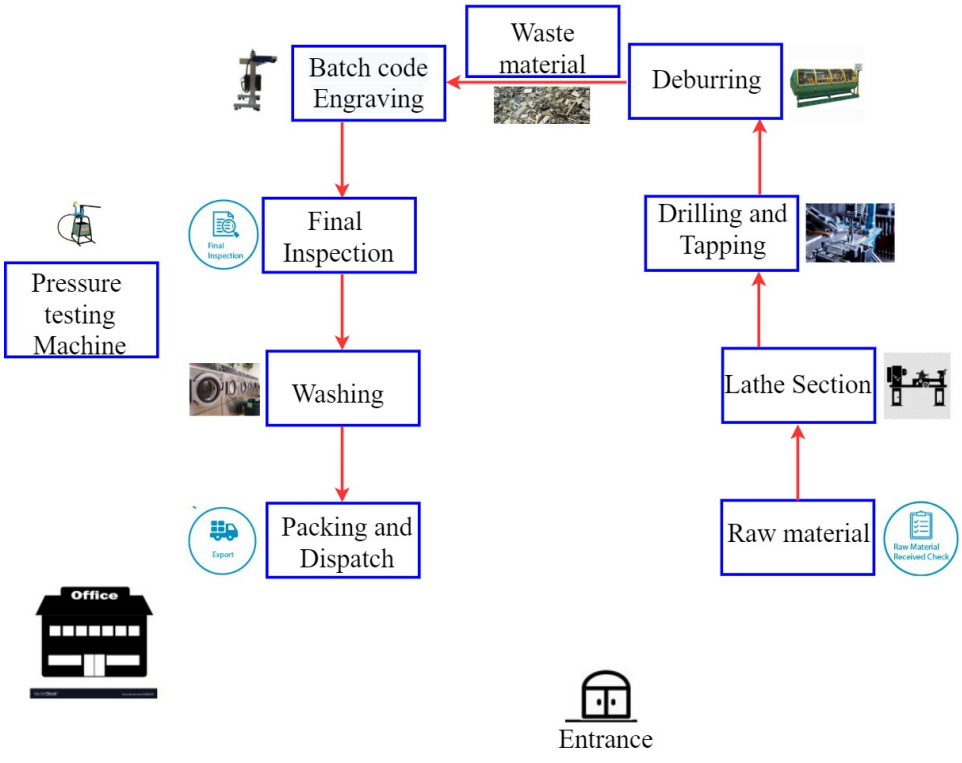
The mitigation in overall environmental effect has been attained by a corresponding reduction in the usage of raw material, consumption of lubricant, and power utilisation. The enhancement activities were recommended and applied for each factor. Table 7 illustrates the executed activities and proposed actions for each ecological factor to improve the environmental sustainability of the industry.

Figure 16 Lifecycle assessment after inclusion of environmental impacts mitigation measures (see online version for colours)



After the incorporation of power-saving actions, power consumption reduces from 7.5 kWh to 6.1 kWh. The saving in the overall power consumption of the organisation leads to reduction in the overall cost of product. The water consumption was also minimised from 72 litre to 60 litre because of the amalgamation of the proper water circulation system and uncomplicated coating for water tank. In perspective of material sustainability, several analyses and tests were carried out for vehicle assembly parts to get the proper design. The raw material consumption was brought down from 15.50 kg to 12.50 kg through understanding with improved specifications for the product. After the incorporation of the execution methods, the overall environmental impacts were again assessed by LCA technique and it obtained to be 32.70 Pt which was 44.70 Pt earlier. Figure 16 illustrates the LCA after the inclusion of the environmental impact removal aspects. Furthermore, the possibility still occurs for the mitigation in the environmental impacts by the utilisation of substitute material and minimisation of material consumption.

Figure 17 Plant layout before analysis (see online version for colours)



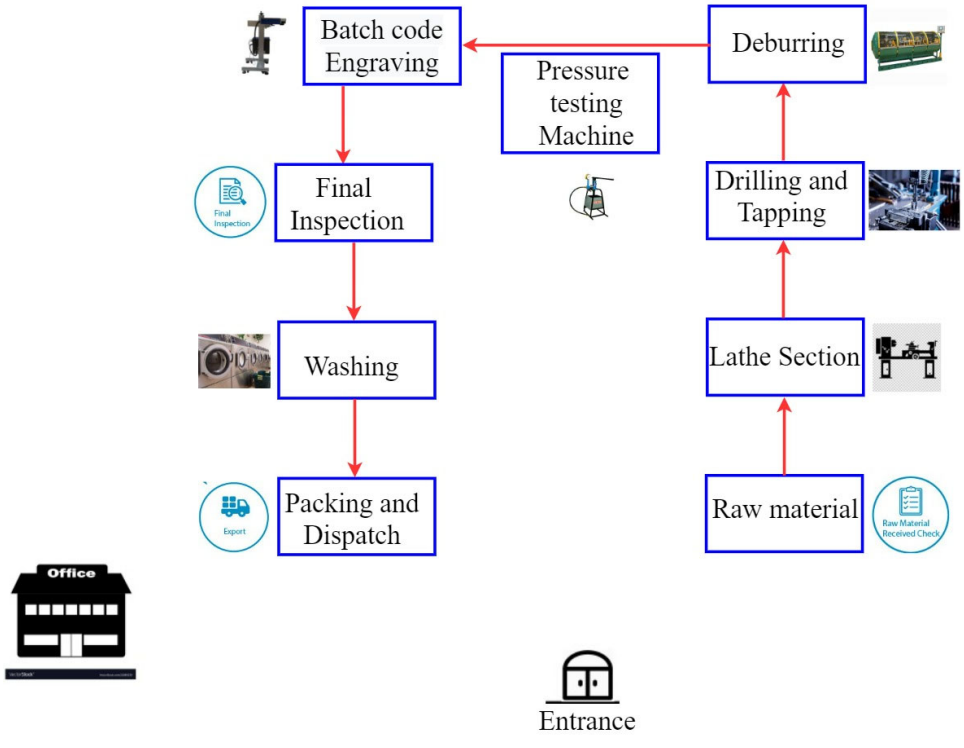
Moreover, to determine the main cause of critical factor that is inessential worker movements, a brainstorming session was conducted among selected experts. The result of the brainstorming session reveals that improper plant layout is the main cause of inessential worker movements within the plant. The current plant layout was outlined and analysed those methods were not accurately aligned and caused in the inessential movement of workers and materials. The faculty plant layout also assists in enhanced electricity consumption for jib crane operation and other related material handling

equipment. To improve the existing layout, primarily movements of workers were traced with the existing layout to find out materials, tools, etc. Thus, the movements of the semi-finished products, raw material, and material handling equipment are also tracked. Figure 17 illustrates the plant layout before analysis. It has been observed by the methodical study of the plant that in the existing plant needed floor space was not efficiently planned. The possible solutions for execution were investigated and further steps were instigated to improve the prevailing plant layout.

It has been recognised that in the existing layout there was no appropriate space for the storage of tools or accessories and as a part of the same workers have to move every time to find out the needed tools. That is why an appropriate toolset box was unified on each machine tool to save time to find out the tools. This has assisted in saving time for workers and increased their overall efficiency. Furthermore, the pressure testing machine that was firstly positioned near the office, moved nearby to the deburring section that was initially occupied with waste material. The resulting movement of the machine tool assists in the attainment of the U-shaped layout of the plant.

Furthermore, efficient floor space usage was attained by the removal of the waste material and repositioning of the machine tools in the plant. The existing developed layout assisted in the attainment of the smooth workflow of material and employees, and subsequently supports a minimisation in waiting and electricity consumption for material handling equipment. Figure 18 depicts the plant layout after analysis.

Figure 18 Plant layout after analysis (see online version for colours)



4.5 Sustain with an adopted solution and make it mistake-proof

After several enhancement activities in the previous step of the GLSS framework, different 'activities' and data were registered form 'next' six months to inspect whether enhancements activities sustain for a longer duration. Distinct measures relate to wastes, environmental, and defects were evaluated again to inspect for any deviation from enhancement step. The improvements attained from implementation of GLSS project are imparted to all the associates included in this project and flowchart is created for the role and responsibilities of each member to sustain enhancements. Table 8 illustrates the Out of Control Action Plan (OCAP) to decide roles and responsibilities to maintain improvements for a long duration. The performance metrics in terms of observation, collection of data, and registering are planned to trace the performance of the system after the execution plan.

Based on the exploration of the current state of VSM, enhancement activities were mapped out and executed to enhance the distinct process measures of the considered organisation. After effective implementation of the recommended activities, future state of VSM was created. It is imperative to dispense appropriate training and education to the workers included in the GLSS project to support improvements made and sustain assumed best practices. The tools like Poka Yoke, visual management, out-of-control action plan, and total productive maintenance have been employed in the present study to dispense pictorial assistance and to control major input-output variables relates to functional and ecological practices.

Table 8 Out of control action plan

Sr. no.	*Control element*	*Control process*	*Responsibility*	*Response plan*
1	Conveyor system	Visual audit	Machine operator	Certify mistake-proofing and inspect appropriate maintenance of crane bearings
2	Location of pressure gun	Visual audit	Machine operator	Instruct machinist for appropriate pressure gun location setting at the tool-workpiece interface
3	Location of drill in the drill and tapping section	Visual audit	Machine operator	Certify appropriate location of drill and assumption by standard operating procedures
4	Hydraulic motor	Metric	Maintenance section	The gap occurs in the sleeve part of the motor are protected in such a way that hydraulic obstruction does not exist
5	Coolant system	Visual audit	Machine operator	Instruct machinist for appropriate supply and outflow of the coolant

5 Results and discussion

On effective implementation of the GLSS approach by the proposed framework, the concerned industry was able to enhance its functional performance and ecological sustainability. Enhancements were perceived in the manufacturing process and ecological

specifications by implementation of adopted GLSS framework. The enhancements perceived stated to lean measures like cycle time and process lead time. The efficient execution of method 7S, Kanban, formation of proper plant layout, and Kaizen activities resulted in a minimisation of the cycle time from 570 minutes to 440 minutes (22.80%). Moreover, process lead time was also reduced from 16.7 days to 13.1 days (21.55%), which assists in a substantial saving in postponement of the final product. The applied enhancement activities fetched enhancement in the environmental measures of raw material consumption, water consumption, power consumption, and overall environmental impacts. Raw material consumption, power consumption, and water consumption were minimised by 19.35%, 18.66%, and 16.66% respectively. As there is a decrease in the principal resource consumption, a minimisation in overall environmental impacts was also detected. The environmental impacts were minimised from 44.70 Pt to 32.70 Pt con 26.84% enhancement.

Furthermore, the methodical application of several enhancement methods carried significant enhancements in prevailing capacity utilisation of plant by 19.80%. The sigma level of the considered industry was enhanced significantly by a minimisation in number of parts rejected. Sigma level was enhanced from 3.65 to 4.08 (for a sample size of 1,000 parts the number of parts found defective was 7 and it is correspondence to the DMPO 7.000 that was previously 18.000). Table 9 represents the process parameters before and after the execution of the GLSS project in the considered industry.

Table 9 Process parameters before and after the implementation of GLSS project

Process parameters	*Before implementation*	*After implementation*	*Percentage improvement (%)*
Cycle time	570 min	440 min	22.80
Lead time	16.7 days	13.1 days	21.55
Raw material consumption	15.50 kg	12.50 kg	19.35
Power consumption	7.5 kWh	6.1 kWh	18.66
Water consumption	72 litre	60 litre	16.66
Sigma level	3.65	4.08	11.78
Production waste	48.30 %	38.80 %	19.66
Environmental impact	44.70 Pt	32.70 Pt	26.84

Table 10 Financial gains from GLSS project implementation

Particulars	*Before GLSS implementation*	*After GLSS implementation*
Total number of products produced/month	13.000	15.060
Number of parts rework/months	185	35
Rework cost/ piece	$4	$4
Total rework cost	$17.760	$3.360
Total earnings obtained	$325.000	$373.000
Possible financial savings because of GLSS project implementation	$48.000	

Moreover, enhancement metrics resulted in the minimisation of rework parts from 185/month to 35/month. This assists in a saving of $ 1,210/month from the rework associated problems in the considered industry. The inclusive implementation of GLSS project caused in a monetary improvement for industry in terms of saving a net value of $ 48,000/year (3,672,967 Indian rupees). Table 10 depicts monetary gains from implemented GLSS project in selected industry.

The considered organisation attained substantial benefits in terms of functional parameters, environmental metrics by the effective implementation of the GLSS project. This proves the competence of the presented GLSS framework to alleviate the current challenges of the industrial sectors.

5.1 Managerial implications

The GLSS framework which is assumed in the present study will encourage the industrial sectors to execute the GLSS approach within the organisation in a pragmatic way. The suggested GLSS framework activities enumerated under each step have been outlined in such a way that it assists to the methodical step-by-step procedure to address both functional and ecological issues. During the execution of the GLSS framework, the organisations should be focused on the existing culture of the organisation towards environmental measures. The organisations may utilise the EVSM to draw the whole process in the quantified value sustainably. A training session about GLSS execution is also needed for employees and supervisors so that they can engage in GLSS execution with full eagerness and attention. The current study's unique contribution lies in supporting industrial sectors to compute several functional, environmental, and societal measures and dispense ways to enhance and sustain the same for improved organisation competitiveness.

6 Conclusions

Approaches to enhance environmental performance must be associated with the conventional industrial initiatives to enhance measures like process efficacy, satisfaction of customers, and receptiveness. GLSS, environmental aspects, and societal contemplations have been combined with an intent to reduce waste, resource consumption, cultivate worker health and well-being. The contribution of the current study lies in two-fold, first, the GLSS framework has been suggested to direct in conducting the activities of implementation of this program. The presented framework dispenses a prospect to the industrial sectors to enhance ecological wastes, improved capacity usage, handling of items, along with enhancement in social subtleties by the deployment of tools like LCA, EVSM, Kaizen, etc. Second, this work exhibits the empirical benefits of using the projected GLSS by its effective execution framework in an industrial environment by methodical insertion of green technology, Lean and Six Sigma tools.

Effective implementation of the suggested framework has assisted to a minimisation in defects, level of rework, and environmental wastes, together with enhancement in functional and financial gain. The efficient execution of method 7S, Kanban, formation of proper plant layout, and Kaizen activities resulted in a minimisation of the cycle time from 570 minutes to 440 minutes (22.80%). The environmental impacts were minimised

from 44.70 Pt to 32.70 Pt contributing 26.84% enhancement. Sigma level was enhanced from 3.65 to 4.08 (for a sample size of 1,000 parts the number of parts found defective was 7 and it is correspondence to the DMPO 7,000 that was previously 18,000). The GLSS project fetches a financial savings of $ 48,000 by the effective implementation of this framework. The current research work allows the organisation to understand its present level of environmental effects and aids it in detecting further means of minimising CO_2 emissions by the integration of more green technology measures. This framework also had a constructive impact on the societal significance as enhancements were perceived relating to the health of human (as an outcome of minimised ecological effects) and shopfloor safety (after the deportment of the 7S).

Limitations and future scope

Despite several contributions, the study has its limitations. This GLSS framework can be employed only in automotive manufacturing sectors, and definite industrial sectors employing with analogous industrial operations. In the present study, the suggested framework has been tested through only in a single automotive manufacturing organisation. In future research, proposed framework can be expanded to another industrial organisation wherever the necessity to implement the GLSS approach is insistent. Future research can also focus on improving the current steps and by incorporating additional tools and techniques into every phase concerning producing reliable outcomes by the application of the proposed framework in several enlightened environments.

In another future research direction, the framework can be improved to encompass its scope for allowing additional sustainability drivers during the GLSS execution and more unconventional tools and techniques can be appended to framework for furthermore improvement.

Abstract
The Covid-19 pandemic has had a significant impact on manufacturing industries and supply chains. Manufacturing industries are struggling to repurpose their production activities and ramp up the supply chain to bridge the demand–supply gap. A framework that can cover Industry 4.0 technologies and reconfigurable manufacturing system (RMS) practices is desperately needed. The current study focuses primarily on the framework that could assist managers in decision-making and the stepwise adoption of RMS during repurposing. The extensive literature review was conducted to identify the prominent Industry 4.0 technologies and RMS practices. To compute the weights of selected practices, the novel Pythagorean fuzzy analytical hierarchy process (AHP) was used; while the Pythagorean fuzzy combined compromise solution (CoCoSo) method was used to prioritize the selected performance metrics. To test the robustness of the developed framework, a sensitivity analysis was carried out. According to the findings, smart factory adoption (SFA) practices were the most significant among the major criteria, followed by reconfiguration practices (RCP), soft computing practices (SCP), sustainable & circular economy practices (SCE), and quality practices (QPS). SFA's advanced technologies and SCP's computer algorithms certainly assist in the repurposing of production activities (RPO). The results of the sensitivity analysis demonstrated the robustness of the developed framework. The developed framework will be useful during RPO, and the identified practices can make a significant contribution. Advanced technologies and sustainable practices can help to improve the organization's work culture. Managers will be able to evaluate the organization's performance with the help of identified performance metrics. The work presented here may be the first attempt to develop a framework for RPO in a pandemic situation.

Keywords Reconfigurable manufacturing system · Industry 4.0 · Repurposing of production operations · Pythagorean fuzzy AHP · CoCoSo method

1 Introduction

The pandemic caused by COVID 19 has had a negative impact on a variety of industries, including manufacturing, tourism, healthcare, and many others. The spending power of a large population has been significantly reduced as a result of the lockdown and quarantine period, which has resulted in a stagnant economy in the majority of regions (Shen et al. 2020). The coronavirus outbreak has also had a significant impact on several manufacturing industries in many countries, and some researchers have developed an accounting index to assess the impact of the virus (He et al. 2020). As a result, manufacturing industries are suffering from disrupted supply chains, a shortage of manpower due to the lockdown, a shortage of raw materials, highly dynamic market needs, disrupted transportation facilities, reduced customer purchasing power, etc. The global economy's growth rate is expected to fall up to –3% in 2020, potentially leading to a global recession. Furthermore, the manufacturing industries are expected to lose around 10.7% in 2020, while the service industries are expected to lose around 16% (Gu et al. 2020). As a result, there is a need to repurpose the manufacturing

operations to maintain the organization's financial performance. Furthermore, the repurposing of essential drugs, healthcare equipment, food and safety-related products, and many other items is a top priority. The majority of the world's supply chain has been severely impacted and must be resumed for the necessary products to reach customers. As a result, according to López-Gómez et al. (2020), a strong roadmap for rapid repurposing of manufacturing and development activities that can reflect national priorities is required to improve global manufacturing capacity. Several researchers, practitioners, and manufacturing organizations are attempting to repurpose activities, but are falling short since new product introduction necessitates the compliance of several resources as well as extensive planning. This situation necessitates the use of advanced technologies capable of meeting pandemic requirements such as customized products and rapid response. The fourth industrial revolution, also known as Industry 4.0, is made up of several advanced technologies, including information technologies used in manufacturing, which can meet such demands (Javaid et al. 2020). According to Liu and Beltagui (2021), digital technologies such as 3D printing can help to increase required flexibility, whereas collaborations with other organizations, in conjunction with digital technologies, can help to reduce product development time and thus lead time. The researchers also stated that technologies such as Computer Numerically Controlled machines can be useful for repurposing. Furthermore, advanced manufacturing systems such as Reconfigurable Manufacturing System (RMS) can help to provide the necessary flexibility during the manufacturing of products required to deal with the pandemic situation as well as to maintain individual country's economic conditions (Pansare et al. 2022a). RMS, the next generation manufacturing system, with its higher reconfigurability, flexibility, and intelligence, can assist in the rapid transition to new products required to deal with the varying needs of a pandemic situation as well as post-pandemic challenges (Khan et al. 2022; Pansare et al. 2021a).

The most important attribute in incorporating changeability in any manufacturing system in the context of Industry 4.0 is reconfigurability (Pansare et al. 2022b). Furthermore, product complexities are constantly increasing, necessitating the use of modern manufacturing systems such as RMS to manufacture them in this scenario (Bortolini et al. 2021). RMS practices and technologies such as Holonic manufacturing, Agent-based design, Cyber-Physical System (CPS), Digital Twins (DT), Industrial Internet of Things (IIoT), and many more are strengthening manufacturing systems in the Industry 4.0 era (Morgan et al. 2021). RMS, when combined with these enabling technologies and practices, can meet the aforementioned requirements and assist manufacturing systems in repurposing their manufacturing operations during a pandemic. However, in the context of Industry 4.0, there is a need to bridge the design, theory, and practices of RMS (Liu et al. 2020).

Looking at the current situation, many manufacturing activities are hampered as a result of the pandemic, and organizations are struggling to ramp up the same using various techniques. Despite wartime efforts to address the issue, manufacturing industries are unable to meet the shortage of supply, dynamic market needs, and unexpected growth in demand for a specific type of product (López-Gómez et al. 2020). While doing so, manufacturing industries face several challenges, such as a lack of employees due to the lockdown, a lack of raw materials, etc. Furthermore, market demands are drastically changing, and products essential for Covid-19 virus protection, as well as products of basic needs, are in high demand. As a result of this shift in demand, many manufacturing industries have become desperate for survival, and they are now forced to manufacture products in response to market demands. Hence, many researchers have concentrated on developing methodologies and frameworks for repurposing manufacturing operations (López-Gómez et al. 2020). Simultaneously, Javaid et al. (2020) attempted to use several Industry 4.0 technologies to deal with a pandemic situation in which advanced manufacturing technologies are used to meet customized requirements. Similarly, many other researchers attempted to discover pathways for the recovery of various industries such as aviation (Dube et al. 2021), tourism (Škare et al. 2021), and others. However, there was a strong need to develop a framework that can use several hybrid technologies, such as RMS-Industry 4.0, to repurpose manufacturing activities while also being able to switch over products demanded by the pandemic situation. It was also necessary to identify several RMS-Industry 4.0 enabling technologies and practices that can assist practitioners during this transition as well as contribute to pandemic preparedness. Furthermore, a set of performance metrics that can reflect the overall impact of this framework and allow organizations to measure their current status must be developed. Given the current pandemic situation, the above-mentioned framework was especially important, as it may also indicate future opportunities for organizational development and market competition even during a down economic period. The following were the study's objectives:

1. To identify RMS-Industry 4.0 practices that assist in repurposing manufacturing organizations during a COVID-19 pandemic situation through a literature review.
2. Identifying and researching the challenges that manufacturing organizations face during and after a pandemic.
3. To present the role of RMS-Industry 4.0 practices in the RPO within an organization and to develop a framework for it.

4. Identifying and prioritizing performance metrics to assess an organization's ability to deal with a pandemic situation.

With the aforementioned objectives in mind, an extensive literature review was conducted to identify RMS-Industry 4.0 practices and performance metrics to assess the impact of these practices in any organization during and after a pandemic situation. This was followed by the development of a framework for these practices as well as performance metrics to assist practitioners in manufacturing organizations in dealing with the pandemic situation. To compute the weights of selected practices and then prioritize the identified performance metrics, the hybrid Pythagorean fuzzy analytical hierarchy process (PFAHP) – combined compromise solution (CoCoSo) method was used. Therefore, the current study explores the novel PFAHP and CoCoSo methods that have a ability to differentiate the alternatives. This contributes to multi-criteria decision-making (MCDM) and demonstrates how these methods can be used. The study also developed a framework for RPO during the COVID-19 pandemic situation; thus, it contributes to the field of manufacturing systems by providing a novel framework that can assist them in repurposing and bringing manufacturing operations back to normal.

The current study is divided into six sections, one of which is the current section. Section 2 presents a literature review related to RMS, Industry 4.0, and research gaps, followed by research methodology in Sect. 3. Section 4 explains the case analysis, including framework development and performance metric prioritization, while Sect. 5 discusses the study findings and their implications. Section 6 summarises the study's conclusions as well as its future scope.

2 Literature review

During the literature review, the Scopus database was used to retrieve the previous research articles that were related to RMS, Industry 4.0, COVID-19, and repurposing of manufacturing operations. Using the keyword 'Reconfigurable Manufacturing System', total 1140 research articles were retrieved that were further filtered and only 454 articles from peer-reviewed reputed journals in the English language were finally selected for further study from 1999 to 2021. Furthermore, the keyword 'Industry 4.0' was used to retrieve 281 articles published in English from 2010 to 2021 from only reputable peer-reviewed journals. Similarly, from 2019 to 2021, 151 research articles related to COVID-19, including the repurposing of several sectors, were chosen from peer-reviewed journals in English. These selected articles were later stored in a central location so that they can be retrieved as needed. Only peer-reviewed articles from reputable publishers such as Emerald insight, Springer link, Elsevier, Taylor & Francis, and Inderscience were chosen for this study, while conference proceedings and book chapters were excluded. The selected articles were investigated further, and the results are presented below.

2.1 Repurposing Production Operations (RPO) in manufacturing industries

As previously stated, the COVID-19 pandemic has had a significant impact on manufacturing operations. As a result, many researchers began to focus on the repurposing of these operations, developing several methodologies and frameworks in the process. In addition, practitioners and managers in manufacturing organizations were working hard to recover from the current situation and restore normalcy to production operations. However, the contributions of a few researchers to RPO are summarised in Table 1 and discussed further below.

During the COVID-19 global emergency, the healthcare sectors faced a challenge due to a lack of ventilators, masks, test kits, etc. As a result, López-Gómez et al. (2020) reviewed key challenges for repurposing their manufacturing activities and proposed probable methods to mitigate the challenges. Furthermore, Deshmukh and Haleem (2020) attempted to prepare a conceptual framework for enhancing manufacturing activities from an Indian perspective, involving a variety of stakeholders. Researchers also proposed using more automation and localized skills during manufacturing activities to meet the increased demand for products. Another researcher Liu and Beltagui (2021) wanted to speed up the innovation process by repurposing; they examined case studies and concluded that exaptation can help during the crisis recovery. Saberian et al. (2021) wanted to reduce the waste generated as a result of the pandemic situation, so they proposed recycling it in civil construction. Researchers also proposed incorporating 1% shredded face masks into recycled concrete aggregate to increase compressive strength. Furthermore, Hill et al. (2020) discovered that by repurposing existing drugs for COVID-19 treatment, the mortality rate and manufacturing costs could be reduced.

2.2 Integrating Industry 4.0- RMS practices

The COVID-19 pandemic has had a significant impact on several manufacturing organizations and their production operations. The pandemic has also had an impact on the market, as the demand for certain types of products, such as sanitizer, masks, and PPE kits, has increased significantly, while the demand for other types of products has decreased significantly. Furthermore, the World Health Organization (WHO) had published a list of critical products to tackle

Table 1 Contribution of researchers for RPO

Sr. No.	Authors	Objectives	Outcomes
1.	(López-Gómez et al. 2020)	To review the challenges for repurposing the manufacturing activities and ways to mitigate them	A roadmap is prepared for rapid repurposing
2.	(Deshmukh and Haleem 2020)	To give an Indian perspective for enhancing post-COVID manufacturing activities. He also involved stakeholders during this process	The conceptual framework is prepared to assess Indian industries
3.	(Liu and Beltagui 2021)	To accelerate the process of innovation through repurposing, its application for manufacturing and design	Suggested the ability of exapt for design and manufacturing
4.	(Saberian et al. 2021)	Repurposing of single-use face masks to reduce waste	The compressive strength is enhanced
5.	(Hill et al. 2020)	To minimize the cost of manufacturing new drugs for the treatment of COVID-19 through repurposing	Repurposed drugs can be manufactured at a low cost

the COVID-19 outbreak and had advised several countries to increase the production of these products (López-Gómez et al. 2020; Qi et al. 2021). Despite the many efforts made by manufacturing organizations, there was still a demand–supply gap, and as a result, manufacturing organizations were shifting to other alternatives. Many governments around the world were encouraging manufacturers to repurpose their production lines to narrow the gap between demand and supply (López-Gómez et al. 2020). As a result, many manufacturing industries were attempting to cope with the situation by employing advanced technologies, while researchers are also contributing to this through their research into advanced technologies and practices. According to Javaid et al. (2020), advanced Industry 4.0 technologies such as information technology may assist manufacturing industries in customizing their products such as gloves, masks, and many others. Javaid et al. (2020) went on to say that the facilities available at Industry 4.0 factories, such as wireless connectivity, sensors, artificial intelligence, etc., can help with RPO. The incorporation of video surveillance and sensors into healthcare products may reduce the workload of COVID-19 doctors. Industry 4.0 information technologies may also assist doctors and staff in maintaining the necessary information to avoid misinformation.

Furthermore, due to changes in product demand, many industries are forced to transition to new products during pandemics. However, insufficient flexibility in the manufacturing system is preventing capacity adjustment and product switchover (Qi et al. 2021). Manufacturing systems, technologies, and practices that assist in this transition are becoming increasingly important at this time. Information technologies and Industry 4.0 are largely assisting in the automation of the manufacturing of healthcare-related products, whereas RMS is assisting in the adjustment of production capacity and required flexibility (Qi et al. 2021). The RMS core characteristics (Modularity, Integrability, Customization, Convertibility, Diagnosability, and Scalability) provide the required flexibility to the manufacturing system and allow it to adjust production capacity in response to market demand (Pansare et al. 2021b). In addition, Psarommatis (2021) used several Industry 4.0 technologies for zero defect manufacturing (ZDM), including Cyber-Physical System (CPS), Artificial Intelligence (AI), Big Data, Cloud Manufacturing, etc. ZDM can be implemented in two stages using these technologies, triggering factors (detection, prediction) and actions (repair, prevention) that may result in improved quality and cost savings. Malik et al. (2020) further said that Industry 4.0 technologies like robots, IoT, etc. could help ramp up ventilator production during a pandemic. Researchesrs demonstrated a model for integrating robots and design guidelines. Morgan et al. (2021) conducted a review of RMS articles and investigated next-generation machines equipped with Industry 4.0 technologies and reconfigurable capabilities. Furthermore, many researchers in the Industry 4.0 and RMS domains attempted to investigate the impact of these technologies and practices in manufacturing in terms of cost, productivity, economy, forecasting, quality, etc. (Bortolini et al. 2018; Jaskó et al. 2020; Liu et al. 2020). Such RMS capabilities can assist in RPO and may help in dealing with pandemic situations; thus, it was necessary to identify major Industry 4.0-RMS practices. The effectiveness of these practices during RPO due to the COVID-19 pandemic must also be measured; thus, the performance metrics identified through the literature review are listed in Table 2.

The advanced technologies of Industry 4.0 and RMS practices can help on a large scale to handle the pandemic situation; meet customer needs, customize required products, and bridge the demand–supply gap. Table 3 shows how the nexus practices assist in overcoming the challenges posed by COVID-19, as well as a set of performance metrics used to assess the effectiveness of the practices.

Table 2 Industry 4.0-RMS practices

Industry 4.0 technologies	RMS practices	Reference
AI, Internet of things (IoT), Big data, Virtual reality, Holography, Cloud computing, Autonomous robots, 3D scanning, 3D printing, Biosensors	-	(Javaid et al. 2020)
CPS, IoT, Machine Learning, Big Data, Cloud Manufacturing, Smart Sensors Network	-	(Psarommatis 2021)
Human–Robot collaborative systems, IoT, Augmented Reality, Big data, additive manufacturing	Modularisation, Digital twins, Industrial Robots	(Malik et al. 2020)
Computational agents, Holonic systems, Service Oriented Architecture, IoT, CPS, Digital Twins	Reconfigurable Machine Tools (RMT), Machine control, Human–Machine interface, Horizontal & Vertical integration, Distributed & decentralized control	(Morgan et al. 2021)
-	AI, Big data, Digital Twins, Virtual models	(Qi et al. 2021)
Cybersecurity, IoT connectivity, Digital Twins, Horizontal & Vertical integration	-	(Jaskó et al. 2020)
CPS, Digital Twins	Configuration design, Optimization	(Liu et al. 2020)
Internet & Wireless Local Area Network, Robots	Reconfigurable ability, tool replacement	(Xu et al. 2021)
Advanced manufacturing solutions, Additive manufacturing, Augmented reality, Simulation, Horizontal & Vertical integration, Industrial internet, Cloud, Cyber-security, Big-data & Analytics	Configuration design, Optimization, Customized products, Quality, Testing	(Bortolini et al. 2018)
-	Prognostics & health management, Cyber-physical systems, Maintenance optimization & Scheduling	(Xia and Xi 2017)
-	CPS, 3D printing, Holonic control, Optimization, controller designs	(Kruger and Basson 2019)
-	Digital Twins, Rapid reconfiguration, Architecture design, CPS, IoT, Smart manufacturing	(Jiewu et al. 2020)
Sustainability, life standard, creativity, High quality, Customization	Reconfigurability, Optimization, waste reduction, Product & Process quality	(Massimi et al. 2020)
-	Total Quality Management (TQM), Mass customization, Concurrent Engineering, Real-time control, Human resource, Shorter lead time	(Bi et al. 2008)
-	Sustainability, Reusability, Environmental emissions,	(Kurniadi and Ryu 2020)

It is also necessary to assess the effectiveness of this nexus effect during RPO, and thus performance metrics are required (Chandak et al. 2022). The performance metrics that can evaluate the performance of the system during RPO have been identified through a literature review, as shown in Table 3. It should be noted that the important performance metrics in RMS are reconfiguration time, which represents the time required to switchover the product (Huang et al. 2019), manufacturing cost (Chen and Huang 2006), reconfiguration cost, and lead time (Puik et al. 2017), which represents the time from order placement to product delivery. Fatimah et al. (2020) considered several dimensions during his waste management study, including employee retention, manpower required, employee availability, etc., that can be used to determine its maturity level. Employee retention indicates how long an employee has been providing a service to the organization, whereas employee availability indicates the absenteeism due to illness or other reasons. These are also significant factors during RPO and must be taken into account. The authors also considered the availability of advanced technologies such as soft computing and advanced machines, as well as energy consumption, as evaluation dimensions. Yurdakul (2002) considered several factors related to product quality such as scrap rate, defectives ratio, customer complaints such as guarantee/warranty, etc. when measuring the performance of a manufacturing system. Here, the scrap rate represents manufacturing rejections, whereas the defectives ratio represents the total number of defectives that require rework or rejections. Furthermore, while evaluating RMS performance, Garbie (2014a, b) took into account machine utilization, throughput, cycle time, breakdowns, etc. The set of performance metrics identified through this literature review may enable an evaluation of the current state of RMS during RPO and the identification of development opportunities.

2.3 Literature gaps

An extensive literature review of articles on Industry 4.0, RMS, and COVID-19 is conducted, and the research gaps are identified as listed below.

Table 3 Nexus effect of Industry 4.0-RMS practices

Challenges incurred due to COVID-19	Industry 4.0-RMS practices	Nexus effect to overcome the challenges	Performance metrics
Rapid increase in demand for particular products like masks, sanitizer, etc	RMT, Scalability, CPS, Customization, Reconfigurability	RMS's scalability enables it to increase production, whereas reconfigurability enables it to switch from one product to another	• Reconfiguration time • Manufacturing cost • Lead time • Employee retention • Number of defectives per day • Reconfiguration cost • Throughput material • Number of warranty/ guarantee claims per year • Machine utilization • Total manpower requirement • Number of soft computing technologies available • Number of breakdowns per fortnight • Cycle time • Overall energy consumption • Number of advanced machines available • Number of training sessions conducted • Number of customized products • Ratings received for online customer feedback • Number of accidents per month • Financial performance (profit percentage) • Number of RMT available • Employee availability • Scrap rate
Unavailability of manpower due to lockdown	Autonomous robots, IoT, Cloud Manufacturing, Smart Sensors Network, CPS, Internet & Wireless Local Area Network	Automation of manufacturing activities in RMS and Industry 4.0 may assist in operating with fewer employees. In addition, IoT, cloud manufacturing, and wireless networks allow for remote work	
Disturbed supply chain management	IoT, Internet & Wireless Local Area Network	The online services that use IoT, the internet, and wireless networks allow for the timely delivery of products. It also allows you to order the raw materials you need	
Increased requirement of customized products	Customized products, customization, creativity,	The ability of RMS and Industry 4.0 permits to satisfy these requirements	
Need of required medical standards	Product & Process Quality, Quality, Testing	The ability to manufacture quality products and testing practices enables the production of products that meet the required standards	
Cost expectations and financial crisis	Optimization, waste reduction	The optimization and waste minimization practices of RMS may assist to meet this challenge	
Protect the employees/ workforce	Autonomous robots, IoT, Cloud Manufacturing, Smart Sensors Network, CPS, Internet & Wireless Local Area Network	Employees must be protected from COVID-19 infections in the workplace. IoT, CPS, cloud manufacturing, and other technologies assist organizations in maintaining a safe distance and avoiding infections	
Business continuity risk and its management	RMT, Scalability, CPS, Customization, Reconfigurability, creativity, Optimization	The nexus effect of Industry 4.0-RMS provides the ability to anticipate likely fluctuations in product demand and the plant's reconfigurability to respond to them. Because of this, business continuity can be ensured	
Maintaining global competitiveness	Optimization, waste reduction, Product & Process Quality, Quality, Testing, Customization	The international supply chain has been impacted by COVID-19, and manufacturing industries are struggling to supply products at the lowest possible cost to maintain competitiveness. It is assisted by the practices mentioned above	
Maintaining productivity along with social distancing	Autonomous robots, IoT, Cloud Manufacturing, Smart Sensors Network, CPS, Internet & Wireless Local Area Network	The advanced technologies and practices of Industry 4.0-RMS allow for social distance while maintaining manufacturing system productivity	

- Several RMS and Industry 4.0 researchers have contributed to this area to increase system adoption and performance. However, the overall representation of Industry 4.0 technologies was seen in very few articles, while the listing of RMS practices was quite lacking in the available literature.
- Although few researchers attempted to identify the challenges faced by manufacturing industries during the COVID-19 pandemic, the use of various technologies and practices to overcome these challenges went unnoticed in the literature.
- Almost no researchers had described the use of the nexus effect of Industry 4.0-RMS to overcome the COVID-19 pandemic and other challenges.
- The framework for overcoming COVID-19 pandemic challenges in the manufacturing sector was quite lacking in the available literature. The previous researchers also did not participate in the development of a set of performance metrics to assess the effectiveness of the prepared framework. Furthermore, the prepared framework must be tested using industrial case analysis.
- Case studies that describe the success stories of using Industry 4.0 and RMS to switchover production as well as adjust production capacity to another product to bridge the supply–demand gap were attended by almost no researchers.
- While maintaining reconfigurability and customization during production, researchers in this domain almost completely ignored the process of incorporating sustainability in the product as well as the manufacturing system.
- The use of Multi-Criteria Decision Making (MCDM) techniques to create a framework that can assist researchers and practitioners in determining the relative importance of practices and performance metrics was lacking in the existing literature. In addition, the inclusion of expert opinion in the preparation of such a framework was seen in only a few articles.
- Researchers in this domain had not yet addressed the methodology for improving and sustaining the supply chain of the manufacturing system in such a pandemic situation.

The gaps identified through the literature review demonstrated the need to prepare the framework for RPO due to the COVID-19 pandemic, which can assist researchers and practitioners in repurposing and ramping up their production activities. As discussed in Sect. 1, López-Gómez et al. (2020) highlighted the need to prepare a roadmap for repurposing manufacturing activities; thus, the identified research gaps were supported, and such a framework can assist in determining the nation's priorities. In addition, during a pandemic, this may help to bridge the demand–supply gap. As stated in the study objectives, the current study focuses on the development of a framework for the RPO and the prioritization of performance metrics that can be used to evaluate the performance of the manufacturing system. As a result, the study attempted to fill the above-mentioned research gap using expert opinion.

3 Research methodology

Initially, an extensive literature review of RMS and Industry 4.0 articles was conducted to identify the technologies and practices used during product manufacturing. For this purpose, the Scopus database was used, and the identified technologies and practices were presented to the expert panel. According to the expert panel's (please see Sect. 4.1 for more information) recommendations, they were further sorted and classified as advanced machines, scalability practices, quality practices, reconfiguration practices, and remote technologies. The expert panel was also asked to give opinion for the hybrid Pythagorean fuzzy AHP – CoCoSo approach. Based on this, the RPO framework was developed, as discussed in the following section. The Pythagorean fuzzy AHP was used to compute the weights of the major and sub-criteria, whereas the CoCoSo method was used to rank the performance metrics and compute the adoption index. Finally, the sensitivity analysis was performed, and the study's implications were listed. The sensitivity analysis was carried out to ensure that the developed framework is robust. Figure 1 depicts the research methodology used for the current study.

4 Case analysis

4.1 Industry identification and data collection

The primary goal of the presented study was to develop a framework that could assist practitioners during RPO via RMS and Industry 4.0 during the COVID-19 pandemic; thus, twenty different manufacturing industries were approached and the entire concept was explained to them. Three industries agreed to participate in the process; however, it was a difficult task for the authors to select these industries because they must be similar in terms of products manufactured, turnover, capacity, number of employees, etc. As a result, the three industries that were ultimately chosen are involved in the production of various types of plastic bottles, employing approximately 125 people, including technical and non-technical staff. All three industries have a monthly capacity of approximately 10,000 bottles and an annual turnover of 55 to 60 crore rupees. The manufactured bottles are used for a variety of applications including drinking water, sanitizer dispensing, healthcare applications, etc.

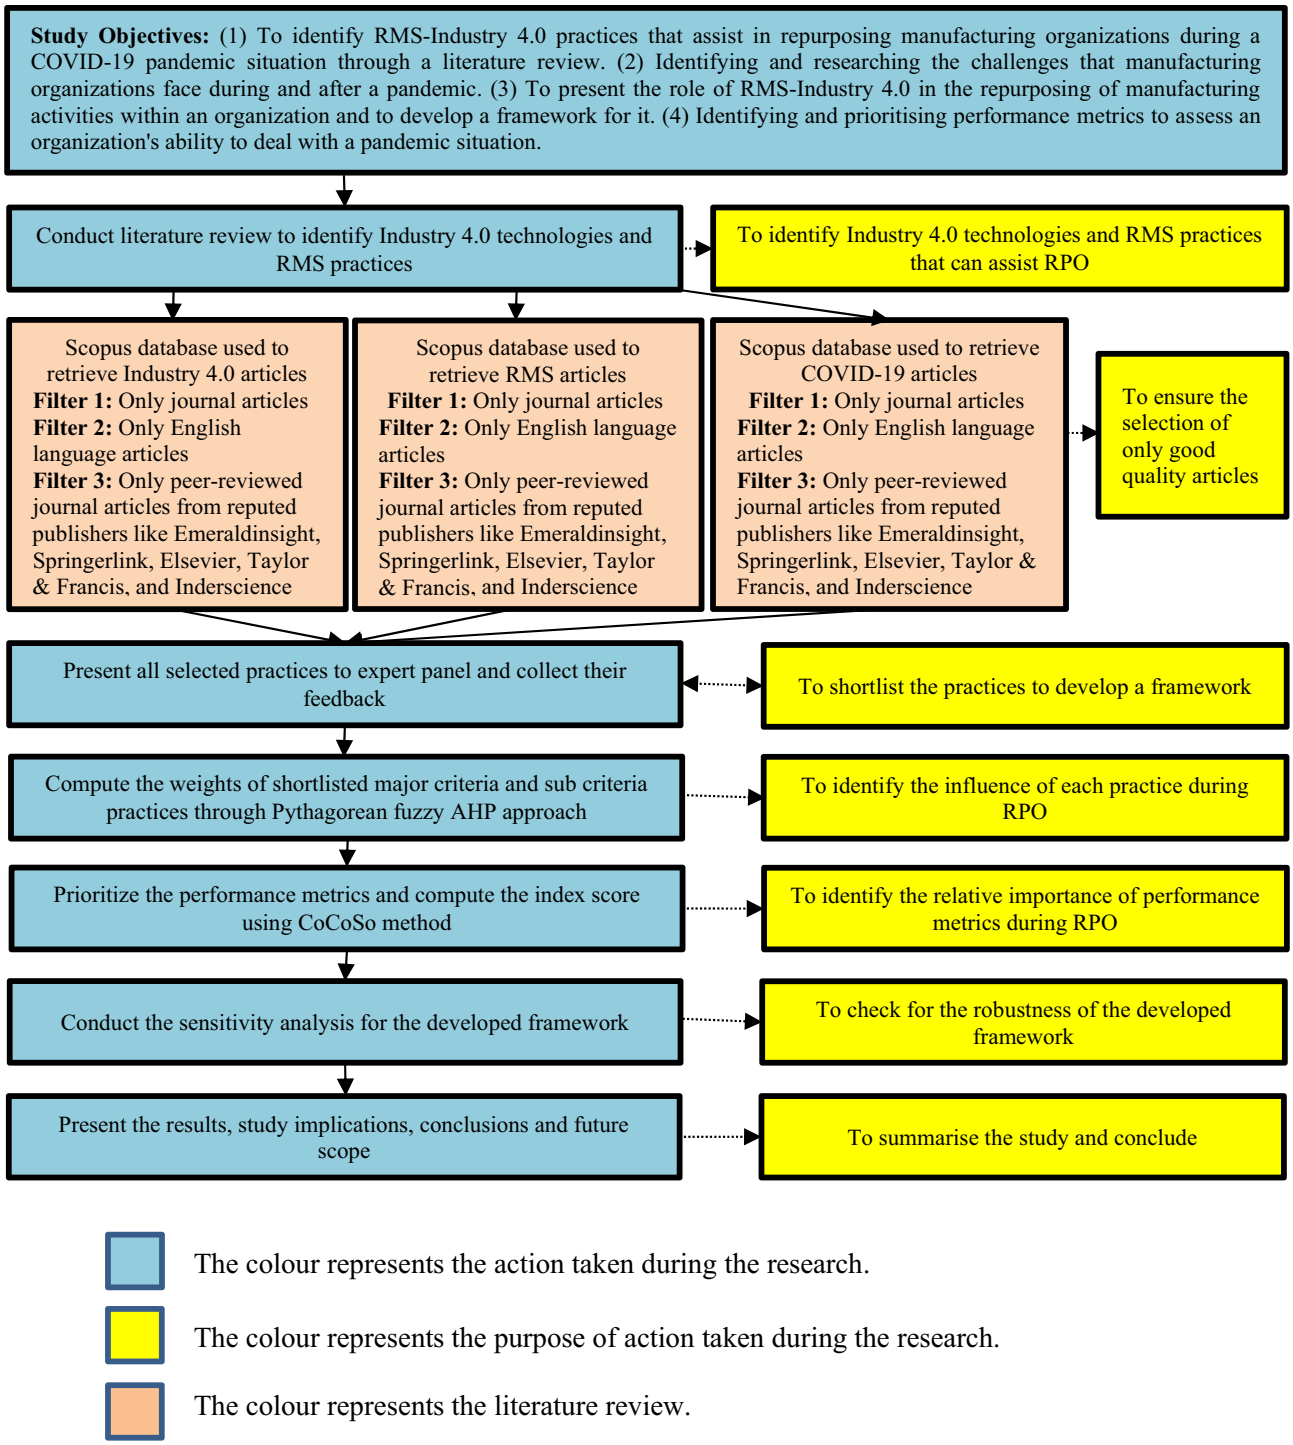

Fig. 1 Research methodology

The bottles produced are shipped to various parts of India as well as to countries outside of India. Following a lengthy discussion with industry officials, it was decided to form a panel of experts comprised of 15 members from various industries to ensure that the proposed framework development process is carried out effectively. As summarised in Table 4, all of the experts were highly qualified and had extensive experience in a variety of fields.

Following a series of meetings with the expert panel, the identified Industry 4.0-RMS practices were further filtered, and the ultimately selected practices were further classified, as discussed in Sect. 4.2. The expert panel was now tasked

with creating a pairwise comparison for major criteria and sub-criteria practices. For the initial pairwise comparison required by the CoCoSo approach, expert opinion was also gathered, standard weight computation and prioritization process was executed, the results were presented and discussed with the expert panel, and minor changes were made in accordance with the panel's recommendations.

4.2 Framework development

The chosen practices were then presented to an expert panel for their input, and minor changes were made based on their suggestions. The expert panel also proposed categorizing the practices into five major criteria, as depicted in Fig. 2.

The developed framework have five levels, as shown in Fig. 2. Level 1 includes the developed framework's objective as well as indications of where the framework can be applied. Level 2 displays the major criteria practices to highlight the categorization of the selected practices based on the expert panel's recommendations. The major criteria practice indicates the area of application of selected practices, which can assist practitioners to implement them. Level 3 displays the sub criteria practices according to the major criteria practices to which they belong. This is the most important level for the framework because it contains several sub-criteria practices to be used for RPO. Level 4 of the developed framework lists the selected performance metrics. This can help practitioners evaluate the effectiveness of the adopted practices in the manufacturing system, as well as identify areas for further improvement. Finally, level 3 displays the five organizations where the expert panel formation and framework case analysis was carried out. The framework depicted in Fig. 2 demonstrates how it can be implemented in the organization in stages and evaluated using a set of performance metrics. This can help practitioners understand the chronology in which the framework must be implemented.

4.3 Framework analysis

The hybrid Pythagorean fuzzy AHP-CoCoSo method was used to compute the weights of selected Industry 4.0-RMS practices during RPO and performance metric ranking. The execution of the entire process is discussed further below.

4.3.1 Application of Pythagorean fuzzy AHP method

Many researchers have criticized the AHP process for the inaccuracy of the ranking and the need for interdependence among the criteria and alternatives, which can lead to inconsistencies (Bag et al. 2021). The intuitionistic fuzzy sets, hesitant fuzzy sets, and Pythagorean fuzzy sets all have the ability to deal with vagueness and uncertainty; however, the intuitionistic fuzzy sets are more capable of dealing with imprecision, whereas the hesitant fuzzy sets are made up of discrete values in the interval [0, 1] rather than a single number. Also, Pythagorean fuzzy sets give decision makers more flexibility when assigning values where the sum of membership and non-membership grades is greater than unity but the sum of squares is in the interval [0, 1]. To address this, Interval-valued Pythagorean fuzzy AHP was used, with the linguistic terms used listed in Table 5 (Bakioglu and Atahan 2021).

The following steps are to be executed for Pythagorean fuzzy AHP,

Table 4 Members of an expert panel

Expert code	Age group (Years)	Educational qualification	Role in industry	Department of work	Work experience (Years)
E1	41–50	Post graduate	Founder/Director	Administration	23
E2	31–40	Graduate	Manager	Design	18
E3	51–60	Ph. D	Vice president	Manufacturing	28
E4	41–50	Post graduate	Senior Manager	Manufacturing	23
E5	41–50	Post graduate	Sales Manager	Marketing	19
E6	41–50	Graduate	Logistics Manager	Administration	24
E7	60+	Ph. D	Consultant	Design	40
E8	21–30	Graduate	Production Engineer	Manufacturing	06
E9	51–60	Ph. D	Senior Manager	Manufacturing	31
E10	41–50	Post graduate	Senior Manager	Design	23
E11	51–60	Post graduate	Director	Administration	32
E12	41–50	Graduate	Production Manager	Manufacturing	22
E13	51–60	Post graduate	General Manager	Manufacturing	33
E14	51–60	Post graduate	Senior Manager	R & D	32
E15	51–60	Ph. D	Senior Manager	Design	25

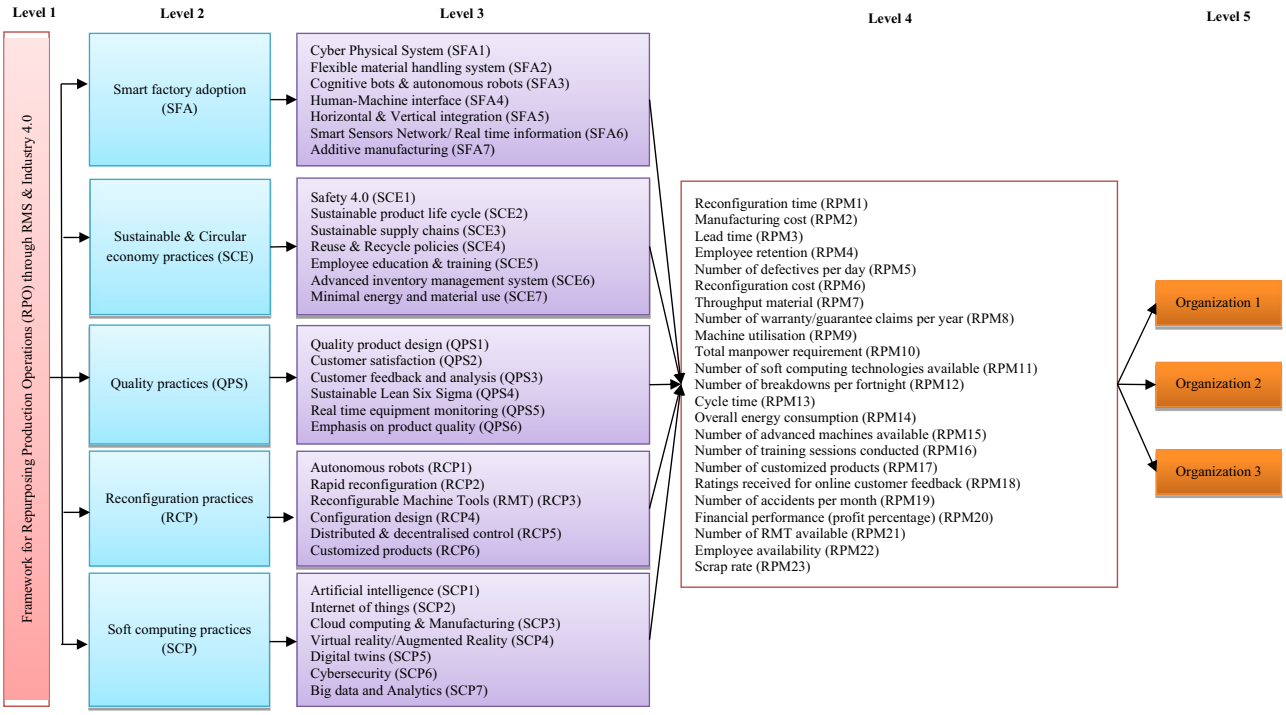

Fig. 2 A developed framework for prioritizing RPO performance metrics

Step 1: Identify the alternatives (i = 1, 2,…, m)
Step 2: Construct the pairwise comparison matrix $A = (a_{ik})_{m\times m}$
Step 3: Compute the difference matrices $D = (d_{ik})_{m\times m}$
Step 4: Compute the interval multiplicative matrix $S = (s_{ik})_{m\times m}$
Step 5: Calculate the determinacy value $\tau = (\tau_{ik})_{m\times m}$
Step 6: Compute the matrix of weights $T = (\tau_{ik})_{m\times m}$
Step 7: Compute the normalized weights w_i using the following equation,

$$w_i = \frac{\sum_{k=1}^{m} t_{ik}}{\sum_{i=1}^{m}\sum_{k=1}^{m} t_{ik}}$$

Table 5 Linguistic terms used in Pythagorean fuzzy AHP

Linguistic variables	Pythagorean fuzzy numbers			
	μ_L	μ_U	V_L	V_U
Certainly low importance (CLI)	0.00	0.00	0.90	1.00
Very low importance (VLI)	0.10	0.20	0.80	0.90
Low importance (LI)	0.20	0.35	0.65	0.80
Below average importance (BAI)	0.35	0.45	0.55	0.65
Average importance (AI)	0.45	0.55	0.45	0.55
Above average importance (AAI)	0.55	0.65	0.35	0.45
High importance (HI)	0.65	0.80	0.20	0.35
Very high importance (VHI)	0.80	0.90	0.10	0.20
Certainly high importance (CHI)	0.90	1.00	0.00	0.00
Exactly equal (EE)	0.1965	0.1965	0.1965	0.1965

The sample pairwise comparison by one of the experts is shown in Table 6.

As previously stated, the experts' opinions were gathered for pairwise comparisons of major criteria as well as sub-criteria Practices, and the weights were computed using Pythagorean fuzzy AHP. As shown in Table 7, this is followed by the computation of global weights for sub-criteria Practices.

4.3.2 Application of Pythagorean fuzzy CoCoSo approach

Yazdani et al. (2019) proposed a novel CoCoSo method, where the obtained solution is consistent with weight variation, providing stability to the decision-making process when compared to other techniques. Also, when compared to other techniques, the CoCoSo method combines the simple additive method with the exponentially weighted product method to obtain the compromise solution (Yadav et al. 2021). Reasearchers also included a Pythagorean fuzzy set in this method, which can effectively deal with uncertain issues in decision-making. Another reason for using this method was the total absence of counterintuitive phenomena, as well as the higher resolution when distinguishing between alternatives. Due to the Pythagorean fuzzy set, the approach can effectively deal with uncertainty issues and can differentiate the best alternative. The steps in the Pythagorean fuzzy CoCoSo method are as follows (Lahane and Kant 2021).

Table 6 Pairwise comparison for smart factory adoption practices

Criteria	SFA1	SFA2	SFA3	SFA4	SFA5	SFA6	SFA7
SFA1	EE	BAI	HI	BAI	AAI	AAI	LI
SFA2	AAI	EE	BAI	AAI	LI	LI	AI
SFA3	AAI	AAI	EE	HI	HI	HI	HI
SFA4	BAI	AI	AI	EE	LI	BAI	LI
SFA5	HI	AAI	AAI	AI	EE	HI	AAI
SFA6	AAI	BAI	AI	EE	AAI	EE	BAI
SFA7	HI	HI	AI	LI	EE	AAI	EE

Step 1: Initially, the decision matrix $D = (d_{ij})_{m\times n}$ where, (i = 1, 2,…m; j = 1, 2,…n) is to be constructed using the linguistic scale as shown in Table 8 and expert opinion.

Step 2: The linguistic decision matrix is then converted into Pythagorean fuzzy decision matrix as per the equation $P = (P_{ij})_{m\times n}$ where, (i = 1, 2,…m; j = 1, 2,…n)

Table 7 Global weights of major and sub-criteria practices

Major Criteria	Major criteria weights	Sub-criteria	Sub-criteria weights	Global weights
Smart factory adoption (SFA)	0.2214	Cyber Physical System (SFA1)	0.1661	0.0368
		Flexible material handling system (SFA2)	0.1307	0.0289
		Cognitive bots & autonomous robots (SFA3)	0.1457	0.0322
		Human–Machine interface (SFA4)	0.1352	0.0299
		Horizontal & Vertical integration (SFA5)	0.1399	0.0310
		Smart Sensors Network/ Real time information (SFA6)	0.1251	0.0277
		Additive manufacturing (SFA7)	0.1574	0.0348
Sustainable & Circular economy practices (SCE)	0.1905	Safety 4.0 (SCE1)	0.1624	0.0309
		Sustainable product life cycle (SCE2)	0.1327	0.0253
		Sustainable supply chains (SCE3)	0.1482	0.0282
		Reuse & Recycle policies (SCE4)	0.1331	0.0253
		Employee education & training (SCE5)	0.1407	0.0268
		Advanced inventory management system (SCE6)	0.1283	0.0244
		Minimal energy and material use (SCE7)	0.1546	0.0294
Quality practices (QPS)	0.1860	Quality product design (QPS1)	0.1739	0.0323
		Customer satisfaction (QPS2)	0.1679	0.0312
		Customer feedback and analysis (QPS3)	0.1577	0.0293
		Sustainable Lean six sigma (QPS4)	0.1652	0.0307
		Real time equipment monitoring (QPS5)	0.1535	0.0286
		Emphasis on product quality (QPS6)	0.1818	0.0338
Reconfiguration practices (RCP)	0.2068	Autonomous robots (RCP1)	0.1598	0.0330
		Rapid reconfiguration (RCP2)	0.1798	0.0372
		Reconfigurable Machine Tools (RMT) (RCP3)	0.1760	0.0364
		Configuration design (RCP4)	0.1671	0.0346
		Distributed & decentralised control (RCP5)	0.1519	0.0314
		Customized products (RCP6)	0.1654	0.0342
Soft computing practices (SCP)	0.1953	Artificial intelligence (SCP1)	0.1538	0.0300
		Internet of things (SCP2)	0.1453	0.0284
		Cloud computing & Manufacturing (SCP3)	0.1504	0.0294
		Virtual reality/Augmented Reality (SCP4)	0.1402	0.0274
		Digital twins (SCP5)	0.1338	0.0261
		Cybersecurity (SCP6)	0.1399	0.0273
		Big data and Analytics (SCP7)	0.1366	0.0267

Step 3: The score function is to be computed using $R = (r_{ij})_{m\times n}$ using the equation,

$$r_{ij} = \mu_{ij}^2 - \nu_{ij}^2 - \ln(1+\pi_{ij}^2)$$

Step 4: The score function matrix is then to be converted into an orthogonal Pythagorean fuzzy matrix $R' = (r'_{ij})_{m\times n}$ by using the following equation,

$$r'_{ij} = \begin{cases} \frac{r_{ij}-r_j^-}{r_j^+-r_j^-}, & if\ j \in B, \\ \frac{r_j^+-r_{ij}}{r_j^+-r_j^-}, & if\ j \in C \end{cases}$$

where, $r_j^- = \min r_{ij}$ and $r_j^+ = \max r_{ij}$

Step 5: Using the following equation, compute the weighted comparability sequence.

$$S_i = \sum_{j=1}^{n} w_j * r'_{ij}$$

Step 6: The power weight of comparability sequences is to be computed now for each alternative.

$$P_i = \sum_{j=1}^{n} (r'_{ij})^{w_j}$$

Step 7: For each alternative, the relative weight is determined using an equation,

$$K_{ia} = \frac{P_i + S_i}{\sum_{i=1}^{m}(P_i + S_i)}$$

$$K_{ib} = \frac{S_i}{\min\limits_i S_i} + \frac{P_i}{\min\limits_i P_i}$$

Table 8 Linguistic scale for Pythagorean fuzzy CoCoSo method

Linguistic term	Pythagorean fuzzy number	
	μ	ν
Extremely low (EL)	0	1
Very low (VL)	0.1	0.9
Low (L)	0.2	0.8
Middle low (ML)	0.3	0.7
Below middle (BM)	0.4	0.6
Middle (M)	0.5	0.5
Above middle (AM)	0.6	0.4
Middle high (MH)	0.7	0.3
High (H)	0.8	0.2
Very high (VH)	0.9	0.1
Extremely high (EH)	1	0

$$K_{ic} = \frac{\lambda S_i + (1-\lambda)P_i}{\lambda \overset{max}{_i} S_i + (1-\lambda)\overset{max}{_i} P_i} 0 \le \lambda \le 1$$

Step 8: Compute the assessment value (K_i) by using an equation,

$$K_i = \sqrt[3]{K_{ia}K_{ib}K_{ic}} + \frac{K_{ia}+K_{ib}+K_{ic}}{3}$$

Step 9: The selected alternatives are ranked based on descending order of K_i

The linguistic decision matrix prepared with expert opinion for the selected performance metrics is shown in Table 9, and the ranking obtained for performance metrics after following the procedure for the Pythagorean fuzzy CoCoSo method is shown in Table 10.

4.4 Sensitivity analysis

It is critical to perform sensitivity analysis tests to ensure the suitability of the developed framework as well as its behavior under varying conditions (Yadav et al. 2020). The weights were varied by 5% and 10%, resulting in a total of 23 experiments, the details of which are shown in Table 11 and the results of which are shown in Fig. 3. Figure 3 shows that there are fewer variations in RPM 10, whereas significant variations are seen in other performance metrics. However, no significant change in ranking was observed, indicating that the developed framework is robust under varying conditions.

5 Discussion on results

The results obtained through the Pythagorean fuzzy AHP-CoCoSo method and its implications are discussed in the current section.

5.1 Study findings

During this study, an extensive literature review was conducted, and 33 Industry 4.0 technologies and RMS practices, as well as 23 performance metrics, were identified. To compute the weights of the selected practices, the Pythagorean fuzzy AHP method was used, while the Pythagorean fuzzy CoCoSo method was used to prioritize the selected performance metrics. The current section discusses the obtained results.

Among the major criteria practices, smart factory adoption received the most weight, indicating that SFA practices are extremely beneficial to RPO. Morgan et al. (2021) conducted a review of RMS and Industry 4.0 technologies

Table 9 Linguistic decision matrix for Pythagorean fuzzy CoCoSo method

that were useful during COVID-19 and presented a vision of next-generation manufacturing machines that supported the current findings. Morgan et al. (2021) examined several smart technologies and smart machines that can be useful during a pandemic. Such technologies give the manufacturing system flexibility while also reducing lead time and manufacturing costs. The reconfiguration practices came in second, emphasizing the importance of reconfigurability and the technologies required for it. A similar discussion was observed in the article Prasad and Jayswal (2018), where the researchers stated that RMS is capable of adjusting its capacity and functionality as it can be upgraded to current technology. This can help manufacturing systems quickly transition to a new product in response to market demands. Also. Soft computing practices such as AI, IOT, cloud computing, BDA, etc. are extremely useful in such situations; thus, SCP was ranked third. During his literature review, Morgan et al. (2021) discussed the same and summarized the importance of such technologies in RMS and pandemic situations. The SCE and QPS ranked fourth and fifth, indicating that these practices are equally important for remaining competitive in the market.

According to global weights, rapid reconfiguration has obtained the maximum weight, implying that RMS reconfigurability is critical during pandemic to meet changing customer needs. Several researchers, including Morgan et al. (2021), had emphasized RMS's capability. According to Prasad and Jayswal (2018), the reconfigurability of the manufacturing system is assessed in terms of cost, time, and effort for product changeover, all of which are significant factors during a pandemic. The CPS and RMT have occupied the second and third positions in terms of global weight, highlighting the importance of technologies for RPO. According to Morgan et al. (2021), several technologies such as CPS and RMT that enable RMS to be capable of smart manufacturing are extremely useful during pandemic situations because they can help to increase reconfigurability and flexibility. Practices such as additive manufacturing also assist in product development; thus, during pandemic situations where demand is constantly changing, the practice is extremely beneficial for RPO. As Dantas et al. (2021) discussed, technologies such as CPS and additive manufacturing can help during product optimization and thus reduce product cost to help RPO. RMS practises such as configuration design and the ability to provide customized products were ranked fifth and sixth, respectively. These practices can help meet volatile customer demands in a pandemic situation while keeping manufacturing costs to a minimum. Among the QPS, the RMS feature, i.e. the emphasis on product quality, was the most important and ranks seventh. Because the RMS focuses on product flexibility and quality (Bortolini et al. 2018), the expert panel may gave it the most weight.

Table 10 Ranking obtained using Pythagorean fuzzy CoCoSo method

Code	Performance Metrics	K_{ia}	K_{ib}	K_{ic}	K_i	Rank obtained
RPM1	Reconfiguration time (RPM1)	0.0449	6.1364	1.0000	3.0447	1
RPM2	Manufacturing cost (RPM2)	0.0446	5.6199	0.9929	2.8483	3
RPM3	Lead time (RPM3)	0.0445	5.5857	0.9892	2.8327	4
RPM4	Employee retention (RPM4)	0.0422	3.1040	0.9381	1.8584	21
RPM5	Number of defectives per day (RPM5)	0.0439	4.5503	0.9779	2.4378	14
RPM6	Reconfiguration cost (RPM6)	0.0445	5.6710	0.9892	2.8643	2
RPM7	Throughput material (RPM7)	0.0397	2.0738	0.8835	1.4165	23
RPM8	Number of warranty/guarantee claims per year (RPM8)	0.0445	5.5470	0.9904	2.8193	6
RPM9	Machine utilisation (RPM9)	0.0444	5.2418	0.9878	2.7039	8
RPM10	Total manpower requirement (RPM10)	0.0436	4.0553	0.9696	2.2449	17
RPM11	Number of soft computing technologies available (RPM11)	0.0443	5.1062	0.9863	2.6522	9
RPM12	Number of breakdowns per fortnight (RPM12)	0.0432	3.6334	0.9615	2.0785	19
RPM13	Cycle time (RPM13)	0.0441	5.0391	0.9814	2.6235	10
RPM14	Overall energy consumption (RPM14)	0.0433	3.8016	0.9634	2.1440	18
RPM15	Number of advanced machines available (RPM15)	0.0445	5.5776	0.9913	2.8313	5
RPM16	Number of training sessions conducted (RPM16)	0.0441	4.8238	0.9810	2.5427	11
RPM17	Number of customized products (RPM17)	0.0439	4.4843	0.9758	2.4115	15
RPM18	Ratings received for online customer feedback (RPM18)	0.0436	4.0843	0.9694	2.2557	16
RPM19	Number of accidents per month (RPM19)	0.0440	4.6731	0.9793	2.4850	13
RPM20	Financial performance (profit percentage) (RPM20)	0.0440	4.8021	0.9793	2.5333	12
RPM21	Number of RMT available (RPM21)	0.0443	5.3003	0.9863	2.7245	7
RPM22	Employee availability (RPM22)	0.0427	3.3704	0.9501	1.9696	20
RPM23	Scrap rate (RPM23)	0.0372	2.7420	0.8272	1.6406	22

The selected performance metrics were then ranked using the Pythagorean fuzzy CoCoSo method, with the descending order being RPM1 > RPM6 > RPM2 > RPM3 > RPM15 > RPM8 > RPM21 > RPM9 > RPM11 > RPM13 > RPM16 > RPM20 > RPM19 > RPM5 > RPM17 > RPM18 > RPM10 > RPM14 > RPM12 > RPM22 > RPM4 > RPM23 > RPM7. The reconfiguration time was on the first position, indicating the time required to switch to another product during RPO. According to Puik et al. (2017), reconfiguration time is an important factor in determining product lead time, whereas Garbie (2014a, b) stated that when evaluating RMS, reconfiguration is an extremely important issue. During RPO, it is critical that the required products reach the customers in a timely manner, which supports the obtained results. Because lockdown has significantly reduced consumer purchasing power, manufacturing costs and thus reconfiguration costs must be kept to a minimum. Similar discussions were observed in Xia et al. (2017), where the researchers attempted to reduce manufacturing costs by reducing reconfiguration cost; thus, reconfiguration cost was ranked second and manufacturing cost was ranked third. During the Covid-19 pandemic, lockdown had a significant impact on people's financial situation. As a result, manufacturers are struggling to produce products at the lowest possible cost and with the shortest possible lead time (López-Gómez et al. 2020). The lead time was ranked fourth, while the availability of advanced machines was ranked fifth. According to Morgan et al. (2021), advanced machines, particularly those with control capabilities, are extremely beneficial to reconfiguration tasks, which support the obtained results. Furthermore, as discussed by Morgan et al. (2021), RMS focuses on product quality; thus, warranty claims have occupied the sixth position in the ranking. During their study, the researchers also emphasised the importance of RMT, which supports the seventh position for the number of RMT available. The set of performance metrics and their ranking can help practitioners evaluate manufacturing systems and make decisions.

5.2 Theoretical implications

The work presented here contributes to the theory of Industry 4.0 and RMS in three parts. First, it broadens the application of the novel Pythagorean fuzzy AHP-CoCoSo method and may assist future researchers in using it in their research. During this process, a critical review of articles on Industry 4.0, RMS, and repurposing was conducted in order to identify the prominent practices that can assist RPO. This contributes to the theoretical enrichment of the manufacturing

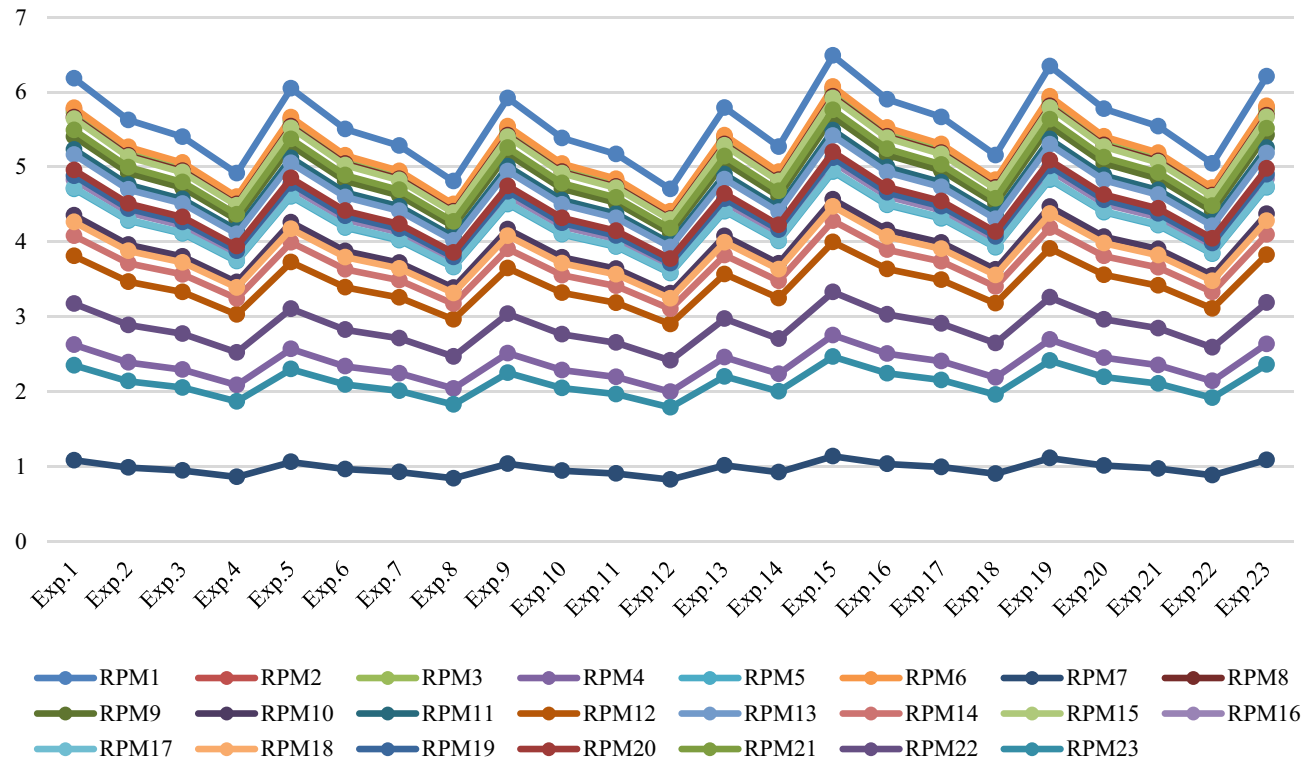

Fig. 3 Sensitivity analysis of K_i values

domain by demonstrating the useful framework development process by identifying practices and applied methods. The presented work's findings, as well as the relative importance of the practices and performance metrics, highlight the need for additional research in this domain to increase the adoption of selected practices. Researchers can use this as their future agenda and develop a detailed plan for implementing these practices in industries.

Second, as seen in a few articles, the presented research establishes a link between Industry 4.0 and RMS to assist RPO (Morgan et al. 2021). This demonstrates RMS's ability to adopt advanced Industry 4.0 technologies and provide manufacturing flexibility with the help of these technologies. As product complexity increases and customer demands become more customized, the developed framework and this connection can assist in satisfying such demands. This creates a strategy for dealing with the dynamic market demand situation as well as RPO due to a pandemic situation. This approach can be used to deal with future challenges, such as the ones we are currently facing due to COVID-19.

The importance of advanced technologies in manufacturing, as highlighted by the major criteria weights, was the third contribution. The study contributes to the proposition that important performance metrics such as lead time, flexibility, capacity, etc. are determinants of advanced technologies used in the manufacturing system. Furthermore, the set of identified performance metrics and their prioritization provides a roadmap for evaluating the manufacturing system and assessing the efficacy of the identified practices.

5.3 Managerial implications

The presented work have managerial implications too that can improve the adoption of RMS in industries and also assist during RPO. The proposed framework can assist managers in decision-making during the pandemic situation and for RPO that can benefit society during critical situations of a pandemic. The managers may refer to the framework, selected practices, and ranking so that decisions for step-by-step RPO can be taken effectively and efficiently. The proposed framework may also assist managers to evaluate the performance of the organization which can become the basis for future improvements. This can lead to social and economic benefits for an organization. The framework can assist managers to take care of several aspects simultaneously as listed in major criteria practices. The proposed framework may motivate managers to improve the infrastructure, technologies, and work culture in an organization. This may lead to the overall growth of the organization, improved customer satisfaction, and social contributions for fighting the pandemic situations by reducing the gap between demand and supply. The framework guides and motivates the managers

to switch over the products that are in large demand in a pandemic situation and also the products that require dealing with pandemic situations.

5.4 Implications for researchers and practitioners

The presented research has a significant contribution for researchers and practitioners of the RMS and Industry 4.0 domain. During the presented work, the key Industry 4.0-RMS practices were identified that can assist during RPO during the Covid-19 pandemic. This can also help to increase the adoption of RMS in the industries. The framework developed for RPO was rarely observed in the past literature; hence, it can assist the practitioners during decision making, implementing the selected practices, evaluating the performance of the organization, etc. The prioritized performance metrics may assist practitioners to decide a suitable action plan at the initial stage of RPO that can reduce the risk of failure. This may also assist during the successful adoption of RMS in the industry. It is slightly challenging to incorporate all the practices in any manufacturing system; however, the weights computed in the presented work may assist to decide the priority of their implementation during RPO. In practice, this means that among the SFA practices first preference must be given to the cyber-physical system and additive manufacturing as compared to real-time information systems. This may result in the efficient adoption of RMS during RPO. The RMS adoption is at the initial stage in developing countries like India. Also, most of the manufacturing countries around the globe are struggling for RPO during a pandemic situation. The researchers and practitioners may use the developed framework as a ready reference to increase their organizational performance. The identified and ranked performance metrics can also assist them during the evaluation of performance. The proposed framework can also assist to reduce the difficulties during the adoption of RMS in the Covid-19 pandemic as the framework provides a structured approach of the same. This may also assist in step-by-step improvement in the performance of the organization by incorporating the practices in ranked order. The developed framework may also lead to social, economic, and sustainability including environmental benefits as several aspects related to it have been taken care of while selecting the practices. It may also assist to frame the long-term strategy of the organization during a pandemic situation and may lead to high returns for the society. The proposed framework can assist in maintaining the supply chain during a pandemic situation as the organizations in several geographical locations think of RPO and bridge the gap between demand and supply of that area. This may also assist to boost the missions of countries like 'Make in India', 'clean India', etc.

6 Conclusion and future scope

The research presented here has provided a novel framework for RPO in which advanced Industry 4.0 technologies and RMS practices can greatly assist in dealing with pandemic challenges. To find answers to the proposed research questions, 33 Industry 4.0-RMS practices and 23 performance metrics were identified. Following that, the weights of selected practices were computed using the Pythagorean fuzzy AHP method, and performance metrics were prioritized using the CoCoSo technique. It was also ensured that the selected practices would be beneficial to RPO, and the performance metrics would reflect the effectiveness of the practices selected. When selecting practices and performance metrics, manufacturing companies' challenges are taken into account.

The efforts had resulted in the development of a framework that can assist in RPO in the post pandemic situation. The obtained results show that in the manufacturing industries, the adoption of advanced technologies such as SFA, which includes CPS, the use of robots, additive manufacturing, etc., is required for RPO. This suggests that advanced technologies and computer algorithms can greatly assist RPO during pandemic situations and that practitioners and decision-makers should focus on them for effective repurposing. Furthermore, practices such as RMT adoption and rapid reconfiguration are extremely beneficial for RPO and can help to reduce manufacturing costs. During the prioritization of performance metrics, reconfiguration time was ranked first, indicating the importance of the time required to switch to another product to meet dynamic customer needs in a pandemic situation. The cost of doing so is also important; thus, reconfiguration cost has taken the second place in the ranking. The top rankings of performance metrics show that manufacturing lead time and manufacturing costs are the top priorities for any company in a pandemic situation.

However, the presented research work may have some limitations and can be attempted by future researchers. The framework was prepared based on MCDM techniques and expert opinion, but, the expert opinions are always subjective, and biasing may impact the results. Hence, the computations using the hybrid approach have to be attempted with due care. Also, the framework development process and the case organization were restricted to the three organizations in the Indian manufacturing environment. The future research work may be extended to organizations from different geographical locations with required modifications and the results can be compared. More advanced MCDM techniques may also be employed for the same and the results may be compared.

Development of Ultra High Performance Concrete using Microfine and GGBS

Hitesh Makad
Civil Engineering Department
Pacific University, Udaipur, Rajasthan

Pradyumn Dashora
Assistant Professor, Civil Engineering Department
Pacific University, Udaipur, Rajasthan

Abstract: - Ultra high performance concrete is advanced level of concrete which possesses compressive strength in excess of 60 MPa. UHPC having good mechanical strength and durability. This provides long service life to the constructed structure with higher level of performance in terms of durability, performance, maintenance etc. In the present study the development of ultra high performance concrete by using Microfine and ground granulated blast furnace slag are used as a replacement of binding agent cement. The main aim is to develop Ultra high performance concrete which can give higher durability with greater performance and less maintenance of concrete during the service life of the structure. Ultra High Performance Concrete can also fulfill the requirement of architecture because it can be used for elevation design to make elevation more attractive and aesthetic along with that it also covers resistance against buckling behavior so that it will not buckle in case of Slender column.

Keywords:- *Mechanical Properties; Compressive Strength; Split Tensile Strength; Ground Granulated Blast Furnace Slag; Microfine etc.*

I. INTRODUCTION

The Ultra high performance concrete is the cementitious mixture which provides high mechanical strength with great performance. The world's population is getting increases very fast and there is requirements of efficient material in the construction are on the peak therefore the UHPC having potential to give best results in terms of both strength and performance. Research and development on new UHPC have been running from last 15 years and many researchers have given the solution for the proportion from which we can have high performance concrete related to strength and serviceability of concrete. This concrete can be used for Heavy Construction like Bridge, Dams, Flyover, Multi Storey Structure, Road pavement etc. Due to its performance it can create revolution in construction industry.

The construction material used to enhance the durability and workability of concrete are different types of fibers, micro fine, Ground granulated blast furnace slag etc. Concrete is the most popular and most consumed material in the construction industry and it has been used widely since the invention of the concrete and that also will be demanded in future.

At the time of invention of concrete nearby around 1960's the starting progress was very slow because the maximum compressive strength could achieve 15 MPa to 20 MPa only but now it has become very high like 80 Mpa to 100 MPa and even more. There is a increase in the strength along with the performance of the concrete and it's safe to use and have highly attracted the construction industry for concrete uses.

Because of the high costing the use of ultra high performance concrete is limited and the design codes which provide information regarding designing of ultra high performance concrete are also limited. To reduce the initial cost of ultra high performance concrete Microfine and Ground Granulated Blast Furnace Slag have been incorporated. Basically GGBS and Microfine are the waste by product of Steel Manufacture industry. These are capable enough to enhance the strength and durability of concrete.

For achieving higher ductility, small fraction of Steel fiber can be used. These waste materials having homogeneous structure and can provide homogeneity to the concrete.

II. MATERIALS

A. Materials

a. Ground Granulated Blast Furnace Slag (GGBS) and Microfine:

The nano material used in this project is Ground Granulated Blast Furnace Slag due to their rich mechanical strength and bonding strength along with Microfine for improving intermolecular bond between ingredients of concrete. GGBS and Microfine added as a replacement of Cement with certain percentage depending upon mix design.

- Physical Composition of GGBS:
  Color: White
  Specific Gravity: 2.92
  Bulk Density: 1060-1160 kg/m^3 (Loose) and 1260-1360 kg/m^3
  Fineness: > 350 m^2/kg

- Physical Composition of Microfine:
  Fineness: > 550 m^2/kg
  Compressive Strength: >15 (in N/mm^2 at 28 Days)
  Initial Setting Time: 150 minutes
  Final Setting Time: 180 minutes
  Grain Density: 2.92 kg/m^3

b. Cement:

The strength of concrete mainly depend upon the binding material cement. The Ultra high performance concrete must needed use of ordinary Portland cement of

ISSN No:-2456-2165

high quality. The quality of cement directly affects the strength of concrete and its durability. The physical and chemical property of the cement having predominant role in the performance of the concrete. Following are the key factors which are needed in the cement for achieving Ultra high performance concrete.

Cement Grade: Ordinary Portland Cement 53 – ACC
Conforming IS: 269
Minimum Compressive Strength (7 Days): 29.7 N/mm^2
Air Content in mortar: between 5 to 15%

The Portland cement of grade 53 was used in this study. All the experiments were performed as per IS 12269:2013. Various test performed on the cement like normal consistency, fineness, initial setting time and final setting time as per Indian standard.

c. Fine and Coarse Aggregate:

The distribution of aggregate normally creates uniformity in the concrete mix. The workability of concrete depends on the fine aggregate and coarse aggregate dispersion in the concrete. If the sand having sticky property then it will give the minimum compressive strength and workability to the concrete. The suitable range of fineness modulus for sand is 2.5 to 3.2 for Ultra high performance concrete. By crushing stones the coarse aggregate are obtained generally and having key role in the workability and compressive strength in the concrete. Many tests have been performed on coarse and fine aggregate to make it suitable for Ultra high performance concrete.

Aggregates having predominant role in strength and durability of concrete. The bifurcation of the aggregate are carried out by using Indian standard suggestions like if the particle size of the aggregate is less than 4.75 mm then it is categorized as fine aggregate and if the particle size are more than 4.75 mm then aggregates are categorized as coarse aggregate.

d. Admixture:

In this study, the strength enhancer and water amout reducer admixture is used. Perma Plast PC-405 admixture is used with the mixture. As per the suggestion or recommendation the minimum dose of admixture must be in the range of 0.2 to 1.5 % by weight of cement content. The dose of admixture should not be less or more than the range otherwise it would have diverse results in final observation.

III. METHODS AND EXPERIMENTAL DATA

A. Concrete Mix Design:

Mix design was done as per Indian Standard 10262:2009 with incorporation of GGBS and Microfine in certain % as a trial mixture.

Testing:

a. Compressive Strength Test:

The Following data were observed as per mix design and proportion calculated.

Mix Design	W/C Ratio	GGBS (%)	Micro fine (%)	Compressive Strength in N/mm^2			
				3 days	7 days	14 days	28 days
M50	0.35	10	10	16.2	27.5	39.8	42.5
		15	10	17.5	28.6	41.2	43.5
		20	10	18.5	32.4	42.3	45.8
		30	10	21.1	36.2	47.3	51.5
		40	10	19.5	33.2	43.2	45.1
M40	0.35	10	10	10.2	21.2	31.4	33.5
		15	10	11.5	23.4	32.6	35.1
		20	10	14.2	25.4	34.5	38.0
		30	10	16.1	27.4	37.5	42.2
		40	10	14.1	24.2	33.2	37.5

Table 1: Compressive Strength Test Values of M50 and M40

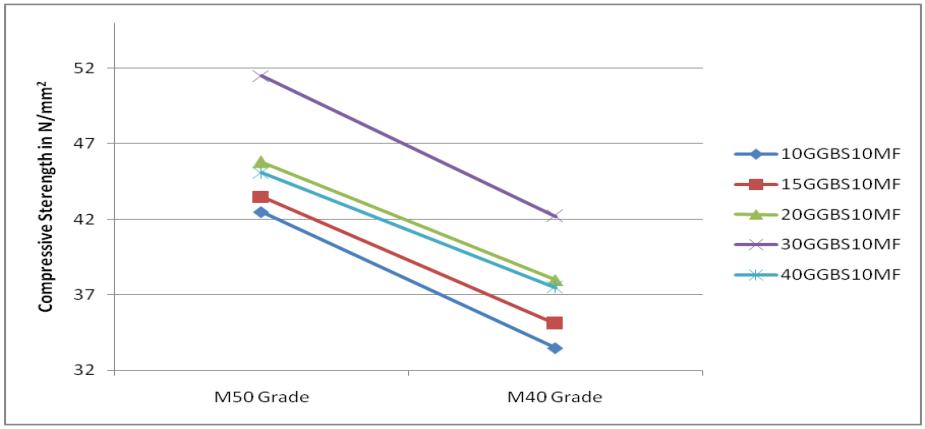
Graph-2 Compressive Strength data comparison for Mix-40

ISSN No:-2456-2165



Graph-3 Comparative Graph for CS of Mix-40 and Mix-50

b. Split Tensile Strength Test:

This Test is performed to determine the split tensile strength of concrete. A Cylindrical mould is prepared having size 150 mm diameter and 300 mm length as per Indian Standard Specifications. After Preparing Specimen is prepared, the loads are applied on it across the vertical diameter. For this test various equipments and tools are used like grinding machine, compressive strength machine, capping fixture, PI tape, Ruler etc.

The Loads are applied as triaxial compression and it is applied until the tensile load failure point reaches.

Mix Proportion	Split Tensile Strength Value in (N/mm2)		
	7 Days	14 Days	28 Days
Mix 50 (W/C = 0.35) + GGBS (30%) and Microfine (10%)	5.40	7.00	7.75
Mix 40 (W/C = 0.35) + GGBS (30%) and Microfine (10%)	4.12	5.63	6.45

Table 2: Split Tensile Strength on different trials

c. Flexural Strength Test:

Flexural strength test is used to find out tensile property of the concrete. The core concept behind this test is to determine how much load the beam can resist under bending. For performing this test, specimen is prepared having size 150 mm x 150 mm and length 700 mm. This mould is poured with concrete mix and further this specimen is placed to perform three point load experiment. The loading conditions are applied at one third and two third by the total length of the specimen. Tests are always performed after the minimum curing required as per the Indian Standard.

Mix Proportion	Flexural Tensile Strength Value in (N/mm^2)		
	7 Days	14 Days	28 Days
Mix-50 (W/C = 0.35) + GGBS (30%) and Microfine (10%)	5.92	7.75	9.40
Mix-40 (W/C = 0.35) + GGBS (30%) and Microfine (10%)	4.55	6.24	6.92

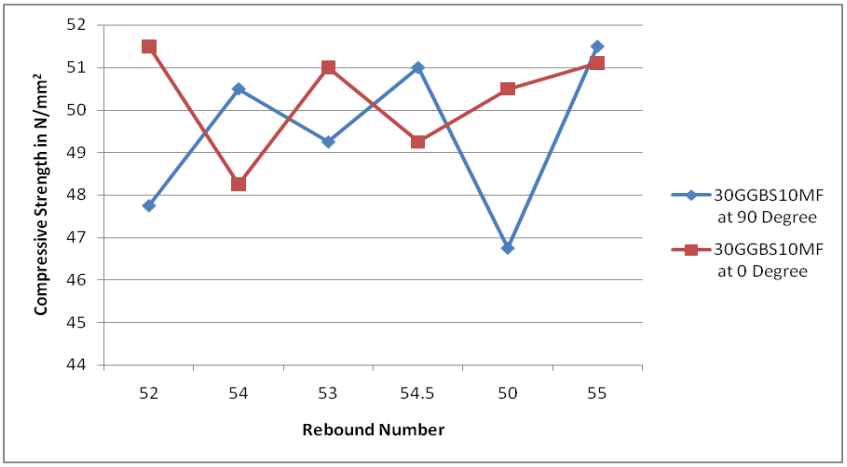
Table 3: Flexural Tensile Strength on different trial

d. Rebound Hammer test:

Rebound hammer test comes under non-destructive test in which compressive strength of the concrete is identified without any dismantle of concrete.

This test is used to assess the durability workability and consistency of concrete. it is the one of the convenient method used to determine the compressive strength of concrete without any physical destruction. In this experiment instrument is used in which a plunger is fitted and it is connected to a spring that used to control the mass. After that marking is done on the surface and the minimum horizontal distance between two marks must be 25 mm. From the end of the surface it must be 50 mm. we need to impose total 10 numbers of marking on the surface of concrete to identify the compressive strength by using by performing rebound hammer test.

ISSN No:-2456-2165



Graph-4 Comparison of CS at 0 and 90 degree.

e. Ultrasonic Pulse Velocity Test*:*

The ultrasonic pulse velocity test is also comes under non destructive test. This test is used to determine the quality of concrete in terms of uniformity and consistency of mix. In this experiment, Ultrasonic waves passes through the concrete specimen and the time taken by the Ultrasonic waves to pass that specimen is noted. If the time consumed by the ultrasonic wave is more that means there is something which is uniform and well organize structure. If the time taken by the wave is less that means there is something which is not well organized or disturbed arrangement of mixture ingredient. Further, there is no need to disintegrate the structure to determine these values.

Spot No.	Pulse Velocity (Km/Sec)		Concrete Quality (Grading)
	Direct Method	Semi Direct Method	
1	4.05	4.00	Good
2	4.25	3.95

Table 4: Pulse Velocity test Observations

IV. CONCLUSIONS

By adding GGBS and Microfine to achieve UHPC, the following conclusions were made as per expectations and observation received.

- GGBS and Microfine both are capable to enhance the Physical property of concrete like compressive strength, Ductility and performance of concrete under service period.
- The Compressive Strength found 43.5 N/mm ^{2} and 52.75 N/mm ^{2} after 28 days for Mix-40 and Mix-50.
- By considering economic point of view, the UHPC is 15.5% Cost effective than conventional concrete due to using Industrial waste by product.
- The Best results found when we add 30% GGBS and 10% Microfine as a replacement of cement.
- The Split and Flexural tensile strength were maximum when 30% GGBS and 10% Microfine is added.
- The Water Cement ratio is 0.25 for getting best result under this proportion.
- Ultrasonic Pulse Velocity and Rebound hammer test results were also up to the mark as per expectation and categorized as good.
- UHPC is also capable to protect itself from corrosion and acid Attack..

Abstract. *Here, XFEM is used to model structural discontinuities like cracks and holes in order to forecast the strength and dependability of the structure under service conditions. By contrasting the numerical outcomes of several issues with the analytical and experimental findings, the method's resilience has been shown. Additionally, XFEM is coupled with a stochastic method to predict the sensitivity of a structure with discontinuities (cracks and holes) under tensile loading conditions in terms of output COVs and fracture strength in terms of mean values of stress intensity factors (SIFs) using input individual and combined randomness in various system parameters. The second order perturbation technique has been utilized in stochastic / perturbation theory to forecast how constructions would fracture. The perturbation technique is also utilized as Taylor series expansion method and yields accurate results if the input randomness is less than twenty percentage.*

Keywords. XFEM, COV, MMSIF, Stochastic, Perturbation

1. Introduction

We are aware that randomness always exists in reality and affects every aspect of a construction, including its geometry, strength, lifespan, susceptibility to damage, and fracture parameters. Even with the finest quality control procedures, randomness in system attributes has a major impact on how the mechanical

component responds to fracture. Therefore, randomness, external loads, material qualities, crack parameters, and geometry must all be taken into account when performing a fracture analysis on a structure. The stochastic fracture analysis increases the safety of structures by offering a reliable prediction of the fracture behaviour of the structure. The reliability evaluation methodologies can aid in the creation of preliminary recommendations for reliable designs. Many scholars have successfully analysed the stochastic fracture behaviour of the structure. Through the use of several numerical examples and the scaled boundary finite element method (SBFEM), Chowdhury et al. [1] completed the shape sensitivity analysis (Rahman and Chen [2]; Reddy and Rao [3]) of stress intensity variables to the crack size and direction. They performed the reliability assessment by Monte Carlo simulations (Chakraborty and Rahman [4, 5]; Choi et al. [6]; Evangelatos and Spanos [7]; Haldar and Mahadevan [8]; Khasin [9]; Lal and Palekar [10]). Some academics have talked about their work using the perturbation technique to forecast the material's stochastic reaction. In this regard, Rahman and Rao [11] introduced a stochastic meshless technique for resolving random material property boundary-value issues in linear elasticity. For the purpose of forecasting stochastic structure response, they created a meshless formulation. Classical perturbation expansions were produced in conjunction with the meshless equations to forecast the response's second-moment characteristics.

The XFEM has been further improved or enhanced by many researchers through coupling the XFEM with another technique to overcome the difficulties faced by the general XFEM. In the direction, a new set of enrichment functions was proposed for solving the Poisson equation in 1D and 2D spaces and was reduced the analysis error by Paweł [12]. The XFEM was coupled with a constitutive law with embedded discontinuity (CLED) approach for modelling of mixed mode cracking in concrete structure for simplifying the numerical implementation (Pietruszczak and Haghighat, [13]). Improved XFEM was developed for 3D and demonstrated better accuracy, convergence and efficiency. It overcomes the linear dependency problem by utilizing an extra degree of freedom free partition of unity approximation which is based on local least-squares fitting with a one-point interpolation constraint (Tian et al., [14]).

Using XFEM and various independent, combined uncorrelated and correlated input random Gaussian variables using SOPT and MCS, Lal and Markad [15] presented mixed mode SIFs and crack propagation analysis of the symmetric angle-ply laminated composite plate with through-thickness arbitrary curve cracks subjected to tensile and shear stress. The stochastic finite element technique is an extension of the MCS with uncertainty in the system parameters, such as materials, geometry, etc. given by Arregui-Mena et al. [16]. The spectral stochastic finite element approach and the perturbation technique (SSFEM). Lal and Markad [10] utilised a C^0 FEM based on higher order shear deformation plate theory was used to evaluate the second order statistics of MMSIFs of single edge V-notched angle-ply laminated composite plates under in-plane tensile load with uncertainty in material parameters, crack opening, and fracture length (HSDT). With the help of FOPT, SOPT, and MCS, the probabilistic evaluation was carried out.

The few researchers predicted how an infinite plate with a separate circular hole and a crack would fracture under tensile force. To the author's knowledge, XFEM with SOPT has not been used to investigate the stochastic fracture behaviour in terms of normalised MMSIFs and corresponding COVs of the infinite plate with various positions of a separate circular hole and a crack with various crack angles under tensile loading with input random parameters such as crack length, normalised radius of the hole, crack angle, and the central distance between separate hole and crack.

By incorporating the individual and combined randomness in the normalised crack length, crack angle, and normalised radius of the hole in an isotropic plate with a hole emanating cracks using SOPT, the stochastic fracture response through the normalised MMSIFs is calculated. Some results are validated with MCS. Present work is also focuesed on effect of combined loading over stochastic fracture response of the structural plate in terms of normalized MMSIFs.

2. Mathematical formulation

The XFEM is useful for modelling discontinuities like fractures, holes or voids, inclusions, interfaces, etc. while including discontinuous functions in the FE mesh. The level set method (LSM) has been successfully

used in conjunction with the XFEM to address these problems by providing further enrichment functions like crack faces and crack tips. Here, the XFEM software is built upon the 2D MATLAB code by Pais [18].

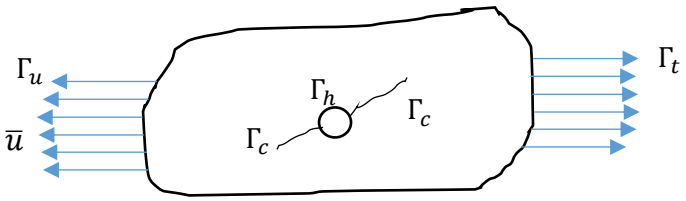

Fig. 1 Area under consideration with cracks, holes, and boundary condition

2.1 Equilibrium equation

The surfaces of cracks Γ_c and holes Γ_h are assumed traction free as are mentioned by Daux et al. [20], and shown in figure 1. The equilibrium equation in the domain Ω is:

$$\tilde{\nabla} \cdot \boldsymbol{\sigma}_t + \mathbf{f}_b = 0 \tag{1}$$

Small strains and displacements are taken into consideration in the current work. Thus, the relationship between strain and displacement illustrates the kinematics equations:

$$\boldsymbol{\varepsilon} = \boldsymbol{\varepsilon}(\mathbf{u}) = \tilde{\nabla}_s \cdot \mathbf{u} \tag{2}$$

Here, $\tilde{\nabla}_s$ is the symmetric part of the gradient operator and $\mathbf{u}$ is a displacement field vector. The boundary conditions for the displacements on the boundary Γ_u are:

$$\mathbf{u} = \bar{\mathbf{u}} . \tag{3}$$

The constitutive relation for elastic material can be shown by Hooke's law as:

$$\boldsymbol{\sigma}_t = \boldsymbol{D} \cdot \boldsymbol{\varepsilon}(\mathbf{u}) \tag{4}$$

where $\boldsymbol{D}$ is Hooke tensor or constitutive matrix for isotropic materials for plane stress and strain conditions in 2D.

The equilibrium equations' weak form is provided by:

$$\int_{\Omega} \boldsymbol{\varepsilon}(\mathbf{u}) : \boldsymbol{D} : \boldsymbol{\varepsilon}(\mathbf{v}) d\Omega = \int_{\Omega} \bar{\mathbf{b}} \cdot \mathbf{v} d\Omega + \int_{\Gamma_t} \bar{\mathbf{t}} \cdot \mathbf{v} d\Gamma \quad \forall \mathbf{v} \in \gamma_0 \tag{5}$$

The linear, FF and bilinear, SS forms of the equation (5) are:

$$FF(\mathbf{v}) = \int_{\Gamma} \bar{\mathbf{b}} \cdot \mathbf{v} d\Omega + \int_{\Gamma_t} \bar{\mathbf{t}} \cdot \mathbf{v} d\Omega \tag{6}$$

$$SS(\mathbf{u}, \mathbf{v}) = \int_{\Omega} \boldsymbol{\varepsilon}(\mathbf{u}) : \boldsymbol{D} : \boldsymbol{\varepsilon}(\mathbf{v}) d\Omega \tag{7}$$

Potential energy (Π) of an elastic body is $\Pi = \frac{1}{2} SS(\mathbf{u}, \mathbf{u}) - FF(\mathbf{u})$ (8)

By applying a variant of the previous equation and substituting $\frac{\partial \Pi}{\partial \mathbf{u}} = 0$, the minimization of the elastic body's potential energy may be solved, and the following set of discrete equations is produced as a result.

$$[\mathbf{K}]\{\mathbf{d}\} = \{\mathbf{f}\} \tag{9}$$

where, $[\mathbf{K}]$ is the global stiffness matrix, $\{\mathbf{d}\}$ are the global degrees of freedom and $\{\mathbf{f}\}$ are the applied loading or force.

$$\mathbf{K}_{ij}^{e} = \begin{bmatrix} \mathbf{K}_{ij}^{uu} & \mathbf{K}_{ij}^{ua} & \mathbf{K}_{ij}^{ub} & \mathbf{K}_{ij}^{ug} \\ \mathbf{K}_{ij}^{au} & \mathbf{K}_{ij}^{aa} & \mathbf{K}_{ij}^{ab} & \mathbf{K}_{ij}^{ag} \\ \mathbf{K}_{ij}^{bu} & \mathbf{K}_{ij}^{ba} & \mathbf{K}_{ij}^{bb} & \mathbf{K}_{ij}^{bg} \\ \mathbf{K}_{ij}^{gu} & \mathbf{K}_{ij}^{ga} & \mathbf{K}_{ij}^{gb} & \mathbf{K}_{ij}^{gg} \end{bmatrix} \tag{10}$$

$$\mathbf{f}_i^e = \left\{ \mathbf{f}_i^u \;\; \mathbf{f}_i^a \;\; \mathbf{f}_i^{b_1} \;\; \mathbf{f}_i^{b_2} \;\; \mathbf{f}_i^{b_3} \;\; \mathbf{f}_i^{b_4} \;\; \mathbf{f}_i^g \right\}^{\mathbf{T}} \tag{11}$$

$$\mathbf{d} = \left\{ \mathbf{u} \;\; \mathbf{a} \;\; \mathbf{b}_1 \;\; \mathbf{b}_1 \;\; \mathbf{b}_1 \;\; \mathbf{b}_1 \;\; \mathbf{g} \right\}^{\mathbf{T}} \tag{12}$$

2.2 XFEM Approximation

XFEM Approximation for Cracks and voids are defined as,

$$\mathbf{u}^{fi}(\mathbf{x}) = \mathbf{u}^{\mathbf{FEM}} + \mathbf{u}^{\mathbf{ENR}} = \sum_{i=1}^{n} \mathcal{N}_i(\mathbf{x}) \left\{ \bar{\mathbf{u}}_i + \sum_{j=1}^{m} \mathbf{F}^j(\mathbf{x}) \mathbf{a}_i^j \right\} \tag{13}$$

Heaviside function for a discontinuous function for the crack and voids defined as,

$$\mathcal{H}_1(\mathbf{x}) = \begin{cases} 1 \text{ for } \boldsymbol{\varphi}(\mathbf{x}) > 0 \\ 0 \text{ for } \boldsymbol{\varphi}(\mathbf{x}) = 0 \\ -1 \text{ for } \boldsymbol{\varphi}(\mathbf{x}) < 0 \end{cases} \quad \text{and} \quad \mathcal{H}_2(\mathbf{x}) = \begin{cases} 1 \text{ for } \chi(\mathbf{x}) > 0 \\ 0 \text{ for } \chi(\mathbf{x}) \le 0 \end{cases} \tag{14}$$

2.3 Level Set Method

For crack, level set method implemented by eq. (15), and for voids by eq. (16). The sign distance function $\phi(\mathbf{x}, \mathrm{t})$ to the curve Γ_c

$$\phi(\mathbf{x}) = \begin{cases} \min\limits_{\mathbf{x}_c \in \Gamma} \left\| \mathbf{x} - \mathbf{x}_c \right\| = d\left(\mathbf{x}, \mathbf{x}_i\right) & \forall \left(\mathbf{x} - \mathbf{x}_c\right) \cdot e_2 \ge 0 \\ \min\limits_{\mathbf{x}_c \in \Gamma} \left\| \mathbf{x} - \mathbf{x}_c \right\| = -d\left(\mathbf{x}, \mathbf{x}_i\right) & \text{otherwise} \end{cases} \tag{15}$$

$$\chi(\mathbf{x},0) = \min_{\mathbf{x}_c^i \in \Omega_c^i} \left\{ \left\| \mathbf{x} - \mathbf{x}_c^i \right\| - \mathrm{r}_c^i \right\} \qquad \text{where, } i = 1, 2, ..., n_c \tag{16}$$

where, d is the absolute distance, $\mathbf{x}_i$ is the point on crack closest to a point x with any point $\mathbf{x}_c$ on the crack surface Γ_c. r_c^i is the radius of the *i*th hole.

2.4 Evaluation of Stress Intensity Factors (SIFs)

For general mixed-mode problems in two dimensions, SIFs and J-integral can be stated as,

$$J = \frac{K_I^2}{E^*} + \frac{K_{II}^2}{E^*} \tag{17}$$

where, $E^* = \begin{cases} E & \text{for plane stress} \\ \dfrac{E}{1-\nu^2} & \text{for plane strain} \end{cases}$ (18)

The J -integral also follows the path-independence and it is explained

$$J = \int_{\Gamma} \left(W n_j - \mathbf{t}_i \cdot \frac{\partial \mathbf{u}_i}{\partial x} \right) d\Gamma \tag{19}$$

where, W is the strain energy density. For the plate of the elastic material, it can explain that $W = (1/2)\boldsymbol{\sigma}_{ij}\boldsymbol{\varepsilon}_{ij}$.

Now, two equilibrium, independent states of a cracked body are considered. Consider the state1, $\left(\boldsymbol{\sigma}_{ij}^{(1)},\boldsymbol{\varepsilon}_{ij}^{(1)},\mathbf{u}_{j}^{(1)}\right)$, corresponds to the present or actual state and state 2, $\left(\boldsymbol{\sigma}_{ij}^{(2)},\boldsymbol{\varepsilon}_{ij}^{(2)},\mathbf{u}_{j}^{(2)}\right)$, is an auxiliary state. Further, $\boldsymbol{\sigma}_{ij}^{(2)}$, $\boldsymbol{\varepsilon}_{ij}^{(2)}$ and $\mathbf{u}_{j}^{(2)}$ are the auxiliary stress field, auxiliary strain filed and auxiliary displacement field, respectively. Thus, superposition of these two states brings another equilibrium state, say, $\left(\boldsymbol{\sigma}_{ij},\boldsymbol{\varepsilon}_{ij},\mathbf{u}_{j}\right)$. Now, we have:

$$\boldsymbol{\sigma}_{ij}=\boldsymbol{\sigma}_{ij}^{(1)}+\boldsymbol{\sigma}_{ij}^{(2)}\quad \boldsymbol{\varepsilon}_{ij}=\boldsymbol{\varepsilon}_{ij}^{(1)}+\boldsymbol{\varepsilon}_{ij}^{(2)}\qquad \mathbf{u}_{j}=\mathbf{u}_{j}^{(1)}+\mathbf{u}_{j}^{(2)} \tag{20}$$

The strain energy densities are:

$$W=W^{(1)}+W^{(2)}\quad W^{(1)}=\frac{1}{2}\boldsymbol{\sigma}_{ij}^{(1)}\boldsymbol{\varepsilon}_{ij}^{(1)}\qquad W^{(2)}=\frac{1}{2}\boldsymbol{\sigma}_{ij}^{(2)}\boldsymbol{\varepsilon}_{ij}^{(2)} \tag{21}$$

$$W=\frac{1}{2}\boldsymbol{\sigma}_{ij}\boldsymbol{\varepsilon}_{ij}=\frac{1}{2}\left(\boldsymbol{\sigma}_{ij}^{(1)}+\boldsymbol{\sigma}_{ij}^{(2)}\right)\left(\boldsymbol{\varepsilon}_{ij}^{(1)}+\boldsymbol{\varepsilon}_{ij}^{(2)}\right)=\frac{1}{2}\left(W^{(1)}+W^{(2)}\right)-\boldsymbol{\sigma}_{ij}^{(1)}\boldsymbol{\varepsilon}_{ij}^{(2)} \tag{22}$$

2.5 Stress intensity factor (SIF)

The Mode-I and Mode-II SIFs are formulated as,

$$K_{I}=K_{I}^{(1)}+K_{I}^{(2)}\quad K_{II}=K_{II}^{(1)}+K_{II}^{(2)} \tag{23}$$

The Mode-I and Mode-II SIFs for the actual state can be obtained by choosing the auxiliary state (state 2), e.g., if auxiliary state 2 is chosen to be state for Mode-I, then the auxiliary state is Mode-I near tip displacement and stress field, then by putting $K_{I}^{(2)}=1$ and $K_{II}^{(2)}=0$ in the equation (23), we have:

$$K_{I}^{(1)}=\frac{M^{(1,\text{Mode I})}E^{*}}{2} \tag{24}$$

Similarly, if auxiliary state 2 is chosen to be state for Mode-II, then the auxiliary state is Mode-II near tip displacement and stress field, then by putting $K_{I}^{(2)}=0$ and $K_{II}^{(2)}=1$ in equation (23), we have:

$$K_{II}^{(1)}=\frac{M^{(1,\text{Mode II})}E^{*}}{2} \tag{25}$$

where, $M^{(1,\text{Mode I})}$ and $M^{(1,\text{Mode II})}$ are interaction integrals.

3. Results and discussion

By incorporating the individual and combined randomness in the normalised crack length $\left(e_1 = a/W\right)$, crack angle $\left(e_2 = \alpha\right)$, and normalised radius of the hole $\left(e_3 = R/W\right)$ in an isotropic plate with a hole emanating cracks using SOPT, the stochastic fracture response through the normalised MMSIFs is calculated. Some results are validated with MCS. The input random variables are indicated by the parameter { e_i (*i*=1, 2 and 3). Furthermore, it is assumed that the input COV for individual and combined randomness in all the parameters is 15% or 0.15 variation of characteristics from their mean values in order to forecast the stochastic MMSIFs of the plate under tensile, shear, and combination (tensile and shear) loadings. The percentage of the input random parameters has been randomly adopted because in perturbation technique, for input COVs < 0.2 or 20 %, the solution can be obtained up to the acceptable accuracy (Stefanou [20]). The normalized MMSIFs in terms of K_I and K_{II} are expressed as:

For Tensile loading

$$K_I = K_{I,\text{mean}} / \left(\sigma\sqrt{\pi a}\right) \text{ and } K_{II} = K_{II,\text{mean}} / \left(\sigma\sqrt{\pi a}\right) \tag{26}$$

For Shear loading

$$K_I = K_{I,\text{mean}} / \left(\tau\sqrt{\pi a}\right) \text{ and } K_{II} = K_{II,\text{mean}} / \left(\tau\sqrt{\pi a}\right) \tag{27}$$

where K_I , K_{II} , $K_{I,\text{mean}}$, $K_{II,\text{mean}}$, σ , τ and λ are normalized Mode-I and Mode-II SIFs, numerical Mode-I and Mode-II SIFs, tensile, shear and combined stresses, respectively and where, $\lambda = \sigma = \tau$.

3.1 Convergence and validation study

The results of Grasa et al. [21] using a first-order perturbation technique (FOPT) on the basis of analytical and XFEM solution for an isotropic edge cracked plate subjected to tensile loading are available and are compared with the mean value of Mode-I SIF using the current perturbation-based SOPT combined with XFEM, and they are in good agreement as shown in Table 1.

Table 1 Validation of SIFs of an isotropic edge cracked plate subjected to tensile loading

Analytical Solution [21]	XFEM with FOPT [21]	% Error	XFEM with SOPT	% Error	XFEM with MCS	% Error
99.8182	98.951	0.87	100.4834	0.67	100.1276	0.31

Rarely are the SOPT findings for the stochastic fracture analysis of the investigated model under various stress situations available in the literature. To validate the current stochastic fracture analysis for a/W= 0.4 with $\alpha = 30^0$, as indicated in Table 2, the current mean and corresponding COV $\{e_i(i=1, 2 \text{ and } 3) = 0.15\}$ of MMSIFs K_I and K_{II} acquired by SOPT are compared with those obtained by MCS.

Table 2 Behaviour of the analyzed model under different loading conditions for normalized crack length (a/W= 0.4) with crack angles ($\alpha = 30^\circ$) through individual randomness in a/W by MCS with different numbers of samples

Total no. of samples	Tensile loading				Shear loading			
	K_I		K_{II}		K_I		K_{II}	
	Mean	COV	Mean	COV	Mean	COV	Mean	COV
9000	0.809	0.121	0.354	0.223	2.527	0.059	1.296	0.125
9500	0.822	0.084	0.342	0.197	2.536	0.051	1.193	0.097
10000	0.828	0.056	0.334	0.167	2.540	0.047	1.128	0.081
10500	0.828	0.056	0.334	0.167	2.540	0.047	1.128	0.081
11000	0.828	0.056	0.334	0.167	2.540	0.047	1.128	0.081

The results obtained by both SOPT and MCS are in very good agreement. In the direct MCS method, the different sets of random samples of random system properties are generated first by direct use of the computer by using Gaussian random number generation. These sets of random samples are substituted in the response equation of MMSIFs and again generated the random samples of MMSIFs. The mean of these random samples gives the mean value of MMSIFs, while the variance of random samples gives the variance of MMSIFs. The optimum numbers of samples are decided on the basis of convergence of mean results. In the present analysis, 10,000 samples are used for satisfactory convergence of the results. Therefore, the 10,000 random samples are used for further computation of results using MCS. In the present study, MCS is used only for validation purpose due to higher consumption of computational time, particularly for fracture problem with very high mesh density.

Fig. 2(a) and 2(b) show the line diagram of an isotropic rectangular plate with the analyzed model with dimensions of length $(2L)$, width $(2W)$, crack length $(2a)$, and hole radius (R) and a central cracked plate without hole with required above-mentioned dimensions, under shear (τ) stress.

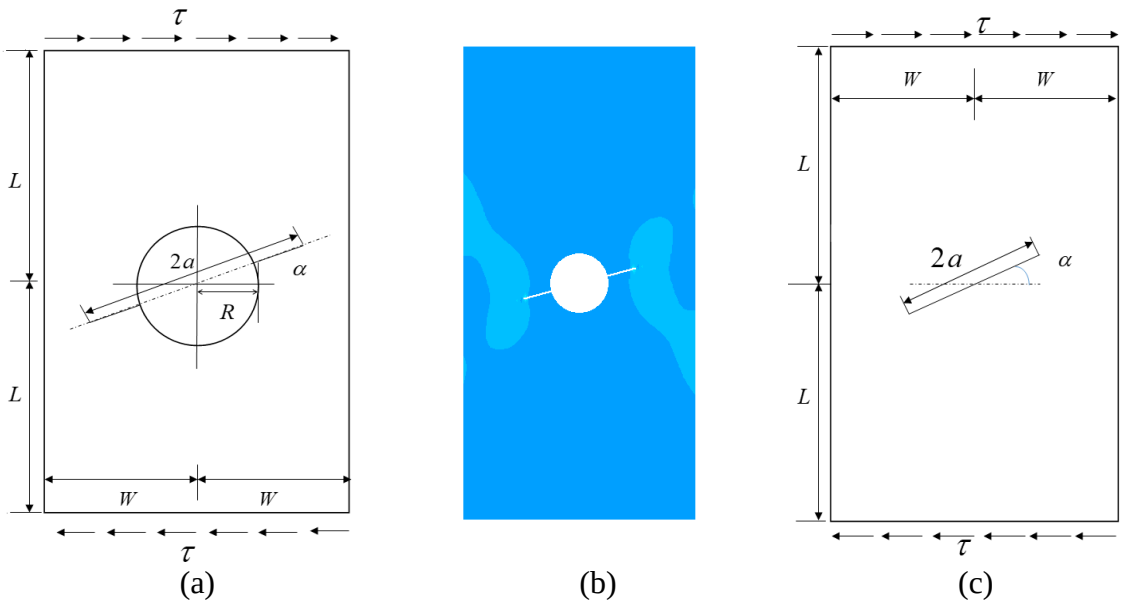

Fig. 2 (a) A line diagram and (b) the stress contour (general) of a plate with radial cracks on a hole and (c) a line diagram of central crack under shear loading

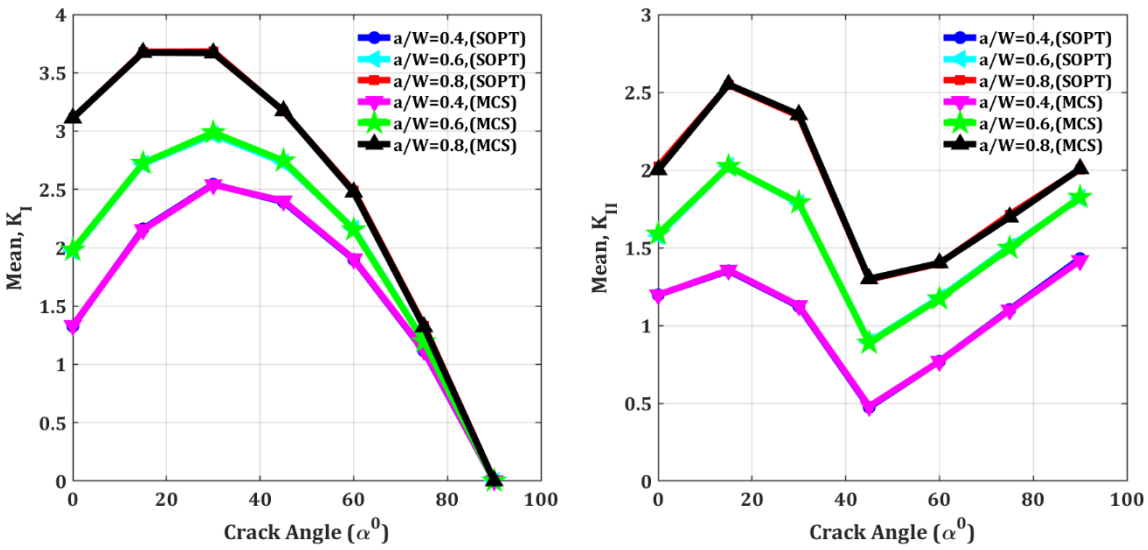
The behaviour of mean values of normalized MMSIFs of the analyzed model under uniform shear loading w.r.t. different crack angles is presented in Fig. 3(a) and 3(b). It is again clear that the SOPT results are in good agreement with those of MCS.

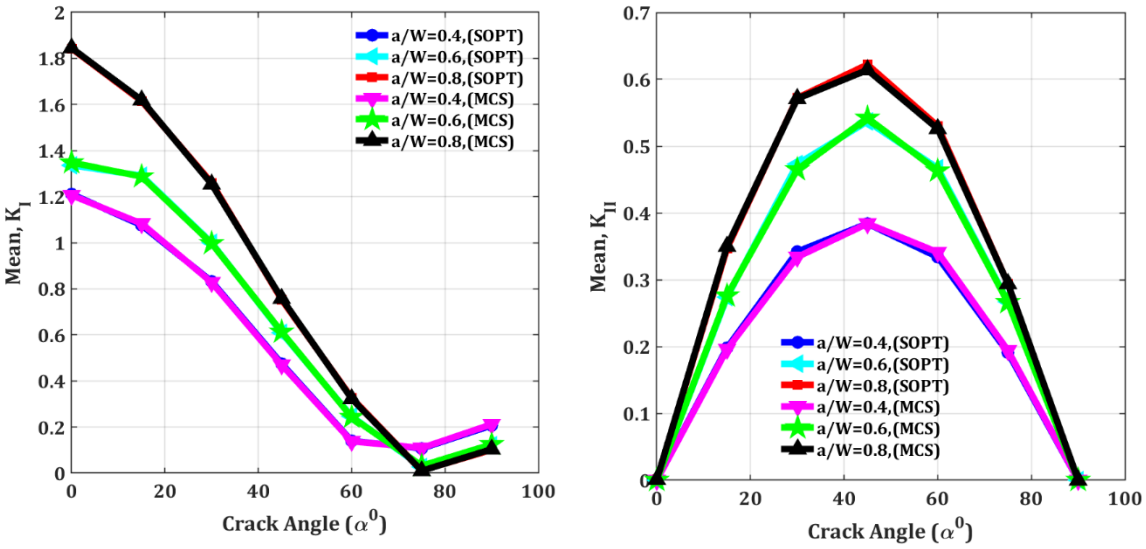


(a) (b)

Fig. 3 The mean values of normalized MMSIFs (a) K_I and (b) K_{II} of a plate under shear loading with individual randomness in e_1, e_2 and e_3

It can be seen that the mean values of K_I are largest at a crack angle α = 30°, and due to the increment in *a/W*, the mean values of K_I starts to dominate at α= 15°. As the crack angle (α) increases from 0° to 30°, the mean values of K_I are increased. Then, these values are continuously decreased to zero at 90° crack angle. Now, the mean values of normalized Mode-II SIFs K_{II} of the analyzed model are maximum at 15° crack angle and are minimum at 45° crack angle. At α = 0° and 90°, the mean values of K_{II} are nearly equal as the normalized crack length increases (*a/W*= 0.8). From crack angle 45° to 90°, the mean values of K_I and K_{II} continuously decrease and increase, respectively.

Fig. 4(a) and 4(b) show the behaviour of the mean values of normalized MMSIFs K_I and K_{II} of the analyzed model under uniform tensile loading with individual randomness { e_i (*i*=1, 2 and 3)} with respect to different crack angles using SOPT and MCS.



(a) (b)

Fig. 4 The mean values of normalized MMSIFs (a) K_I and (b) K_{II} of plate under tensile loading with individual or combined randomness in e_1, e_2 and e_3

It is clear that the SOPT results are in good agreement with those obtained using MCS. It can be seen that the mean values of normalized Mode-I SIFs K_I of the analyzed model are the largest at a crack angle α = 0°, and the SIFs K_I are decreased with increment in the crack angle till 75°. At 90° crack angle, the SIFs K_I for the shorter crack lengths *a/W* are further increased and it is so because the compressive stresses dominant and so the tips of longer crack will get less influence of the buckling, as compared to the shorter ones and the results is the higher SIFs in shorter cracks and the lower SIFs for longer cracks. The mean values of normalized Mode-II SIFs K_{II} of the analyzed model are largest at a crack angle α = 45° and are minimum (zero) at α = 0° and 90°. For the crack angles α and (90◦ -α), the mean values of K_{II} are almost equal if the normalized crack length (a/W = 0.4 and 0.6) is shorter. For the longer cracks (a/W = 0.8), the mean values of K_{II} are not the same.

Fig. 5(a) and 5(b) show the line diagram of the analyzed model with dimensions of length $(2L)$, width $(2W)$, crack length $(2a)$, and hole radius (R) and a central cracked plate without hole with required above-mentioned dimensions, under combined tensile (σ) and shear (τ) stresses.

The behaviour of the mean values of normalized MMSIFs K_I and K_{II} of the analyzed model w.r.t. different crack angles using SOPT is predicted and compared with the deterministic values of normalized MMSIFs K_I and K_{II} of the plate with a central crack without any hole with the same geometrical properties subjected to combined loading, as shown in Fig. 6(a) and 6(b).

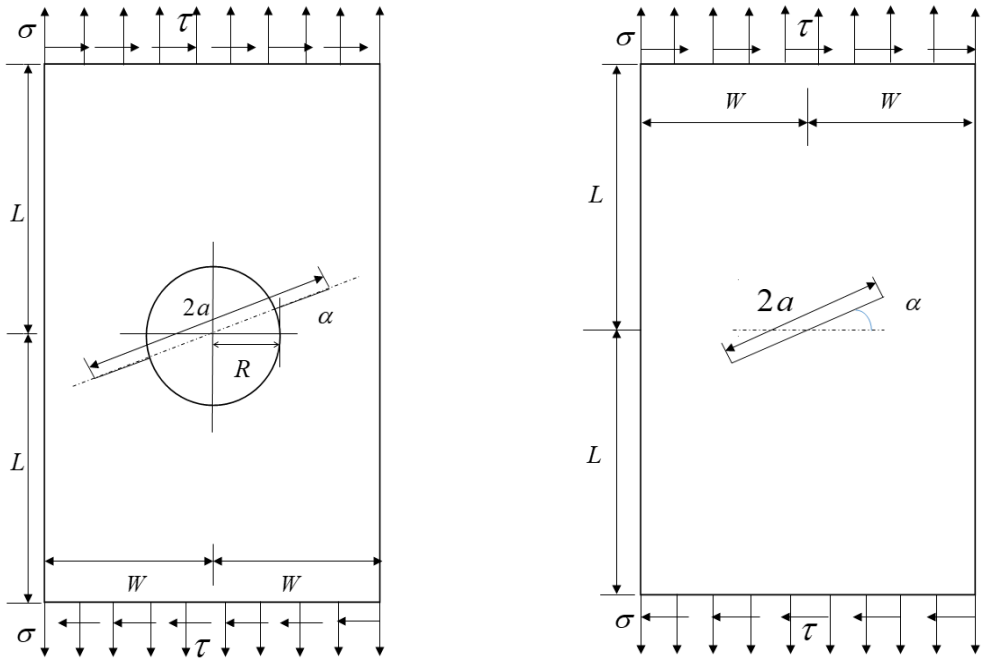


Fig. 5 Line diagrams of the plates with (a) hole emanating radial cracks and (b) a central crack subjected to combined loadings

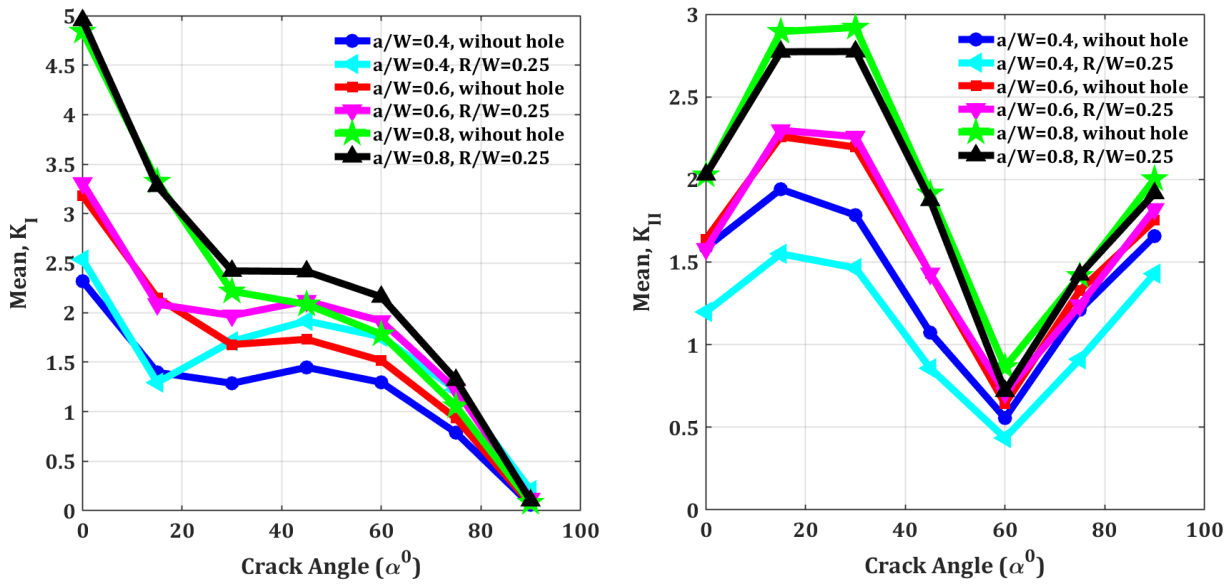
It can be seen that the mean values of normalized Mode-I SIFs K_I are highest at crack angle α = 0°. Also, as the crack angle (α) is increased, the mean values of K_I are decreased from 0° to 90° crack angle. At 90° crack angle, the mean values of K_I are zero. For the crack angle 15°, the mean values of K_I are increased for shorter crack length (a/W = 0.4) because due to combined loading the stress concentration on the periphery of the hole, from where the cracks are emanating, will be maximum and the stress concentration zone will be upper and lower parts of the sides of the hole and crack. As the crack makes an angle of 30°, the tip of the crack will be much nearer to the stress concentration zone and more stresses will be on a crack tip, therefore, the mean values of K_I are continuously increased till angle 45° and remain

critical. After 45° angle, the crack tips gradually leave the stress concentration zone till angle 90°. But, for longer crack, the crack tip remains somewhat away from the periphery of the hole. That is why the stress concentration zone becomes unable to produce much effect on the crack tip. If the length of the emanating cracks is very large, then the hole becomes the part of crack only.

The mean values of normalized Mode-II SIFs K_{II} are highest at a crack angle α = 15° but as a/W increases, the values of K_{II} start to dominate at α = 30°. From crack angles 30° to 60° and 60° to 90°, the mean values of K_{II} decreased and increased, respectively. Now, the mean values of normalized Mode-II SIFs K_{II} of an isotropic plate with a hole emanating radial cracks are the largest at 15° crack angle and are minimum at 60° crack angle.

At 90° crack angle, the mean value of K_I is zero because here, the effect of K_I is completely ineffective under the shear and combined loading. The mean values of normalized MMSIFs K_I and K_{II} of an isotropic plate with a hole emanating radial cracks subjected to combined and shear loadings are much higher as compared to those are under tensile loading. So, it can be concluded that the combined loading is much critical as compared to tensile and shear loading for the present problem.

Under all types of loading conditions, the gaps between the graphs, for the mean values of normalized MMSIFs K_I and K_{II} and the deterministic values of MMSIFs $K_{I,\text{det}}$ and $K_{II,\text{det}}$, are decreased as (a/W) is increased. It is so because the smaller crack with the hole has the influence on stress concentration as well as it works as a small edge crack on the periphery of the hole, whereas for the larger crack, the hole works as a part of the crack only or the role of the hole is just like a crack. Also, the mean values of normalized MMSIFs K_I and K_{II} are increased with increment in a/W.



(a) (b)

Fig. 6 Comparison of the behavior of the mean and deterministic values of normalized MMSIFs (a) K_I and (b) K_{II} of the plate with a hole and without hole with central cracks of different lengths subjected to combined loading

At the crack angles α = 0° and 90°, the mean values of K_{II} for a plate emanating radial cracks are nearly equal to the deterministic values of $K_{II,\det}$ for the cracked plate without hole with the increment in normalized crack length (a/W = 0.8). At 60° crack angle, the mean values of K_{II} are nearly equal to the deterministic values of normalized Mode-II SIFs $K_{II,\det}$ of an isotropic cracked plate without a hole.

4. Conclusions

The fracture behaviour of the plate with discontinuities subjected to shear and combined loading conditions are much more critical as compared to tensile loading. Hence, proper control of these types of loading will increase the reliability of structures. The input random variables such as normalized crack length, crack angle, and normalized radius of the hole show much influence on the stochastic fracture behavior of the plate with discontinuities. So, the reliability and safety in a structure can be enhanced by controlling the input random variables properly.

Under tensile loadings, the plate is the least critical and sensitive when the geometry (hole emanating cracks) at the centre position and is the most critical and sensitive when the geometry is either side of the central part of the plate. Under shear and combined loadings, the plate is the least critical and sensitive when the geometry is below the central part of the plate and is the most critical and sensitive when the geometry is above the central part of the plate.

Abstract: In this paper, we have presented a new approach to factorization of apolynomial,with the help of Vedic mathematics and modern mathematics concepts. This method is based on the Vedic mathematics sutras Vilokanam, Gunita Sumaccaya: Samuccaya Gunita, and Paravartya Yojayet given by Swami Bharti Krishna Maharaj. It is an easier and more useful method for studentsto easily factorize this type of polynomial with mental calculation.

Keywords: Modern Mathematics, Fundamental Theorem of Algebra, Vedic Mathematics, Vilokanam, Gunita Samuccaya: Samuccaya Gunita, Paravartya Yojayet, polynomial.

Introduction:
Vedic mathematics is an ancient Indian system of mathematical calculations or operation techniques that was developed in 1957. It consists of 16 sutras (formulae) and 13 sub-sutras (Sub Formulae) that can be utilized to solve problems in arithmetic, algebra, geometry, calculus, and conics. [1]. Various methods have been developed for the factorization of polynomials. In the Vedic method by Jagadguru Shankaracharya Shri Bharati Krishna Thirtha Swamiji, He introduced the method of factoring cubic polynomials [1]. In this study, we use the same concept for factorization of the nth type of polynomial equation with the help of modern mathematics.

The introduction of a method for factorizing nth-degree polynomials, which can be expressed as $x^n + a_1x^{n-1} + a_2x^{n-2} + \cdots + a_k$, (where x is variable of polynomial, n is degree of polynomial and$a_1, a_2, \ldots, a_k$ are constant terms of polynomial)

Type (1): When thepolynomial doesnot have a factor $(x-1)$**and**$(x+1)$**.**

Step (1)
If the Sum of the coefficients of this polynomials$s_c = 0$.Then one factor of the polynomial is $(x-1)$ and if the sum of the coefficient of odd power of the polynomialss_0 = sum of the coefficient of even power of the polynomial s_e. Then one factor is $(x+1)$. If both conditions are not satisfied. Then the given polynomial does not have $(x+1)$ and $(x-1)$ factors.

Step (2)
The polynomial equation is of the nth degree. So, By the Fundamental Theorem of Algebra, every polynomial equation of n degree has n roots. Here, the polynomial is nth degree, so it has nth roots called, them $a_1 a_2 a_3, \dots, and\ a_n$.

Hence
$A = a_1 + a_2 + a_3 + \cdots + a_n$ = Sum of roots = coefficient of x^n …Condition (1)
$B = a_1 a_2 a_3, \dots, a_n$ = Product of four roots = last term .... Condition (2)

Step (3)
Write down all possible factors of the last term of the given polynomial without 1. As in Step (1) we said that$(x+1)$ and$(x-1)$ are not factors of the given polynomial.
(Note that here we take the last term as only a positive number and write all the positive factors of the last term)

Step (4)
Apply Vilokanam Sutras (mere observation) for condition $B = a_1 a_2 a_3, \dots, a_n$. (Assume B as a positive number)
Observe Step 3 and make possible groups of the nth term that satisfy the condition. And write down all the possible groups.

Step (5)
1) If only one group satisfies Step (4), then that group factor is the factor of the given polynomial.
2) If more than one group of factors satisfies Step (4), Then use (+ or – sing) with factor check condition number (1).
3) From those groups, if one group satisfies the condition (1), Then that group factor with their sign is a factor of the given polynomial.
4) If more than one group also satisfies the condition (1) with their sign. Then check those groups with their (+ or -) sign condition (2). When checking the condition, if only one group satisfies the condition. Then this group, with their sign all factors are factors of the given polynomial.

If more than one group satisfies condition (2) then try Step (6).

Step (6)
Here by Gunita Samucaaya: Samucaaya gunita, we can verify that the factors are right or wrong and check by these Steps which factors groups are factors of the given polynomial.
By checking the Sum of the coefficients in the product of the polynomial =Product of the sum of the coefficients of factors.

Example: Factories$x^3 - 8x^2 - 5x + 84$

Step (1)
The sum of the coefficient $s_c = 1 - 8 - 5 + 84 = 72$, $s_c \neq 0$.

So $(x-1)$ is not a factor of the given polynomial.
Also, the sum of the coefficient of odd power $s_0 = 1 - 5 = -4$.
The sum of thecoefficient of even power $s_0 = -8 + 84 = 76$.
The sum of the coefficient of odd power $s_0 \neq$sum of the coefficient of even power s_e.
Therefore $(x+1)$ is not a factor of the given polynomial.

Step (2)
The polynomial is three degrees. So, it has three roots called $k_1, k_2 \; and \; k_3$.

Hence
$A = k_1 + k_2 + k_3$ =Sum of roots = coefficient of $x^2 = -8$… (1)
$B = k_1 k_2 k_3$ = Product of four roots = 84.... (2)

Step (3)
For the given polynomial, the last term is 84 (we take the last term as positive). So, factories 84 without 1.

$$2\,,3\,,4\,,6\,,7\,,12\,,14 \; and \; 21.$$

Step (4)
From these factors, there are possible groups that satisfy the condition $B = k_1 k_2 k_3$.
Group 1: $(2 \times 2 \times 21) = 84$
Group 2: $(2 \times 3 \times 14) = 84$
Group 3: $(3 \times 4 \times 7) = 84$
Group 4: $(2 \times 6 \times 7) = 84$
So here four groups satisfy this step.

Step (5)
Check condition (1)
Here only satisfies cases $(3, -4, -7)$Satisfies Step 2 conditions (1)

$$A = k_1 + k_2 + k_3 = 3 - 4 - 7 = -8$$

Check this case for Step 2 condition (2)

$$B = (3)(-4)(-7) = 84$$

Here in this case$(3, -4, -7)$Both conditions satisfy so the factors of the given polynomial are $(x+3, x-4, x-7)$

Step (6)
Here, The sum of the coefficient product of the polynomial= 72
Product of the sum of the coefficients of factor$(1+3)(1-4)(1-7) = 72$.
Here the sum of the coefficient of product= product of the sum of the coefficient of factors.
Hence result verified by Gunita Samuccaya: Samuccaya Gunita.
$\therefore x^3 - 8x^2 - 5x + 84 = (x+3), (x-4), (x-7)$.

Example: Factories$x^4 + 6x^3 - 25x^2 - 222x - 360$

Step (1)
Here, $s_c = -600 \neq 0$ and$s_0 = -216$, $s_e = -384$, and $s_0 \neq s_e$.
Therefore, $(x-1)$ and $(x+1)$ are no factors in the given polynomial.

Step (2)
This polynomial is of the fourth degree. So, it has four roots called them $p_1 p_2 p_3 \; and \; p_4$

Hence
$A = p_1 + p_2 + p_3 + p_4$ =Sum of roots = coefficient of $x^3 = 6$... (1)
$B = p_1p_2p_3p_4$ = Product of four roots = -360... (2)

Step (3)
For the given polynomial, the last term is 360 (we take the last term as positive). So, factories 360 without 1
I.e. (2, 3, 4, 5, 6, 8, 9, 10, 12, 15, 18, 20, 24, 30, 36, 40, 45, 60, 72, 90, 120,180, 360).

Step (4)
From these factors, possible groups that satisfy the condition $B = p_1p_2p_3p_4$

$(45 \times 2 \times 2 \times 2) = 360$, $(30 \times 3 \times 2 \times 4) = 360$, $(20 \times 3 \times 3 \times 2) = 360$

$(18 \times 5 \times 2 \times 2) = 360$, $(15 \times 6 \times 2 \times 2) = 360$,$(15 \times 4 \times 3 \times 2) = 360$

$(12 \times 5 \times 3 \times 2) = 360$, $(10 \times 9 \times 2 \times 2) = 360$,$(10 \times 6 \times 3 \times 2) = 360$

$(9 \times 5 \times 4 \times 2) = 360$, $(8 \times 5 \times 3 \times 3) = 360$,$(6 \times 6 \times 5 \times 2) = 360$

$(6 \times 5 \times 4 \times 3) = 360$.

Step (5)
Check condition (1)
Case (1)

$$A = p_1 + p_2 + p_3 + p_4 = 6$$
$$= 15 - 4 - 3 - 2 = 6$$

Therefore, case 1 four-factor group is $(15, -4, -3, -2)$

Case (2)

$$A = p_1 + p_2 + p_3 + p_4 = 6$$
$$= 12 - 5 - 3 + 2 = 6$$

Therefore, case 2 four-factor group is $(12, -5, -3, 2)$

Case (3)

$$A = p_1 + p_2 + p_3 + p_4 = 6$$
$$= 9 - 5 + 4 - 2 = 6$$

So, case 3 the factor group is $(9, -5, 4, -2)$

Case (4)

$$A = p_1 + p_2 + p_3 + p_4 = 6$$
$$= -6 + 5 + 4 + 3 = 6$$

Therefore, case 4 the factor group is $(-6, 5, 4, 3)$

In these four cases, all four factors satisfy these conditions
Therefore, we check all four groups from which case satisfies condition (2)

Here cases (1) and case (4) satisfy condition (2)
Case (1)

$$B = (15 \times -4 \times -3 \times -2) = -360$$

Case (4)

$$B = (-6 \times +5 + 4 \times +3) = -360$$

Therefore, four factors of a given polynomial are $(x + 15), (x - 4), (x - 3), (x - 2)$

otherwise, four factors of the given polynomialare$(x-6),(x+5),(x+4),(x+3)$.

Step (6)
So here, by using sutra Gunita Samuccaya:Samuccaya Gunita.
We can check the Sum of the coefficients in the product of polynomials =Product of the sum of the coefficients of factors.

The sum of the coefficient product of the given polynomial is $=-600$

Here first we Check the condition for factors$(x+15),(x-4),(x-3),(x-2)$
Product of the sum of the coefficients of factors.

$$=(1+15)(1-4)(1-3)(1-2)=(16)(-3)(-2)(-1)=-96$$

So here factor groups $(x+15),(x-4),(x-3),(x-2)$is is not a factor of the given polynomial

For factors, $(x-6),(x+5),(x+4),(x+3)$
The Product of the sum of the coefficients of factors

$$=(1-6)(1+5)(1+4)(1+3)=(-5)(6)(5)(4)=-600$$

Here, this all-factor group satisfies Step 6 conditions.
The sum of the coefficients of the product = product of the sum of the coefficients of the factors.

$$\therefore x^4+6x^3-25x^2-222x-360=(x-6)(x+5)(x+4)(x+3)$$

Type (2): When the polynomial has $(x-1)$either$(x+1)$factors,otherwise if both $(x-1)$and $(x+1)$are factors of the given polynomial.

1) If the polynomial satisfies the Step 1 condition in the Type (1) Method.Then the polynomial is divided by$(x-1)$If $s_c=0$, otherwise if $s_0=s_e$Then divided by$(x+1)$.Otherwise if both Step 1 conditions are satisfied then the polynomial is divided by both $(x-1)$ *and* $(x+1)$Using paravartyayojayet. After dividing among factors by polynomial then the remaining Quotient is the new polynomial.

2) By using the new polynomial, we can find the Remaining factor of the polynomial by using the above Type-1 method.

Example: Factories $x^5+3\cdot x^4-113x^3-447\cdot x^2-104\cdot x+660$

Step (1)
Here $s_c=0$ and$s_0\neq s_e$.
Therefore, $(x-1)$ is one factor of the given polynomial.

By using Paravartya sutras, divide the polynomial by $(x-1)$

$x-1$	1	$+3$	-113	-447	-104	$:+660$
$MD\ 1$				1 4 -109 -556 $:-556$		
	1	$+4$	-109	-556	-660	$:\ 0$

New Polynomial (Quotient)= $x^4+4x^3-109x^2-556x-660$

(Note: here we will use Type (1) method on the new polynomial to get the remaining factors of the given polynomial)

Step (1)
Here $s_c \neq 0$ and$s_0 \neq s_e$.
Therefore $(x-1)$ and $(x+1)$ are not factored into the given new polynomial.

Step (2)
The new polynomial is of the fourth degree. So, it has four roots called them $n_1, n_2, n_3 and\ n_4$

Hence
$A = n_1+n_2+n_3+n_4 = 4 \ldots (2)$
$B = n_1n_2n_3n_4 = -660 \ldots (3)$

Step (3)
Here are factors of 660 (without 1)

$2, 3, 4, 5, 6, 10, 11, 12, 15, 20, 22, 30, 33, 44, 55, 60, 66, 110, 132, 165, 220, 330\ and\ 660.$

Step (4)
From these factors, there are possible groups that satisfy the condition. $B = n_1n_2n_3n_4$

$(55\times3\times2\times2)=660,\ (33\times5\times2\times2)=660, (22\times5\times3\times2)=660$
$(15\times11\times2\times2)=660, (11\times10\times3\times2)=660, (11\times5\times6\times2)=660$
$(11\times5\times4\times3)=660$,
So here, seven groups satisfy this condition.

Step (5)
Check condition (1)

Case (1)

$$A = 15-11+2-2=4$$

Therefore, case 1 four-factor group is $(15, -11, 2, -2)$

Case (2)

$$A = -11 + +10 + 3 + 2 = 4$$

Therefore, case 2 four-factor group is $(-11, 10, 3, 2)$

In these two cases, all four factors satisfy these conditions.

Therefore, we check all four groups to see which case satisfies condition (2).

Here only case (2) satisfies condition (2)

Case (2)

$$B = (-11 \times 10 \times 3 \times 2) = 660$$

Therefore, factors of the given new polynomial are $(x - 11,\ x + 10,\ x + 3,\ x + 2)$

So, all factors of the given main polynomial

$x^5 + 3 \cdot x^4 - 113x^3 - 447 \cdot x^2 - 104 \cdot x + 660$is $(x - 11, x + 10, x + 3,\ x + 2, x - 1)$

Step (6)

Here, byGunita Samuccaya:Samuccaya Gunita verify.

The sum of the coefficient product of the main polynomial = 0

Product of the sum of the coefficients of factors

$$(x - 11)(x + 10)(x + 3)(x + 2)(x - 1) = 0.$$

The sum of the coefficients of the product of the sum of the coefficient of factors.

Hence, result verified by Gunita Samuccaya: Samuccaya Gunita.

Conclusion:

On the basis of the above discussion, we may conclude that the Vedic mathematics method of factorization of polynomials is a mental calculation technique that requires few algebraic procedures, making it faster than the standard method. In this study, we apply the method to cubic, four-degree, and five-degree polynomials. Using these methods, we can also find the nth degree polynomial equation. This method can factorize only a particular polynomial,which can be expressed as $x^n + a_1x^{n-1} + a_2x^{n-2} + \cdots + a_k$.

Limits of detection
Size and shape dependent physicochemical attributes

ABSTRACT

Over the past few years, water quality monitoring has swiftly emerged as a thrust area for most of the developing nations. Despite its renewable essence, incessant industrialization and urbanization have depleted the natural water resources, culminating in adverse impact on potable water quality. As a consequence, reliable technologies with utmost sensitivity and accurate predictions *vis-à-vis* authentic qualitative standards are urgently needed. Herein, interest in using gold nanoparticles (Au NPs) biosensors to gauge the qualitative profile of water resources has been quite significant. Major fascinations for Au NPs biosensing driven water quality monitoring are steadfast preparation methodologies, well-understood mechanisms for size-shape modulation and inert sensitivity manifested remarkable functionalization abilities. The size-shape modulated functionalization advances for Au NPs are the dynamic outcomes of their quantum effects, anchored *via* single or multidimensional quantum confinements (QCs). Morphologies as vibrant as rod, spherical, cylindrical, shells and combinatorial regime have been the backbone aspects of Au NPs based biosensors. With such insights, the present article focuses on last decade noted advances aimed at Au NPs biosensors assessed water quality. The studies discussed herewith were retrieved from Pubmed using the keywords, "Gold Nanoparticle Biosensors for Water Quality Monitoring". The knowledge shared herein could consolidate the fabrication of future Au nanomaterials based sensing technologies *vis-à-vis* functionalization mechanisms, cost considerations, precision aspects, integrated possibilities and long-term cautions.

1. Introduction

Deteriorating potable water quality has been an emerging global concern, manifested *via* unchecked human, industrial and agricultural exploitations. Pollutants from diversified sources (industrial and agricultural) contaminate the water bodies, rendering them unsafe for human consumption. Layman understanding of a contaminant *vis-à-vis* qualitative screening of any water resource implies any material prevailing at a more than optimum extent. Broadly, water contaminants can be chemical and biological, the former comprising insecticides, pesticides, aromatic compounds, heavy metals (HMs) *etc.*, the usual discards of industrial, agricultural and human activities. The mounting risk of all these contaminants relates to their persisting tendency with a non-biodegradable essence. Notable of these entities in the biological domain include humans, animals and microbial (fungal, bacterial and algal) excreta [1–3]. Emerging concern for declining water quality is well-inferred from the World Health Organization (WHO) recognition of "Safely Managed Drinking Water Services" as a global aim. Statistics report staggering 76 million annual cases of waterborne illness from United States [4]. Similarly, in Bangladesh, one of every five food poisoning deaths attributes to poor water quality [5]. Thereby, accurate, precise and reproducible detection of pollutants is the major step towards reclaiming freshwater resources for minimizing environmental and health damage [6,7]. Declining water quality on the global front is

aptly inferred by a mere 2.5% contribution of freshwater despite 70% of earth's surface being covered with water. More timid concerns include ~70% industrial wastes being dumped into water each year with 80% water pollution caused by domestic sewage. Estimates predict a staggering 6 billion pounds of garbage (majorly plastic) in oceans each year, with >4 lakh diarrhoea deaths due to polluted drinking water consumption. Shockingly, 368 million people use unsafe water globally with 80% land contributed wastes. The International Organization for Standardization (ISO) demarcates qualitative profile of water samples into I to III types, with type I being recognized as ultrapure (>18 MΩ-cm resistivity, $\sigma < 0.056$ μS•cm^{-1}, < 50 ppb total organic carbons).Corresponding nomenclature for drinking water are ISO24510 and ISO24511 while for wastewater is ISO24512. In India, decline in polluted rivers extent from 70% in 2015 (275 out of 390) to 46% in 2022 (279 out of 603) reflects awareness for conservation of water resources. However, increasing population, casualty for industrial effluent disposal has rendered 38.2% freshwater resources as polluted. As per 2018 Composite Water Management Index report, India ranks 120th amongst 122 countries on water quality index, with ~80.6% water being contaminated. Consensus for human consumption suited water deems (1–2) ppm as biological oxygen demand (BOD), (6.5–8) as optimum pH, (150–250) as total dissolved solids (TDS) as ideal. The physicochemical properties (PCPs) are more reliable than external energy driven UV spectroscopy, High Performance Liquid Chromatography (HPLC), Gas Chromatography (GC) [8,9]. A reliable aspect of PCPs is their temperature sensitivity as authentic qualitative indicators. For instance, recognition of *E. coli* strains (spreading fatal diseases) *via* incubation elapses 18–72 h to fetch reproducible results which could be done in (1–2) h using temperature specific density, ρ surface tension, γ and viscosity, η measurements [10].

Recent thrust into gold nanoparticles (Au NPs) with their high native stability and shape-size modulated quantum confinements (QCs) promises a well controlled, accurate and reproducible contaminants sensing *via* functionalized assays. A native inertness of Au (atomic number: 79, electronic configuration: [Xe] $4f^{14}$ $5d^{10}$ $6s^{1}$) entrusts Au NPs sensing advances *vis-a-vis* minimal cross-reaction risk with the corresponding analytes. Such attributes of Au NPs are the reasons for their portable, sensitive, automated and online feasible sensing configurations [11]. The efficacy of a biosensor is adjudged by probe-analyte specificity and sensitivity of transduction system intercepted analyte-probe biophysical interactions. Classification of biosensors could be made *via* screened analyte or workable detection mechanism. The detection mechanism based classifies configurations as electrochemical, calorimetric, optical and acoustic, characterized *via* differences in measurable prospects of probe-analyte combinations. A fair degree of similarity prevails in some types, such as electrochemical biosensors include both amperometric and potentiometric similar to optical fibre and surface plasmon resonance (SPR) regimen under optical regime. Incorporation of nanomaterials (NMs) simplifies the classification criteria, *via* specific NM based naming such as those using rod shaped NMs and quantum dots (QDs) being recognized as nanowire or QD based biosensors [12,13]. The rationale of amalgamating NMs in biosensors relates with their constricted energy levels driven prompt response, QC manifested alterations in optical, electronic and chemical properties. A prompt sensing of external stimulus in NMs is attributed to their high surface area (SA) manifested low E_a, whereby quick response to native energy levels is accomplished. The miniaturized dimensions of NMs make the sensing assembly robust and easy to relocate. A prominent distinction of NMs comprising sensors accounts for multifunctional probe sensitivity including temperature, pressure, optical, physical modulations due to missing quantum effects in bulk state. Analogy of this comparison could be understood *via* shrinking size of our electronic integrated circuits, whereby functionality is enhanced. Explicit benefit (s) for Au NPs relates to their distantly located 6 s sub-shell valence electron, which they can easily lose to form Au^{+} and readily couple with anionic surface sensitivity. Besides, the diversity of morphologies (rod, spherical, stars, shells and others) makes Au NPs suitable for a wide range of physical phenomenon and interacting receptiveness [13–16].

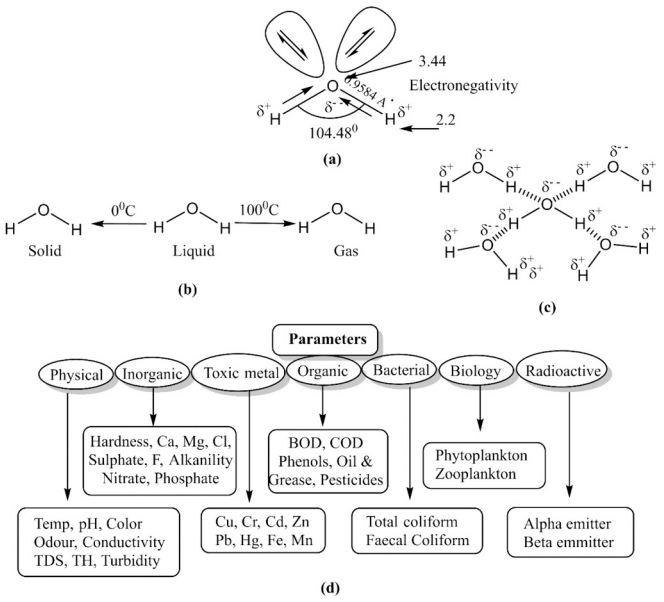

Fig. 1. Defining prospects of water, comprising its (a) Molecular structure with characteristic bond length and bond angle, (b) Temperature dependent prevalence of water in solid, liquid and gaseous states, (c) Possible inter and intra molecular hydrogen bonding attributing to a cage like networking of water molecules, (d) Native physical, chemical and biological attributes of water. With a polar nature and manifold usage, water has a unique ability of dissolving every substance to some extent, accounting for diversified contamination risks.

This article focuses on recent advances on Au NPs-biosensors monitored water quality. A high ground state stability conferred robust functionalization of Au NPs is the basis of not merely the sensing applications but also the targeted drug delivery where binding with specific cell surface receptors is needed. Readers are suggested to acquaint themselves with such distinctive abilities of Au NPs from the specific literature sources [17–19]. The unique optical traits of Au NPs, inspired by integrated oscillations of surface electrons are responsible for surface plasmon resonance (SPR). Surface plasmons (SPs) refer to the coherent electronic oscillations generated *via* electromagnetic radiations (EMR) at the metal-dielectric interface. Prominent optical sensitivities of Au NPs are explicit functions of dielectric environment and the EMR incident frequency. Herein, the SPR implication is manifested by resonance of oscillating SPs with incident EMRs, generating a characteristic stimulus at metal-dielectric interface [20,21]. The exclusive SPR frequency is decided by physical dimensions, morphology and chemical composition of NPs. For spherical regime, the resonant frequency falls within visible region of electromagnetic spectrum [22]. The high aspect ratio of Au NPs is sensitively affected by the dielectric nature of interacting vicinity (interfacial refractive index, RI) [23]. These features comprise physicochemical intricacies for analytes *via* interacting regimes substantiated surface absorption/desorption, aggregation and optical sensitivity. Analyte-detection corresponds to a binding extent proportionate SPR change of Au NPs, perceived *via* colorimetric changes [24,25]. Sensing platforms using Au NPs are optimized *via* enhanced localized electromagnetic field driven SPR changes. Such enhancements (Surface-Enhanced Raman Scattering) considerably improve the sensing sensitivity, distinctly identifying each target [26]. The robust functionalization techniques *vis-à-vis* NPs assembly on surface engineered platforms such as graphene and its derivatives encompass significant precision in electrochemical responses [27,28]. The shape-size controlled PCPs of Au NPs enable a precise detection of micro/nano-scale pollutants at parts per billion resolutions. Keeping above aspects in mind, hereby the major focus is on prospective attributes of Au NPs monitored water quality.

Table 1
Pure water standardized parameters as per WHO standards [34].

Parameter	Optimized range
pH	6.5–8.5
Turbidity (NTU)	1
Total Dissolved Solids (mg•L^{-1})	(150–250) but accepted till 500
Total hardness (as $CaCO_3$, mg•L^{-1})	200
Total alkalinity (as $CaCO_3$, mg•L^{-1})	200
Electrical conductance (μS•cm^{-1})	400

NTU: Nephelometric Turbidity Units.

Table 2
Native concentrations (mg•L^{-1}) of various ions fixed for water quality as per WHO standards [35,36]. The relative extents could ascertain the contamination extent.

Metal Ion	Ideal extents for potable water (μg•L^{-1})
Na^+	200
Ca^{2+}	100
Mg^{2+}	50
K^+	20
HCO_3^-	125–350
Cl^-	250
SO_4^{2-}	250
NO_3^-	50
Fe^{2+}	0.3
Mn^{2+}	0.1–0.5
Zn^{2+}	0.01–3
Al^{3+}	0.2
Pb^{2+}	0.01
Cu^{2+}	2
Cd^{2+}	0.003
Hg^{2+}	6 (For inorganic Hg)
Cr^{2+}	< 2
As	10
Se	40
U	30
F^-	1500

Emphasis has been paid to limit of detection (LOD) precision, selectivity, structural extensions and shape-size modulated PCPs.

2. Defining aspects of pure water and diversifications of contaminants

In its unadulterated form, water prevails as odourless, tasteless and colourless liquid with a bond angle of 104.48°, 0.9584 Å O—H bond length and an electronegativity of 3.44. Physical state of water varies with temperature, enabling a molecular distinction *via* varied intermolecular forces (Fig. 1). The intrinsic blueness of water is due to red light absorption [29]. With an ability to dissolve almost every material to a certain extent, water exhibits a highest density (1000 kg•m^{-3}) at 4 °C, prevailing in liquid state even at higher temperatures. In solid state (ice), the assembly of water molecules has one molecule as bonded to four others *via* intermolecular hydrogen bonding (HB), conferring strong cohesiveness, room temperature (RT) γ of 71.97 dynes•cm^{-1} and η as 0.8903 cP (Fig. 1b) [30–33]. Qualitative considerations on a global front distinguish the water resources as potable, palatable, contaminated and infected with surface water, oxygen depletion, nutrient, microbiological, groundwater and chemical mediated pollutions being distinguished. Screening of water quality is accomplished through physical, chemical and biological assessments Table 1 comprises the WHO recommendations for human usage compatible water traits, with acceptable TDS extents till 500. Human feasibility of water body could be adjudged by its high oxidation reduction potential (ORP), whereby plentiful oxygen implying a native cleansing ability *via* breakdown of waste products (contaminants, dead plants and animals) [34]. Table 2 comprises the regulatory guidelines recommended titre of ions in potable water, providing the basis for screening contamination [35,36]. Qualitative analysis could be accomplished *via* physical, chemical and biological assessments amongst which the physical standards (electrical conductivity, salinity, TDS, turbidity, melting and boiling points, odour, colour and taste) exhibit a highest consensus (Fig. 1d) [37,38].

Impurities in water are broadly distinguished on the basis of their biological or chemical origin, wherein the former includes the invasive and non-indigenous microbial species dwelling in a water sample. The biological and chemical contaminants affecting water quality are distinguished *via* microbial pathogens, excessive pesticides use, unmanaged industrial effluents, heavy metal prevalence (Fig. 2) [39–50]. Inceptive conceptualization of 'biological pollutants" was proposed by Elliott in 1972, considering them for invasion biology, *vis-à-vis* bacterial, algal and related toxins [51]. Though microbial contamination *via* improper wastewater management remains a biological concern, it can be tackled *via* pre-treating the toxic waste streams. Readers are advised to consult specific literature to have a better knowledge on microbial contaminant's health issues and environmental impacts [52–58]. Of late, microbial enzymes facilitated metallic NPs are being increasingly employed as remediation agents as several xenobiotics are easily degraded into simpler forms by microbes [59,60]. So, using recombinant DNA technology, the gene expressions controlling these enzymatic activities could be enhanced. Similarly, adversities of fertilizers and pesticides could be mitigated *via* nanocarrier mediated delivery [61–63]. Nanocarriers encompass a structural protection of delivered fertilizers and moderate the loading extents to counter undesired soil stress. Co-delivery of fertilizers with ecofriendly antioxidants safeguards them from oxidative damage, synergizing their antimicrobial activities with moderated administered quantities. Nonionic surfactants and plant extract capped NPs could be compatible stabilizers for such formulations, reducing the non-specific interactions [64].

3. Preparation methods for gold nanoparticles

With an atomic number of 79, Au exhibits [Xe] $4f^{14}$ $5d^{10}$ $6s^1$ electronic configuration. Owing to completely occupied energy shells, Au has a high ground state stability, minimizing the interfering possibility in sensing applications [65,66]. Preparation method for Au NPs (perhaps any singular metal NPs) comprises the reduction of chosen precursor salt, wherein zerovalent Au state (or the desired metal) is attained. The reduction of precursor salts could be accomplished *via* external energy (physical method), using microbial enzymes or plant metabolites (mostly natural polyphenols) or synthetic reducing agents (chemical method). The physical methods employ external energy, usually generate a lot of wastes and are environmentally threatening are the typical Top-down methodologies whereby no control in particle size dimensions could be exercised. Multiple methods using external energy as a source to reduce the metal salt precursors are known, such as laser beam ablation, ionic bombardment and others. Although the concerns of high energy dependence and enormous waste generation are resolved in chemical and biological methods for NPs preparation, the biological methods (nature friendly approaches using microbial enzymes or extracts of varied plant resources) suffer from scale up compatibility as the plant growth varies from one to other region [67–75]. Chemical methods of preparing metal NPs utilize the synthetic reducing agents and function without drastic energy inputs, enabling remarkable control in optimizing the particle dimensions *via* their "Bottom-Up" working principles (Fig. 3) [76–88]. Chemical methods of NPs preparation use moderate energy sources such as microwave treatment, emulsification, sustained ultrasonication (at low frequency), or a combination of these. The primed approach for Au NPs preparation was proposed by Turkevich, *via* varying precursor (mostly chloroauric acid, $HAuCl_4$)-reducing agent (trisodium citrate, $Na_3C_6H_5O_7$, sodium borohydride, $NaBH_4$ etc) interacting stoichiometries.

The nanoscale attributes of prepared NPs are explicit functions of their size-shape modulations, wherein a smaller size corresponds to stronger QC mediated changes in optical, physical, chemical and

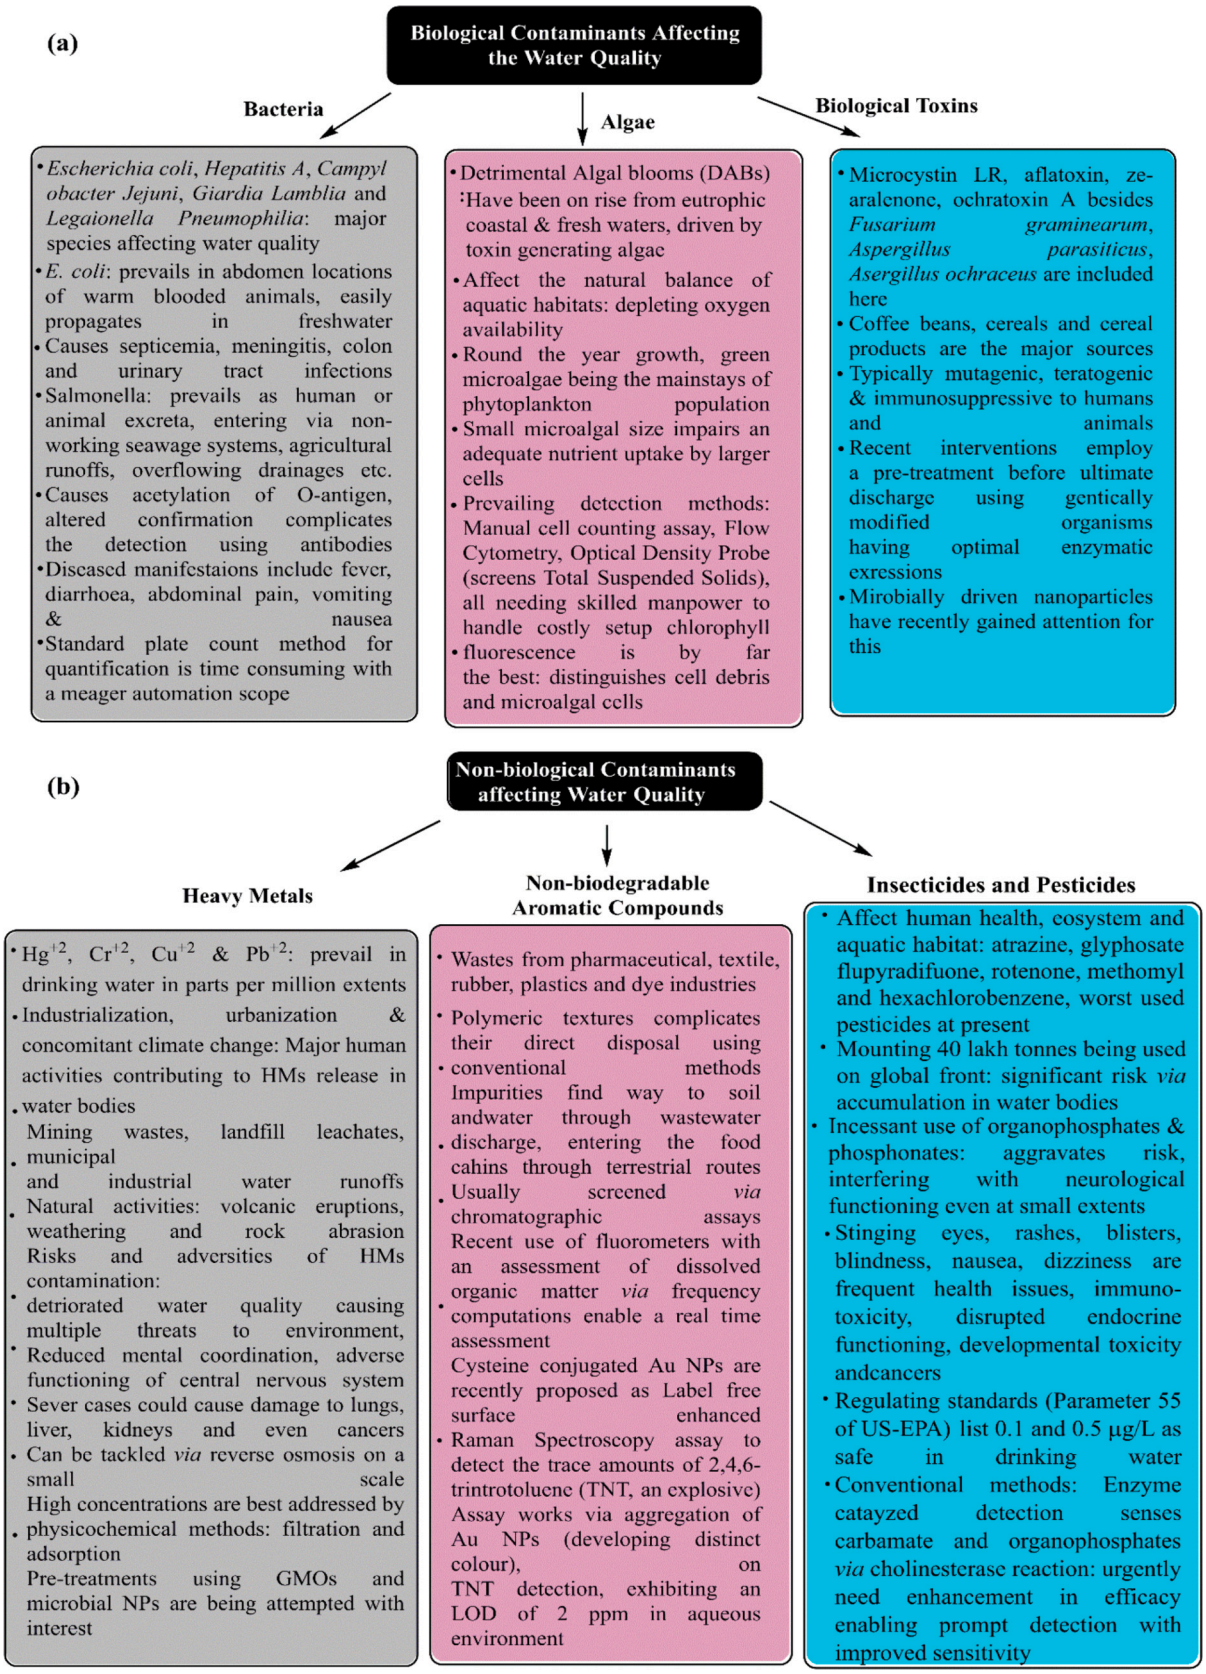

Fig. 2. (a) Major biological contaminants affecting the water quality, distinguished as bacteria, algae, and biological toxins, (b) Prominent non-biological contaminants affecting water quality, distinguished as heavy metals, insecticides and pesticides, and non-biodegradable aromatic compounds.

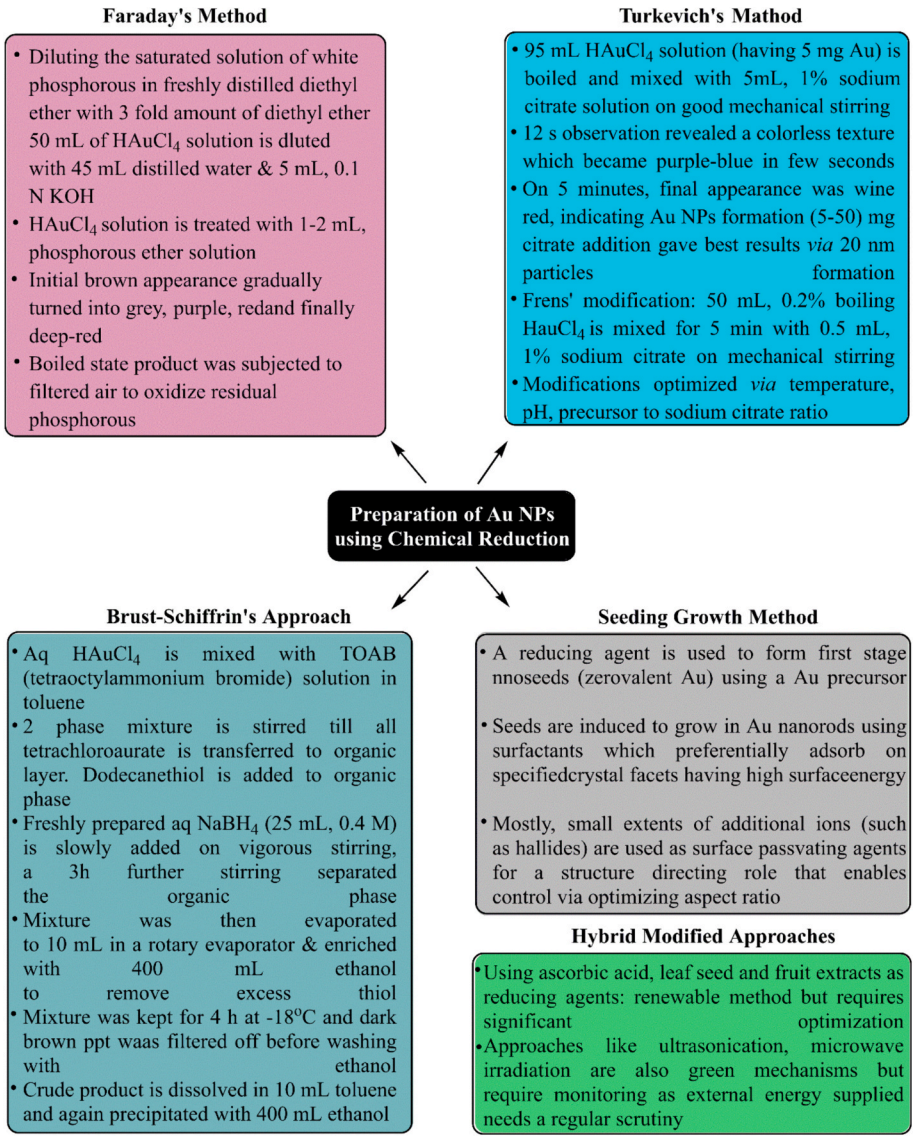

Fig. 3. Salient aspects of prominent chemical reduction methods for preparing Au nanoparticles, varying precursor to reducing agent stoichiometry is the basis of altered morphology and diversified applications.

electronic properties. Smaller dimensions attribute to a low energy band gap, owing to which, electrons from valence band are easily transitioned to conduction bands, generating the exciton promptly. The working mechanism for controlling the size and shape of NPs, is the optimized precursor to reducing agent stoichiometry, wherein rod or spherical morphology could be obtained. Other than precursor to reducing agent ratio, working pH, temperature and the precursor type are the prominent factors affecting the pace of NPs formation. From the precursor viewpoint, oxides are most easily reduced while nitrates are relatively tough to treat. With reference to pH and temperature, the optimum responses are generally retrieved for physiological pH and temperature albeit there may be variations for chemical methods. A number of iterations for size and morphology control of Au NPs *via* varied precursor and reducing agent ratios, have been comprehensively discussed in the publications on Turkevich's method and its optimizations [77–79].

Keeping such performance regulating attributes of Au NPs in mind, the next section discusses about the last ten year studies on Au NPs biosensors monitored quality of water resources.

4. Recent studies on gold nanoparticles monitored water quality

As discussed in earlier sections, preferential use of Au NPs and corresponding assemblies in biosensing (environmental and health concerns, majorly) is due to their high native stability, enabling multiple functionalization abilities. Our cautious literature search consolidated Au NPs as sensing probes, *via* (i) aggregation based singular or combined use, (ii) engineered electrodes as sensing platforms, (iii) functionalization with peptides, amino-acids, antibodies or manifold enzyme-conjugated biomolecules (DNA or RNAzymes), (iv) anchoring over graphene and reduced graphene assemblies, and (v) a miscellaneous approach (comprising integration of two or more of first four principles. The separate listing of graphene or graphene oxide conjugated Au NPs as functionalization assays is due to chemically distinct nature of graphene from the biological entities (proteins, antibodies and others). The surface versatility and tuneable energy levels of graphene makes it unique for engineered optoelectronic responses *via* numerous functionalization routes encompassed enhanced interactions for industrial, biological and energy harvesting [89,90].

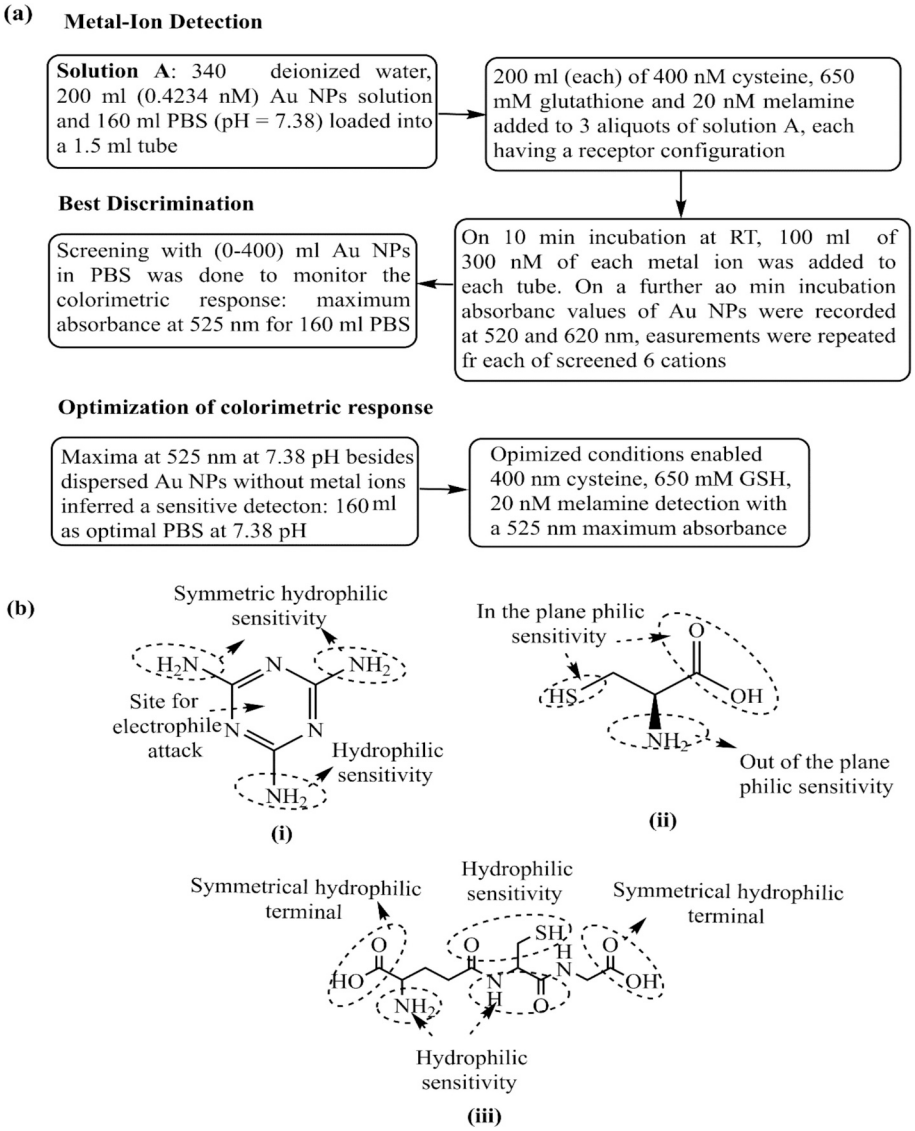

Fig. 4. (a) Metal ion detection and colorimetric response optimization steps for the 2019 study by *Li and colleagues* [95], (b) Molecular structures of (i) melamine, (ii) cysteine, and (iii) glutathione, with plentiful –OH, -SH and $–NH_2$ functional groups conferring a hydrophilic sensitivity. This implies that detection of these moieties mandates the probe interaction *via* hydrogen bonding, philic-philic or philicphobic interaction forces.

4.1. Aggregation facilitated singular or combinatorial assays

This section comprises the studies monitoring water quality *via* singular and combined (with other metal/metal oxide NPs) use of Au NPs. Working principle herein, uses distinct optical properties of monodispersed and aggregated states, the latter resulting in diminished energy due to increased sizes and reduced QC. So, the screened stimulus is detected *via* changes in native SPR of Au NPs through modulated dispersion regimes. The observed SPR of Au NPs varies as per the capping agent interaction with underlying NPs. Irrespective of formation mechanism, the SPR is observed corresponding to 520 nm, a variation arises due to distinct dispersion interception in course of UV–Vis spectroscopy [91]. The morphologies and architectures of NPs are the riders of their sensing abilities due to varied QC extents. For instance, a number of studies employ combinative use of NPs whereby the participation of capping layer is reduced to bare minimal. Regarding the morphology specific distinctions, the rod regime is better suited for sensing applications due to its capability of screening multiple functional responses on the same surface simultaneously. For instance, carbon nanotubes functionalized with Au NPs-anchored enzymes have been significantly explored as corresponding substrate detection(s) assemblies. Such distinctions are not feasible with spherical NPs which are better suited for adsorption, drug loading and charge transfer driven transport and surface engineering needs. The core-shell architecture is a characteristic configuration of NPs whereby enhanced protection, encapsulation extent and controlled release could be achieved *via* surrounding the functional NPs with a compatible shell. The functional aspects of shell material include a high dispersibility, biofunctionalization ability and control of optical properties. The uniqueness of these NPs pertains to their core-shell organic and inorganic sensitivity, with sizes in the order of few μm. These heterogeneous arrangements are highly stable in ambient conditions (at <200 °C) with minimal oxidation in (200–400)^{o}C. Unlike the conventional NPs, the specific characterizations for core-shell NPs are aberration corrected scanning tunnelling electron microscopy (equipped with high angle annular dark field detector), energy-dispersive X-ray spectrometry, electron energy loss spectroscopy. The shell protection in makes these NPs as highly useful for biomedical applications (bioimaging, drug delivery, sensing and gene delivery) [92–93].

Exploiting such remarkable attributes of core-shell morphology, a

2017 study by *Dong and colleagues* [94] developed Ag (core) and Au (shell) containing NPs which were conjugated with iridium (III) complex to screen cyanide presence in the water samples. The mechanism involved luminescence monitoring, getting quenched on (Ir(7-chloro-2-phenylquinoline)$_2$(4,7-dimethoxy-1,10-phenanthroline) (complex I) adsorption over Au surface of Ag@Au NPs. Electrostatic interactions between cationic, (Ir(7-chloro-2-phenylquinoline)$_2$(4,7-dimethoxy-1,10-phenanthroline) and Au shell, stabilized the assembly. The source of quenching was energy transfer from Ag@Au NPs to complex I *via* (300–800) nm absorption over Ag NPs. Such binding force dynamics engineered resonance of core-shell NPs and complex I- luminescence. Cyanide screening was facilitated by restoration on loss of Au shell, with Ag core being unable to do so. Inspection revealed a high sensitivity with 0.036 μM LOD with null detection of 10 fold contents of erstwhile anions. The approach could be extended to CN^- similar impurities *via* interacting with complex I. The optimized functioning of designed Au—Ag comprising core-shell NPs draws considerable interest wherein Au NPs as shell attributed to a flexible geometry and topology with low reactivity of Ag NPs containing core. Such an integrated assembly enabled thermal and oxidative stability of core NMs, making them suitable for biomedical, electrical and semiconducting applications. Thus, Au NPs as shell, conferred protection to Ag core and engineered a precise stimulus detection.

Subsequent 2019 effort used a colorimetric assay comprising cysteine, L-glutathione and melamine as recognition entities for screening toxic metal ions. Binding affinities of toxic cations with these recognition receptors were screened *via* Au NPs aggregation and consequent colorimetric response. The optimized configuration achieved significant Ti^{4+}, Cr^{3+}, Mn^{2+}, Fe^{3+}, Pb^{2+} and Sn^{4+} discrimination, in deionized water (DW) and real samples. Fig. 4a illustrates the detection procedure optimization for this study wherein, selective response was monitored *via* screening the absorption with and without Ti^{4+}, Cr^{3+}, Mn^{2+}, Fe^{3+}, Pb^{2+}, Sn^{4+} bound state of Au NPs at (300–1000,5000,10,000) nM. Six parallel measurements were made for each cation, generating a matrix of 6 ions, 3 receptors and 6 replicates. Thereafter, LDA (Linear Discriminant Analysis) converted this matrix into canonical factors, generating 3D-plots, with 95% confidence. The LDA scores for each cation revealed distinct clustering and discrimination. Analysis for intuitive distribution revealed a possible prominence in 300–10,000 nM range, exhibiting Ti^{4+}, Cr^{3+}, Sn^{4+}, Mn^{2+}, Pb^{2+} as preferentially captured by cysteine and melamine. Lower Au NPs absorbance differences with and without cations inferred a moderate receptor binding, with strongest affinity for cysteine. The discrimination accuracy (DA) were 75% (cysteine), 72.2% (glutathione), 72.2% (melamine), 94.4% (cysteine-glutathione), 91.7% (melamine-glutathione) and 91.7% (melamine-cysteine) and 100% (cysteine-glutathione-melamine), signifying a synergistic response.

Fig. 4b depicts melamine, cysteine and glutathione structural distinctions, wherein plentiful –OH, =O and –NH_2 functionalities exhibit a hydrophilic sensitivity. While glutathione is a physiological antioxidant, melamine is a toxic molecule with an excessive use being prohibited by FDA. The quantitative performance of developed probe was monitored using (100−1000) nM cationic extents, at 100 nM intervals. Maximum response was ascertained for 800 nM Ti^{4+}, 800 nm Cr^{3+}, 200 nM (each for) Mn^{2+}, Pb^{2+}, Sn^{4+} and 400 nM Fe^{3+}. The sensor array demonstrated nM sensitivity for Ti^{4+}, Cr^{3+}, Mn^{2+}, Fe^{3+}, Pb^{2+}, Sn^{4+}, with (100–900) nM linear responses for Ti^{4+}, Cr^{3+}, Mn^{2}, Pb^{2+}, (100–800) nM for Fe^{3+} and (100–1000) nM for Sn^{4+}. A linear variance of dose-response curve inferred stable cation-recognition receptor interactions with discrimination analysis revealing (Ti^{4+}-Mn^{2+}), (Ti^{4+}-Mn^{2+}-Sn^{4+}) and (Ti^{4+}-Cr^{3+}-Mn^{2+}-Sn^{4+}) for 1:9, (2:8, 3:7, 4:6, 1:1, 6:4, 7:3,8:2, 9:1), (2:2:6, 2:6:2, 6:2:2, 4:4:2, 4:2:4, 2:4:4) and (2:2:2:3, 2:3:3:2, 2:2:2:3, 3:2:2:3, 3:3:2:2, 3:2:3:3) stoichiometries, facilitating a 300 nM detection. Analysis of real water samples from *Yuyuantan Park* in Beijing, revealed no ion detection by ICP-MS but on being spiked at 300 nM to the sensor array, the screened ions were distinguished. Identification for screened

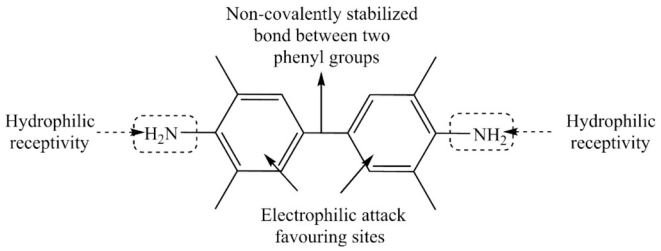

Fig. 5. Molecular structure of 3,3′,5,5'tetramethylbenzidine (TMB), the –NH_2 substituted phenyl rings confer a moderate interaction with Au NPs functionalized MOF framework. No steric hindrance in the –NH_2 groups vicinity argues well for their probing involvement. The (50–200) nM linear detection range with 8.1 ng•mL^{-1} LOD and (106–110)% recovery rate in 2019 study by *Li and colleagues*, creating interest for possible structural similarities with screened ampicillin, tetracycline and oxytetracycline [96].

cations was also made on serum samples, revealing a unique response alongwith LDA assisted six samples being clustered as distinct groups [95]. The working principle could be used to estimate the chemically similar impurities (similar group elements from periodic table), illustrating usefulness *via* characteristic Au NPs aggregation encompassed distinctive optical responses.

The next 2019 effort was the study by *Li and colleagues* [96] who screened antibiotics contaminated water samples using metal organic framework (MOF) conjugated aptamer functionalized with 3,3′,5,5'tetramethylbenzidine (TMB)-H_2O_2. The assay monitored TMB catalytic oxidation (included as label) from colourless to blue, using aptamer as antibiotic recognizer, *via* ascertaining the variations in MOFs catalytic activity. Out of Fe-MIL-53, Fe-MIL-88 A and Fe-MIL-100 ligands, Fe-MIL-53 was chosen due to its superior topological flexibility and small electron transfer impedance. Working configuration comprised quenched MOF catalysis through antibiotic-Au NPs-aptamer conjugate coating on MOF outer surface, increasing the impedance *via* reduced electron transfer. Selectivity and sensitivity of the assay revealed a (50–200) nM linear detection with 8.1 ng•mL^{-1} LOD and (106–110)% recovery, exhibiting suitability for chloramphenicol detection besides viable potential for ampicillin, tetracycline and oxytetracycline screening. Fig. 5 depicts TMB structure wherein –NH_2 substituted phenyl rings manifest a hydrophilic likability with an electrophilic proximity of π-conjugation rich phenyl rings. Development of such probes argued variability for a feasibility to screen hydrophilic contaminants. One concern shared by the authors though, points to 8.1 ng•mL^{-1} LOD, unable to screen fewer extents. A feasible extension of the work could be the SPR variations of Au NPs alone and their compatibility with Ag, Cu, Co, Mn for consolidated probe configuration to screen water-borne pathogens.

Next in line is a 2021 study wherein Au NPs functioned as segmented bridge for growing Ag shell and gather together the Au-Fe_3O_4 NPs with a dumb-bell morphology exhibiting a magnetic sensitivity. The assembly was optimized to screen aflatoxin *via* modulating the transverse relaxation time of examined water molecules. The Ag@Au-Fe_3O_4 nanoscale assembly was controlled *via* H_2O_2 which on horseradish peroxidase degradation, reduced Ag^+ to Ag^0, accompanied with transformation of dispersed Au-Fe_3O_4 NPs to Ag@Au-Fe_3O_4 aggregated entities. Detection sensitivity of assay was 3.81 pg•mL^{-1}, on par with competitive immunoreactions, improving the ELISA and HPLC screening by 21 and 9 folds [97].

A nearly similar but recent study used Au@MnO_2 core-shell morphology to screen *E. coli* contamination *via* accessing β-galactosidase action on single particle enumeration *via* colour code distinction. Presence of *E. coli* in tested water stream hydrolyzed *p*-aminophenyl β-D-galactopyranoside to p-aminophenol (AP) *via* endogenous β-galactosidase. Detection was confirmed *via* MnO_2 shell-AP reaction, resulting in blue shift of localized SPR (bright yellow to green colour change) with

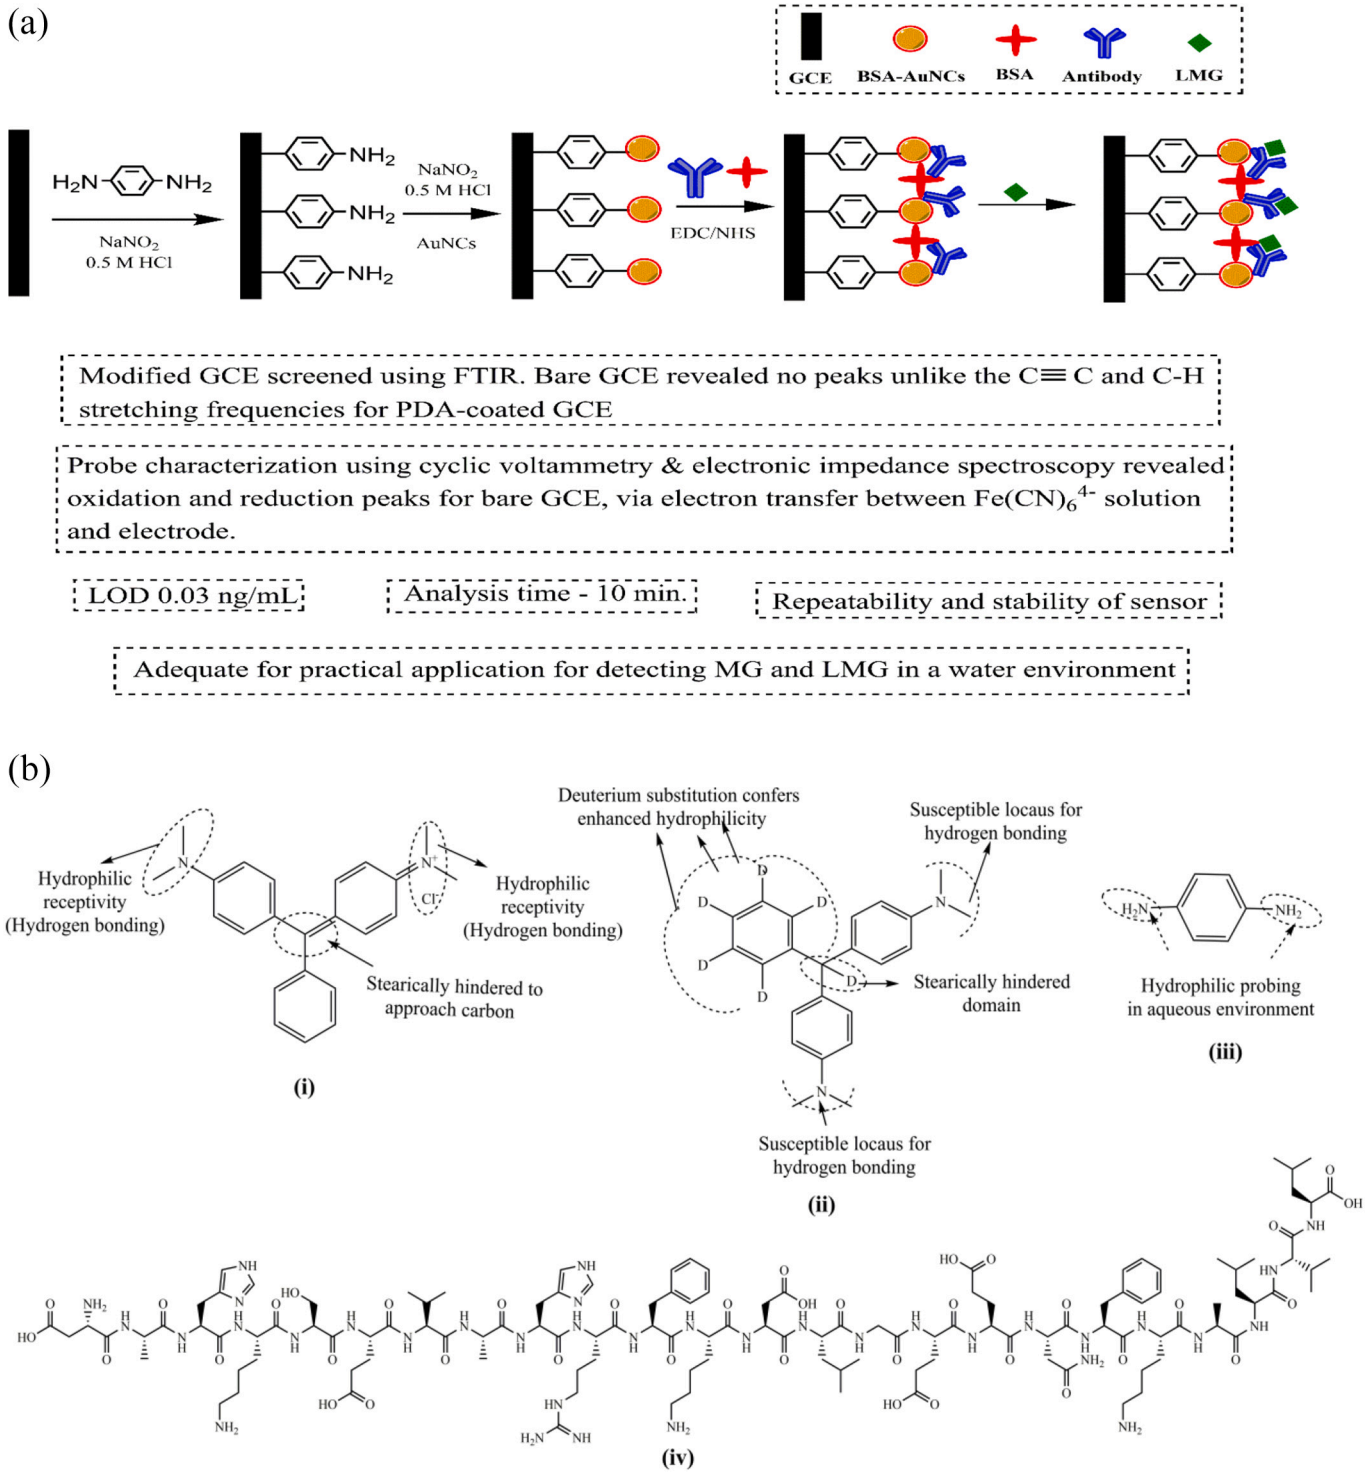

Fig. 6. (a) Optimization of probe assembly *via* N,N′-(3-dimethylaminopropyl ethylcarbodiimide hydrochloride) EDC-NHS (N-hydroxysuccinimide) assisted chemical reaction and the subsequent validation *via* cyclic voltammetry and electrical impedance spectroscopy for the 2016 study by *Zhu and colleagues* [101], (b) Characteristic hydrophilic and hydrophobic functionalities of (i) Malachite green (MG), (ii) Leucomalachite green (LMG), (iii) 1,4-phenylenediamine (PDA) and (iv) Bovine serum albumin (BSA), pertaining to the discussion of 2016 study by *Zhu and associates*. The matching of distributive hydrophilicities amongst PDA, BSA and MG, LMG offer enhanced understanding of probe design for distinctive MG and LMG recognition.

concomitant Mn^{+2} formation. The assay exhibited an LOD of 15 CFU•mL^{-1} over a (100–2900) CFU•mL^{-1} dynamic range, enabling an ultrasensitive and economic *E. coli* screening in river water. The robust configuration with dynamic working feasibility of the probe demonstrated the assembly as ultrasensitive, low cost measure to screen other than *E. coli* bacterial contaminations in river water and food samples [98]. Comparative analysis of last two studies [97,98] conceptualizes a wide anticipation of Au NPs comprising biosensors, *via* compatibility with Fe_3O_4 as well as MnO_2 and providing ultrasensitive detection of distinct contaminants. Such prospects illustrate the multifunctional analytical perceptivity of Au NPs with immense scope of modulated energy levels.

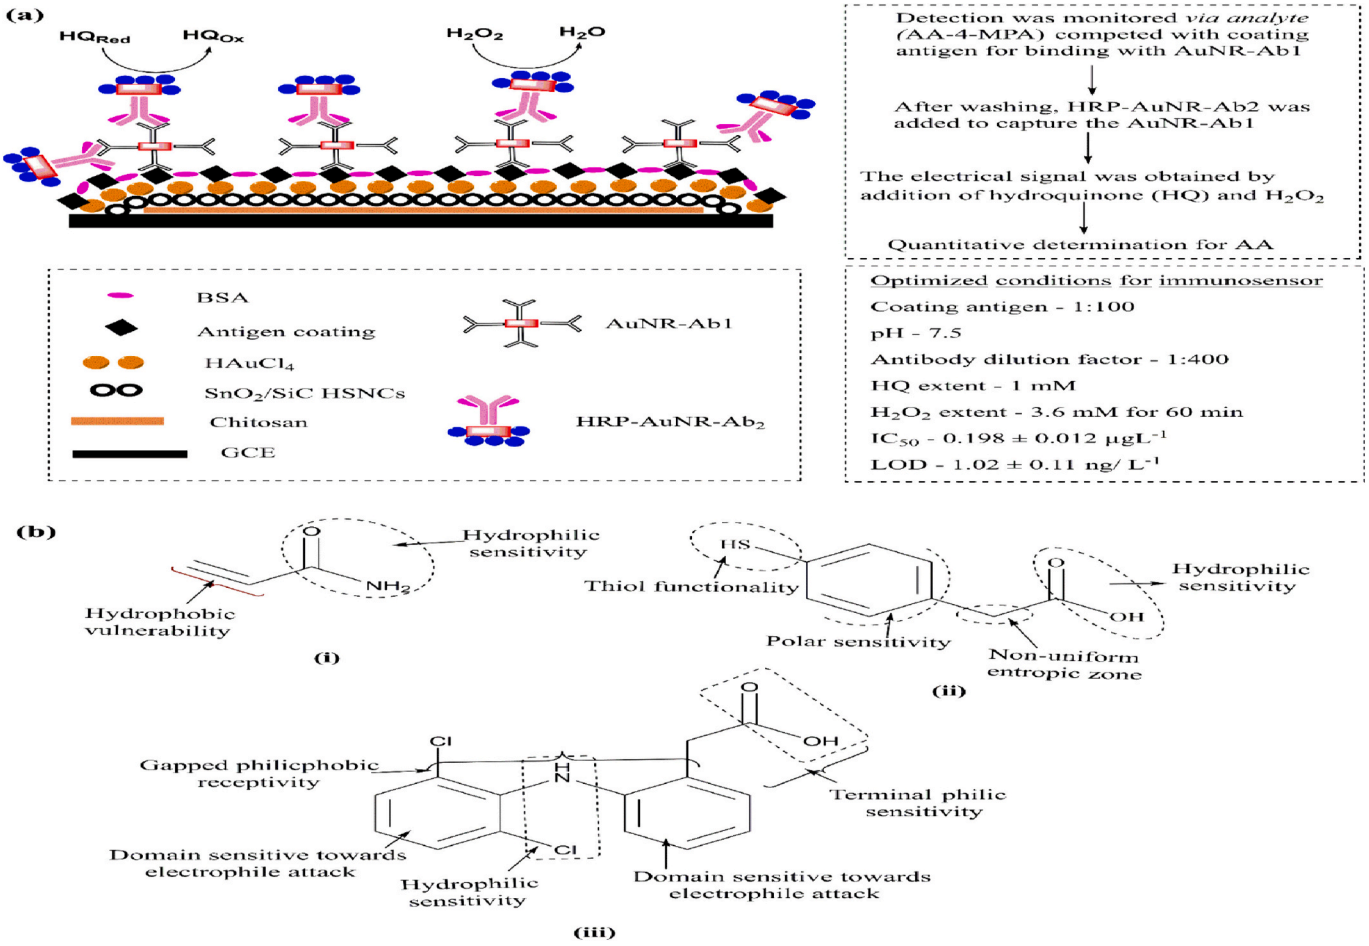

Fig. 7. (a) Schematic representation ofpH, dilution factor and H_2O_2extent driven detection methodology using Au nanorods conjugated with hollow SnO2-*SiC* spherical nanochains on chitosan pre-coated glassy carbon electrode, (b) Molecular structures of (i) acryalamide and (ii) 4-mercaptophenylacetic acid, and (iii) diclofeanc, with –NH, Cl, and –COOH and pi-conjugation conferring phenyl rings confer a distributed philicphobic receptivity. The structures pertain to the screened impurities in food and water samples in the 2018 study by *Wu and colleagues* [102].

Another worthwhile effort from 2021 optimized a surface-enhanced Raman Scattering (SERS) coupled wavenumber selection chemical signal monitored approach for screening Hg^{+2} in aqueous environment. Optimized probe configuration involved Au@Ag core-shell NPs which were used as SERS substrates while rhodamine 6G (R6G) was included as Hg^{+2} signaling probe. The Au NPs were prepared *via* 30 min uninterrupted stirring of 50 mL, 0.25 mM $HAuCl_4$ and 750 μL, 1% $C_6H_5Na_3O_7•2H_2O$ mixture at boiling conditions. Henceforth, 2 mL, 1% $C_6H_5Na_3O_7•2H_2O$ was added again to the reaction mixture. Finally, to develop Ag NPs shell, 9 mL, 1 mM $AgNO_3$ was injected at the rate of two drops per minute, followed by another 30 min stirring to obtain Au@Ag NPs. Physical indication of NPs formation was red wine to orange-yellow conversion. Characterization of as formed NPs corroborated their nanoscale traits, with 28.51 nm as average hydrodynamic diameters (using DLS), a spherical morphology (*via* TEM) and an SPR peak within (388–498) nm alongside a face-centred cubic, crystalline texture. The Hg^{+2} screening by optimized probe was accomplished *via* quenching of R6G strong SERS signal due to its interaction with Au@Ag NPs, resulting in progressive replacement of Ag^{+} by the bound Hg^{+2}. Enhanced extents of bound Hg^{+2} within $(10^{3}–10^{-2})$ μg•g^{-1} resulted in disorganized Ag shell morphology in the TEM micrographs of the probe, revealing an aggregated state. Correspondingly, a blue shift in UV–Vis SPR peak of Ag shell of Au@Ag NPs was noticed, reducing Hg^{+2} to Hg^{0} on the Ag shell surface of Au@Ag NPs, following Hg^{+2}-citrate ion of Au@Ag NPs complex formation. The SERS coupled sensing revealed a good efficacy over the SPR methodology, developing 0.9745 and 0.9773 as correlation coefficients within $(10^{2}–10^{-3})$ μg•g^{-1}. Specificity analysis of probe for 1 μg•g^{-1} Hg^{+2} with and without 100 μg•g^{-1} Ba^{+2}, Ca^{+2}, Cd^{+2}, Co^{+2}, Cu^{+2}, Fe^{+2}, Fe^{+3}, Mg^{+2}, Mn^{+2}, Ni^{+2}, Pb^{+2} and Zn^{+2} revealed Hg^{+2} acceptable SERS signal, inferring a good sensitivity. The recovery (88.45–94.73)% and (3.28–5.76)% coefficient of variations revealed a suitability of optimized SERS modulation for Hg^{2+} screening in aqueous conditions [99].

Summarizing the findings of singular or combined state Au NPs prevalence mediated SPR varied sensing responses, reveals a high sensitivity, reproducibility and specificity of various contaminants in examined water samples. There seems a possibility of still higher accuracies being accomplished *via* optimum combinatorial approaches whereby detection precision and reproducibility could be improvised. The accuracy of responses is sharply affected by the respective preparation methods of NPs with a higher reliability of chemical approaches.

4.2. *Use of Au nanoparticles modified electrodes as sensing platforms*

This section comprises the studies where Au nanothin layers functionalized electrodes (electrochemical detection) have been used as sensing platforms. A high electrical conductivity of Au augments its electrochemical abilities, paving way for accurate and precise stimulus detection [100]. Added incentive herewith is the robust size-shape modulation of Au NPs whereby detection platform geometry could be modulated. Herein, many studies have demonstrated thin film monodispersed textures of Au NPs in combination with other elements (such

as zirconium, vanadium *etc.*) for improved responses. A serious challenge in such probe configuration is the rigorous characterization *vis-à-vis* stimulus nature and intensity. The working principle screens the probe electrical and optoelectronic response in varying environments. Ahead is the discussion of post 2015 studies in this regard.

The 2016 attempt by *Zhu and associates* [101] reported a sensitive electrochemical impedance spectroscopy (EIS) assay for malachite green (MG) and leucomalachite green (LMG) detection using bovine serum albumin-functionalized Au nanocluster (BSA-Au NC) Ab composite film conjugated immunosensor. The investigators modified GCE with 1,4-phenylenediamine (PDA, for $–NH_2$ group), to obtain a stable surface suited for covalent binding. Fig. 6a summarizes the optimized probe configuration *via* EDC (N,N′-(3-dimethylaminopropyl ethylcarbodiimide hydrochloride))-NHS (N-hydroxysuccinimide) conjugation and its validation *via* cyclic voltammetry (C*V*) and EIS scrutiny. Analysis revealed an agreement for circuit model over the scanned frequencies with negligible resistance R_s (95 Ω) and impedance variations Z_w (1.45 m Mho) for each impedance scan, inferring no electrode surface modification. Owing to this, R_{et} was chosen for interfacial properties, increment in which deciphered electrically insulated LMG and Ab interactions. The analysis efficacy varied with incubation time and solution pH, examined *via* Ab-modified electrode immersion in LMG solution (10 ng•mL^{-1}) at (6–8.5) pH for (10–60) min. For calibration curve and interaction specificity, the EIS response to LMG concentrations was investigated at 5 mV, (0.1 Hz-100 KHz) and 0.29 V. The R_{et} increased with increasing LMG extents, supported by relative resistance and calibration curve linearity within (0.1–10.0) ng•mL^{-1}. With a 0.03 ng•mL^{-1} LOD, the R_{et} change was steady at >10 ng•mL^{-1} LMG. The EIS repeatability for 10 ng•mL^{-1} LMG with five assessments deciphered a 5.6% relative standard deviation (RSD) at 4 °C. Till 2 weeks, no significant reduction was noticed and impedance remained 90% of initial extent. Commercial feasibility was determined *via* EIS and ELISA inspections of (1–5) ng•mL^{-1} LMG spiked farm water samples. Analysis revealed good recoveries and EIS precision on comparative assessments with ELISA and Mass spectroscopy estimations, demonstrating suitability for aqueous MG and LMG screening. Fig. 6b depicts MG (i), LMG (ii), 1,4-PDA (iii) and BSA (iv) structural distinctions, wherein hydrophilic proximity favours 1,4-PDA coated BSA-Au NC constituted electrodes. The hydrophilicity of BSA argues well for its functionalization with Au-BSA NCs. Distinct binding accuracies with detection thresholds for MG and LMG were due to higher LMG hydrophilicity as it is substituted with five deuterium atoms. The structural distinctions of LMG and MG also provide a clue for the LOD dissimilarities as exposed hydrophilicity of LMG seems readily accessible by Au-BSA NC hydrophilic sensitivity. These attributes could be conceptualized for probe configurations *via* structure-activity-relationships modulations.

Subsequent attempt on Au NPs monitored water quality used high SA, hollow SnO_2-*SiC* spherical nanochains and Au nanorods (NRs), anchored on a chitosan pre-coated GCE for acrylamide (AA) screening in water and food samples. The 50 nm long, 20 nm wide Au NRs were prepared *via* seed mediated mechanism, using $HAuCl_4$ as precursor, $NaBH_4$ as reducing agent and CTAB as capping agent. The coating antigen, AA-4-mercaptophenylacetic acid-ovalbumin conjugate (AA-4-MPA-O*V*A) was immobilized on electrode while AA-4-MPA specific polyclonal Ab was conjugated to Au NR as primary antibody (AuNR-Ab_1). The Horseradish peroxidase labelled anti-rabbit Ab goat was conjugated to Au NRs as secondary antibody (HRP-AuNR-Ab_2). Sensing configuration involved dropping 5 μL, 0.2% chitosan solution over the electrode and RT drying. Subsequently, 0.5 mg SnO_2-*SiC* HSNC was monodispersed in 1 mL DW followed by its 5 μL-deposition on chitosan coated electrode, and a second RT drying. Thereafter, electrochemical deposition was done in 4 mL, 0.5 mM $HAuCl_4$ *via* (−0.3 to 0.3) V ranged CV for 5 cycles at 50 mV•s^{-1}. Fig. 7(a) summarizes the detection methodology optimization for validated pH, dilution factor and H_2O_2 extents. Real analysis on drinking water, coffee and potato chips revealed (45.9 ± 2.7) ng•kg^{-1} as LOD for (187 ± 12.3) ng•kg^{-1} to (104 ± 8.2) μg•kg^{-1} linear range. The AA content was ascertained as 1000 fold higher for coffee and potato chip, ruling out LOD quantification. Distinguishing aspects comprised stability monitoring *via* 4 °C periodic current response time assessments, revealing 97.3, 93.6, 90.7% initial current retaining on one, three and six weeks. Likewise, electrode regeneration monitoring revealed (15–50)% reduced output with no reuse feasibility, due to varied pH triggered electrode surface tampering. The AA recoveries ranged (86–115)% with (6.4–8.6)% variation coefficients, and (86.5–112), (4.3–9)% extents for coffee and potato chips. Selectivity analysis for AA-4-MPA revealed no cross-reactivity to 4-MPA, 4-aminothiophenol, AA, methacrylamide, methyl acrylate and acrylic acid [102]. The $–CO-NH_2$, –COOH, -HS functionalities of AA and 4-MPA exhibit compatibility whereby 4-MPA as electrode coating agent attributed well for immobilized Au NRs, vide interfacing thiol linkage (Fig. 7(b)). A pertinent concern herewith is the inadvertent AA use in childcare products (talc, soaps *etc.*), accounting for its recent suspension by US-FDA.

A recent investigation by *Iqbal and colleagues* [103] used DNA aptamer conjugated magnetic beads to quantify the *C. parvum* oocysts, frequent contaminants in potable water. A sensitive 3′-biotinylated R4–6 aptamer was used as secondary ligand for immobilizing streptavidin coated magnetic beads. The ligand bound magnetic bead assembly was then included within Au NPs modified screen printed carbon electrode (SPCE). The detection efficacy for *C. parvum* oocysts inferred specificity using square wave voltammetry with no *Giardia duodenalis* cysts binding, another ubiquitous water-borne pathogen. The sensing LOD was ascertained as 50 units with steadfast *C. parvum* oocyst detection in raw lake and river water. The study also screened a combination of Au NPs coated carbon electrode and aptasensor functionalized magnetic beads for deleterious aqueous contaminants, revealing significance *via* manifold Au NPs morphologies. The subsequent attempt was a 2019 study by *Costa-Rama and colleagues* [104], wherein a paper-based platform was used to screen diclofenac (DCF, an anti-inflammatory drug) in contaminated water samples. Carbon-ink paper was used as working electrode and two metallic wires, linked *via* Au connectors functioned as reference and counter electrodes. Porous paper membrane aided the sample preconcentration apart from its de-coupling and detection, accomplishing a 60 folds enhanced sensitivity and 8000 fold lower LOD over the DCF pre-concentration on the working electrodes. The detectable adsorption attributed to (0.10–5) μM and (5–100) μM linear detection. Feasibility for DCF contamination in spiked tap water samples revealed a 70 nM LOD with 5% RSD accuracy. Structural versatility of probe aided in integrated assembly of eight electrochemical cells, with -NH, Cl, and -COOH functionalities inferring an aqueous persistence besides π-conjugation supported electrophilic receptivity (Fig. 7biii). The cationic probes efficiently immobilized and detached the drug. It is essential hereby to understand the mitigating philicphobic sensitivities in such assays, necessitating a modulation of philicphobic force gradients is needed, could be accomplished *via* computational techniques ascertained most stabilized combination with least binding energy.

A latest attempt herein used Au NPs-PPy (polypyrrole)-$Ti_3C_2T_x$ (titanium carbide) nanocomposite, prepared *via* robust layer by layer self-assembly. Probe analysis using XPS and XRD revealed $Ti_3C_2T_x$ (a natural 2D material consisting of layered nitrides) significance in the formation and alignment of PPy (an organic polymer derived from pyrrole oxidative polymerization) besides Au NPs growth. Screening of composite texture revealed enhanced stability with improved electrochemical performance wherein Au NPs conferred the ability to form covalent bonds with biomaterials *via* Au—S linkage. Sensing response of optimized assembly for Pb^{+2} detection revealed a $5•10^{-14}$- $1•10^{-8}$ M linear working range with $1•10^{-14}$ M LOD. Besides the probe exhibited good selectivity and sensitivity for Pb^{+2} screening in environmental fluids (Nong Fu spring and tap water) [105]. Another significant effort from 2023 itself demonstrated an integrated nanoscale configuration of an electrochemical biosensor wherein functional probe design comprised a

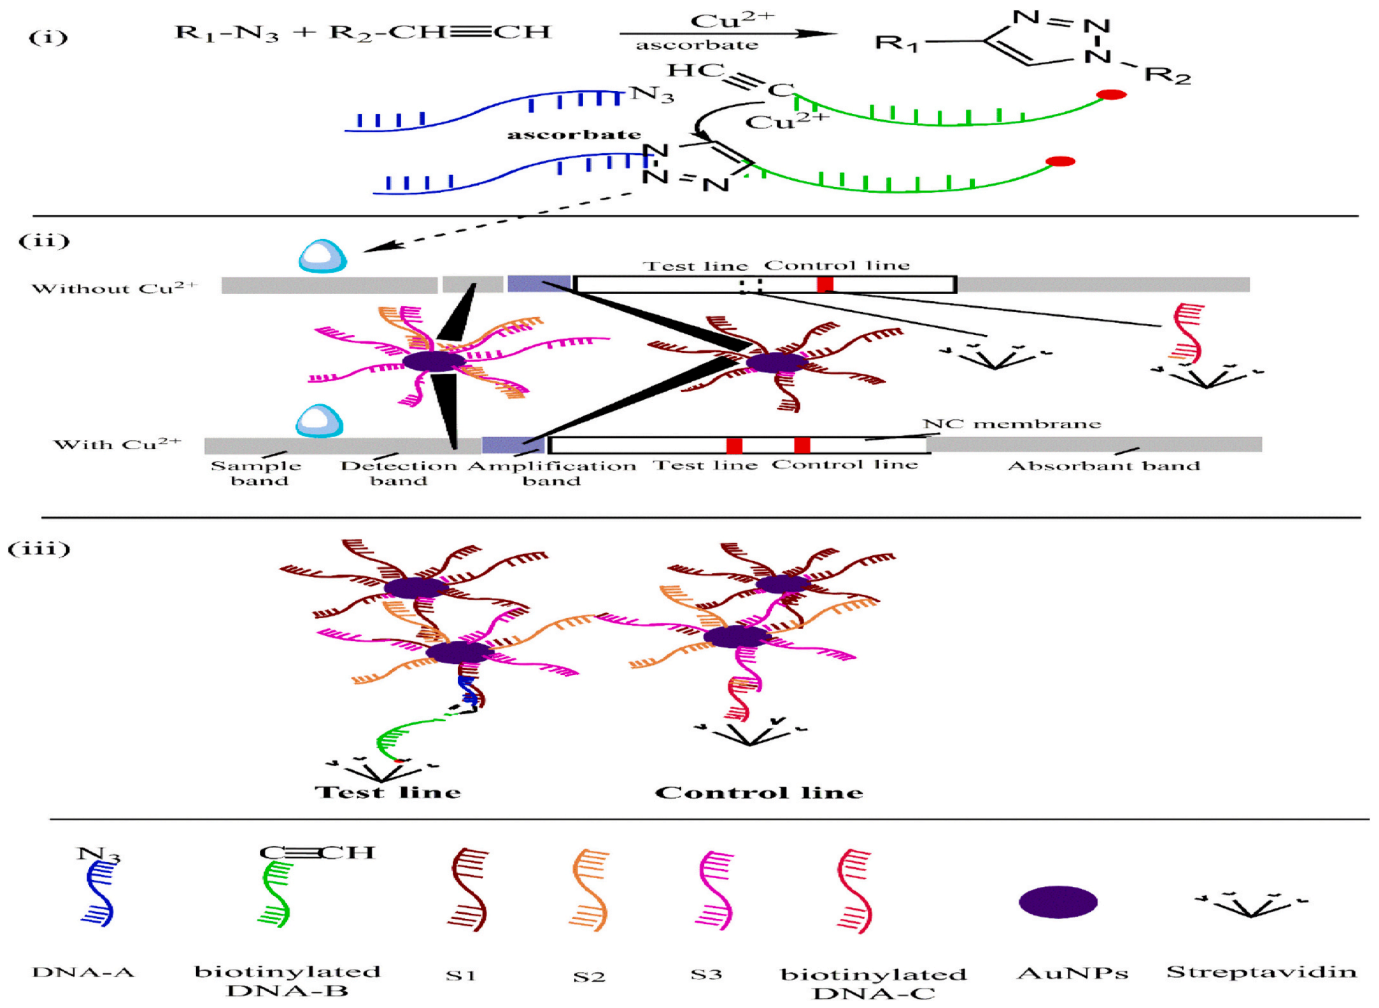

Fig. 8. Representative aspects of (a) Lateral flow test strip (SA-LFTS), (*Wang and colleagues* 2017), (i) Cu^{+2} detection based on Cu^{+}-catalyzed click chemistry, (ii) Visual detection of generated click-ligated ssDNA product, SA-LFTS includes an additional amplification pad (compared with traditional LFTS) that confers higher sensitivity [108]. The streptavidin-biotin interaction at the test line allows an easier implementation of the test, and (iii) The test and control lines of SA-LFTS assay after flow with Cu^{+2} addition. Au NPs are captured *via* streptavidin-biotin interaction and ssDNA hybridization.

carbon nanotubes-Au NPs and *E. coli*-polyclonal Ab and BSA engineered glassy carbon electrode (GCE), immersed in 0.1 M phosphate buffered saline (pH = 7). The sensor worked *via* acetaminophen (a non-opoid analgesic and antipyretic drug used to treat pain and fever) conjugation, detecting *E. coli* aqueous contamination *via* conductivity and current variations. Precision of the working assay was screened using square-wave, differential pulse and cyclic voltammetry, deciphering an LOD of 3.02 CFU•mL^{-1} *E. coli* detection in 3 min with reasonable accuracy, specificity, repeatability and reproducibility. Since *E. coli* is a frequent invader of food and drinking water, the demonstrated sensor configuration provides vital clues to integrate nanostructures for their synergistic bio-electronic response [106]. Thus, a generalized assessment of the studies in this section infers that Au NPs coating over the GCE surface either as nanothin films or *via* nanocomposite texture, efficiently screens aqueous contaminants with low response times. Indeed, probe functioning do requires a rigorous optimization as is the electrode stability for repeatable accuracies.

4.3. Biomolecules functionalized Au nanoparticles as water quality monitoring probes

This section comprises biomolecules (such as antibodies, enzymes, peptides, aptamers, engineered oligonucleotides *etc.*) functionalized Au NPs as water quality sensing probes. Select ligands or surface pre-treatments used *via* Au NPs functionalization herein comprise alkane thiol conjugation, Ab linking *via* avidin-biotin mutual interception, biocompatible peptide-dye conjugation and combinatorial regimen with other conducting/semi-conducting materials. Functionalization method needs a rigorous monitoring to ensure minimal interactions failing which, the probe's working efficacy could be tampered with.

The first major post 2015 effort herein used oligonucleotide functionalized Au NPs for rapid and specific *Staphylococcus aureus* (*S. aureus*) detection using a colorimetric mechanism. The probe configuration involved functionalization of a chemically modified 11-mer sequence onto the Au NPs *via* chemical conjugation. Analysis revealed Au NPs aggregation in response to *S. aureus* detection (as supernatants). The designed Au NPs-oligonucleotide assembly exhibited a biological suitability in creek and ocean water besides being storable as lyophilized powder, suggesting transportation and packaging robustness. Another advantage comprised the bacterial enzyme detection proximity (besides *S. aureus*) through modifications in oligonucletide array and coated NPs morphology. It is pertinent to mention here that *S. aureus* is a Gram-positive bacterium with a spherical morphology familiarly prevailing in the upper respiratory tract and on skin. The bacterium is positive for catalase and NO_3^- reduction, ruling out a mandatory need of oxygen for growth. Opportune pathogenic expressions are widely manifested as common cause of skin infections (abscesses), respiratory infections (sinusitis) and food poisoning. Major cause of such pathogenic

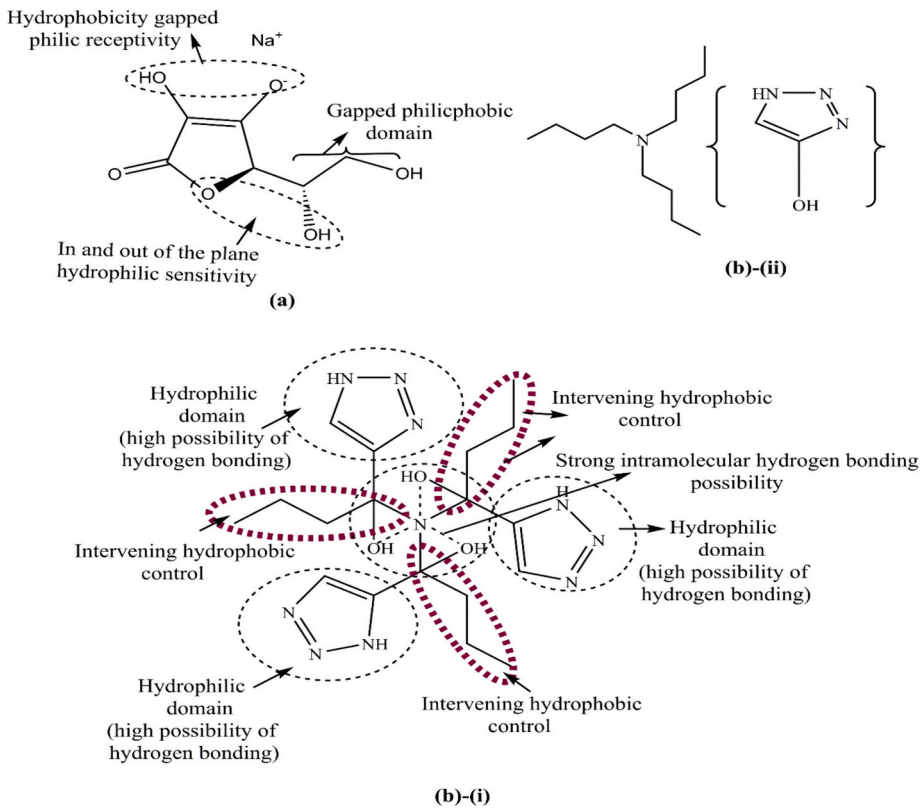

Fig. 9. Structural proximities of a) sodium ascorbate (SA), and (b)-(i) tris-(hydroxypropyltriazolylmethyl) amine (THPTA) and (ii) overlapping hydrophobic and hydrophilic domains in THPTA structure. While SA facilitated the reduction in the Cu^{+} catalyzedazide-alkyne cycloaddition and chemical ligation of alkyne and azide modified ssDNA, the intent of adding THPTA was to stabilize water-soluble copper(I) ligand exclusively used in copper(I)-catalyzed alkyne-azide cycloaddition.

expressions is the virulence factor generation, including protein toxins and cell-surface proteins binding for inactivating the antibodies [107].

Progressing to 2017, the first notable attempt by *Wang and colleagues* [108] demonstrated a signal-amplified lateral flow test strip (SA-LFTS) for Cu^{+2} aqueous screening using click chemistry based Cu^{+} hybridization of ssDNA. The alkyne and azide modified ssDNA perceived Cu^{+2} *via* Cu^{+} aided cycloaddition *vis-à-vis* alkyne and azide groups modified ssDNA, chemical ligation. The ssDNA-Au NPs hybridization resulted in high sensitivity with naked eye visualization of test strip ligated ssDNA. Primitive SA-LFTS features comprised DNA-A (azide group) and biotinylated DNA-B (alkyl group) as Cu^{+2} recognition reagents. Assay worked through azide cycloaddition and alkyne functionalized ssDNA to generate a click ligated, ssDNA chain (like, DNA-A-DNA-B). This ssDNA was biotinylated and applied to the test strip (Fig. 8(i & ii)). The reaction commenced with ssDNA-DNA-Au NPs probe I hybridization on strip detection pad (partially complementary to DNA-A). Upon test line migration of this complex, it was captured by strepdivin-biotin complex *via* Au NPs binding. The Au NPs binding with DNA-C was deciphered as red band on control line, confirming a proper functioning of test strip. Thereafter, DNA-Au NPs probe II was hybridized with DNA-Au NPs probe I on the amplification pad, resulting in Au NPs test line accumulation. Monitoring the test line colour change validated Cu^{+2} existence, based on which the quantitative screening was optimized using portable strip reader recorded relative intensity. Fig. 8(iii) illustrates the

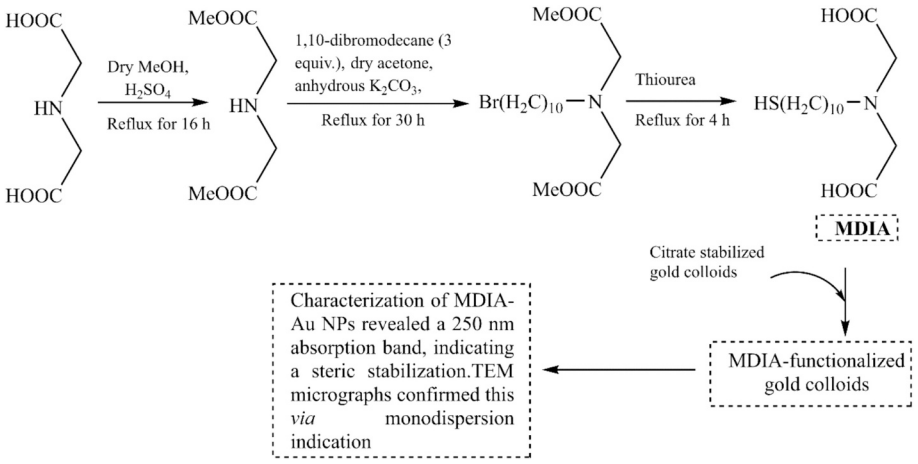

Fig. 10. Optimized procedure for 10-mercaptodecyl-1-iminodiacetic acid (MDIA) synthesis and its functionalization with Au nanoparticles, for the 2017 study by *Chai and colleagues* [110].

optimized probe configurations, wherein sodium ascrorbate moderated Cu^{+} catalyzed azide-alkyne cycloaddition and subsequent ligation of alkyne-azide modified ssDNA. The optical response for sodium ascorbate variations revealed 800 μM as adequate extent which was similarly ascertained as 1 mM for tris-(hydroxypropyltriazolylmethyl) amine (THPTA, for enhanced Cu^{+} binding) with a pH of 7 (highest relative intensity). Functional assay retrieved an LOD of 4.2 nM, ~four orders lower than US Environmental Protection Agency (EPA) prescribed 20 μM. Specificity for Cu^{+2} was monitored *via* test line colour intensity and Mg^{+2}, Hg^{+2}, Pb^{+2}, Ca^{+2}, Cd^{+2}, Zn^{+2}, Fe^{+3}, Na^{+}) responses. Except 100 nm Cu^{+2}, no ion developed a bright red band. Practical feasibility was studied using (20, 200 nM, 2 μM) Cu^{+2} spiked municipal and river water, retrieving (92.30–106.52)% recoveries, confirmed by inductively coupled Mass Spectroscopy (ICP-MS).

Fig. 9a depicts sodium ascorbate and THPTA distinctions, wherein oxygen, OH and Na^{+} functionalities of the former confer a hydrophilic sensitivity while the in and out O, –OH placements in the 5-membered ring and extended aliphatic chain manifested hydrophilicity. Similarly, the terminal –OH in aliphatic chain conferred philicphobic sensitivity. For THPTA, alternative hydrophilic and hydrophobic domains manifest a homogenization (Fig. 9b-i). The overlapping hydrophilic domains (-OH substituted pyrimidine ring) and N centred 3 alkyl chains (ACs) are demarcated in Fig. 9b-(ii). The THPTA inclusion in the probe assembly stabilized water-soluble Cu (I) ligand, widely used in Cu(I)-catalyzed alkyne-azide cycloaddition [109]. These logics could be extended to detection assays *vis-à-vis* moderate analyte-probe interactions. Stronger DNA-Au NPs hybridization with sodium citrate affirmed a best sensing, leaving aside PBS and Tris-HCl.

Another significant 2017 study from *Chai and colleagues* [110] used 10-mercaptodecyl-1-iminodiacetic acid (MDIA) to modify Au NPs for RT Cu^{+2} sensing from solution. Fig. 10 illustrates MDIA synthesis, its post synthesis characterization and Au NPs (made using Turkevich's method)-functionalization Subsequent to Cu^{+2} binding, the MDIA@Au NPs absorbance decreased with a distinct 560 nm band besides a red to purple change. These observations were complemented by TEM micrographs, exhibiting Cu^{+2}-carboxylate ligand complex formation on Au NPs surface with. The estimated LOD for Cu^{+2} was $1\bullet10^{-4}$ mol•L^{-1}, ascertained *via* colour change intensity. The 520 nm absorbance changes *via* calibration plot, revealed a linear trend for ($5\bullet10^{-6}$ to $5\bullet10^{-4}$) mol•l^{-1} Cu^{+2}. The 3.9% RSD for five assessments inferred reproducibility of the assay. The EDTA effect on MDIA@Au NPs *vis-a-vis* enhanced Cu^{+2} extents revealed sudden intensity increments *via* RT (610 to 520) nm blue shift, with red to purple colour change, indicating strong EDTA-Cu^{+2} interactions. The assay reusability screening revealed an aggregation (red to purple) on Cu^{+2} and EDTA addition. Continued EDTA addition generated red colour again, suggesting a reversible aggregation *via* metal ion chelation. The Cu^{+2} holding MDIA@Au NPs were thus, centrifuged to separate Cu^{+2} complex and the MDIA@Au NPs were dispersed in distilled water, promptly developing a red colour. Similar observations on equal Cu^{+2} addition to MDIA@Au NPs inferred the assay reusability. Analysis for Cu^{+2} detection from acidic waste having (30, 40, 50, 60 and 70) μM Cu^{+2}, was done *via* mixing 1 mL concentrated MDIA@Au NPs with 9 mL acid etching solution. On 30 min stirring, the mixture was centrifuged to retrieve the supernatant which on Atomic Absorption Spectrophotometer (AAS) screening, revealed 3051 mL•g^{-1} as absorption coefficient. Thus, this study used MDIA functionalized Au NPs to screen Cu^{+2} with a feasibility to screen erstwhile chelating agents other than EDTA.

Next in line is a 2018 study, using monoclonal antibodies (MAbs) and 6-carboxyfluoroscein labelled single stranded-thiol oligonucleotides (6-FAM-SH-ssDNAs) functionalized Au NPs. The study screened triazophos (a pesticide) *via* ovalabumin conjugated haptens competitive assay for antibodies anchored Au NPs. Functionalization with 6-FAM quenched the Au NPs fluorescence *via* inverse variance with analyte extent. Sensing parameters included an hour of salting whereby (166 ± 9) ss DNAs were loaded on Au NPs. Feasibility studies were done on water,

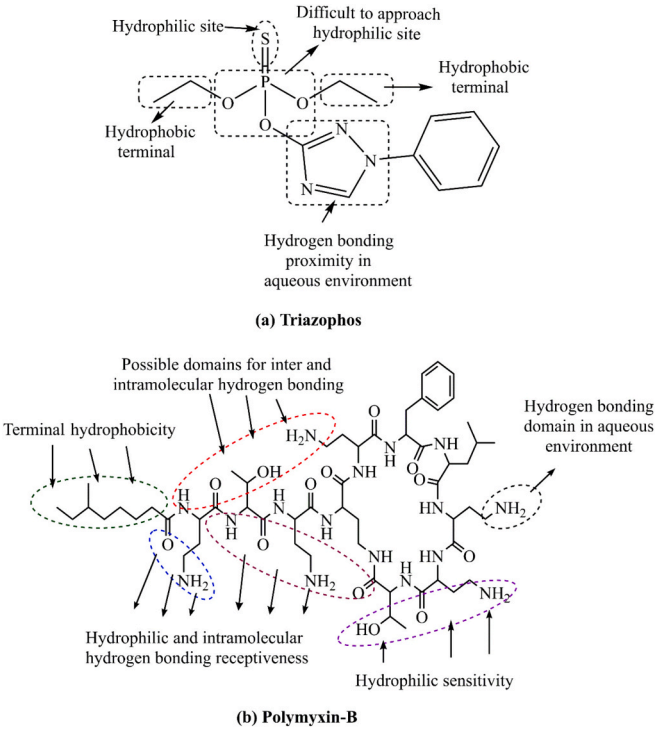

Fig. 11. (a) Distribution of hydrophilic and hydrophobic force factors in the insecticide triazophos, and (b) the drug polymyxin-B. Manifold hydrophilic sensitivities in both compounds confer the possibility of significant hydrogen bonding, with the latter exhibiting significant intra and inter molecular controls.

rice, cucumber, cabbage and apples, revealing (0.01–20) μg•L^{-1} linear range, 6 ng•L^{-1} LOD, (85–110.3)% recovery and (9.4–17.4)% RSD. The assay revealed 0.9794, 0.9758, 0.9783, 0.9841, 0.9709 correlations with liquid chromatography-tandem mass spectrometry (LC-MS) [111]. Specificity studies deciphered >2000 μg•l^{-1} IC_{50} for chlorpyrifos, chlorpyrifos methyl, parathion, malathion, diazonin and fenitrothion. The P and S double bond besides multiple N substituted 5-membered ring in traiazophos endow a tough biodegradation (Fig. 11a). Assay efficacy could be improved *via* S and P double bond interception, with 3 O linked to P and hydrophobic sensitivity at the terminal locations. The S atom in P—S linkage restricts the approachability to P *via* its lone pair electrons and reduces the hydrophilic activities of the pesticide. The π-conjugation at the terminal location of middle O atom linked to P manifests a electrophilic sensitivity and could be re-engineered *via* substitution to augment the detection *vis-à-vis* moderate cationic probe sensitivity.

The first noted attempt from 2019 used polymyxin-B conjugated Au NPs (PMB-Au NPs) for lipopolysaccharide (LPS) (a bacterial endotoxin) detection. Sensing probe comprised a U-bent fibre optic probe (UFOP), entrapping LPS from aqueous solutions using biomimetic self-assembled octadecyltrichlorosilanes (OTS) layer functionalization. Fig. 12 summarizes the UFOP fabrication and its characterization for sensing response. The OTS coating of fibre surface was engineered *via* incubation with fixed fluoro-LPS on getting rid of excess LPS. Real time probe efficacy was ascertained from an improved RI sensitivity whereby a glass flow cell having OTS functionalized UFOPs was dipped in samples with varied LPS amounts. Inspection revealed an LPS RI of ~1.5 contrary to 1.45 for bulk OTS solution, due to an additional LPS layer *via* displacing water (RI = 1.33). The LOD with OTS free UFOP was 0.1 μg•mol^{-1}, assuming 10 kDa as LPS molecular weight.

Screening of PMB bound Au NPs at 525 nm revealed an enhanced absorbance, varying exponentially with LPS amount with 1 ng•mL^{-1} as least screened LPS extent; two orders higher than direct assay

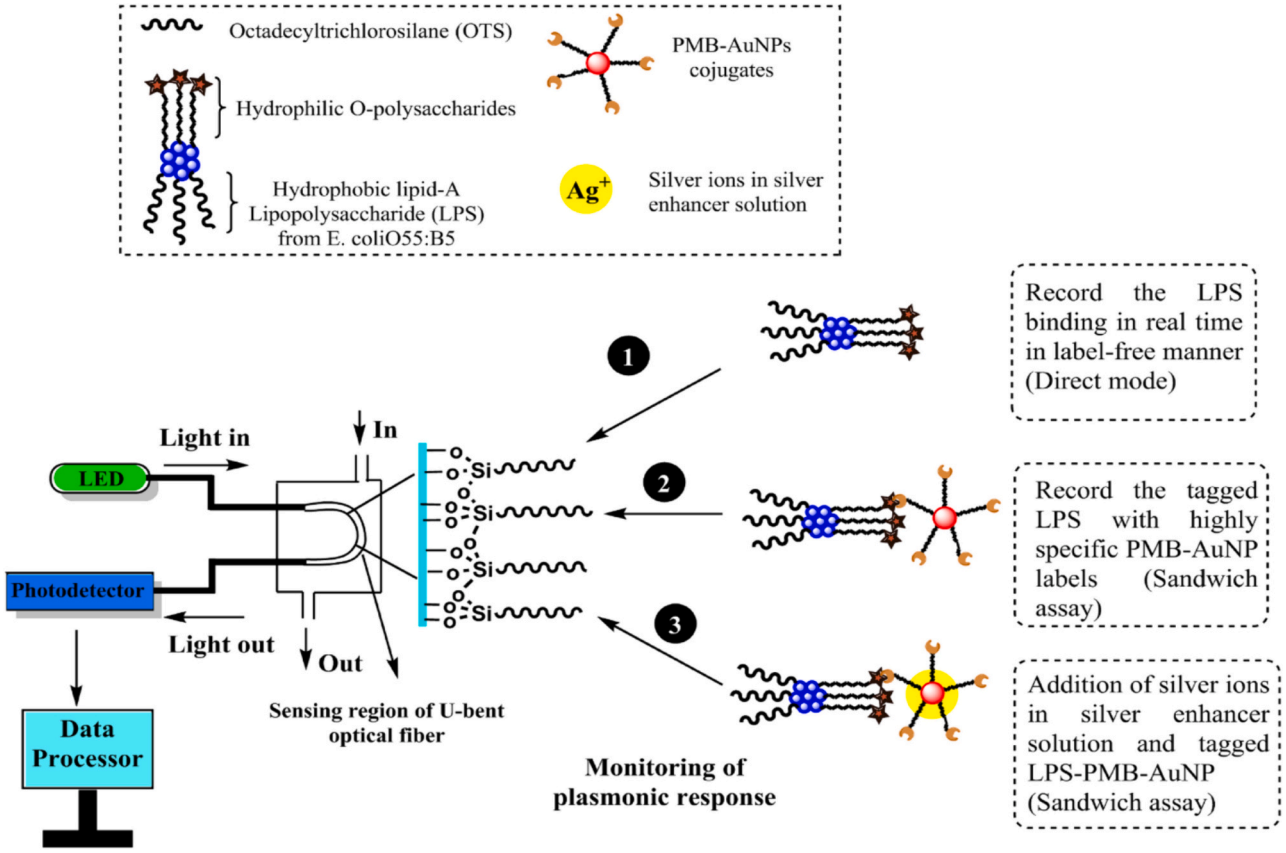

Fig. 12. Fabrication steps forU shaped bent fibre optic probedevelopment and its characterization for sensing response, for the 2018 study of *Zhang and colleagues* [111].

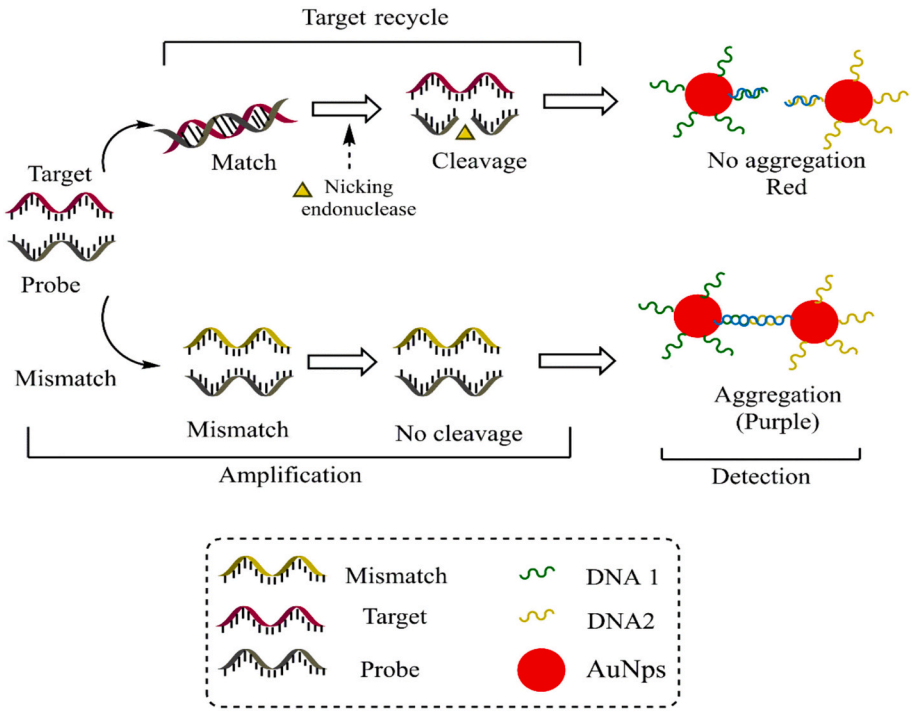

Fig. 13. Optimization of probe design, in terms of amplification and detection procedures for DNA nanoparticles mediated zebra mussel DNA identification in contaminated water samples [116].

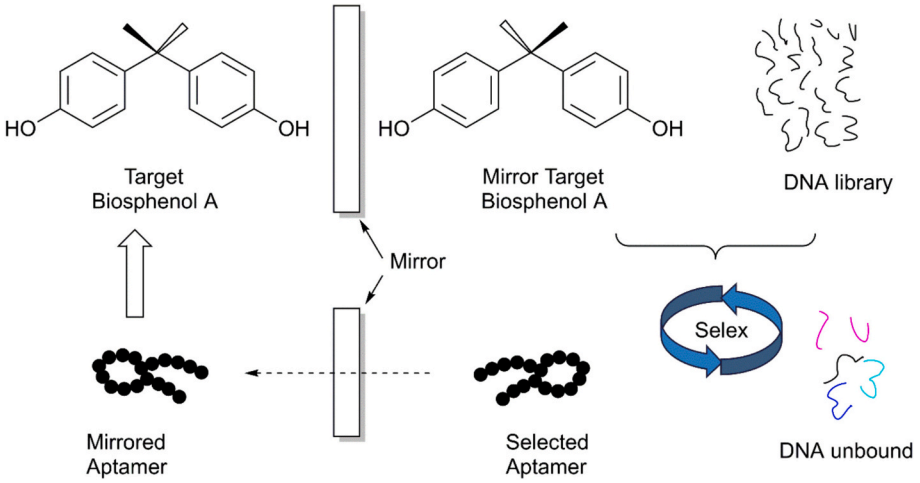

Fig. 14. Optimization of probe design for D-oligonucleotide enantiomers mediated Bisphenol A detection in contaminated water samples [119].

[112,113]. Linear detection within (0.1–100) ng•mL^{-1} with 0.97 correlation coefficient, supported the SEM observations. Specificity inspection for threonine, tyrosine, lactic acid, human immunoglobulin (IgG), normal saline and dextrose normal saline revealed (10−100) folds higher LPS extents. The response was monitored *via* incubation in 100 ng•mL^{-1} LPS-interferers and PMB-Au NPs, revealing least LPS contamination for human IgG with none signal being >15% without interferers. Sensitivity enhancement *via* catalytically assisted Ag deposition on Au NPs, facilitated prompt Ag^{+} reduction and subsequent nucleation [114]. Upon 3 min Ag enriching, unfolded probes exhibited a dose dependent signal with 36 fold higher sensitivity, 0.998 correlation coefficient and a (0.1–100) ng•mL^{-1} linear response. The LOD was 0.4 ng•mL^{-1}, better than sandwich assay regime. The Ag enhancement revealed a large red shift on Ag NPs deposition over the fibre surface

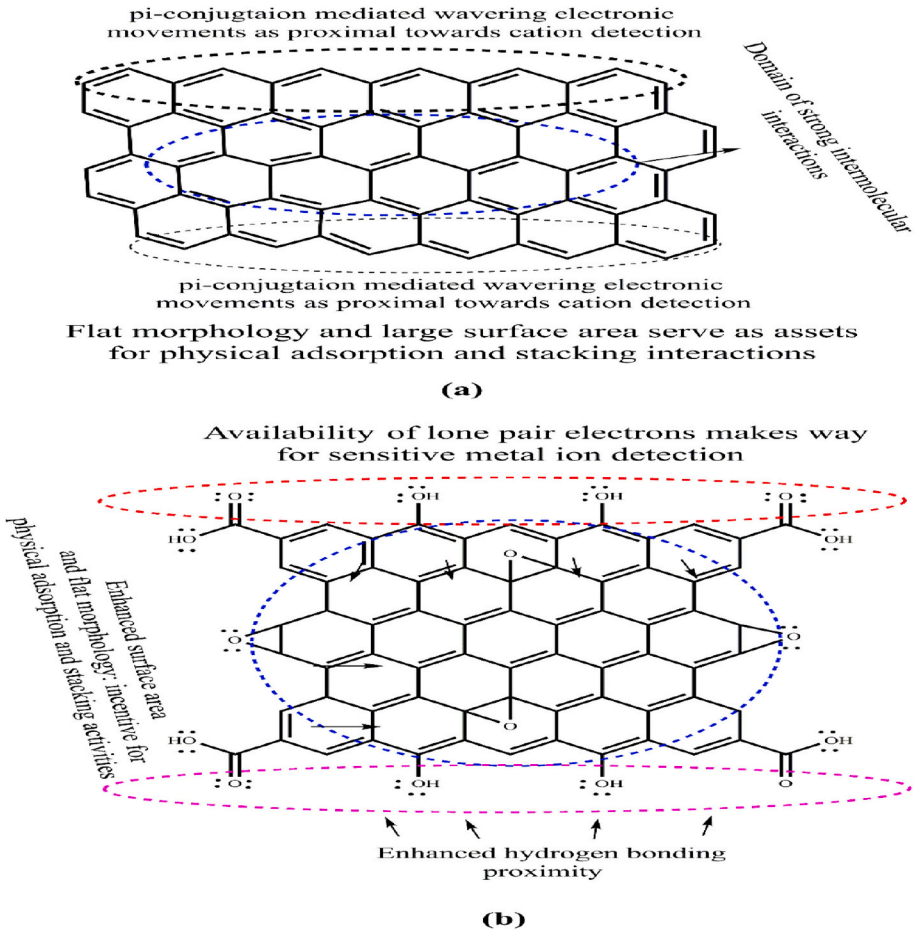

Fig. 15. Schematic representation of (a) sp^2 hybridized pure carbon hexagonal lattice, and (b) representative chemical structure of graphene oxide. While hexagonal lattice depicts the large surface area of graphene the formation of graphene oxide is attributed towards enhanced interactive functionalities *via* conjugated O and –OH functionalities. Varying oxygen contents in graphene oxide formed from graphene are the basis of multiple applications.

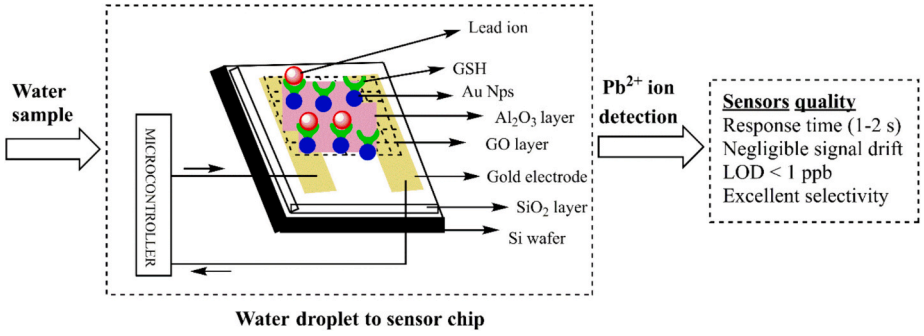

Fig. 16. Pictorial depiction ofsensor chip describing the functional biosensing mode for the 2017 study by *Maity and colleagues* [127].

[115]. Fig. 11b depicts the PMB structure, wherein O, -OH and $–NH_2$ groups manifest a hydrophilic sensitivity. Closer O and $–NH_2$ placements besides –NH, =O, -OH,$–NH_2$ functionalities infer a sensitivity for intra and inter molecular HB. A weaker hydrophobicity with only one AC attributed the probe-analyte interactions a stronger hydrophilic sensitivity.

Next in line is a 2021 effort, wherein target DNA amplification mediated signal enhancement was validated *via* dual mode colorimetric naked eye and smartphone screening, for screening zebra mussel DNA. Of note, zebra mussel is an invasive, fingernail sized mollusk native to Eurasian freshwaters, named so due to zig-zagged shell stripes. Analyte DNA amplification was accomplished *via* nicking endonuclease cleavage of probe-complimentary target hybridization subsequent to which, modified probe interacts with DNA functionalized Au NPs. Fig. 13 depicts a target DNA amplification and detection, improving the naked eye sensitivity by 12 folds for ~8 nM LOD in controlled conditions and 22.5 nM in complex environment. The assay discriminated zebra mussel DNA sequences besides 130 fold improved sensitivity *via* smart-phone monitored environmental samples. The 0.17 nM LOD was highly relevant to gauge aggregation with reduced naked eye subjectivity [116]. Subsequent study using biomolecules functionalized Au NPs for water quality screening used D-oligonucleotide enantiomers for ascertaining bisphenol A (BPA) contamination. Of note, BPA is a prominent plastic monomer widely reported for its endocrine disruptive actions [117,118]. The study exploited aptamer binding ability of D-oligonucleotides enantiomers *via* Biolayer interferometry alongside screening biological stability on nucleases exposure. Fig. 14 depicts the optimized probe configuration as label free Au NPs colorimetric assay for BPA detection with 0.057 ng•mL^{-1} LOD over (100 pg•mL^{-1}-10 mg•mL^{-1}) range [119]. Another 2022 effort from *Ye and colleagues* [120] demonstrated multiplex sensors with specific locus centred aptamer functionalized Au NRs facilitated Pb^{+2} and Hg^{+2} detection. The detection of heavy metals (Pb and Hg) was optimized *via* distinct responses of individual Au NRs with characteristic spectra shifts in the scattering spectrum. Inspection of bound Pb and Hg using a spectral imaging dark field microscope ascertained the response of manifold single plasmonic nanosensors with high time resolution and precision. The LOD for the assay was determined *via* monitoring concentration specific response of position specific nanosensors for Hg^{+2} and Pb^{+2} containing mixtures. Inspection revealed 5 nM (Pb^{+2}) and 1 nM (Hg^{+2}) sensitivities, exhibiting the feasibility to screen other heavy metal ions (alike periodic table groups).

4.4. Gold nanoparticles anchored graphene and reduced graphene assemblies

Large SA and functionalization diversity of graphene and its derivatives are the reasons for their remarkable applications in catalysis, energy storage and conversion. Structural distinctions of graphene include a single, thin layer of tightly packed pure carbon atoms as hexagonal honeycomb lattice with sp^2 hybridization and a 0.142 nm C—C bond length (Fig. 15a). With a thickness of ~one atom and (100−300) times higher strength than steel, graphene oxide (GO) is the most used graphene derivative, prepared *via* graphite oxidation (Fig. 15b). Multiple applications of GO include use in electrodes, solar cells, polymer filler for improved tensile strength, elasticity, conductivity *etc.* [121,122]. The studies using graphene/GO-Au NPs as probes for screening water quality are as discussed ahead.

First major post 2015 study herein, examined NO_3^- *via* absorption spectrum, involving Au NPs interaction with $-NH_2$ modified GO ($-NH_2$@GO), avoiding aggregation due to low NO_3^- amount remaining untraced *via* conventional assay. The optimized probe configuration exhibited a reduced aggregation on NO_3^- and modified GO interaction, screening NO_3^- *via* absorption spectrum, superseding the Au NPs due to anionic impurities. Optimization involved no pretreatment, screening 5 nM NO_3^- in DW, much lower than 161 μM (absorption spectroscopy) [123]. The Au NPs used herein were prepared *via* citrate reduction and optimized *via* 10 min, 8000 rpm centrifugation of their 4 mL quantity on aqueous washing and subsequent dispersion in 0.2 mL H_2O. Real screening was done *via* deliberate NO_3^- contamination on 10 min centrifugation of river water (pH = 7) at 10,000 rpm. Finally, 20 μL, 1 mg•mL^{-1} $-NH_2$@GO was mixed with sample (1:1) and incubated for 1 h at RT, before examining its UV–visible absorption. A decisive step in probe optimization involved ethylenediamine (EDA) modification of GO sheets, prior to $–NH_2$ functionalization. The $-NH_2$@GO mixing with Au NPs induced their aggregation *via* electrostatic interactions, nullified *via* NO_3^- π-aromatic cloud interception of $-NH_2$@GO [124]. Detection sensitivity (ΔR) was monitored *via* subtracting $R_{nitrate}$ to R_{blank} ratios, where $R_{nitrate}$ was 620 to 520 nm absorbance ratio of NO_3^- contaminated samples in UV–visible spectra while R_{blank} was similar extent for blank samples. A high ΔR inferred a NO_3^- contamination with a higher sensitivity, where (1.51–4.53) μg•mL^{-1} increment enhanced ΔR. Since 6.03 μg•mL^{-1} GO decreased the ΔR, 4.53 μg•mL^{-1} was chosen as optimum GO. The investigators noted inadequate signal distinctions for blank and NO_3^- contaminated samples due to excessive aggregation. The optimum incubation for detection sensitivity was ascertained as 1 h. Polarity changes inferred $-NH_2$@GO-NO_3^- interactions, with −29.4 mV ζ-potential for GO being enhanced to −18.9 mV for EDA modified GO and yet again decreasing to −26.6 mV on NO_3^- incubation. These surface polarity changes for NO_3^- neutralizations were supported by SEM and TEM inferred Au NPs aggregation for null and 50 mM NO_3^-. Selectivity was ascertained *via* Cl^-, Br^-, I^-, SO_4^{2-} recognition, where only NO_3^- decreased absorption ratios at 620 and 520 nm (Au NPs SPR) [125]. Commercial feasibility was monitored *via* screening NO_3^- contaminated river water, wherein 5 nM was retrieved as LOD, in river and DW [126]. The sensing precision could be further improved using GO derivatives and highly diverse morphologies for Au NPs shapes and sizes (obtained on altered precursor to reducing agent ratios).

Next in line is a 2017 effort, wherein an ultrasensitive pulse-driven capacitance based Pb^{+2} recognition was accomplished *via* self-assembly driven GO monolayer to monitor the contamination of water samples. Intact field effect transistor (FET) comprised thermally reduced

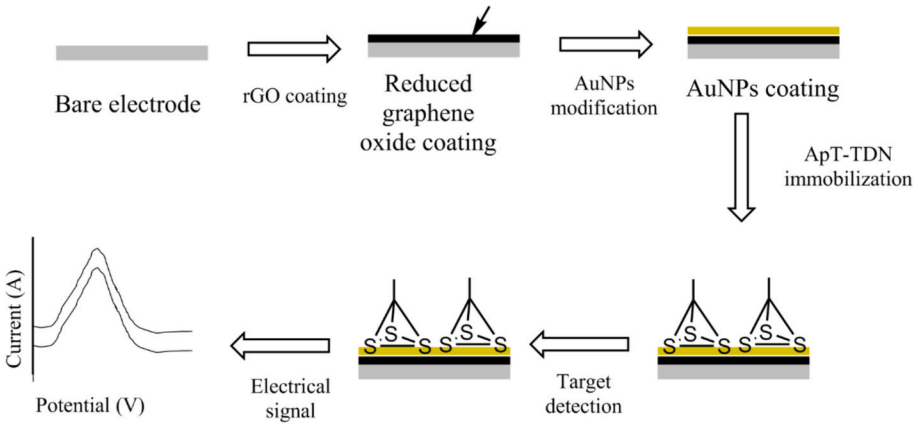

Fig. 17. Optimized probe configuration, comprising Au NPs functionalization on the electrochemically reduced graphene oxide surface and concomitant enrichment by tetrahedral DNA nanostructures for ampicillin detection in aqueous environment [128].

GO channel with a defunct thin Al_2O_3 layer as a top gate combined with sputtered Au NPs conjugated glutathione (GSH) as probe. Fig. 16 summarizes the sensor chip configuration, working module and electronic properties for the probe. For real application, a miniaturized Arduino-based microcontroller was programmed to generate pulses, capacitance signal reading and continuous data recording. The Pb^{+2} probe-specificity was ascertained *via* its insignificant responses for Zn^{+2}, Mg^{+2}, Hg^{+2}, Cd^{+2}, Fe^{+3}, Na^{+} and Ag^{+}. Sensitivity was monitored *via* monitoring real time capacitance transient for Hg^{+2} (5–100 ppb) with Pb^{+2}, revealing an insignificant relative capacitance change for Hg^{+2} solution. Commercial feasibility was adjudged *via* water samples from the city of Flint, fresh tap water from Milwaukee, Lake Michigan and river Mailwaukee, revealing agreements with ICP analysis for Flint water, having 2.38 ppb Pb^{+2} than <0.8 ppb for others. The 180 and 30% capacitance transient responses for Flint water and Milwaukee tap water enabled a (0.4–2.38) ppb Pb^{+2} screening in Flint water. The assay time for background stabilization subsequent to Pb^{+2} monitoring was ascertained as 10 s, was much lower than FET resistance (in min) and inductive/optical plasma methods (in hours). Approximate linear range (5–20) ppb estimation for ~15 ppb extent projects probe suitability for drinking water [127]. Intriguingly, functionalization with doped graphene could improvise the accuracy *via* reduced interception time. The optimized configuration (rGO passivated by thin Al_2O_3 as top gate with GSH functionalized sputtered Au NPs) could be engineered for other impurities too. Besides, portable configuration could be employed in remote locations and moderate economies.

Latest attempt in rGO-Au NPs screened water quality is a 2022 study whereby, aptamer mediated electrochemical sensing was optimized *via* surface engineering and DNA nanotechnology to monitor ampicillin contamination in animal products. The working electrode was modified in SPCE *via* electrochemically rGO and Au NPs enhanced electrochemical conductivity (Fig. 17). Subsequent surface engineering *via* self-assembled tetrahedral DNA nanostructures (TDN) improved the detection sensitivity, *via* aptamer nano-spacing immobilized over electrode surface. These aptamers were put in solution for target binding, and accessed *via* differential pulse voltammetry for bound ampicillin extents. Analysis revealed a (10 pM-1 mM) detection in <30 min with 1 pM LOD, ~100 folds higher than without TDN functionality. Feasibility monitoring revealed a reusable tendency on DW rinsing besides 15 day storage stability and reproducibility [128].

4.5. Miscellaneous platform configurations of Au nanoparticles as water sensors

An integrated approach using microfluidics and porosity modulated papers as sensing platforms (microfluidic paper based provisions, μPADs) *vis-à-vis* laser printing (LP) devices feasibility for pesticide screening in aqueous conditions. Optimized probe configuration was accomplished *via* studies with varied paper platform porosities, textures and channel thickness. The Au NPs for the probe were prepared using citrate reduction, ensured *via* terminal colour change to blue. The as prepared NPs were thoroughly screened for their nanoscale traits, using DLS, UV–Vis spectroscopy and SEM. Optimized LP-μPAD configuration was prepared using Adobe illustrator software (V2019), wherein a laser printer was employed to print a hydrophobic barrier over the filter paper having a highest printing ability (600 DPI). Printed filter papers were uniformly heated in an incubator at 170 °C till 30 min (forming requisite hydrophobic barrier) to ensure optimum paper impregnation with toner ink. The 2023 effort from Turkey involved a thorough probe characterization to screen the titre of atrazine (a chlorinated triazine systemic herbicide used to selectively control the annual grasses and broadleaf weeds prior to their emergence) in water *via* colorimetric assessments using a smart-phone assisted imaging. Analysis revealed an LOD of 10.9 μM with high repeatability and reproducibility. Thereby, the probe configuration in this study conceptualized a successful integration of laser assisted viewing across the microfluidic, capillary flow assisted paper channels for specific detection of pesticides. Interference studies revealed the pesticide screening as unaffected by added NaCl quantities and varied pH levels. On the whole, the study presented LP assisted capillary flow monitoring as effective and low-cost remedy for accessible water quality monitoring [129].

5. Summary and future directions

We have presented a comprehensive account of Au NPs sensing distinctions (shape-size modulated structure-function diversity) alongwith the discussion of prominent research attempts using their diversified regimens for screening the contamination of water resources. The reason for unceremonious interest in Au NPs as sensing moieties for validating the upright quality of water resources is the remarkable stability of Au which assists in their robust functionalization. Besides the steadfastness of manifold reproducible and nature friendly preparation methods (largely bottom-up) with a well-understood mechanism and physical indications are the additional impetus. The first mechanism of Au NPs use in biosensing relies on their monodispersed or aggregated state variations in SPR. Second workable strategy involves the coating of electrodes with Au nanothin films (due to electrically conductive nature of Au). Third strategy towards Au NPs use as water quality assessment agents involves their functionalization with biomolecules such as antibodies, engineered DNA or RNA fragments, proteins, carbohydrate derivatives and others. This configuration of Au NPs could be used for *in vivo* screening owing to a compatible functioning of the probe. Fourth

Table 3
Summary of post 2000 studies with a brief description of probe configurations and major findings, complete discussion of these attempts features in the text.

Sensed stimulus	Sensing configuration of Au NPs	Response characteristics (linear range, LOD and sensitivity)	Reference
Singular or combinatorial existence driven SPR changes			
Aflatoxin B1-MRS	Dumbbell similar Au-Fe_3O_4 NPs as magnetic nanoprobes	• Au NPs as core facilitated the growth of Ag shell and gather Au-Fe_3O_4 NPs, modulating transverse relaxation time of neighbouring water molecules • Ag(shell)-Au-Fe_3O_4 core-shell NPs as probe were generated by H_2O_2 • On horseradish peroxidase degradation, H_2O_2 reduces Ag^{+} to Ag^{0}, accumulating dispersed Au-Fe_3O_4 as Ag@Au-Fe_3O_4 NPs • With 3.81 pg•mL^{-1} sensitivity, the Ag@Au-Fe_3O_4 NPs as nanoprobes • 21 and 9 folds better efficacy than ELISA and HPLC • Consistency with HPLC for real samples inferred accuracy for optimized configuration.	[97]
Escherichia coli contamination	Au@MnO_2 NPs in core-shell morphology having MnO_2 as shell	• LOD: 15 CFU•mL^{-1} • Dynamic range: (100–2900) CFU•mL^{-1} • Ultrasensitive and low cost *E. coli* screening in river water	[98]
Hg^{+2}	Au@Ag core-shell NPs as SERS substrates while rhodamine 6G (R6G) as a Hg^{+2} signaling probe	• Hg^{+2} screening accomplished *via* quenching of R6G strong SERS signal on interaction with Au@Ag NPs, slowly replacing Ag^{+} by bound Hg^{+2} • Blue shift in UV–Vis SPR peak of Ag shell of Au@Ag NPs, reducing Hg^{+2} to Hg^{0} on Ag shell surface of Au@Ag NPs, on Hg^{+2}-citrate ion of Au@Ag NPs complex formation • 0.9745 and 0.9773 as correlation coefficients within (10^{2}–10^{-3}) µg•g^{-1} • (88.45–94.73)% recovery and (3.28–5.76)% as coefficient of variations	[99]
Electrochemical Configurations			
Pb^{+2}	Au NPs-Ppy-$Ti_3C_2T_x$ nanocomposite prepared *via* layered self assembly PPy is an organic polymer retrieved *via* oxidative polymerization of pyrrole	• XPS and XRD inspections revealed $Ti_3C_2T_x$ significance in PPy formation, alignment and Au NPs growth • Au NPs facilitated covalent linkage, *via* Au—S functionality • Response analysis inferred a 5•10^{-14}-1•10^{-8} M linear working range with 1•10^{-14} M LOD • Good selectivity and sensitivity for Pb^{+2} in Nong Fu spring and tap water • *E. coli* identification was accomplished *via* square-wave, differential pulse and cyclic voltammetry	[105]
Escherichia coli screening in pharmaceuticals or certain real samples	• Multi-walled CNTs-Au NPs-*E. coli* polyclonal Ab-BSA optimized at pH = 7 using PBS buffer • Acetaminophen was added for *E. coli* detection *via* conductivity and current variations	• Square-wave voltammetry revealed 3.02 CFU•mL^{-1} as LOD 3 min with adequate sensitivity, repeatability and reproducibility • Could be explored for drug safety, quality control, clinical diagnostics and environmental assessment	[106]
Au NPs functionalized with compatible biomolecules			
Zebra mussel DNA (an invasive, fingernail sized mollusk)	Nicking endonuclease assisted Au NPs signal amplification	• 12 fold higher naked eye sensitivity • LOD: ~8 nM in controlled and 22.5 nM in complex environment • Smartphone improved sensitivity by 130 folds with 0.17 nM LOD, • Probing aggregation tracking with increased accuracy and reduced naked eye subjectivity	[116]
Bisphenol A (widely reported for its endocrine disruptive activities)	First ever use of nuclease resistant spiegelmer in a label-free Au NP based colorimetric assay	• Aptamer-target interactions supported by chemically made spiegelmers were screened using biolayer interferometry	[119]

(*continued on next page*)

Table 3 (*continued*)

Sensed stimulus	Sensing configuration of Au NPs	Response characteristics (linear range, LOD and sensitivity)	Reference
Pb^{2+} and Hg^{2+}	Multiplexed nanosensors having locus fixation aptamer functionalized Au NRs	• Stabilities in multiple biofluids was examined *via* exposure to nucleases • 0.057 ng•mL^{-1} LOD over (100 pg•mL^{-1} to 10 mg•mL^{-1}) range. • Highly sensitive and selective efficacy, non-biodegradable platform for sensitive bisphenol A detection • Home-built spectral imaging dark-field microscope screened thousands of single plasmonic nanosensors • Explicit Au NRs responded to Pb^{+2}, Hg^{+2} *via* discrete SPR alterations • LOD: 5 nM for Pb^{2+} and 1 nM for Hg^{2+}, exhibiting suitability for other heavy metal ions too	[120]
Au NPs functionalized Graphene oxide or its functionalized derivatives			
Antibiotic ampicillin	Electrochemically reduced graphene oxide-Au NPs surface coated by self-assembled tetrahedral DNA nanostructures	• (10 pM-1 mM) detection in <30 min with 1 pM LOD • ~100 fold better than without TDN. • Reusable platform on rinsing with deionized water besides 15 day storage stability and reproducibility	[128]
Integrated Configurations (Not matching any of the above)			
Atrazine (a pesticide)	Dual chromatic laser-printed microfluidic paper-based analytical device (μPAD)	• LP assisted capillary flow as effective and low-cost remedy for accessible water quality monitoring • Optimized LP-μPAD was prepared using Adobe illustrator, wherein a LP aided imprint of a hydrophobic barrier over the 600 DPI ability filter paper • Atrazine titre was screened using 170 °C dried filter papers *via* colorimetric assessments and a smart-phone assisted imaging • LOD of 10.9 μM with high repeatability and reproducibility	[129]

Abbreviations: SPR: surface plasmon resonance, MRS: magnetic relaxation switching, MOF: metal organic framework, IgG: immunoglobulin G, NPs: nanoparticles, NRs: nanorods, LOD: Limit of Detection, MDIA: 10-mercaptodecyl-1-iminodiacetic acid, LPS: lipopolysaccharide, NPs: nanoparticles, PPy: polypyrrole, FAM: carboxyfluoroscein, GO: Graphene oxide, GSH: glutathione, ppb: parts per billion, LP: laser printer, rGO: reduced graphene oxide.

configuration of Au NPs monitored water quality involves their functionalization over the surface-active graphene oxide and its related configurations. Functionalization holds the backbone aspects of Au NPs use in water quality monitoring and could be done in covalent/non-covalent mode to engineer the interaction potentials. Table 3 summarizes the post 2020 attempts for the discussed Au NPs configurations where the LOD differences convey the precision sensitivity of miniaturized dimensions. Distinct responses are the typical outcomes of characteristic size-shape modulations wherein quantum effects are exhibited at ease with larger SA. Future insights for similar applications of Au NPs could be consolidated *via* ascertaining a reproducible performance of their composite configurations alongwith improving their specific response. Docking simulations for integrated prevalence and optimized combinations with Au NPs could help predict their stability and a transition driven energetic excitations and de-excitations. Enhanced precision of characterization techniques is a crucial aspect of reliance for such diversified applications of Au NPs. Collaborative participation of chemists with material scientists and electronics expert could strengthen the Au NPs accuracy further with the integration of micro and nano electromechanical systems (NEMS and MEMS) could still fasten the read out mechanisms of analyte-probe interactions. Micromachining and surface engineering of NMs alongwith predictive *in situ* tools consolidate the constitutional energy levels for infinitesimal responses.

6. Conclusions

The native state high stability of Au NPs encompassing their manifold functionalization, consolidates their dynamic shape-size modulated PCPs. Although singular or combined use of Au NPs remains the most understood mechanism working *via* reversible aggregation, functionalization has recently turned the attention to biomolecules coupled Au NPs assay. Despite sophisticated characterization *via* CV and EIS, better probe performance could be accomplished subject to computational assessment of combinatorial stoichiometry stability. As lifestyle changes and industrialization loom high, there is a need for high precision assisted sensing tools wherein Au NPs as the emerging frontrunners. Contaminations like antibiotics, pesticides and microbial colonies are prominent interferers in edible texture of water resources at large. Perhaps the scenario urgently needs co-operation between engineers and bio-scientists for diligent detection efficacy and time-lapse of interactions. Cautions must be exercised for a characterization specific size and functionalization abilities. These cautions must warn with results of earlier findings so that sustainability aspect is not tampered with. Likewise a rigorous tract of known response time (size-shape artefacts, reducing and capping agents for making Au NPs) must be adequately referred and update so that necessary cautions and resource conservation could be strengthened in future attempts.

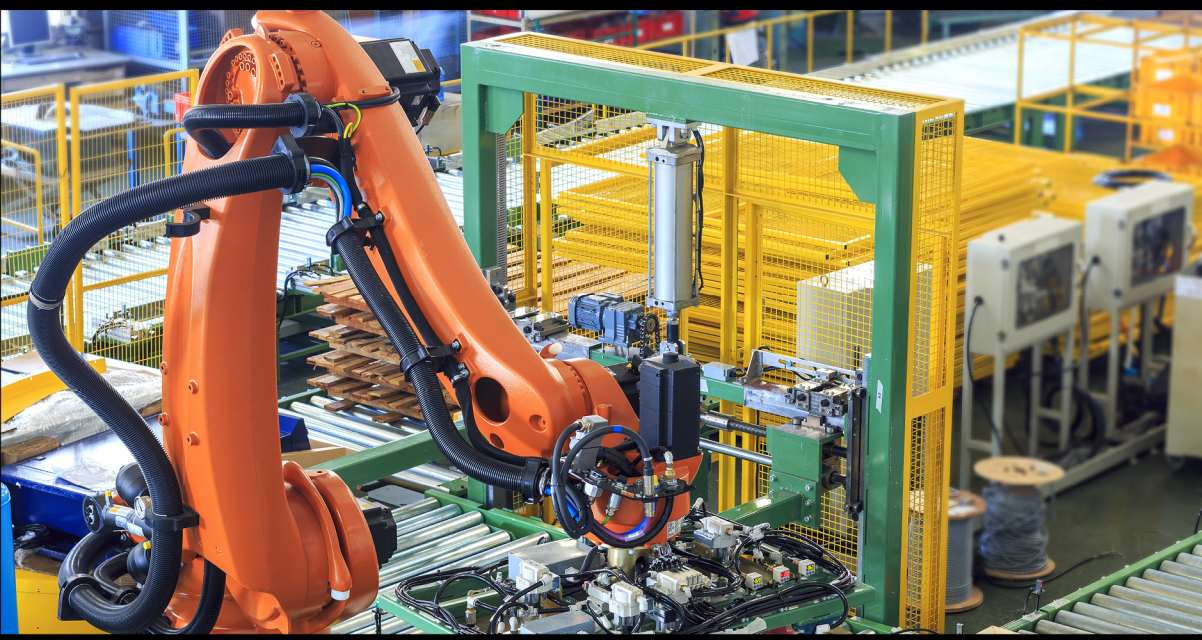
Handbook of Smart Manufacturing

Forecasting the Future of Industry 4.0

EDITED BY
Ajay, Hari Singh, Parveen,
and Bandar AlMangour



CRC Press
Taylor & Francis Group

Handbook of Smart Manufacturing

This handbook covers smart manufacturing development, processing, modifications, and applications. It provides a complete understanding of the recent advancements in smart manufacturing through its various enabling manufacturing technologies, and how industries and organizations can find the needed information on how to implement smart manufacturing towards sustainability of manufacturing practices.

Handbook of Smart Manufacturing: Forecasting the Future of Industry 4.0 covers all related advances in manufacturing such as the integration of reverse engineering with smart manufacturing, industrial internet of things (IIoT), and artificial intelligence approaches, including artificial neural network, Markov decision process, and heuristics methodology. It offers smart manufacturing methods like 4D printing, micro-manufacturing, and processing of smart materials to assist the biomedical industries in the fabrication of human prostheses and implants. The handbook goes on to discuss how to accurately predict the requirements, identify errors, and make innovations for the manufacturing process more manageable by implementing various advanced technologies and solutions into the traditional manufacturing process. Strategies and algorithms used to incorporate smart manufacturing into different sectors are also highlighted within the handbook.

This handbook is an invaluable resource for stakeholders, industries, professionals, technocrats, academics, research scholars, senior graduate students, and human healthcare professionals.

Index 357

Preface

Smart manufacturing is a broad category of manufacturing that employs computer-integrated manufacturing, high levels of adaptability and rapid design changes, digital information technology, and more flexible technical workforce training. Other goals sometimes include fast changes in production levels based on demand, optimization of the production system, efficient production, and recyclability. This book is expected to provide the compiled smart manufacturing knowledge to the involved stakeholders from users in the industry to the academics and researchers. The detailed description of various smart manufacturing techniques like 3D printing, 4D printing, and approaches that makes manufacturing digital such as Industry 4.0 techniques are included in this book along with various smart materials like polymers, metals, ceramics, composites, biomaterials, biodegradable materials, responsive materials, functionally graded materials, and various applications of smart industries. In addition to above various case studies of smart manufacturing specially related to production, mechanical, industrial, computer science, electronics engineering, and biomedical are covered to help undergraduates, postgraduates, and research scholars. This compilation will bring to its readers the latest developments/advancements in smart manufacturing, which is currently not available at one place. This book will bridge the gap between R&D in smart manufacturing and professionals.

This book is an outcome of the extensive research accomplished by various researchers, academicians, scientists, and industrialists in smart manufacturing. The area is under-explored and the outcomes are worth the research effort. Experimentation, modeling, characterization, and simulation techniques are the powerful tools for developing new concepts, approaches, and solutions to devise valuable information on the process which led to need of compiling this work. Since, the information related to smart manufacturing is scattered into patents and research publications and not at one place in a systematic form, editors recognize their ethical responsibility to compile, share, and spread the knowledge accumulated and technology developed, with the students, researchers, and industry people, to draw the benefits of this work in the form of a book and gain technical competence in the frontal area.

The book consists of 18 chapters that describe perspectives of smart manufacturing with Industry 4.0 aspects. “Smart Manufacturing and Industry 4.0: State-of-the-Art Review” determines the dimensions that help in implementing smart manufacturing in the I4.0 environment in SMEs. “Study and Analysis of IOT (Industry 4.0): A Review” provides an overview of analysis of IOT adaptation effect in past and present industries. “Recent advances in Cybersecurity in Smart Manufacturing Systems in the Industry” discusses advances in the security of smart manufacturing systems, strengths and weaknesses of the manufacturing systems, existing threats, and preparedness for future cyber-attacks. “Integration of Circular Supply Chain and Industry 4.0 to Enhance Smart Manufacturing Adoption” focuses to develop a framework based on

the Fuzzy Analytical Hierarchy Process (FAHP), one of the multi-criteria decision-making methods (MCDM), which computes and assigns weights to each identified circular supply chain practice within an industry. "Artificial Intelligence with Additive Manufacturing" summarizes the role of artificial intelligence in additive manufacturing in a manner to show how innovative additive manufacturing plays a role in today's industry. "Robotic Additive Manufacturing Vision towards Smart Manufacturing and Envisage the Trend with Patent Landscape" foresees robotic additive manufacturing in various aspects covering basic system step to futuristic vision. "Smart Materials for Smart Manufacturing" demonstrates the various kinds of smart nanomaterials and their advantageous properties in both historical and future applications. "Smart Biomaterials in Industry and Healthcare" explores smart materials for bringing advancement in biomedical engineering and other industrial applications. "Ferroelectric Polymer Composites and Evaluation of Their Properties" presents the results of a study of ferroelectric polymer composites with a high permittivity. "4D Print Today and Envisaging the Trend with Patent Landscape for Versatile Applications" analyzes the future trend with the aid of patent landscape analysis. "Investigating the Work Generation Potential of SMA Wire Actuator" aims to develop an elementary mathematical model of an SMA wire actuator in biasing conditions on the SIMULINK platform while including the traveled path history of SMA material and thereby, carries out a parametric study that determines the most influencing parameter that affects the work generation capability of wire actuator. "Troubleshooting on the Sample Preparation during Fused Deposition Modeling" deals in-depth with the challenges and issue during the printing and suitable solution for better print quality. "Hybrid Additive Manufacturing Technologies" focuses to produce and compare research studies on the different hybrid additive manufacturing processes. "Smart Manufacturing Using 4D Printing" deals with the concepts and regulations governing 4D printing, along with the materials utilized, applications, and obstacles that still need to be removed. "Developments in 4D Printing and Associated Smart Materials" provides a brief overview of 4D printing processes using various composites and intelligent materials including smart materials, and shape memory alloys. "Role of Smart Manufacturing Systems in Improving Electric Vehicle Production" explores the current market need for manufacturing that closely relates to an electric vehicle and develops a structural framework that utilizes the interpretative structural modeling approach and MICMAC approach to achieve the objective. "Safety Management with Application of Internet of Things, Artificial Intelligence, and Machine Learning for Industry 4.0 Environment" evaluates the major issues regarding health and safety integration with the Industry 4.0 revolution. "CPM/PERT-Based Smart Project Management: A Case Study" optimize the design and installation time of the 8-megawatt power plant to be built for a cement factory in Barbados.

This book is intended for both the academia and the industry. The postgraduate students, PhD students, and researchers in universities and institutions, who are involved in the areas of smart manufacturing with Industry 4.0 perspectives, will find this compilation useful.

The editors acknowledge the professional support received from CRC Press and express their gratitude for this opportunity.

Reader's observations, suggestions, and queries are welcome,

Dr. Ajay
Dr. Hari Singh
Mr. Parveen
Dr. Bandar AlMangour

Taylor & Francis

Acknowledgments

The editors are grateful to the CRC Press for showing their interest to publish this book in the area of smart manufacturing and Industry 4.0. The editors express their personal adulation and gratitude to Ms. Cindy Renee Carelli (Executive Editor) CRC Press, for giving consent to publish our work. She undoubtedly imparted the great and adept experience in terms of systematic and methodical staff who have helped the editors to compile and finalize the manuscript. The editors also extend their gratitude to Ms. Christina Graben, CRC Press, for support during her tenure.

The editors wish to thank all the chapter authors for contributing their valuable research and experience to compile this volume. The chapter authors, corresponding authors in particular, deserve special acknowledgments for bearing with the editors, who persistently kept bothering them for deadlines and with their remarks.

The editors, Dr. Ajay, Mr. Parveen and Dr. Bandar AlMangour, wish to thank Prof. Hari Singh for his unreserved guidance, valuable suggestions, and encouragement in nurturing this work. Prof. Hari Singh is a wonderful person and the epitome of simplicity, forthrightness, and strength and is a role model for editors.

Dr. Ajay also wishes to express his gratitude to his parents, Sh. Jagdish and Smt. Kamla, and his loving brother Sh. Parveen for their true and endless support. They have made him able to walk tall before the world, regardless of sacrificing their happiness and living in a small village. He cannot close these prefatory remarks without expressing his deep sense of gratitude and reverence to his life partner, Mrs. Sarita Rathee, for her understanding, care, support, and encouragement to keep his morale high all the time. No magnitude of words can ever quantify the love and gratitude the he feels in thanking his daughters, Sejal Rathee and Mahi Rathee, and son Kushal Rathee who are the world's best children.

Finally, the editors obligate this work to the divine creator and express their indebtedness to the "ALMIGHTY" for gifting them power to yield their ideas and concepts into substantial manifestation. The editors believe that this book would enlighten the readers about each feature and characteristics of smart manufacturing and Industry 4.0.

Editor's Biography

Dr. Ajay is currently serving as an associate professor in the Mechanical Engineering Department, School of Engineering and Technology, JECRC University, Jaipur, Rajasthan, India. He received his PhD in the field of advanced manufacturing from Guru Jambheshwar University of Science & Technology, Hisar, India after B.Tech. (Hons.) in mechanical engineering and M.Tech. (Distinction) in manufacturing and automation. His areas of research include artificial intelligence, materials, incremental sheet forming, additive manufacturing, advanced manufacturing, Industry 4.0, waste management, and optimization techniques. He has over 60 publications in international journals of repute including SCOPUS, Web of Science, and SCI indexed database and refereed international conferences. He has also co-authored and co-edited many books and proceedings including: *Incremental Sheet Forming Technologies: Principles, Merits, Limitations, and Applications*, CRC Press, ISBN: 9780367276744; *Advancements in Additive Manufacturing: Artificial Intelligence, Nature Inspired and Bio-manufacturing*, ISBN: 9780323918343, ELSEVIER; *Handbook of Sustainable Materials: Modelling, Characterization, and Optimization*, CRC Press, ISBN: 9781032286327; and *Waste Recovery and Management: An Approach Towards Sustainable Development Goals*, CRC Press, ISBN: 9781032281933.

He has organized various national and international events, including an international conference on Mechatronics and Artificial Intelligence (ICMAI-2021) as a conference chair. He has more than 20 national and international patents to his credit. He has supervised more than 8 MTech, PhD scholars, and numerous undergraduate projects/ thesis. He has a total of 15 years of experience in teaching and research. He is a guest editor and review editor of the reputed journals including Frontiers in Sustainability. He has contributed to many international conferences/symposiums as a session chair, expert speaker, and member of the editorial board. He has won several proficiency awards during the course of his career, including merit awards, best teacher awards, and so on.

He is adviser of the QCFI, Delhi Chapter student cell at JECRC University and has also authored many in-house course notes, lab manuals, monographs, and chapters in books. He has organized a series of Faculty Development Programs, International Conferences, workshops, and seminars for researchers, PhD, UG, and PG students. He is associated with many research, academic, and professional societies in various capacities.

Prof. Hari Singh is currently a professor in the Mechanical Engineering Department at NIT Kurukshetra, India. He completed his bachelor's degree in mechanical engineering with Honours in 1987, master in mechanical engineering in 1994, and PhD in 2001 from Regional Engineering College, Kurukshetra (now, NIT Kurukshetra). He has 34 years of teaching and research experience in the present institute. He has published 150 research papers in various journals of repute and national/international conference proceedings. He has attended a number of

conferences abroad in Brazil, Australia, Hong Kong, Singapore, France, Italy, and the United Kingdom. He has supervised 15 PhDs and 8 are in progress. He has also supervised 42 MTech students for their dissertations. He has three patents to his credit. His areas of interest include conventional and unconventional manufacturing processes, product and process improvement, single and multi-response optimization, design of experiments, Taguchi methods, response surface methodology, etc. He has memberships in various professional societies like the Institution of Engineers (India), Indian Society of Theoretical and Applied Mechanics (ISTAM), Indian Society of Technical Education (ISTE), and International Association of Engineers (IAENG).

Mr. Parveen is currently serving as an assistant professor and head in the Department of Mechanical Engineering at Rawal Institute of Engineering and Technology, Faridabad, Haryana, India. Currently, he is pursuing a PhD from the National Institute of Technology, Kurukshetra, Haryana, India. He completed his BTech (Hons.) in mechanical engineering and MTech (Distinction) in manufacturing and automation. His areas of research include materials and their synthesis and characterization techniques, die-less forming, bio-additive manufacturing, CAD/CAM and artificial Intelligence, machine learning and Internet of Things in manufacturing, and multi-objective optimization techniques. He has over 20 publications in international journals of repute including SCOPUS, Web of Science, and SCI indexed database and refereed international conferences. He has more than eight national and international patents in his credit. He has supervised more than 2 MTech scholars and numerous undergraduate projects/theses. He has a total of 12 years of experience in teaching and research. He has co-authored/co-edited the following books:

- Waste Recovery and Management: An Approach Towards Sustainable Development Goals, CRC Press, Taylor and Francis, ISBN: 9781032281933
- Handbook of Sustainable Materials: Introduction, Modelling, Characterization and Optimization, CRC Press, Taylor and Francis, ISBN: 9781032295874

He has organized a series of faculty development Programs, workshops, and seminars for researchers, UG-level students. He is associated with many research, academic, and professional societies in various capacities.

Bandar AlMangour is currently an Assistant Professor at King Fahd University of Petroleum and Minerals (KFUPM) in the Department of Mechanical Engineering. Prior to joining KFUPM, AlMangour has served in multiple operational and research roles within SABIC, Saudi Arabia, and has pursued his Postdoctoral Fellowship at Harvard University. Dr. AlMangour received his Ph.D./MSc, with distinction, in Materials Science and Engineering from UCLA in 2017 and 2014 respectively, an MEng in Materials Engineering from McGill University in 2012, and a BSc in Mechanical Engineering from KFUPM in 2005. He sits on the Editorial (Advisory) Board of several international journals and he is a member of several professional organizations. His research is generally concerned with the investigation of fundamental industrial problems related to the processing, microstructure and

behavior of materials, ranging from metals, to (nano-) composites, for advanced structural applications. His research focuses on advanced materials processing (additive manufacturing, friction joining, laser processing, powder metallurgy, bulk nanostructured alloys and composites), mechanical behavior at multiple length scales, and surface engineering. AlMangour has authored more than 40 peer-reviewed papers in internationally recognized journals, and his research works have been presented at well over two dozen international conferences, including invited talks in UAE, Turkey, and Greece.

1.1 INTRODUCTION

The term "smart manufacturing," or SM, was used to describe a new approach to production that is in step with the trends of "industry 4.0". The potential of I4.0 in data networking and information technology have considerable effect on manufacturing operations [1]. With big data processing, artificial intelligence, and intelligent robots, "smart manufacturing" improves factory output while cutting costs in energy and labour. This allows for the machines and tools that are used in smart manufacturing to be interconnected with one another [2]. Smart manufacturing is a subset of I4.0 that seeks to improve production by applying AI techniques including machine learning, big data analytics, and computer simulations. [3]. It also refers to the adoption of cutting-edge cyber technologies by corporate executives, including enhanced sensing, control, modelling, and platform technologies in I4.0 environment [4].

The manufacturing plans of most influential countries in the global market are focused on the industries of the future. This is a major development in the implementation of intelligent production methods. Germany was the first country to launch the I4.0 initiative for smart manufacturing, which is now recognized across the globe as the generational leap in technology that will revolutionize the manufacturing industry [2]. I4.0 was recognised for the first time in German industries, where it has led to increased productivity with the adoption of SM practices and more effective utilisation of the resources that are available [5,6]. It encouraged the businesses to adopt smart manufacturing practices, IIoT, cloud analytics and big data etc. Notably, it has resulted in high performance and, in comparison to the past, significantly greater positive effects. Role of work, management, and social ecosystem elements in SM need to be considered. [7]. The job profiles are undergoing transformations as a direct result of the opportunities made available by I4.0. Leaders in the corporate and public sectors, as well as academics and practitioners,

need to collaborate to learn more about smart manufacturing's potential and its necessary infrastructure. [8,9].

At present, investigations into smart manufacturing are underway, but lacks Industry 4.0 adoption. Also, the present literature is devoid of assessment of the different facets of Industry 4.0 [10]. Several supplementary investigations have delved into the current literature and identified hindrances to the adoption of intelligent manufacturing [10–13]. Zhou et al. [14] examine the main topics of smart factories and SM within the context of Industry 4.0, while also presenting obstacles, prospects, strategic planning, and crucial technologies.

The adoption of I4.0 concept among practitioners is popular as a means of putting smart manufacturing practises into effect. Industry 4.0 is not yet ready to be implemented because there is a lack of technical know-how and terminology [15]. Currently, there is limited knowledge about the possible advantages and disadvantages associated with the introduction of intelligent manufacturing [16,15]. Companies are unable to implement I4.0 because they are unable to comprehend the particulars of the implementation that are relevant to their own organisation [17]. Organizations have not conducted any specific research in their business operations, as such research has not been found [17,15]. As a direct consequence of this, the vast majority of businesses are unable to devise an appropriate strategy for implementing industry 4.0 [18].

For in-depth understanding of the dimensions that influence the success of I4.0 implementation, a Petersen et al. [19] guidelines-based SLR was carried out. The participants in this study will be provided with a tool that will assist them in determining which aspects of their organization are the most important and in formulating a strategy to improve those aspects using the findings of this study.

The entire research paper is broken up into six sections. After the introduction has been finished for section 1, the related work, which is contained in section 2, is presented. The discussion of the methodology can be found in Section 3. Section 4 contains a presentation of the results. In section 5, the validity threats are detailed, and in section 6, the conclusions are discussed.

1.2 RELATED WORK

Numerous research has been performed to identify and evaluate dimensions. All the studies are distinct from one another in terms of the approaches and procedures that were utilized to give the facets of putting the I4.0 concept into practice in manufacturing firms. The contributions that were made by the related work can be found in this section.

In order to give the reader a full picture of what SMSs are and how they work, Qu et al. [20] summarises the background, definition, goals, functional requirements, business needs, and technological requirements of SM. At the same time, it describes where things stand in terms of progress. Based on this, we present a model of autonomous smart manufacturing that is driven by fluctuating demand and key performance measures. The technological differences between traditional production and smart manufacturing were explored by Phuyal et al. [2]. In this study, as well as its current implementation status. Recent developments and their consequences were reviewed for this field.

To ascertain the dimensions, Elibal and Ozceylan [21] conducted a relevant literature study. The authors employed various database search to examine 90 distinct studies. There is a discussion on the categorization of the studies, which includes things like meta-models, combinations of models, comparison models, and so on. To conduct this research, qualitative analysis is performed. In the study, the descriptive evaluation model for the review study was presented, and the limitations of the existing model were discussed. The study has some problems with its validity. Ghobakhloo et al. [7] in their work determined drivers of I4.0 concept. They also described a descriptive evaluation of the 745 studies that were eligible for consideration. The study found that organisational factors, technology factors, and environmental factors are the primary determinants of I4.0. The author discussed both the study's theoretical underpinnings and its potential real-world applications. However, the study does not address whether the model being used is accurate. Hizam-Hanafiah et al. [22] and Kamble et al. [23] analysed various studies and proposed numerous dimensions. The authors identified technology as the most crucial dimension, with 44 percent of the 158 dimensions pertaining to technology. Consequently, technology is deemed the most significant factor. They refer to three critical dimensions, including technology, based on aspects, and process integration. The author put forth strategic guidelines in their proposal. The study does not include the validation component. In their presentation on I4.0 dimensions, Liao et al. [24] used SLR. The author went over the repercussions of putting industry 4.0 into practice as well as the research agenda for the foreseeable future. However, many of the studies suffer from the same types of shortcomings.

Despite the significance and potential opportunities in SM fields with I4.0 adoption, there has been limited research conducted on identifying the dimensions of SM. In this study, the dimensions are identified from selected studies and ranked according to their importance [25]. However, previous studies lack validation aspects as they mostly rely on qualitative analysis without strong evidence to support the SLR. Therefore, the dimensions are identified quantitatively from the selected studies to provide stronger evidence.

1.3 METHODOLOGY

This section presents details about the research techniques that are employed. Following Petersen et al. [19] guidelines for conducting SLR and Aria and Cuccurullo [26] for conducting bibliometric mapping, methodology based on five phases is adopted. In the first phase, the authors define the parameters of the work and formulated research questions. Three research questions are formulated. RQ1 and RQ2 were answered using SLR and RQ3 was answered following the bibliometric analysis. Search methodology is the focus of the next phase. In this step, the author searched for relevant articles in a scientific database by entering a string of search terms that makes use of "AND" and "OR" Operators. In accordance with the approach proposed by Kitchenham and Charters [27], a search string was constructed by combining relevant keywords

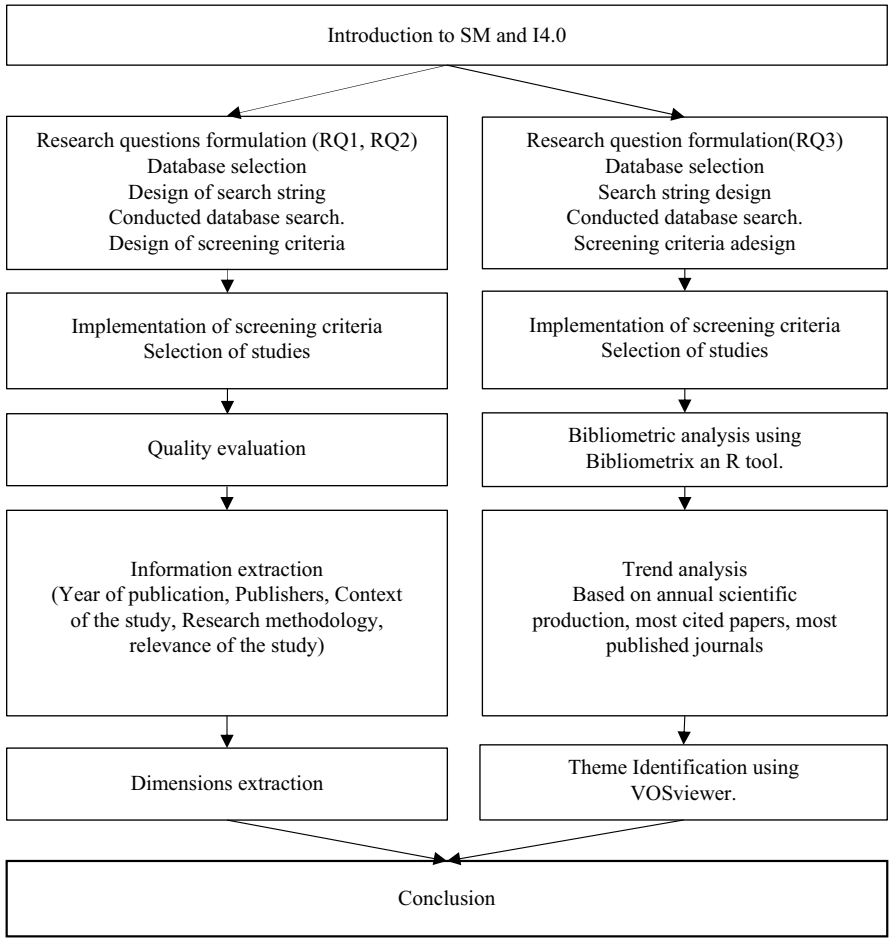

FIGURE 1.1 Methodology flowchart.

using PICO approach. The third phase presents screening of the studies. In the fourth phase, the work is reviewed on the basis of their titles and keywords. The final phase of the study involved mapping research questions. To minimize bias in the study, a quality evaluation was conducted. The results were analyzed and presented in Figure 1.1, which illustrates the research process.

1.3.1 Research Questions

The following research questions are framed to meet the research objectives:

RQ1: What are I4.0 dimensions which help in smart manufacturing?
RQ2: What are those dimensions which are critical for SM systems?
RQ3: What are the future research directions for SM systems?

1.3.2 Search strategy

The work utilized the PICO (Population, intervention, comparison, and outcome) approach recommended by Kitchenham and Charters [27] to guide the search process.

1.3.2.1 Population

It refers to the targeted group. In this study, the population was Smart Manufacturing or Industry 4.0 elements.

1.3.2.2 Intervention

Various maturity models and industry reports served as interventions.

1.3.2.3 Comparison

Empirical studies were conducted to compare the different smart manufacturing techniques and methods.

1.3.2.4 Outcomes

The study's outcomes involved the extensive literature review and empirical analysis of dimensions.

To conduct the study, the author searched for studies in popular databases utilizing search strings tailored to each database. The author utilized the "AND" operator to form the search string. Search string for the databases is as follows:

("smart manufacturing" AND "industry 4.0")

1.3.3 Selection of studies

Our study used screening criteria to select relevant articles. The inclusion year (2007–2022) for articles in English language. We identified seven criteria for selecting articles, labelled as C1 to C7, which are listed in Table 1.1, we provide the criteria that will be used to determine what will and will not be considered for screening.

1.3.4 Data extraction

The study has gathered information regarding smart manufacturing. Additionally, a data attributes sheet has been generated that outlines the research questions (See Table 1.2).

1.3.5 Quality evaluation

According to the standards in Table 1.3, a quality evaluation has been performed. The purpose of this step was to ensure that only relevant studies were considered and to strengthen the validity of our findings. For a comprehensive breakdown of the quality evaluation scores, please refer to Table A1 in appendix section.

TABLE 1.1
Criteria for Screening

Criteria Id	Criteria Type	Explanation
C1	Inclusion	Publication year: 2007–2022
C2	Inclusion	English language articles
C3	Exclusion	Books, book chapters, dissertations, and theses
C4	Exclusion	Articles containing less than six pages
C5	Inclusion	Articles including the terms "SM," "I4.0," and "digital transformation".
C6	Inclusion	Articles that address SM and I4.0.

TABLE 1.2
The Data Attributes in the Present Study

Class	Elements	Address Research Question
Intuitive information	Publication year, publisher, author, title and abstract	1
Methodology	Study design, case study, survey, evaluation study	2
Setting	Work motivation, validity threats, subjective research	2
Results and conclusion	Work limitations, address challenges, future work discussion	1, 2

TABLE 1.3
Quality Evaluation Parameters (QEP)

QEP ID	Description
QEP1	Does the article state its research aims clearly?
QEP2	Does the study explore dimensions related to its research aims?
QEP3	Does the article provide a literature review and outline the main contributions?
QEP4	Does the work describe the design of research methodology?
QEP5	Does the study present research findings?
QEP6	Are the research objectives and conclusions of the work explained in a clear manner?
QEP7	Does the article discuss future research or areas for further investigation?

1.4 RESULTS AND DISCUSSION

1.4.1 Discussion on RQ1 and RQ2

In accordance with Petersen et al. [19], the results of SLR are discussed. A pilot study was conducted using PICO criteria [28] to develop the search string. Applying the search criteria to the databases identified 3001 studies, which were screened based on selection criteria and publication date from 2007 to 2022. This resulted in 115 studies, with 40 duplicates removed, leaving 75 studies for quality assessment. Based on quality scores less than 3, approximately 13.37% of studies were removed, and 65 final articles were selected for the study. The search results are shown in Table 1.4. The number of academic studies showed a constant trend from 2007 to 2015, with only 1 or 2 studies, but the trend increased continuously from 2016–2022. The distribution of primary research according to year is presented in Figure 1.2.

The author aimed to respond to RQ1 by identifying dimensions. Additionally, the author calculated the frequency/percentage of each dimension. The authors identified 8 dimensions. To address RQ2, the author selected five dimensions that had a percentage equal to or greater than 25%. Table 1.5 provides the order and variables of the identified dimensions.

1.4.1.1 Technology (E_8)

The study found that technology is the most significant dimension in SMEs' digital readiness, with 92.31% of the selected studies focusing on various technological areas. Cyber-physical systems, as noted by Rahamaddula et al. [29] and Swarnima et al. [30], are particularly critical for integrating digital and physical entities. Saad et al. [31] outlines the importance of technology in smart manufacturing in industry 4.0 environment has further highlighted the growing significance of AI, ML, and cloud computing [32–34].

1.4.1.2 Organizational strategy (E_1)

The study identifies the second most significant dimension as strategy with a frequency of 30. 46.15% studies considered organization strategy as a dimension for smart manufacturing. Strategy involves planning for products and services that align with smart manufacturing requirements. Additionally, the strategy includes the funding strategy, which refers to the financial investment made for implementing smart manufacturing practices.

1.4.1.3 People/culture/employees (E_3)

The current research reveals that people/culture is identified as crucial dimensions. It is ranked at 5 with frequency 17 and 26.15%. This dimension relates to the employee attitude towards use of digital means for work [35,36,29]. As a final recommendation, it is essential to foster a learning culture to achieve smart manufacturing culture [37]. People/culture/employees are crucial to the success of SM. A skilled workforce and a culture of collaboration and continuous improvement are essential for implementing and optimizing advanced technologies.

TABLE 1.4
Search Results

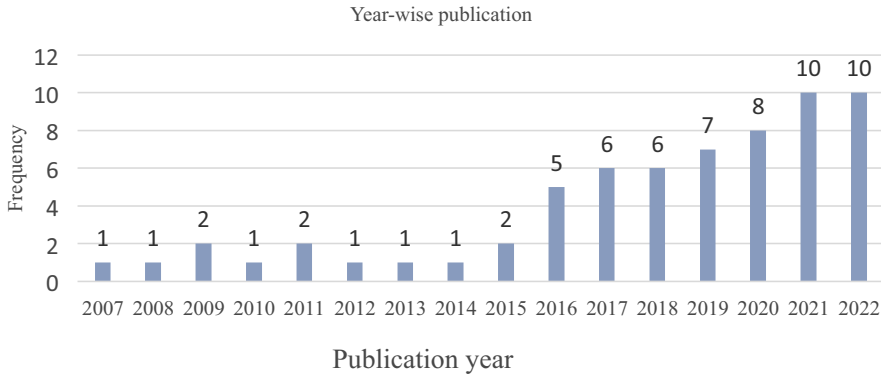

FIGURE 1.2 Year-wise studies.

1.4.1.4 Processes (E4)

smart manufacturing processes are crucial to the success of modern manufacturing operations. By optimizing processes, manufacturers can increase efficiency, reduce waste, improve product quality, and be more responsive to customer needs, ultimately leading to greater competitiveness in the marketplace. Findings reveals that, processes with frequency 27 and 41.54 % were ranked third. This dimension encompasses various types of processes such as business, communication, and management processes.

1.4.1.5 Products (E_6)

Product as a dimension (Frequency 21, percentage 32.31) ranked at four. One of the main goal of SM is to produce high-quality products that meet or exceed customer expectations while minimizing waste and reducing costs. It requires in-depth knowledge of the product and its manufacturing process [34]. Digital features in products enhance customer interest and promote association with the industry 4.0 ecosystem [38–41].

1.4.1.6 Customers (E_5)

According to the study, the sixth-ranked dimension is customers (Frequency 12 and percentage 18.46). Customers are important in smart manufacturing because they have high expectations for the products they purchase. They want products that are high-quality, reliable, and meet their specific needs. By understanding customer preferences and behaviours, manufacturers can tailor their products to meet those needs more effectively. This can lead to increased customer satisfaction and loyalty, which is essential for the long-term success of any business [5,29].

1.4.1.7 Innovation (E_2)

According to the information provided in Table 1.5, innovation (Frequency 10, percentage 16.67) is ranked seventh among the critical dimensions for industry 4.0.

TABLE 1.5
Identified Variables

S. no.	Dimensions	Definition	References	Frequency	Percentage	Ranking
E_1	Organisational Strategy	Organisational Strategy refers to the approach and plan of action adopted by an organization to align its resources, goals, and capabilities with the opportunities and challenges posed by the new technologies and digitalization. It involves the development of a clear roadmap for Industry 4.0 adoption, infrastructure, organizational structure, workforce planning, and continuous improvement strategies. Organisational strategy is critical for SMEs in their implementation of smart manufacturing practices ensuring its long-term sustainability and competitiveness.	[3,17,42–51,30,52–61,35–41]	30	46.15	2
E_2	Innovation	Innovation in this context includes the exploration and implementation of new business models, supply chain strategies, and value creation opportunities to stay competitive in the rapidly evolving digital landscape.	[33,39,40,43,44,47,51,59,62, 63]	10	16.67	7
E_3	People/culture/ Employees	People/culture/employees refer to the human aspect of the organization, including its employees' skills, knowledge, behaviour, and attitudes towards digital transformation. It involves the organization's culture, values, leadership, and change management strategies necessary for successful adoption of smart manufacturing practices. It also includes the development of a skilled workforce capable of operating and maintaining advanced digital technologies.	[17,29,58,60,62,64–67,33, 36–39,44–46]	17	26.15	5

(*Continued*)

TABLE 1.5 (Continued)
Identified Variables

S. no.	Dimensions	Definition	References	Frequency	Percentage	Ranking
E_4	Processes	Processes refer to the methods and procedures used in making products. It includes adoption of technology with process automation, industrial robots. Processes in I4.0 involve the integration of various systems across the entire value chain, including design, production, supply chain, logistics, and customer service. Smart processes are designed to be flexible, adaptable, and responsive to changes in customer demand, market trends, and technological advancements.	[3,29,50,55,60–63,65, 66,68,69,33,70–75,35–38,43, 38,43,45,46]	27	41.54	3
E_5	Customers	This dimension includes understanding and meeting customer expectations, providing customer-tailored products, and using data analytics to improve customer experience. Customer retention is a key focus, and companies strive to create a customer-centric environment to improve their competitiveness in the market.	[29,36,64,76,38,39,42,44, 55,57,60,62]	12	18.46	6
E_6	Products	Products refers to the physical goods or digital services produced by a company or organization using advanced technologies and processes. These products may be customized or personalized for individual customers and may incorporate digital features and connectivity to enhance their functionality and value.	[3,35,62,64,65,69–73,75,77, 36,78,38,42,43,46,57,59,60]	21	32.31	4

E_7	Services	Services refers to the digital features and capabilities that are integrated with the products offered by an organization. This includes data-driven services, remote monitoring, product configuration, product simulation, and condition monitoring, among others. By leveraging digital technologies and integrating them with their products, organizations can improve their competitiveness and customer satisfaction.	[35,36,44,50,59,60,64,71,79]	9	13.85	8
E_8	Technology	It involves the integration of physical and cyber systems, resulting in smart and efficient manufacturing processes. Technology is a critical dimension in Industry 4.0 as it enables companies to improve their operations, increase productivity, reduce costs, and develop new products and services.	[3,7,38–40,42–46,50,51,17, 52–55,57–60,62,63,29, 64–73,30,74–83,31,84–90, 33,35–37,91,92]	60	92.31	1

Innovation allows manufacturers to improve their processes and operations, resulting in reduced costs and improved quality. For example, the implementation of predictive maintenance systems can reduce downtime and prevent costly equipment failures. Similarly, the use of robotics and automation can increase production efficiency and reduce labour costs.

Innovation can also enable manufacturers to create new products and services, opening new markets and revenue streams. For example, smart products equipped with sensors can provide valuable data used to improve customer satisfaction.

1.4.1.8 Services (E_7)

According to the findings presented in Table 1.5, the dimension of services ranks at the eighth position (frequency 9, percentage 13.85. In I4.0, services refer to the digital features offered by an organization that attract end-users to adapt to the industry 4.0 environment. Such services may include product configuration, development, and simulation, as well as remote and condition monitoring, and other data-driven services that are integrated with digital technologies.

Sections 4.1.1 through 4.1.8 presents discussion on variables. Based on the analysis, it is apparent that Technology (E8), Organizational strategy (E1), Processes (E4), Products (E6), and People/culture/employees (E3) are the most crucial dimensions for SMEs. Dimensions reporting a frequency of more than 25% considered critical. The selection of these critical dimensions is subjective, and further input from experts in the field may be necessary to support the findings.

1.4.2 Discussion on RQ3

For the identification of future research theme, the authors have conducted bibliometric analysis. The work is done on Bibliometrix and Vosviewer. The authors selected the WoS database. Authors designed the search string such that it covers the objective of the chapter. The search string is as follows: ("smart manufacturing" AND "industry 4.0"). the authors conducted the search from the web of science database using the string followed by screening of the articles (Table 1.6).

186 articles are selected for further analysis. The authors have gone through the most relevant sources. The analysis shows that the IJPR journal receives a total of 598 citations on the topic followed by Journal of manufacturing systems with 386 citations. Figure 1.3 shows the most cited sources form the smart manufacturing and industry 4.0.

The authors now conducted the keyword cooccurrence analysis using VOSviewer. Which result in making the five clusters. Figure 1.4 shows the keyword cooccurrence analysis and clusters. These clusters are identified by the colors. Each cluster contain several elements. The details of the clusters are given in Table 1.7.

TABLE 1.6
Screening Results

Description	Type	Article Count
Search using keywords ("smart manufacturing" AND "industry 4.0")	Inclusion	609

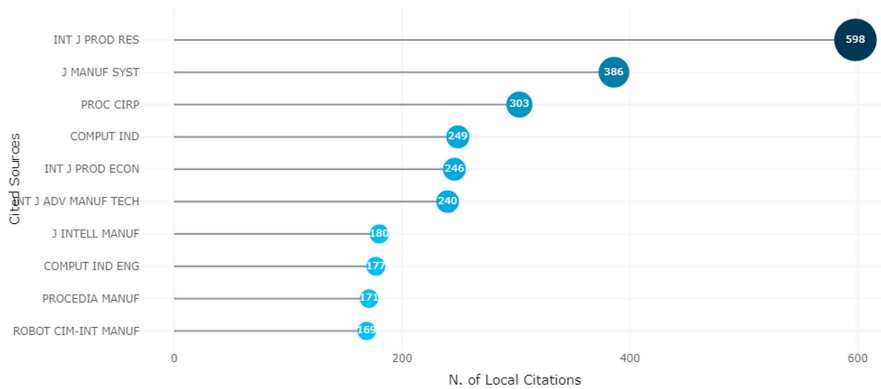

FIGURE 1.3 Most cited sources.

1.4.2.1 Theme based on blue cluster.

> ***"Enhancing Smart Manufacturing through CPS and Industrial Internet: Investigating Decision-Making in Smart Factories."***

The theme directs researchers and academicians to exploring the challenges and barriers to the implementation of SM systems in I4.0 environment and developing strategies to overcome them. The research will investigate how CPS

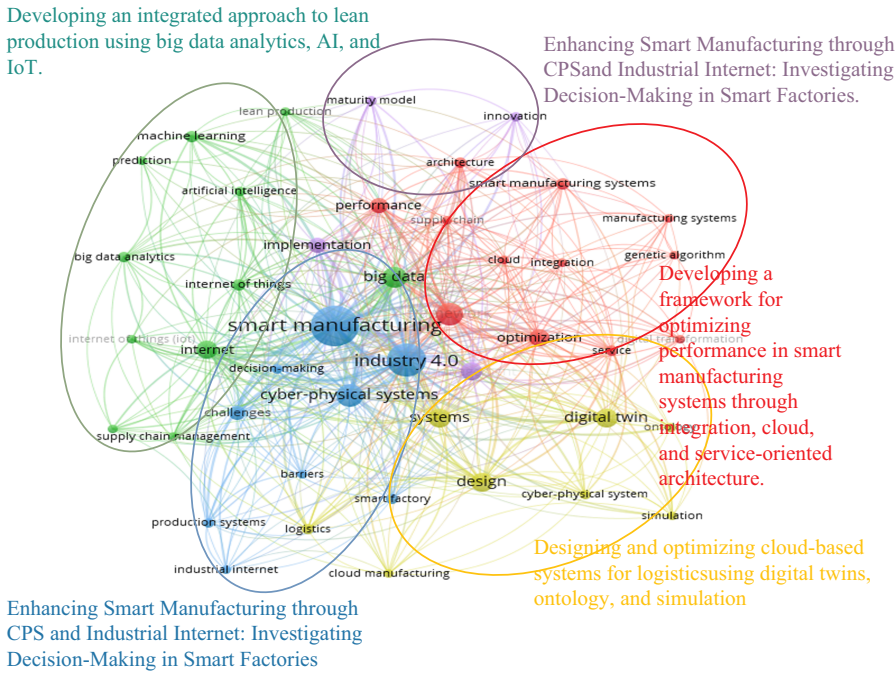

FIGURE 1.4 keyword cooccurrence network analysis with research themes.

and IIoT can be integrated to create a smart factory environment. The decision-making processes involved in the implementation of such systems will also be studied to ensure effective implementation. Finally, the proposed strategies will be evaluated in terms of their effectiveness in addressing the identified challenges and barriers and their ability to facilitate the implementation of SM systems in I4.0 environment.

1.4.2.2 Theme based on yellow cluster.

> ***"Designing and optimizing cloud-based systems for logistics using digital twins, ontology, and simulation."***

This covers areas on utilizing cloud manufacturing, digital twins, and simulation technologies to design and optimize manufacturing and logistics systems. The design aspect of this theme emphasizes the importance of considering both product and process design in the development of such systems. Ontology can be used to standardize data and communication protocols, while logistics can help ensure efficient material flow and inventory management. Finally, the use of digital twins allows for virtual testing and optimization of the proposed systems before implementation, reducing risks and costs.

1.4.2.3 Theme based on red cluster.

Developing a framework for optimizing performance in smart manufacturing systems through integration, cloud, and service-oriented architecture.

This theme focuses on developing framework that incorporates elements of cloud computing, service-oriented architecture, and integration to optimize performance in smart manufacturing systems. The framework will be developed through digital transformation of existing manufacturing systems and supply chain networks. Optimization techniques such as genetic algorithms will be used to fine-tune the system performance. The use of SM systems can help ensure effective data collection, decision-making. Finally, the framework will be evaluated to improve the performance of SM systems in real-world settings.

1.4.2.4 Theme based on green cluster.

"Developing an integrated approach to lean production using big data analytics, AI, and IoT."

The theme focuses on utilizing big data analytics to improve SCM by developing a framework that incorporates IoT, ML, and AI. The framework will be deployed on cloud computing platforms and will leverage lean production principles to reduce waste and improve efficiency. The internet will play a key role in facilitating data exchange and communication between different supply chain partners. The use of ML will enable prediction of supply chain events and help in making data-driven decisions.

1.4.2.5 Theme based on purple cluster.

"Developing a maturity model for effective innovation management implementation".

It focuses on developing a maturity model for effective innovation management implementation. The research points towards identification of factors that help in innovation management implementation. The maturity model can help organizations assess their current innovation management capabilities and identify areas for improvement. The research can use case studies to evaluate the effectiveness of model in different organizational contexts. The findings of the research can help organizations improve their innovation management capabilities and drive growth and competitiveness.

1.4.2.6 Co-citation network analysis

The authors have conducted the co-citation network analysis for deeper understanding of the emerging themes. Analysis was done using the tool VOSviewer. The result of co-citation network reveals that there are four clusters with minimum cluster size 17 and minimum link strength 2. Figure 1.5 shows the co-citation

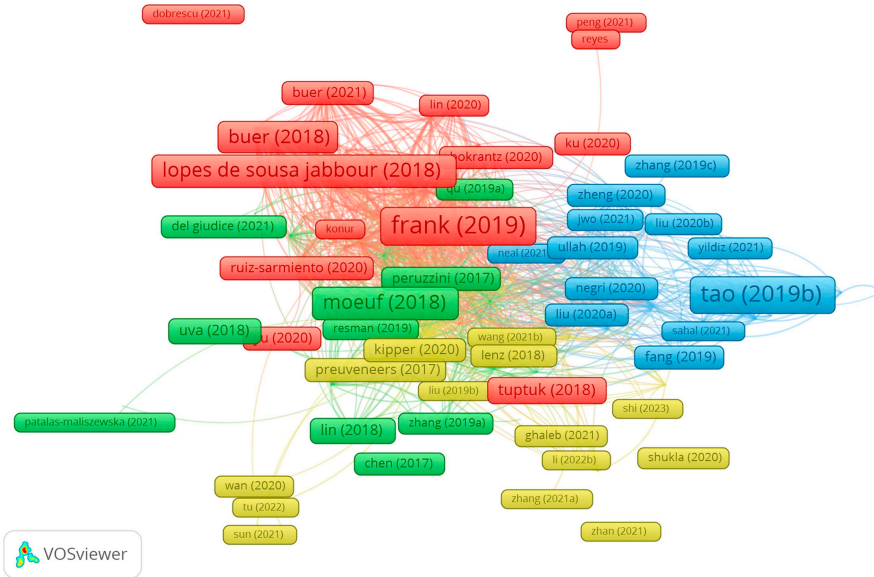

FIGURE 1.5 Co-citation network analysis of articles (VOS viewer).

network analysis of the selected articles. Table 1.8 presents the co-citation network details with top terms and themes.

The themes discussed can be used for research in smart manufacturing by providing a framework for investigating and improving various aspects of manufacturing operations, including maintenance, supply chain management, logistics, quality control, and performance optimization. For example, researchers can explore how data-driven approaches, such as condition-based monitoring and predictive maintenance, can be leveraged to improve equipment reliability and reduce downtime. Collaborative networks and cyber-physical systems can be studied to enable effective communication and coordination between different parts of the manufacturing process, from suppliers to customers. Augmented reality and machine vision can be investigated to enhance human-centered manufacturing, while blockchain and security monitoring can be explored to ensure data integrity and cyber resilience. Optimization techniques, such as simulation modelling and parameter identification, can be applied to improve manufacturing efficiency and quality.

Overall, the discussed themes provide a comprehensive framework for investigating various research questions related to smart manufacturing and offer opportunities for improving manufacturing processes through the integration of advanced technologies and data-driven approaches.

1.5 VALIDITY THREATS

Despite the use of SLR guidelines there are still potential validity issues with the findings. To further minimize bias, we followed the selection criteria guidelines and invited a guest researcher to validate the study selections, resulting in a 70% agreement

TABLE 1.8

3 (Blue)	Enhancing Manufacturing Performance and Security through Digital Twins and Autonomous Collaboration	29	2021	Optimization, onto-based modelling, digital twin, CPS, autonomous collaboration, reinforcement learning, human-in-the-loop SM, web-based digital twin, security monitoring, quality, mes integration, cognitive twin, blockchain, data formats, human decision models, simulation modelling, product management, iot enabled, simulation-based approach, edge computing.
4 (Yellow)	Maximizing Efficiency and Quality in Industry 4.0 Ecosystems through Condition-Based Monitoring and Data-Driven Approaches	21	2020	Condition-based monitoring, synchroperation, bottleneck detection model, data-driven models, data analytics, SM systems, cyber-physical factories, logistics management, quality improvement, I4.0 ecosystem, parameter identification, machine learning, training, anomaly detection model, dynamic environment.

on the selections. However, there is still the possibility of publication bias, where researchers may only present positive results from their research. To address this, we utilized multiple search libraries. Finally, there is a possibility of data extraction bias, but we minimized it by using a data extraction template to record unbiased data.

Also, there may be the possibility of biasness while conducting bibliometric analysis such as biasness in database selection, incompleteness of data, citation practices, self-citations, inaccurate citation data, changing publication practices etc. However, to avoid such threats, the authors have conducted the word co-occurrence network analysis and co-citation network analysis for exploring future research directions.

1.6 CONCLUSION

Smart manufacturing has emerged as a transformative approach to manufacturing that integrates cutting-edge technologies and innovative processes to enable more efficient, flexible, and sustainable production. The success of smart manufacturing depends on several dimensions that are critical for achieving operational excellence and competitive advantage. To this end, the author conducted review of studies published from 2007 to 2022, eight dimensions that aid manufacturing firms in opting smart manufacturing practices. RQ1 was addressed by extracting data from 65 studies to identify 8 key dimensions, namely technology, organizational strategy, people/culture/employees, processes, products, customers, innovation, and services. To address RQ2, dimensions (Count percentage > 25%), which included technology, organizational strategy, products, processes, and people/culture/employees. The RQ3 was addressed by conducting a bibliometric analysis resulting in five potential research directions (keyword co-occurrence network analysis) and another four themes (using co-citation network analysis). This finding underscores the high demand for research on smart manufacturing. These findings can inform future smart manufacturing research. Further work on these themes can add value to research domain and ultimately lead to achieve socio-economic goals.

ORIGINAL RESEARCH PAPER

Orthopaedics

A RESEARCH ON PREVALENCE OF LOW BACK PAIN DISABILITY IN MARBLE FACTORY WORKERS

KEY WORDS: Work related musculoskeletal disorders, Low back pain, WMSDs, Disability

Dr.Arvind Kumar (PT) Ph.D. Scholar, M.P.T. (Orthopaedics), M.B.A. (Hospital Management), Dean, School Of Physiotherapy, Swarnim Startup & Innovation University, Gandhinagar, Gujarat, India.

ABSTRACT

INTRODUCTION: WMSD's among marble factory workers are common. They are a major concern of workers, union, employers and government. Work-related musculoskeletal disorders (MSDs) are disorders of body structures such as tendons, joints, muscles, ligaments, bones, nerves or a local blood circulation system caused or aggravated primarily by the nature of performance of work. The aim of this study was to determine the prevalence of low back pain in marble factory of Aburoad, to know the relation between low back pain and physical activity.

Most work related MSDs are resulting from repeated exposures to low - or high intensity workloads over a prolong period of time. This indicates a strong relationship between factors within the working environment and the development of MSDs, and that these conditions result in significant reduction in productivity

OBJECTIVE: The objective of the study was to study and identify issues and problems of MSDs, specifically LBP. It was believed that results of this study would provide a base for planning interventional programs at work place and improving workers health.

MATERIALS AND METHODS: A questionnaire was formulated with few variables which were specifically focused.

A general set of subjective variables such as name, age, sex, occupation, hand dominance, hypertension, weight, BMI were included. Few specific variables were-Nature of job, experience in years, working hours & overtime, drug addiction (alcohol, tobacco intake),routine of work (sitting/standing/walking/bending/lifting heavy loads), rest time-up to 3 categories(30 minutes/45 minutes and above)

MATERIALS: It included demographic identification form, modified oswestry disability index of LBP, NPRS scale, consent form, tapes, Mats etc.

SETTING OF THE STUDY: Data were collected at 5 marble factories.

PATIENTS: 180 subjects with LBP were involved in the study after screening of approximately 328 workers.

SAMPLING TECHNIQUE: Simple convenient sampling

SAMPLE SIZE: Total 180 subjects of 5 factories with low back pain participated in study.

SELECTION CRITERIA: The study populations were selected according to inclusion/exclusion criteria.

RESULTS: There was a higher prevalence of LBP in factory workers doing more of bending and sitting activities when compared to the standing positions. Even we found that the workers lifting more of heavy weight more than 20 kg reported of having LBP, which is in concordance to the support etal's study that the workers who had to lift the object up to 25 kg or more. There were significantly associated with LBP.

CONCLUSION: Work related musculoskeletal disorders in marble factory workers were common as a higher prevalence of LBP. This perception of intensified workloads, repetitive and monotonous work with limited job control and clarity might be one of the factors associated with MSDs. Further research is needed to investigate the effect of risk factors as general health status on prevalence musculoskeletal disorders.

INTRODUCTION-

The impairments of ligaments, muscles, joints, tendons, nerves, bones, etc. caused by the performance of work are called as work-related musculoskeletal disorders (WSDs). Work-related musculoskeletal disorders are a major public health problem in the industry and also more common in developing countries [1,2,3,4,8].WMSD's among marble factory workers are common. They are a major concern of workers, unions, employers, and government. Work-related musculoskeletal disorders (MSDs) are disorders of body structures such as tendons, joints, muscles, ligaments, bones, nerves or a local blood circulatory system.

Work-related physical handling of materials, especially heavy load lifting, frequent bending, twisting, working in awkward postures and vibration of whole-body, are well-established risk factors for LBP.[6,7]

Improper body movements such as manual handling, working in sitting, bending, lifting heavy loads etc. is directly related to prevalence of LBP.[6]

Evidence showed that in the period 2004-2005, 11 million days of work were lost because of musculoskeletal disorders in the U.K.[4]

These disorders are cumulative once resulting from exposure to high and low-intensity loads over a long period of time. The major factor contributing to musculoskeletal disorders is poor working posture resulting in a minor to a severe back problem.

There are various risk factors known to be included in workplace activities such as heavy load lifting, repetitive task, and awkward working postures as well as the nature of job cutting shearing drilling, etc. caused or aggravated primarily by the nature of the performance of work.[8]

Low back pain is not life threatening disorder but it has a long term impact on expenditures for affected workers.[9]

The aim of this study was to determine the prevalence of low back pain in the marble factory of Aburoad city and to know the relation between low back pain and physical activity.

Most work-related MSDs are resulting from repeated exposures to low - or high-intensity workloads over a prolong period of time. This indicates a strong relationship between factors within the working environment and the development of MSDs, and that these conditions result in a significant reduction in productivity.[10]

Approximately 100 million occupational disorders are occurring throughout the world annually.[11,12]

Marble is commonly used in the sculpturing of the statue, the construction of buildings and monument.[13]

The workers in the marble factory are involved in awkward posture and long hours of standing work.

Epidemiological data concerning WMSD are usually available in industrially developed countries. So we preferred study setting, which is also an industrial area and where ample amount of marble factories are available and Aburoad has opted for such a study setting.

Many studies have been conducted in various developed countries, in a large European survey showed that 45% of 130 million population workers were exposed to manual material handling and awkward postures.

Another study conducts in Iranian Communication Company showed a significant association between job tenure and MSD in the lower back region as well.

The aim of this study justifies on the prevalence of musculoskeletal disorders in marble factory workers, which can contribute to more effective strategic planning in the country.

Many active workers have musculoskeletal disorders as discomfort or pain may become incompatible which may lead to sick leave.

This study in active suspected workers who have minor problems –may help prevent the progression of the disease.

OBJECTIVE:

The objective of the study was to study and identify issues and problems of MSDs; specifically LBP. To assess occupational risk factors related to the prevalence of LBP It was believed that the results of this study would provide a base for planning interventional programs at the workplace and improving workers health.

INCLUSION CRITERIA:

Age: - 20-60
Gender: - Both male and female
Completing a minimum of 3 months period of occupation
Workers involved in sitting and standing activities
Nature of job involving bending and lifting activities
Good communication activities
Working hours more than 7

EXCLUSION CRITERIA:-

Acute health condition
Cancer
RA
Any health conditions that could alter the perception of pain
TB
Workers who involve in washing, cleaning activities

OUTCOME MEASURE:-

MODI
NPRS

MATERIALS AND METHODS:-

A questionnaire was formulated with few variables which were specifically focused.

A general set of subjective variables such as name, age, sex, occupation, hand dominance, hypertension, weight, BMI were included. Few specific variables were-Nature of job, experience in years, working hours & overtime, drug addiction (alcohol, tobacco intake), a routine of work (sitting/standing/walking/bending/lifting heavy loads), rest time-up to 3 categories (30 minutes/45 minutes and above).

Data were collected at 5 marble factories in Aburoad between February to March 2018.

The objective of the study is to "Study and identify the issues and problems of MSD" that to specifically LBP. It is believed that the results of this study would provide a base for planning interventional programs at the workplace and improving workers health.

MATERIALS: -

It included demographic identification form, modified Oswestry disability index of LBP, NPRS scale, consent form, tapes, Mats, etc.

SETTING OF THE STUDY:-

Data were collected at 5 marble factories.

PATIENTS:-

180 subjects with LBP were involved in the study after a screening of approximately 328 workers.

SAMPLING TECHNIQUE:-

Simple convenient sampling

SAMPLE SIZE:-

A total of 180 subjects of 5 factories with low back pain participated in the study.

SELECTION CRITERIA:-

The study populations were selected according to inclusion/exclusion criteria.

RESULTS:-

The prevalence of LBP was found to be 54.87 %. There was a higher prevalence of LBP in factory workers doing more of bending and sitting activities when compared to the standing positions. Even we found that the workers lifting more of heavyweight more than 20kg reported having LBP, which are in concordance to the Supreet et al's study that the workers who had to lift the object up to 25 kg or more. There were significantly associated with LBP and that to 1.27 times more frequently

DISCUSSION:-

This study describes the prevalence and risk factors for LBP among marble industry workers. More than 80% of the population experience LBP at some time during their lives. The prevalence of MSWDS among industry workers who usually are in full working activity is high. There are very few studies identified the prevalence of musculoskeletal pain among marble factory workers in India. Similarly, one study was conducted among dentists using questionnaires sent by mail with a prevalence rate of 58%. Similarly, another study conducted by Ardiana Murtezani et.al. mentioned a low back pain prevalence of 61.6% among industrial workers which is consistent with most of the epidemiological studies investigating over the year LBP prevalence in workers. The possible cause of this rising prevalence is due to the time spent by workers in a seated position or frequently turning and twisting torso and exposure to awkward postures, vibration, and load lifting.

Literature shows that manual handling, frequent bending, twisting, heavy load lifting, repetitive tasks, and heavy physical work are the risk factors for WMSD especially LBP.[14,18] Another study conducted by Supreet et.al. in India mentioned that the increasing age doubles the risk of having LBP and they found a higher prevalence in the age group of 30-40 and 50-60 years.

According to them the jobs involved in lifting or moving weights of 25 kgs or more have been found to have strong occupational associations with LBP. Work activities such as lifting, pulling, pushing, sitting and bending were highly associated with LBP (Anannont sak et al 1996).

This perception of intensified workloads, repetitive and monotonous work with limited job control and clarity might be one of the factors associated with MSD.

Almost similar results were found in our study as well, there was a higher prevalence of LBP in factory workers doing more of bending and sitting activities when compared to the standing position. Even we found that the workers lifting more of heavyweight i.e. more than 20 kg reported of having LBP, which are in concordance to the Supreet et al's study that the workers who had to lift the object up to 25 kg. or more there were significantly associated with LBP and that too 1.27times more frequently.

Most of the marble factory workers affected by LBP were age group between 30-39 & 50-59 years,Mostly sufferer ware doing sitting job.

CONCLUSION:

Work-related musculoskeletal disorders in marble factory workers were common as a higher prevalence of LBP. This perception of intensified workloads, repetitive and monotonous work with limited job control and clarity might be one of the factors associated with MSDs. Further research is needed to investigate the effect of risk factors as general health status on prevalence musculoskeletal disorders.

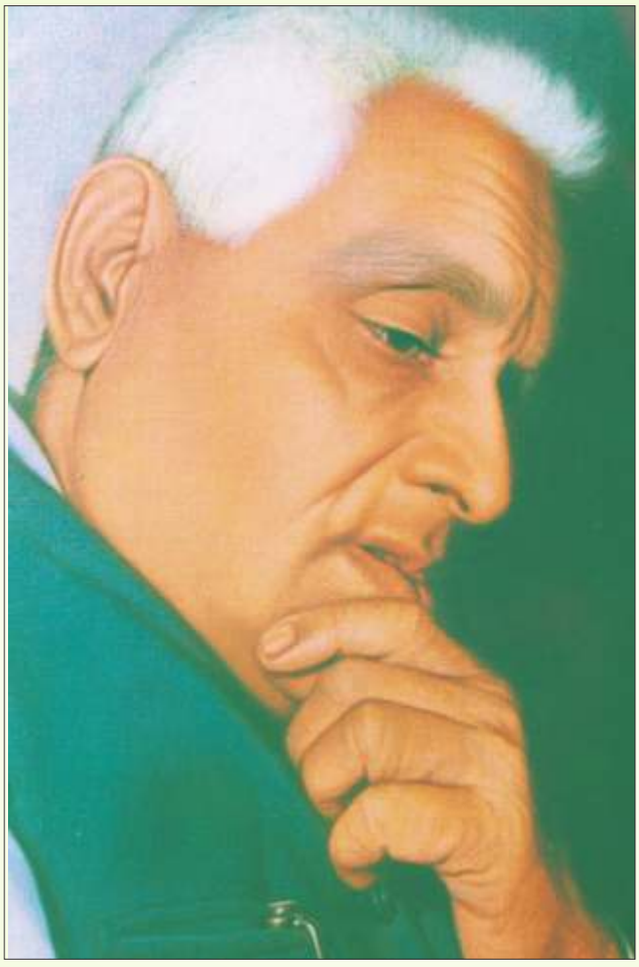
30 Minutes of brisk walking benefit health

Janardan Rai Nagar
Rajasthan Vidyapeeth
(Deemed) University, Udaipur

Our Beloved Founder



Late Manishi Pt. Janardan Rai Nagar

16th June 1911 - 15th August,1997

Popularly known as 'jannu bhai', the Late manishi's vision, farsightedness and sacrifice have enabled us reach the stature we enjoy today. He lit the lamp of knowledge by giving birth to an institution , named 'Hindi Vidyapeeth' on August 21, 1937 to spread education among those who were economically handicapped, and thereby enable them to learn the meaning of freedom Since then, the institution has been catering to the growing educational needs of an economically poor society having a rich socio-cultural heritage. Although the Manishi is not amongst us today, his ideals inspire us to fulfil the mission of imparting qualitative education to the society through preservation of our long cherished sociocultural values. We cherish his deeds and ideals, and strive to walk on the path shown by him.

Vice Chancellor's Message

It gives me immense pleasure to learn that the 8th Volume of Indian Journal of Physical Therapy and Rehabilitation is being published by department of physiotherapy. Sincere effort and keen interest taken by the members of department in the development of academic and research activities deserve all the admiration. I wish to express with a deep sense of joy and satisfaction on the release of this volume and the same moment to continue even in greater magnitude in the coming years so that the department accomplishes commendable place in the luminous field of physiotherapy at the international level.

Wishing all a scintillating success.

Prof. S.S. Sarangdevot
Vice Chancellor

Principal's Message

I have immense pleasure to gather that the Department of Physiotherapy, Janardan Rai Nagar Rajasthan Vidyapeeth (Deemed) University, Udaipur, is going to publish its 8th Volume of Indian journal of Physical Therapy and Rehabilitation this year.

We must engage in research and voice our opinions by publishing them in this, our local journal. To ensure wide leadership, the journal will carry a variety of articles of general interest, as well as scientific articles, based on topics relevant to our region. Articles in the following categories are welcome: Editorials, Letter to Editor, Major and Minor Reviews, Original Research, Notable Clinical cases, To conference report, New technique I clinical update. With so many categories, I am sure that all of you will be able to make regular contributions to this journal.

This is a major milestone for the physiotherapy field and I encourage all my staff and colleagues in the health care Sec-tor, both public an private, to embrace and support this Journal. The continuing success of this journal should give us a sense of pride and achieve meant. Please contribute articles to this journal in a timely manner to ensure it becomes an important forum for the exchange of ideas and knowledge which will ultimately transfate to better health care.

My Congratulations to the entire team of my Department of Physiotherapy working for this remarkable Endeavour and I wish editor in chief all the best for the successful publication of the journal.

DR. SHAILENDRA MEHTA
Principal
Department of Physiotherapy

The Editor's Desk

It gives me immense pleasure to write editorial for this 8th volume of IJPTR. The Department of Physiotherapy J.R. Nagar Rajasthan Vidyapeeth University Journal with a vision to promote physiotherapy science including all the specialities of Physiotherapy and uptake knowledge through new innovative research papers, case reports and Review articles in various field of physiotherapy specialities. This Journal with consistent precious publications ultimately aims to reach out to the International standards.

Our world is changing we face mounting challenges of Health Care to name a few. Their solution will require new ideas, discoveries, talents and innovations the fruits of research. To achieve them we must start by changing the way we do research there has to be free movement of people & ideas.

At this Juncture i wish to express my profuse thanks to all those who made an appreciable contribution for this journal and further i anticipate that their majestic effort shall continue, so to bring greater glory to our endeavors.

The arena of physiotherapy which as a matter of fact, works as a back bone of medical rehabilitation field should further be developed, for greater benefit to our suffering humanities

I implore & solicit all our members to spare no stone unturned in this noble and glorious mission.

I whole heartedly wish to express my deepest sense of gratitude to Honb'e chancellor & Honb'e Vice chancellor for their untiring help, relentless support and tremendous encouragement without which the present work would not have achieved its glorious completion.

On the behalf of editorial board I request to all the physiotherapist academicians, clinicians, research scholars and students to contribute articles for this Journal.

I pray to Almighty to grant all of us still greater success in times to come.

EFFECT OF EUHYDRATION AND HYPOHYDRATION ON HEART RATE RECOVERY IN YOUNG UNIVERSITY ATHLETE

Dr. Ronald B*
Dr Anand Misra Dr Arun Mohzi*** MPT (Sports), Dr Shid Dhar******

Abstract: Aims and Objectives: To compare the effect of euhydration and hypo hydration on young University athletes Study Design: Experimental Study. Participants: Total of 60 subjects was included based on the inclusion and exclusion criteria through convenient sampling and . Before exercise all the subjects were measured for urine specific gravity subjects falling under euhydrated level were taken basal heart rate and then asked to follow the protocol same was done for hypohydrated state Outcome measure: Heart Rate. Results: The results of the study show that there is a significant faster heart rate recovery (p=0.000) between the groups for Hypohydration Group . Conclusion:We conclude that during hypohydration the heart rate is much more stable than in euhydrated state .which promotes better cardio vacular endurance.

INTRODUCTION

Water is the largest single component of the human body, accounting for about 50–60% of total body mass. For a healthy lean young male with a body mass of 70 kg, total body water will be about 42 lit. The turnover rate of water exceeds that of most other body components. For the sedentary individual living in a temperate climate, daily water turnover is about 2–3 lit. In other words, about 5–10% of the total body water content is renewed every day.

Water is lost from the body in varying amounts via a number of different routes the main avenues of water loss are urine (about 1400 ml), feces (200 ml), insensible losses from the lungs (400 ml) and loss via the skin (500 ml). The total daily water loss is therefore about 2500 ml, but this varies greatly between individuals and depends on the environmental conditions.

Water is the medium of circulatory function, biochemical reactions, metabolism, and substrate transport across cellular membranes, temperature regulation, and numerous other physiological processes. Fluid-electrolyte turnover and whole-body water balance change constantly because water is lost from the lungs, skin, and kidneys, and because water is gained in food and fluids. Therefore, accurate and precise laboratory and field techniques are needed to evaluate human hydration status.

water to reach the intracellular compartment. The cells imbibe, drinking is inhibited and the kidneys excrete more water.

Methodology

Design

This is an experimental study. All the subjects were recruited from the various colleges and sports center from of Dehradun.

Sampling :

Total of 60 subjects were chosen as per the inclusion and exclusion criteria, and informed consent was obtained from all the subjects after the procedure was explained to them

Procedure :

Euhydrated and Hypohydrated states.1st day the subject were studied for Euhydrated state. And for this he/she was asked to consume normal required water the specific gravity was checked by myself. If it came under the specified limit that is 0.010 they were made to follow the protocol or else follow the above procedure. Temperature was set at25O C. A pre exercise data was recorded of their basal heart rate. Then the Euhydrated subjects had to follow

MPT Scholar, Garden City University, Bangalore* Principal Indore Institute of medical Sciences**
Associate Professor, Garden City University, Bangalore ***

their prescribed exercise protocol which is as follows:

- 5 min warm up at speed of 2m/sec inclination 0 degree
- 20 min running at 7 m/sec speed on treadmill at inclination 1degree
- Then the time taken for recovery heart rate was measured

Throughout this the heart rate was recorded in the last 10 sec of a min.

The same subjects were then studied for hypohydrated state on next day.

Results:

TABLE : INTER GROUP COMPARISON OF HEART RATE RECOVERY TIME BETWEEN GROUP A AND B

VARIABLES	MEAN		SD		T	P

	11	8.75	2.16286	1.81915		

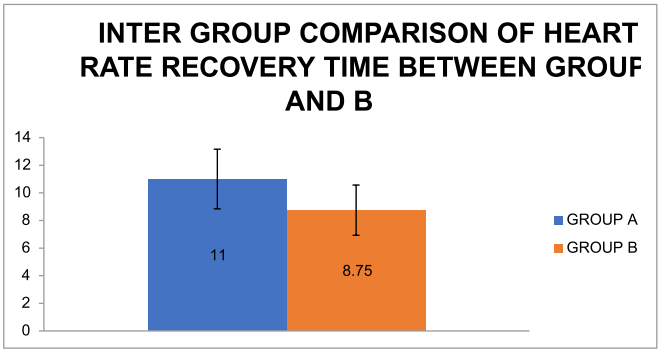

FIG 10: Shows significant difference in heart rate recovery time in group A and B

DISCUSSION

Hypohydration group showed significant early recovery after the exercise protocol. This could be explained by the reason that hypohydration causes decrease in blood volume. As result the arterial blood pressure falls leading to and there is decrease in blood volume level in the body which lead to increase incidence of orthostatic hypotension and syncope. As defense mechanism the body produces sympathoexcitation and increase in volume regulatory hormones like Angiotensin II. This increases blood volume in the body. So when there is increase in blood volume the heart rate does not increase this causes decrease in heart rate. This could be the possible mechanism of faster heart rate recovery in hypohydrated group.28

Adrenaline is a stimulator of heart rate, it increases the heart rate through sympathetic activity and thus increases heart rate but a physiological mechanism also says that when there is too much irritation by adrenaline it may causes decrease in the heart rate known as ADRENALINE BRADYCARDIA.25

In favor of present study it has been proved that during the period of dehydration there is an increase in concentration of epinephrine, norepinephrine and cortisol also cytokine along with adrenaline are precursor of sympathetic activity and shows that IL-6 component of cytokine is released 30 min after the exercise. So it suggest that for the first 30 min there is increased concentration of adrenaline which may cause adrenaline bradycardia, thus decreasing the heart rate3

In previous studies it was seen that when an athlete is made to exercise in a heat stress in a dehydrated state the heart rate recovery was faster in euhydrated subjects than dehydrated group but as per study done by me the heart rate of hypohydration group increased less which shows a contradictory results36, 37 and a need for future research.

Conclusion :

As per previous studies, euhydration and hypohydration both help in heart rate recovery but as per this study, hypohydration group showed an early recovery in a short period of time at 25ºC. This means that if we make an athlete enter a short term sport with moderate intensity in hypohydrated state, it can be beneficial for him/her as there will be early heart rate recovery which shows a better cardiovascular endurance in them.Thus.it will be beneficial for improving their performance at sport.

EFFECT OF VIRTUAL REALITY VERSUS CONVENTIONAL THERAPY ON STATIC AND DYNAMIC IMBALANCE IN STROKE PATIENTS –A COMPARATIVE STUDY

Dr. Anand Misra, Dr. Deepti Garg**
Dr. Anuja Sharma,*, Dr. Subhash Garg******

ABSTRACT

Background: Stroke, or a cerebral vascular accident, is the sudden death of brain cells due to inadequate blood flow. The WHO clinically defines stroke as the rapid development of clinical signs and symptoms of a focal neurological disturbance lasting more than 24 hours or leading to death with no apparent cause other than vascular origin'. (WHO 2005) . Stroke is a global health problem. These include impaired neuromuscular control, altered sensation, neglect (i.e. failure to respond to stimuli on the affected side) and visual deficits. Thus increasing the risk for falls, leading to subsequent injuries.

Methodology: 30 patients were randomly selected male and female both of the age group 40 to 65 of age with difficulty in walking. They were divided into 2 equal groups. Group A was experimental group and was given virtual reality training along with few exercises and group was given conventional therapy alone for 30 minutes, 5 days a week for 4 weeks. Both the groups were assessed pre intervention and post intervention on berg balance scale and TUG test.

Results: After administration of virtual reality exercises among stroke patients of group A group between baseline and post intervention (22.13 points) were large and thus strongly significant ($p<0.001$). Less improvement noted among stroke patients of group B than group A at post intervention stage.

Conclusion: Ultimately, the present research showed that the physiotherapeutic regime such as virtual reality exercises on static imbalances are more effective intervention protocol in improving the balance and better functional status in patients with stroke.

Key-words: Stroke, Virtual Reality, Balance improvement, Head Gear.

INTRODUCTION

Stroke is a global health problem. It is the second commonest cause of death and fourth leading cause of disability worldwide1.

It is defined as the sudden onset of focal neurological deficits, as a result of the interruption of blood flow to a specific part of the brain.2 It is one of the most common causes of death and is the single most common cause of severe disability (30% - 40% of survivors).3This condition is usually characterized by loss of functions of the motor, sensory and higher brain cognitive faculties to various degrees4 typically on side of the body opposite to side of the lesion.3Such motor deficits will lead to dramatic alteration in lifestyle, compromising the functional independence, decreasing mobility and ability to perform activities of daily living.3

Although 60% of the stroke survivors regain walking independence after 3 months, several have continuing problem with mobility due to impaired balance, motor weakness and decreased walking velocities. The ability to walk in stroke subjects can be affected by various neurological deficits, which are typically unilateral. These include impaired neuromuscular control, altered sensation, neglect (i.e. failure to respond to stimuli on the affected side) and visual deficits.7 Thus increasing the risk for falls leading to subsequent injuries. Research reveals that diverse factors, such as timing and force scaling problems, sensory loss, abnormal muscle tone, loss

Principal Indore Institute of medical Sciences* MPT Neuro

of sensory and anticipatory postural control, contribute to the difficulties of dynamic balancing in post-stroke population.8

Deficits due to impaired balance include an increase in a postural sway, a decreased areas of stability in stance, and an uneven weight distribution on stance with less weight placed on the weaker leg.2 Moreover, during ambulation stroke patients have a higher risk of falls.9 Many people returning home after stroke rehabilitation walk at average speed that is insufficient to cross the street safely or even to walk safely in the community.10

Cheng and Marigold showed significant improvement in dynamic balance function measurements following balance training.2 . Two major goals of rehabilitation are the enhancement of functional ability and the realization of greater participation in community life. These goals are achieved by intensive intervention aimed at improving sensory, motor, cognitive and higher level-cognitive functions on the one hand, and practice in everyday activities and occupations to increase participation on the other hand .17 Virtual reality-based therapy, one of the most innovative and promising recent developments in rehabilitation technology, appears to provide an answer to this challenge. Virtual reality typically refers to the use of interactive simulations created with computer hardware and software to present users with opportunities to engage in environments that appear to be and feel similar to real world objects and events 22,23,24. Users interact with displayed images, move and manipulate virtual objects, and perform other actions in a way that attempts to "immerse" them within the simulated environment thereby engendering a feeling of presence in the virtual world . 25,26

Virtual reality has a number of well-known sets, which make it highly suitable as a rehabilitation intervention tool .27 These assets include the opportunity for experiential, active learning and the ability to objectively measure behavior in challenging but safe and ecologically-valid environments while maintaining strict experimental control over stimulus delivery and measurement. VR also provides the capacity to individualize treatment needs, while gradually increasing the complexity of tasks and decreasing the support provided by the clinician .21,28

Given the variety of VR platforms and the diverse clinical populations that may benefit from VR-based intervention, it is helpful to view the VR experience as a multidimensional model that appears to be influenced by many parameters. A conceptual model was developed within the context of terminology established by the International Classification of Functioning, Disability and Health (ICF) 18 and the rehabilitation process 39,40. This model helps to identify the clinical rationale underlying the use of virtual reality as an intervention tool in rehabilitation as well as to design research to investigate its efficacy for achieving improved performance in the real world. The process of using VR in rehabilitation is modeled via three nested circles, the inner "Interaction Space", the intermediate "Transfer Phase" and the outer "Real World".

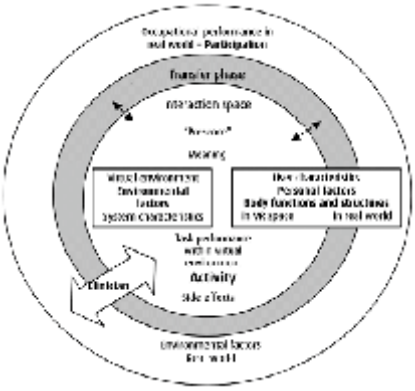

Figure: Model of VR-based rehabilitation within the context of terminology from the ICF(indicated in bold). (Weiss et al., 2006)

The "Interaction Space" denotes the interaction that occurs when the client performs within the virtual environment, experiencing functional or game-like tasks of varying levels of difficulty, i.e., the activity component according to the ICF terminology. This

interaction is influenced by user characteristics, which include personal factors (e.g. age, gender, and cultural background), body functions (e.g. cognitive, sensory, motor abilities) and structures (e.g., the parts of the body activated during the task). It is also influenced by the characteristics of VR platform and its underlying technology (e.g. point of view, encumbrance) that presents the virtual environment and the nature and demands of the task to be performed within the virtual environment.

It is during the interaction process that sensations and perceptions related to the virtual experience take place; here the user's sense of presence is established, and the process of assigning meaning to the virtual experience as well as the actual performance of virtual tasks or activities occurs. The sense of presence enables the client to focus on the virtual task, separating himself temporarily from the real world environment. This is an important requirement when motor and, especially, cognitive abilities and skills are trained or restored. The concept of meaning is also thought to be an essential factor that enhances task performance and skills in rehabilitation in general 16,18 and thus also in the VR-based rehabilitation 40. Environmental factors within the virtual environment may contribute information about issues that facilitate or hinder the client's performance, and may serve as facilitators of performance in the virtual environment leading to improved performance in the real world.

Two outer circles, the "Transfer Phase" and the "Real World" denote the goal of transferring skills and abilities acquired within the "Interaction Space" and eliminating environmental barriers in order to increase participation in the real world (i.e., participation in the natural environment according to the ICF terminology). The "Transfer Phase" may be very rapid and accomplished entirely by the client or may take time and need considerable guidance and mediation from the clinician. The entire process is facilitated by the clinician whose expertise helps to actualize the potential of VR as a rehabilitation tool.

VR-delivered therapy program, increased enjoyment while doing the exercises, improved confidence while walking and fewer incidents of falling.

Analysis of conventional and video capture VR treatment for SCI by specialists in rehabilitation highlighted several key differences between the two methods of intervention 45. First, control over delivery of the stimuli via the VR platform enabled the therapist to intervene more effectively, especially in terms of physical guidance and support. In addition, the VR platform allowed precise control over delivery of the number of stimuli simultaneously presented to the patient as well as their speed and direction. These features appeared to increase the number of times a desired balance-recovery movement was performed by patients. Finally, the ease with which this platform elicited dynamic equilibrium recovery responses, an essential component in balance training and encouraged weight transfer movements was remarkable. In contrast, the static presentation of stimuli during conventional therapy restricts intervention to focus almost exclusively on weight transfer.

Virtual reality (VR), which will be helpful in promotion of visual, auditory, tactile input and motivation and motor learning has been applied to improvement of motor skill after stroke .54 The number of studies and experimental applications exploiting VR in the rehabilitation environment has shown a rapid increase over the last few years. VR technology uses the principles of motor learning and neural plasticity in order to optimize recovery after brain damage .55 Application of VR is also varied, including gait and balance retraining and upper and lower limb rehabilitation. VR is the most recent intervention in stroke rehabilitation .56 VR is a powerful tool in a rehabilitation environment, providing the patients with repetitive practice, feedback information, and motivation for endurance practice .57

NEED FOR THE STUDY

In stroke balance dysfunction is common due to abnormal posture, reduced core stability, functional limitation. Thus the need of this study to find out the effectiveness of virtual reality for improving balance, improve core stability and posture control ,and activity of daily living. Thus improving their multitasking activity of stroke patients.

METHODOLOGY:-

The sampling technique was a purposive sampling technique. A sample size of 30 patients divided into 2 equal groups. The study was a quasi experimental study. Study time was 6months and the treatment was given for 4 weeks and 5days a week. Both the groups received treatment for 30 minutes. Inclusion criteria were no visual impairment, no Hearing disorder, patient must have ability to walk independently without use of walking aids for more than 10 meters, patient is able to understand and follow simple verbal instructions, having motor aphasia. Both males and females have been selected between 40 to 65 years. Patients with orthopedic or neurological diseases uncontrolled BP, presence of cardiac arrhythmias, homonymous hemianopia, mental retarded person, signs of deep vein thrombosis and patients with wernicke's aphasia were excluded. It was measured on the berg balance scale and TUG test.

OBSERVATIONS AND RESULTS:

TABLE-1

Comparison In Score On Berg Balance Scale In Group A And Group B Between Baseline And Post Intervention Sampling Stages

Sampling Stage & group	Score on BBS Mean ± SD	Mean Diff	t-statistic	LOS
Group A (Virtual Reality)				
Baseline	26.93±3.85	22.13 points	24.48	p<0.001 #
Post- intervention	49.07±3.20			
Group B (Conventional Therapy)				
Baseline	25.13±2.64	14.34 points	17.86	p<0.001
Post- intervention	39.47±3.91			

#The mean differences are highly significant at the 0.001 level of significance. [Mean Diff-Mean Difference; LOS-Level of Significance]

Table projects that the virtual reality and conventional exercises were the effective treatment protocols for improving the static and dynamic imbalance of stroke patients. In group A, the static imbalance was significantly differed and improved recorded after administration of a virtual reality exercises among stroke patients at post intervention stage as compared to baseline stage. The stroke patients in group B group also experienced improvement in static imbalance at post stage but less as compared to stroke patients of group A.

After administration of virtual reality exercises among stroke patients of group A group, the average of score (Mean ± SD) at post- intervention (49.07±3.20 points) was increased and improved as compared to score at baseline (26.93±3.85 points). Statistically, the differences in mean score of stroke patients of group A between baseline and post intervention (22.13 points) were large and thus strongly significant ($p<0.001$).

Less improvement noted among stroke patients of group B than group A at post intervention stage. In group B group, the differences in mean score (14.34 points) after administration of conventional exercise between baseline (25.13±2.64 points) and post intervention (39.47±3.91 points) was highly significant ($p<0.001$) that was confirmed statistically. The differences at post- intervention in mean score among stroke patients of group B found to be less (14.34 points) was measured on Berg balance scale as compared to patients of group A (22.13 points).

Moreover, it was inference statistically that stroke patients intervened with virtual reality exercises had more significantly improved static imbalance than stroke patients of group B treated with conventional exercise.

Furthermore, this study reported that virtual reality exercises on static and dynamic imbalance considered as a tool to combat the weak static imbalance statuses among stroke survivors.

TABLE-2

Comparison Between Group A And Group B In Berg Balance Scale Scoring At Baseline And Post Intervention Sampling Stages

Sampling Stage	Group	Score on BBS	Mean Diff	t- statistic	LOS
		Mean ± SD			
Baseline	Group A	26.93±3.85	1.80 points	1.50	p>0.05
	Group B	25.13±2.64			
Post-intervention	Group A	49.07±3.20	9.60 points	7.37	p<0.001 #
	Group B	39.47±3.91			

The mean difference is not significant (insignificant) at the 0.05 level of significance. #The mean difference is highly significant at the 0.001 level of significance. Post-treatment observations recorded after 4 weeks protocol. [Mean Diff-Mean Difference; LOS-Level of Significance]

TABLE-3

Comparison In Time Of Tug Test Between Group A And Group B At Baseline And Post Intervention Sampling Stages

Sampling stage	Group	Time (second) on TUG Test	Mean Diff	t- statistic	LOS
		Mean ± SD			
Baseline	Group A	18.33±1.88	0.80 second	0.96	p>0.05
	Group B	19.13±2.62			
Post (At 4th week)	Group A	9.47±0.83	0.53 second	1.74	p>0.05
	Group B	10.00±0.85			

*The mean difference is not significant (insignificant) at the 0.05 level of significance. Post-treatment observations recorded after 4 weeks protocol. [Mean Diff-Mean Difference; LOS-Level of Significance]

TABLE -7

reports that the difficulty and functional status after administration of virtual reality exercises of stroke patients of group A was not significantly differed at post intervention sampling stage as compared to stroke patients of group B who received conventional exercises. This showed that both the methods had same potential to cope with dynamic imbalances among stroke survivors.

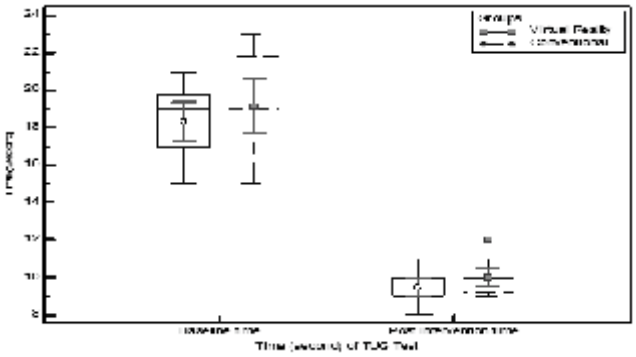

Figure - Box and Whisker diagram depicting the comparison of time (second) of TUG test between group A and group B at baseline and post intervention.

CONCLUSION

Hence, this was concreted statistically that patients with stroke intervened with virtual reality exercises had significantly improved static imbalances with better timings to overcome difficulties. Overall, present research highlighted that the virtual reality exercises is an effective conservative treatment for stroke survivors to improve static imbalances.

Ultimately, the present research showed that the physiotherapeutic regime such as virtual reality exercises on static imbalances are more effective intervention protocol in improving the balance and better functional status in patients with stroke. Finally, the above all statements and inferences from all the tables indicated the rejection of null hypothesis. Therefore, the alternative hypothesis is accepted which stated as "There will be more significant effect of virtual reality as compare to conventional therapy in static imbalance in stroke patients".

DISCUSSION

The aim of study to investigate the effect of virtual reality and conventional therapy in balance imbalance in stroke patients. Thirty subjects suffering from stroke were available for the study. The patients with stroke in group A received virtual reality with sitting, standing and maintenance of trunk stability in standing position while rest other stroke patients of group B received conventional therapy. The scores on Berg balance scale (BBS) and time on timed get up and go (TUG) test had collected prior to administration of exercises and after administration of exercises in groups, the scores had recollected at 4th week.

The result indicates that the stroke patients intervened with virtual reality exercises had significantly improved static imbalance than stroke patients intervened with conventional exercises.

Mancini et al 2002 says that conventional postural control training, which patients might find boring and aimless, leads to a low participation rate and decreased motivation.

Generally, balancing the body is by the coordination of three major systems, including visual, vestibular and proprioceptive sensation. The cortex area of brain, brainstem and cerebellum control the balance of body. The prefrontal cortex is one of the most important brain areas in controlling human balance (Nancy, 1980; Virk et al., 2006; Walker et al., 2010; Bolton et al., 2012).

They provided information about the position and motion of the head with respect to the surroundings, and based on information in the visual surroundings provided by visual cues. The main role of this proprioceptive and somatosensory system is to sense the distributed tactile input stimuli at the neural level, and to provide a relationship between limb position and the central nervous system. The vestibular system, located in the inner ear, is used to control and perceive the motion and position of the head in space (Virk et al., 2006). The function of these systems reduced after the brain is impaired. When one or two of these sensory input systems are dysfunctional the allocation of different gains to the sensory inputs can be exploited to compensate for the impaired systems (Nancy, 1980; Walker et al., 2010). Virk et al. (2006) proposed that such an adaptation can take place in everyday life or in a virtual environment virtual environment to train the eye-head movement, balance in older people can be improved and occupational falls are minimize. Balance control in standing is a complex sensorimotor action based on automatic and reflexive spinal programs under the influence of several distinct and separate supra-spinal centers in the brainstem, cerebellum and cortex (Drew et al., 2004).

Cortical areas were activated to these artificial environment tasks. The prefrontal cortex would be activated when participants performed spatial orientation tasks. Virtual reality training over 4 weeks could activate the region of the prefrontal cortex (Tachibana et al., 2011). Results suggest a corresponding relationship between the prefrontal cortex and spatial orientation ability.

Another study by Basso Moro also demonstrated that, when healthy participants performed an incremental swing balance task in a semi-immersive virtual reality environment, the effect of oxygenation increased in the prefrontal cortex of both hemispheres (Basso et al., 2014). The density of oxygenated hemoglobin increased, but that of deoxygenated hemoglobin was not found in the frontal cortices. Moreover other studies found a positive correlation between presence and parietal brain activation and a negative correlation between presence and frontal brain activation during interactive virtual reality training (Mihara et al., 2008).

The CPT protocol consisted of targeted lower extremity muscle strengthening and static, dynamic balance training, and gait training. A muscle-strengthening exercise for the gluteus medius and

quadriceps muscle (esp. rectus femoris) was activated for improvement of eccentric controlled mobility of pelvis. In addition, strengthening of the tibial anterior and Gluteius medius was facilitated for improvement ankle dorsiflexion and push off (propulsion) at swing phase, respectively. For static balance training, patients were induced to shift their weight onto the paretic limb by verbal and tactile cues. In addition, in dynamic balance training, patients were induced to shift their weight in the anterior posterior and medial lateral planes while performing a functional reaching task .It allowed them to shift their mobile weight during gait training.

Sisto et al 2002 says that A multi-disciplinary approach for postural control is required for patients to maximize restoring lost function The model of vasomotor training was demonstrated in eighteen healthy right-handed volunteers from the analysis of functional magnetic resonance imaging that showed extensive activity in frontal, parietal, temporal, cingulate and cerebellar areas (Prochnow et al., 2013).The head mounted devise will improve the head and trunk rotation and will improve the postural stability and balance .

The environmental based virtual reality system has demonstrated to provide benefits to stroke patients affected by motor impairments and in over study could be especially useful for balance rehabilitation under static conditions. This fact is well documented not only in the field of motor domain. Ultimately, the present research showed that the physiotherapeutic regime such as virtual reality exercises on static imbalances are more effective intervention protocol in improving the balance and better functional status in patients with stroke.

EFFECT OF BMI ON MUSCULOSKELETAL PAIN AMONG TEACHERS OF ABUROAD

Dr.Arvind Kumar (PT)*, Darshana Patel **

ABSTRACT-

OBJECTIVE:

The objective of the study was to assess the effect of BMI on Musculoskeletal pain among teachers & its prevalence.

METHODS:

All Data were collected by a questionnaire. A questionnaire was distributed to all subjects, total 150 (75 males & 75 females), each subjects were passed to complete the self-administered questionnaire if they fulfil inclusion criteria.A standardized Nordic Musculoskeletal Questionnaire (NMQ general section) was used to collect data on Musculoskeletal symptoms (ache, pain, discomfort) from different regions of the body during last 12 months & the earlier seven days, as well as pain affecting work ability during the past 12 month.This was used as an assessment tool for Musculoskeletal pain in different body region. Also, reliability: 0.61 (Cronbach's, Alpha validity 0.71) Numerical Pain Rating Scale(NPRS) was used for the perception of pain intensity, which ranges 0-10 is applied,where 0 means no pain & 10 means 'the worst" unbearable pain.Numerical Pain rating Scale was widely used because it is easily administered & requires little to no training or equipment.

RESULTS:

A total 150 teachers (50% male & 50% female) selected in the study.The study showed significant relationship between the BMI & Musculoskeletal pain in mainly low back pain & knee joint, while other region like Neck, shoulder, Elbow, wrist, Upper back, hip & thigh & Ankle & feet did not show significant relationship with score.

Since the readings are in nominal scale, to find the relation,chi-square test is used. Any statistical test is said as significant if p-value is <0.05.The most reported musculoskeletal pain level showed prevalent of low back severe pain among teachers, followed by knee pain.

CONCLUSION:

This Study has shown that the most of the teachers were suffering from musculoskeletal pain & significant risk factors, & correlations were observed between BMI & Musculoskeletal pain symptoms in teachers.

Key Words: Work related musculoskeletal pain, Low back pain, WMSDs, BMI, Teachers.

INTRODUCTION

In many Countries the prevention of work-related musculoskeletal disorders has been considered as a national priority (1)

Several studies have been conducted on the prevalence of MSDs among teachers in many developed & developing countries of the world. These studies have identified teachers as one of the occupational groups that are at the risk of developing MSDs. (2)

Musculoskeletal disorder has a high impact for the individual as well as for society, the origin of MSDs

Professor & Principal,Venus Institute of Physiotherapy, Swarrnim Startup & Innovation University, Gandhinagar, Gujarat

is complex & Multi factorial. (3) Musculoskeletal disorders defined by the health & safety executive (HSE),The term musculoskeletal disorders (MSDs) includes any injury, damage or disorder of the joints or other tissues in the upper/lower limbs or the back.Uncomfortable working position, working too long without breaks and working in awkward posture. (4)

Musculoskeletal pain is defined as pain perceived related to musculoskeletal, when there is risk of tissue damage or when such damage has occurred, pain can signal that there is a need for recovery of tissues.(5)

Individual factors like age, sex, anthropocentric dimensions, muscle strength, physical fitness, mobility, psychological & social factors contribute to musculoskeletal disorders. (6)

Several studies have linked obesity with musculoskeletal disorders & repetitive work. (7) The epidemic of obesity has become pandemic defined as an epidemic occurring over a wide geographic area & affecting an exceptionally high proportion of populations. The risk in obesity rates was first noted in the United States, but has speed to other industrialized nation & it is even now being documented in developing countries, Indeed the global extent of obesity pandemic was formally recognized by the WHO in 1997, & worldwide obesity rates are increasing dramatically.(8)

Overweight & obesity are one of the world most challenging public health problems (WHO 2003). The prevalence of overweight has reached epidemic proportions in most western countries including Portugal. Overweight & obesity are high among employed adults & have shown a consistent increase over the past few decades. (7)

Obesity is defined as a physiological condition in which excess body fat has accumulated to an extent that can negatively affect health(8). Obesity occurs when energy intake exceed the energy expenditure. Humans expend energy through daily life, we can measure obesity by body mass index(BMI). (9)

Body mass index (BMI) is a ratio derived from the weight(Kg.) and height of a person(metres). The BMI is defined as the body mass divided by the square of the body height, and is expressed in units of kg/m2, resulting from mass in kilograms and height in metres, introduced as a Quetelet Index in 1830's several decades to estimate population trends in fat. (8)

A BMI value in the range of <18.5 kg/m2 is defined as underweight, 18.5 - 24.9 kg/m2 is defined as normal, 25 - 29.9 kg/m2 is overweight, 30-34.9 kg/m2 is obese class 1, 35 - 39.9 kg/m2 is obese class 2, & 40 > 49 kg/m2 is obese class 3/or morbidly obese..(8) High BMI is the independent risk factor for MSDs, for symptoms of neck shoulder upper & lower limbs, evidence was also found that high BMI is an independent risk factors for development of MSD's symptoms.(3)

Compared to normal weight patients, underweight patients & obese class two & three patients had higher odds of reporting moderate to severe pain. (11) According to public health prospective effective well documented initiatives for reducing weight improving physical capacity & reducing Musculoskeletal pain among health care workers are therefore needed.(7)

Some occupational factors have been associated with the development of work related musculoskeletal pain among many groups & these postures have great burden on their health & quality of life. Work-related musculoskeletal pain is the most common cause of chronic pain in general population, with estimated high lifetime prevalence of MSDs. (2)

Teachers have been identified as one of the occupational group that are at the risk of developing work related Musculoskeletal pain (WRMSP), this may due to the fact that teaching is one of most stressful jobs (2)& teaching profession is accompanied by occupational burden that arise from

the specific physiological demand of profession.(12)

College professors are exposed the numerous pressure sources which affect their quality of life & teaching activities. (13) Among these populations, college teachers who are having administrative activities, conciliating teaching research & extension are exposed to numerous pressure sources beyond those arising from changes in labour system, such as high work load, short pause for rest, intensive working place & requirements for beyond those arising from changes on labour & attraction. (13) When, such situations are associated to a high level of stress, quality of life of this category is considerable inspired including several health disorders such as Musculoskeletal problem which are prevalent among teachers.(13) Prolonged exposures to unfavourable working conditions during teaching become a health risk factors. Despite this the impact of muscular pain specifically has not been given sufficient attention in the literature. (14)

Not with standing studies discussing musculoskeletal disorder in this population are still scare in the literature. The incidence of work related Musculoskeletal disorders (WRMSDs) is increasing in recent years, due to organizational changes & work related requirement often leading to medical leaves & workers functional incapacity, so measuring WRMSDs reports is needed to collect data to quantify prevalence & to evaluate different affected populations.

Among tools to evaluate such symptoms, the Nordic Musculoskeletal questionnaire is a tool developed to standardize musculoskeletal pain & discomfort thus helping studies populations. There is much anecdotal evidence amongst education professionals about the aches & pains they experience at work & also from health care professionals (e.g. Physiotherapist, osteopaths, chiropractors) who treat them, (4) & it is worth stressing that these are few scientific studies related to Musculoskeletal risk factors among teachers & this deficit is even more severe with regard to college teachers since studies focus on teachers of other educational levels.

So, college teachers deserve attention on the potential health risk & problem related to their labour activity. (13)

AIM OF STUDY

To assess the effect of BMI on Musculoskeletal pain among teachers & its prevalence.

METHODOLOGY

Study design: Descriptive observational study

Study Setting: Abu Road

Population: Teachers of various school & colleges (Government & private) in Abu road.

Sample size: 170 subjects were being selected for this Study but 20 subjects were excluded from the study.

Sampling Techniques : Convenient sampling techniques.

Source of data collection: Teachers working in academic setup, Abu road (Rajasthan).

Method of data collection : Through the data available; contacts to the teachers working in academic field in Abu road & explain them about the study & procedure & those subject were willing to participate and meet inclusion & exclusion criteria. Then their written consent was being taken & collect their data.

Inclusion criteria:

- Teachers age group of 25 - 40 years.
- Both sex & gender are included.
- Minimum 2 years of job experience.
- Minimum 6 - 8 working hours /day, with minimum 3 lectures per day were accepted in this study.

Exclusion criteria:

- Teachers on leave.
- Part time teachers
- Chronic anomalies
- Any major surgery & other condition
- Any current fracture

Tools

1. Standardized Nordic Musculoskeletal questionnaire
2. Numerical pain rating scale

Material used for this study

1. Weight machine
2. Height measurement tape
3. Data collection form
4. Calculator

PROCEDURE

This Study was conducted at the Aburoad. Prior to the Study written consent was taken from all subjects & also explained about procedure & aim of the Study. Then subject was taken & collected the data, which covered

(1) Personal details (including Age, weight, height, job tenure, education, health, medical background)

(2) Musculoskeletal problem in different body regions

a) Measurement of BMI-

Height was measured in standing position without shoes, using a wall mounted height tape. Weight was measured when the subject was in light clothes, without shoes & empty pockets & then BMI was calculated as weight (kg)/height2 (m)

b). Musculoskeletal problem Assessment

All Data were collected by a questionnaire.

Questionnaire were distributed to all subjects total 150 (75male & 75 female), each subjects was passed to completed the self-administered questionnaire if they fulfil inclusion criteria.

Standardized Nordic questionnaire (NMQ general section) were used to collect data on Musculoskeletal symptoms (ache, pain, discomfort) from different regions of the body during last 12 month & the previous 7 days, as well as pain affecting work ability during the past 12 month. This was used as an assessment tool for musculoskeletal pain in different body region. Also reliability: 0.61(Cronbach's, Alpha validity 0.71) .

After that for the perception of pain intensity through the Numerical pain rating scale scored for 0-10 applied where 0 means no pain & 10 means worst unbearable pain & assessed it.

Numerical Pain rating Scale was widely use because it is easily administered & requires little to no training or equipment.

RESULTS:

Crosstab							
Count							
		LOWERBACK					Total
		4+	4++	0	1+	4+++	
BMI	Normal	20	18	32	1	3	74
	Obese	1	1	3	0	1	6
	Overweight	16	7	36	0	11	70
Total		37	26	71	1	15	150

Table 1:- Shows association between BMI and lower back, where $p \leqslant 0.05$.

Chi-Square Tests			
	Value	P-VALUE	RESULT
Pearson Chi-Square	11.390[a]	.052	P>0.05 NOT SIG

Table 2:- Therefore, we conclude that there is a significant association between BMI and lower back Pain.

Crosstab						
Count						
		KNEE				Total
		4+	4++	0	4+++	
BMI	Normal	19	3	49	3	74
	Obese	1	1	4	0	6
	Overweight	27	2	38	3	70
Total		47	6	91	6	150

Table 3:- The above table shows association between BMI and knee ($p \leqslant 0.05$)

Chi-Square Tests			
	VALUE	P-VALUE	RESULT
Pearson Chi-Square	6.110[a]	.071	P>0.05 NOT SIG

Table 4:-. Therefore from table 3 & 4, we conclude that there is a significant association between BMI and knee Pain.

DISCUSSION

This study analyzed correlation between prevalence of musculoskeletal pain & BMI. The high prevalence of Musculoskeletal disorders among school teachers was well documented (Erick & smith 2011, Durmus & llano 2012, Darkish & Al-unfair 2013, Abdulmonem et la 2014). (15) (16)

This study shows a high prevalence of musculoskeletal pain particularly low back pain & knee pain. According to this review the main risk supporting their causal relationship with low back & knee WMSDs were increase BMI. Similar finding were also reported on a systematic review conducted by the NRC/IOM. (17)

There, was however a paucity of literature MSDs amongst South African school teachers (kormas et al, 2011) this to determine the prevalence & association between BMI & Musculoskeletal symptoms. (4)

A recent study was founded that the causes of LBP to be associated with standing for a prolonged time, specific sitting habits a sudden change in posture & carrying heavy objects (Abolfotouch et al ,2015). This correlates with the current study in which highly significant relationships were founded between standing for a prolonged period of time & low back pain. (P = 0.05).

Standing for prolonged time was the second most common aggravating factors for low back pain & several epidemiological studies showed that the significant association among uncomfortable back support & LBP, & Mengestu & Zeke found the same result with low back pain. Prevalence of 57.5% & Abdulmonem A, Hunam A, Elaf A, Hammer T, Jehan A, also found the same result the prevalence of LBP 66.9% & more over study of Abdulmonem et al, also further confirmed these findings in teachers & concluded that Low back pain had the highest prevalence of all the Musculoskeletal regions in school teachers. (18)

Several study literatures showed that prolonged sitting may lead to acute low back pain (Anderson 1999) due to the compressive load on the spine & changed with in the passive structures. (Sheehan et all.2016). The predominance if Musculoskeletal pain & discomfort symptoms in lumbar spine of teachers was also found by carvalho & Alexander,who evaluated 2006, elementary school professors & have found a prevalence of 63.1% of Musculoskeletal symptoms in lumbar region. (19) (13)

After the low back pain, knee pain is the next most frequent site of musculoskeletal pain found in this study & same result found the previous similar study.

Several justifications presented in the literature for this high percentage among them, poor postures adopted during work, performing repetitive activities and lack of fitness (20) (13).Several study founded very high prevalence of Musculoskeletal pain among school teachers which is affecting their work by missing out working days & Eventually affecting the education system as a whole. (16)

The ministry of health points that preventing WRMSDs should be based on strategies improving worker's health in their workplaces, altering them about ergonomic & environmental risks including physiotherapeutic assistance to evaluate guide & if necessary treat possible disorders. (13)

CONCLUSION

This Study has shown that the most of teachers were suffering from musculoskeletal pain & significant risk factors, & correlations were observed between BMI & Musculoskeletal pain symptoms in teachers.

Based on the outcomes of this study the following conclusions are made:

There is a high prevalence BMI & low back pain & knee pain among teachers in Abu road.

This is needed to supply evidence for a global intervention for teachers, focus on preventing injuries linked to ergonomic strategies directed to movements, postures & the whole overload required during work, thus decreasing the prevalence of WRMSDs, improving teachers's quality of life & productivity.

Health is essential to efficiency of the highest attainable level in almost any line of work. It is peculiarity important for teachers, not only because of strenuous demand & energies but also because teacher's health is the corner stone of any effective school/college health program.

THE EFFECTIVENESS OF ISOMETRIC EXRECISE AS COMPARED TO PNF IN MANAGEMENT OF NON SPECIFIC NECK PAIN

Dr. Dharmang Vyas (PT)*, Dr. Nidhi Shah, Dr. Shreya Patel*****

BACKGROUND AND PURPOSE:

Mechanical neck pain is also known as nonspecific neck pain (1).It is also defined as generalized neck pain provoked by sustained neck posture, neck movement, pain on palpation of cervical musculature without pathologies. There is lack of literature comparing the isometric exercise with proprioceptive neuromuscular facilitation technique on chronic non-specific neck pain. Therefore, the purpose of present study is to compare that which of the two techniques i.e. isometric exercise and the proprioceptive neuromuscular facilitation technique is better to decrease pain, improve ROM and improve function in subjects with non-specific neck pain

OUTCOME MEASURES:

1. NDI: Neck disability index to test the functional improvement in neck pain.
2. VAS: Visual Analogue Scale to assess pain.

METHOD:

50 Participants were screened for inclusion and exclusion criteria. 30 were recruited for the study. Participants were divided into 2 groups. Group A: - PNF group and Group B: - Isometric exercises group. Samples were taken by simple random sampling method, consisting of 25 participants in each group. All the participants were assessed for outcome measures pre and post intervention. Both groups were treated for 4 weeks (4 days a week) and final analysis was done.

RESULTS:

Intragroup comparison of VAS and NDI showed significant improvement in both the groups. But in intergroup comparison VAS with p=0.000 and NDI with p=0.026, Group A showed significant improvement in improving function and reduction of pain in non specific neck pain.

CONCLUSION:

The final conclusion of the study is that, both the groups i.e., PNF and isometric group showed significant improvement in function and pain reduction but, when PNF exercise group was compared to isometric exercise group, the patients with non-specific neck pain showed more significant functional improvement and pain reduction in group A rather than group B. The study concludes that, PNF is more effective than isometric exercise in reducing pain and improving function.

Keywords: Proptioceptive neuromuscular facilitation, physical therapy, non specific neck pain, neck disability index, visual analogue scale, trans electrical nerve stiulation

INTRODUCTION:

Mechanical neck pain is also known as nonspecific neck pain (1).It is also defined as generalized neck pain provoked by sustained neck posture, neck movement, pain on palpation of cervical musculature without pathologies.

The annual prevalence of mechanical neck pain ranges in industrial countries from 27% to 48%.

Assistant Professor, Parul Institute of Physiotherapy, Parul University, Gujarat.

Prevalence is high in middle aged people.In the majority of cases, the pathologic basis for the neck pain is unclear and the complaints are labeled as "nonspecific or mechanical". Precise prognosis by clinical examination is problematic because signs and symptoms are frequently nonspecific.

Mechanical neck pain commonly seen in people involved in occupation like computer processing, clerical job, students and people with sedentary life style awkward occupational posture, heavy lifting and physically demanding work. In a wrong working position, neck extensor muscles would be excessively stretched during a long period of working with forward position of head and neck. The majority of cases of neck pain originate in mechanical factors: repetitive movements, lack of work breaks, static jobs and holding the head and arm position for long period of time.

The structures being deformed in mechanical neck pain may be the skin, subcutaneous tissue, capsule of synovial apophyseal joints, longitudinal ligaments, ligamentumflavum, interspinous ligament, and annulus fibrosus of intervertebral disc.

The symptoms of mechanical neck pain include neck pain with limited range of motion of the neck and a feeling of stiffness. Pain is aggravated by neck movements or sustained neck posturesand tenderness in neck and shoulder region.

Specific treatment for mechanical neck pain includes moist heat pack, cervical mobilization, cervical manipulation, strength training and postural re-education.Manual therapy is commonly used in the treatment of mechanical neck pain. Manual techniques include positional release technique, muscle energy technique, myofascial release technique, cyriax technique, NAGS and SNAGS, manual pressure release, proprioceptive neuromuscular facilitation and ischemiccompression.

PROPRIOCEPTIVE NEUROMUSCLULAR FACILITATION:

Proprioceptive Neuromuscular Facilitation (PNF) involves stretching, resisted movement, traction and approximation to ameliorate muscle decline, disharmony, atrophy and joint movement limitation.

It is very effective in improving flexibility, strength and range of motion.Recently, it has been used in orthopedic diseases of bones and PNF Technique is based on movement pattern to facilitate and correct sensory motor function it has been suggested that PNF correct the impaired impulses emerging from proprioceptive receptors in the muscle. Therefore, it decreases pain and desires to improve thestrength of muscles.

TRANSCUTANEOUS ELECTRICAL NERVE STIMULATION:

Transcutaneous electric nerve stimulation (TENS) isa common therapeutic device used in different painfulsituations in the everyday clinical practice. It is noninvasive, inexpensive and reveals hardly any major side effects.

TENS can be easily self-administered bythe patients following a short training, and the intensityof electrical stimulation can be adjusted by the patientsthemselves according to need.Previous meta-analysisand reviews have reported about the effect of TENS in various painful conditions butbecause of thelimited or contradictory data, the effect of TENS wasoften evaluated as inconclusive.

ISOMETRIC EXERCISE:

Isometric exercise is a static form of exercise in which a muscle contracts and produces force without an appreciable change in the length of the muscle and without visible joint motion. Although there is no mechanical work done, a measurable amount of tension and force output are produced by the muscle.

Sources of resistance for isometric exercise include holding against a force applied manually, holding a weight in a particular position, maintaining a position against the resistance of body weight, or pushing or pulling an immoveable object.

USES OF ISOMETRIC EXERCISE:

- To minimize muscle atrophy when joint movement is not possible owing to external immobilization like casts, splints, skeletal traction.
- To activate muscles to begin to re-establish neuromuscular control but protect healing tissues when joint movement is not advisable after soft tissue injury or surgery.
- To develop postural or joint stability.
- To improve muscle strength when use of dynamic resistance exercise could compromise joint integrity or cause joint pain.

To develop static muscle strength at particular points in the ROM consistent with specific task-related needs.

NEED OF STUDY:

There is lack of literature comparing the isometric exercise with proprioceptive neuromuscular facilitation technique on chronic non-specific neck pain. Therefore, the purpose of present study is to compare that which of the two techniques i.e. isometric exercise and the proprioceptive neuromuscular facilitation technique is better to decrease pain, improve ROM and improve function in subjects with non-specific neck pain.

OBJECTIVE:

To compare the effectiveness proprioceptive neuromuscular facilitation technique versus isometric exercises on chronic non-specific neck pain and functional impairment.

MATERIALS AND METHOD:

SOURCE OF DATA: Physiotherapy OPD under PSAH

STUDY DESIGN: Experimental Design [Comparative study]

RESEARCH DESIGN: Convenient sampling method.

SAMPLE SIZE: The study was done on Thirty (n=30) subjects andthey were divided into two groups.

INCLUSION CRITERIA:

- Age between 30 to 50 years.
- Male and female both
- Patients with non specific neck pain with/without radiculopathy.
- Patients who can understand English or Gujarati or Hindi language.
- Decreased functional performance
- Tenderness around the neck region.

EXCLUSION CRITERIA:

- Patients with neck or upper back injury in last 6 months.
- Patients suffering from giddiness or vertigo
- Patients with neck surgeries.
- Patients suffering from neurological disorders.
- Mentally and physically disabled patients.
- Patients with radiological diagnosis of spondylolisthesis.

OUTCOME MEASURES:

- 1.Neck Disability Index for functional impairment.
- 2.Visual Analog Scale for pain.
- **PROCEDURE:**

The subjects for the study were selected from ParulSevashram Hospital Physiotherapy OPD's for the subjects with neck pain. 50 subjects were screened for neck pain. Out of these 50 subjects, 40 were falling into the inclusion criteria, remaining were excluded because some were under the inclusion age, some had injuries to the cervical spine, some had undergone surgeries following cervical fractures, some had vertigo and some had spondylolisthesis.

The ones falling into the inclusion were assessed for neck pain according to the assessment format.All the participants at the outset falling into the inclusion criteria were explained in detail about the study and their role and importance in the study. Out of 40, 10

patients refused to participate in the study as they were reluctant to undertake exercise routine and/ or home program. The 30 patients willing to participate were asked to give a written informed consent.

Once the consent was signed by the subjects, they were then alternately distributed into 2 groups. Group 1(experimental group/PNF) and group 2 (control group/exercise).

GROUP A:-

PNF techniquesmethods:

The following movement patterns were performed.

A.Head and neck flexion with rotation to right.

B.Head and neck extension with rotation to left.

C.Head and neck extension with rotation to right.

D.Head and neck extension with rotation to left.

GROUP B:-

Isometric exercises:

A. Isometric flexion.
B. Isometric extension.
C. Isometric rotation.
D. Isometric side-flexion.

Stretching exercises:

A. Neck extensor stretching.
B. Neck flexor stretching.
C. Neck side flexor stretching.
D. Neck rotators stretching.
E. Pectoralis stretching.
F. Trapezius self-stretching.

Shoulder girdle exercises:

A. Shoulder circumduction.

B. Isometric shoulder girdle exercises.

RESULT AND INTERPRETATION:

As already mentioned out of 50 patients only 40 were falling into inclusion criteria out of which only 30 patients were included for the study as the rest were not willing to participate in the study.

Therefore the result presented here are of 30 patients of whom 17 were females and only 13 were males. All of these patients were suffering from neck pain. Their main complain was pain on strenuous activities, pain during neck movements and also complained of difficulties in ADL's due to pain and restricted ROM.

For statistical analysis data was collected before and after 4 weeks of intervention. VAS and NDI both were assessed pre and post intervention.

- t test- was used for the comparison between the pre and post values of outcome measures within the groups.
- t test- was used for the comparison between the post- post values of outcome measures between the groups.

The significance level adopted for the statistical tests was <0.05 and CI was kept at 95%

All statistical tests were performed using SPSS Version 16 software.

INTRA GROUP ANALYSIS

REPRESENTS INTRA GROUP COMPARISION FOR VAS AND NDI FOR GROUP A [paired T-test]:

GROUP	OUTCOME	PRE		POST		T-VALUE	P-VALUE
		MEAN	SD	MEAN	SD		
GROUP A (PNF)	VAS	6	1.06	3.8	0.74	12.91	0.000
	NDI	26	4.47	18	3.29	14.96	0.000

VAS: Intra Group Analysis (Group A): the above table shows the intra-group comparison of VAS score for functional assessment in Group A. The comparison was done through paired t test. The p value of Group A comparing pre and post treatment score of VAS is 0.000. The p value is < 0.05 which shows that group A is significant in improving VAS score.

NDI: Intra Group Analysis (Group A): the above table shows the intra-group comparison of NDI score for functional assessment in Group A. The comparison was done through paired t test. The p value of Group A comparing pre and post treatment score of NDI is 0.000. The p value is < 0.05 which shows that group A is significant in improving NDI score.

REPRESENTS INTRA GROUP COMPARISION FOR VAS AND NDI FOR GROUP B [paired T-test]:-

GROUP	OUTCOME	PRE		POST		T-VALUE	P-VALUE
		MEAN	SD	MEAN	SD		
GROUP B (ISOMETRIC)	VAS	7	1.17	5.4	1.24	11.22	0.000
	NDI	26	2.88	20.9	3.51	14.664	0.000

VAS: Intra Group Analysis (Group B): the above table shows the intra-group comparison of VAS score for functional assessment in Group B. The comparison was done through paired t test. The p value of Group B comparing pre and post treatment scores of VAS is 0.000. The p value is < 0.05 which shows that group A is significant in improving VAS score.

NDI: Intra Group Analysis (Group B):the above table shows the intra-group comparison of NDI score for functional assessment in Group B. The comparison was done through paired t test. The p value of Group B comparing pre and post treatment score of NDI is 0.000. The p value is < 0.05 which shows that group B is significant in improving NDI score.

INTER GROUP ANALYSIS

REPRESENTS INTER GROUP COMPARISION FOR VAS AND NDI (INDEPENDENT T- TEST):

	GROUP	MEAN	SD	T-VALUE	P-VALUE
VAS	A	3.86	0.74	4.271	0.000
	B	6	1.24		
NDI	A	18	2.78	2.358	0.026
	B	20.9	3.51		

Inter-group Analysis: The above table shows the inter-group comparison of post treatment NDI scores for functional assessment of Group A and B. The analysis was carried out by unpaired t-test. At baseline, the p value is > 0.05. It shows that there is no significant difference between the pre-treatment scores of both groups. Hence it shows the groups are homogenous. The p value comparing the post treatment score for Group A and B is 0.026 which is suggestive of significant improvement between groups.

DISCUSSION:

This study is done to investigate that whether PNF exercises for neck muscles when combined with TENS and neck mobility exercises helps in improving pain and quality of life in patients with non-specific neck pain. Isometric exercises have recently received increased interest as an effective inexpensive and non-invasive treatment in non-specific neck pain due to its ability to reduce pain and improve muscle strength.

Women of working agehad more neck pain than older ones, a phenomenon notseen among men. Chronic neck pain, defined as continuouspain of more than 6 months' duration, was commoner in women (22%) than men (16%).In a study from Sweden,17% of the population reported chronic neckpainwhile Brattberg reported a prevalence of neck painexceeding 6 months' duration in 19%. Hasvoldin a Norwegian study found that 15%of males and 25% of females complained of neckache weekly. Despite these differences in studydesign, epidemiological studies during a 10-yearperiod show similar prevalence.

In my study pain was assessed using VAS scale and functional disability was assessed using Neck Disability Index (NDI) scale.

The PNF group and the isometric exercise group showed significant reductions of VAS over time (p=0.000). After 4 weeks of the intervention, thePNF group showed a more significantreduction of VAS than the isometric exercise group (p=0.00). The PNF group and the isometric exercise group also showed significant improvement in the NDI scores post intervention (p=0.000). But when both the groups were compared to each other post intervention PNF group showed more significant improvement in VAS and NDI scores than isometric group showed in VAS and NDI score (VAS p=0.000, NDI p=0.026).

Previous study found that PNF techniques when

used is effective in decreasing pain, increasing ROM and improving function in subjects with chronic neck pain and scapular instability. Since majority of middle aged people suffers from neck pain, further study should investigate the best intensity and the rate of progression of strengthening exercises for neck pain. Also which specific exercises should be avoided or modified to provide relief from neck pain.

CONCLUSION:

The final conclusion of the study is that, both the groups i.e., PNF and isometric group showed significant improvement in function and pain reduction but, when PNF exercise group was compared to isometric exercise group, the patients with non-specific neck pain showed more significant functional improvement and pain reduction in group A rather than group B. The study concludes that, PNF is more effective than isometric exercise in reducing pain and improving function.

LIMITATIONS AND FURTHER RECOMMENDATIONS:

Limitation of the study was that the number of subjects recruited for the study were very few (30), 15 subjects in each group. The duration of study was also very short to conclude that the PNF is more effective in reduction of pain and functional improvement than isometric exercise in patients with non-specific neck pain. Effectiveness of treatment and data collection methods may have affected the result of the study.

A STUDY TO FIND OUT THE EFFECT OF JOB STRAIN AMONG BLUE COLLARS AND WHITE COLLARS EMPLOYEES ON RISK OF CARDIOVASCULAR SYSTEM

Dr. Divya Tiwari

ABSTRACT

Background

The study have been conducted with the aim to find out the Job Stress between Blue Collar and White Collars and its risk on Cardiovascular System.Cardiovascular diseases due to job strain is biggest cause of death worldwide, though over last two decades.The objective of this study is to determine the co-relation between risk of cardiovascular diseases due to job stress between blue collars and white collars.

Conclusion

The result had been interpreted and support the previous studies done in association with this study and it had been concluded as follows, the results of this study shows the significant association between risk of heart attack due to job stress.

Key words

Blue Collars, White Collars, Job Strain.

Background

The cardiovascular system includes the heart and two networks of blood vessels: pulmonary circulation, which moves deoxygenated blood from the heart to the lungs, and returns oxygenated blood back to the heart; and systemic circulation, which carries oxygenated blood from the heart to the body's tissues and returns oxygen-depleted blood back to the heart. Blood is that sticky, red fluid which circulates throughout the body in a complex network of veins and arteries, transporting nutrients and oxygen to the body's tissues and removing waste products for disposal. The heart's contractions work to move oxygen into the blood; it also gathers carbon dioxide from the blood so it can be expelled through the lungs. While the lungs play an important role in this process, each of the body's cells is involved. The cardiovascular system includes organs which take up space throughout the body, including the heart and all of the body's veins, arteries and capillaries. The cardiovascular system is basic to life and the beat of one's heart is an automatic function which is controlled by the brain.

Cardiovascular diseases remain the biggest cause of deaths worldwide, though over the last two decades, cardiovascular mortality rates have declined in many high-income countries

Cardiovascular system diseases are the conditions that affect the heart and the blood vessels, which are the main components of the system. These diseases are often linked with a wrong or unhealthy lifestyle.

The human cardiovascular system is composed of a heart, blood, and a network of blood vessels, and is concerned with the circulation of nutrients, gases and hormones throughout the body. Any disease that affects the heart and the blood vessels is termed as a cardiovascular disease, which has become a common health concern mainly in the developed countries. These rising incidence of these cardiovascular diseases are basically attributed to wrong eating habits and a sedentary lifestyle.

A blue-collar worker is a member of the working class who performs manual labor. Blue-collar work

Assistant Professor, Deptartment of physiotherapy
Janaran Rai Nagar Rajasthan Vidyapeeth, (Deemed To-Be University) Dabok Udaipur

may involve skilled or unskilled, manufacturing, mining,construction, mechanical, maintenance, technical installation and many other types of physical work. Often something is physically being built or maintained.

In contrast, the white-collar worker typically performs work in an office environment and may involve sitting at a computer or desk. The term white-collar worker refers to a person who performs professional, managerial, or administrative work.

It is often said that the stress is a bigger killer than any of the disease known and rightly so. Stress is an important risk factor in the development of diseases like hypertension, heart diseases, psychological disorders and sexual disorders.

We generally use the word "stress" when we feel that everything seems to have become too much - we are overloaded and wonder whether we really can cope with the pressures placed upon us. Anything that poses a challenge or a threat to our well-being is a stress.

Stress is the body's reaction to any change that requires an adjustment or response. The body reacts to these changes with physical, mental, and emotional responses.

Stress is a normal part of life. Many events that happen to you and around you -- and many things that you do yourself -- put stress on your body. You can experience stress from your environment, your body, and your thoughts.

Job Stress

Small things can make you feel stressed, such as a copy machine that never seems to work when you need it or phones that won't quit ringing. Major stress comes from having too much or not enough work or doing work that doesn't satisfy you. Conflicts with your boss, co-workers, or customers are other major causes of stress.

It's normal to have some stress. Stress releases hormones that speed up your heart, make you breathe faster, and give you a burst of energy. Stress can be useful when you need to focus on or finish a big project. But too much stress or being under stress for too long isn't good for you. Constant stress can make you more likely to get sick more often. It can also lead to long-term health problems such as heart disease, high blood pressure, back problems, and depression.

Causes of Job Stress

Most of the time, it's the major sources of stress that lead to job burnout and health problems. Job stress can affect your home life too. Here are some common sources of major job stress, with examples of each:

Lack of control- Feeling as if you have no control over your work or job duties is the biggest cause of job stress. People who feel like they have no control at work are most likely to get stress-related illnesses.

Increased responsibility- Taking on extra duties in your job is stressful. You can get more stressed if you have too much work to do and you can't say no to new tasks.

Job satisfaction and performance- Do you take pride in your job? If your job isn't meaningful, you may find it stressful. Are you worried about doing well at work? Feeling insecure about job performance is a major source of stress for many people.

Poor communication- Tension on the job often comes from poor communication. Being unable to talk about your needs, concerns, and frustrations can create stress.

A new job with more responsibility and better pay just opened up in Jill's department. Jill knows she can do this job. And she's been with the company longer than anyone else on her team. She waits for her manager to ask if she is interested. But after several weeks, a coworker is promoted to the new job. Jill feels hurt and angry, but she doesn't say anything.

Lack of support- Lack of support from your boss or coworkers makes it harder to solve other problems at work that are causing stress for you.

Jeff works in a busy office answering customer complaint calls all day. It would be easier to handle all the calls if he could at least trade tips with his coworkers. But everyone else is busy too. His coworkers never make it out of their cubicles during the day, even to let off a little steam.

Poor working conditions- Unpleasant or dangerous physical conditions, such as crowding, noise, or ergonomic problems, can cause stress.

Objective

To find out the effect of Job Strain among Blue collars and White collars employees on risk of cardiovascular system.

Procedure

A comparative study had been conducted to examine the Job Strain among White Collars and Blue Collars Employees. 200 subjects are selected out of which 100 are White Collars - Doctors and nurses and office workers and 100 are Blue Collars –Labourers and Truck and bus Drivers and Fourth class labourers.Permission was obtained from the concerned person. Prior information about the study was given to the subjects. The purpose of study was explained to all subjects an informed consent was taken in their own understandable language from each truck drivers. The subjects were selected based on inclusion and exclusion criteria. A suitable time was set up with the participants. Each one of them was allowed to answer the set of questions separately.

Any doubts regarding the questionnaire had beendecleared at the same time. All questions were explained to each one of the participants in simple words and adequate time was given to them to answer each of the questions. It is completed by the participants in the presence of invigilator. The answered question are collected at the end of the session from each participant.

Data analysis

A group of 200 subjects who had satisfied the inclusion and exclusion criteria were selected.

This is a descriptive research study in which a survey was conducted among blue collar and white collar employees.

Appropriate statistical test is applied to the data for analysis.

Statistical Method

We are using here T–test to find the relationship between BMI, Stress Test, Risk of Heart Attack of both white and blue collar employees.

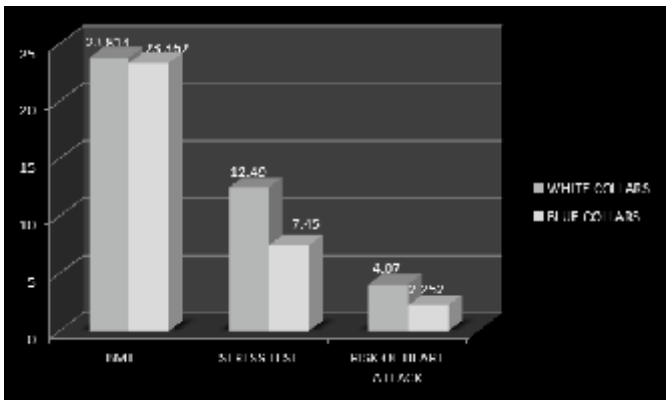
T test:

	BMI	Stressed test	Risk of HA
Mean white collar	23.814	12.49	4.07
SD White collar	2.586445633	3.927358071	1.037236032
Mean Blue collar	23.362	7.45	2.252525253
SD Blue collar	3.416944704	1.725477536	1.100495569

	BMI	Stressed test	Risk of HA
T	1.0596	11.756	12.039
df	198	198	198
Standard error of differences	0.428	0.429	0.151
P	0.2906	Less than0.0001	Less than0.0001

MEAN VALUE OF BMI, STRESS TEST, RISK OF HEART ATTACK

CATAGORY	BMI	STRESS TEST	RISK OF HEART ATTACK
WHITE COLLARS	23.814	12.49	4.07
BLUE COLLARS	23.362	7.45	2.252



This graph is showing Mean value of BMI, STRESS TEST, RISK of HEART ATTACK.

RESULT DISCUSSION

The result from the study furtherstrengthen the evidence that job strain has high risk of cardiovascular diseases.

The prevalence of job strain in this study was found more commonly among White Collars Employees.

Data from the similar studies based on Finnish Longitudinal Study on Municipal Employees showed high rate of Cardiovascular Diseases which caused death. (Mikaela B Von Bonsdorff 2012)

The wide variation in results may be due to many factors, including age, gender, high serum cholesterol level, high blood pressure and other factors like high job demand and high job control.

It is a known fact that excessive Job Stress can lead to Heart Diseases, Depression, Job Dissatisfaction. Stress is the body's reaction to any change that requires an adjustment or response. The body reacts to these changes with physical, mental, and emotional responses.

CONCLUSION

The main objective of this studyhas reached with the help of the methods, which had been used to conduct the study , statistical analysis and its interpretations. The result of this study gave the valuable suggestions in relation with job strain and risk of heart attack among the blue collar employees and white collar employees. In conclusion statistically significant associations were prevalence in job strain found more in white collar employees then blue collar employees.

The physiotherapists has therefore an important role in educating and preventing job stress in the employees. Scientific organisation of the work and stress regime is important. Perform other activities like exercises including breathing exercises, schedule time for fun, take good nutrition, stay positive, dorelaxation techniques - mediation, massage, or yogaetc should be encouraged.

EFFECTIVENESS OF WILLIAM'S FLEXION EXERCISE VERSUS MULLIGAN'S TWO LEG ROTATION AND BENT LEG RAISE TECHNIQUE ON PAIN & DISABILITY IN INDIVIDUALS WITH MECHANICAL LOW BACK PAIN : A RANDOMIZED CONTROL TRIAL

Dr. Khyati Chavda*, Riya Parmar , Priyanka Halpati*****

ABSTRACT

INTRODUCTION:

Mechanical low back is the general term used to any type of back pain caused by strain on muscle of the vertebral column and abnormal stress. Williams explained to adhere to postural principles. The Mulligan bent leg raise technique has been described as a means of improving range of straight leg raise (SLR) in subjects with LBP and or referred thigh pain. The aim of this study is to compare the effectiveness of William's flexion exercise and Mulligan's two leg rotation and bent leg raise technique on patients with mechanical low back pain. This study has two outcome measures for evaluating pain and functional recovery in mechanical low back pain, Numeric Pain Rating Scale (NPRS) and Modified Oswestry Disability Index (MODI).

METHOD:

30 patients with mechanical low back pain, whose informed consents were obtained, were randomly assigned into 2 groups. Group A received William's flexion exercise and other Group B received Mulligan's technique 4 times in a week for 4 weeks. They were pre-tested using NPRS for pain intensity and MODI for functional disability.

RESULTS:

The results showed that there is statistically high significant difference($p<0.05$) showing improvement in means of NPRS and MODI for William's flexion exercise and Mulligan's technique before and after intervention in both the groups but group A showed more significant improvement in compared to group B.

CONCLUSION:

It has been concluded that William's flexion exercise and Mulligan's two leg rotation and bent leg raise technique both significantly improved the pain and disability in patients with mechanical low back pain but the group receiving William's flexion exercise improved more compared to Mulligan's technique.

KEY WORDS:

William's flexion exercise, Mulligan's two leg rotation, Mulligan's bent leg raise, mechanical low back pain.

INTRODUCTION

Low back pain (LBP) is a frequent complaint among adults with 70-85% having experienced at least one episode of LBP at some point in their lives.[1] In India, nearly 60% of people have significant back pain.[2] Low back pain is pain, muscle tension, or stiffness localized below the costal margin and above the inferior gluteal folds, with or without sciatica, and is defined as chronic when it persists for 12 weeks or more. Specific LBP is defined as symptoms caused by a specific pathophysiologic mechanism, such as herniated nuclei pulposus, infection, osteoporosis, rheumatoid arthritis,

*Assistant professor, Parul Institute of Physiotherapy, Parul University, Vadodara, Gujarat
**Physiotherapist, Parul Institute of Physiotherapy, Parul University, Vadodara, Gujarat
***Physiotherapist, Parul Institute of Physiotherapy, Parul University, Vadodara, Gujarat

fracture, or tumour).[3] The remaining patients, who comprise the majority of patients, are commonly referred to as having “non-specific LBP” (NSLBP) or “axial LBP” (ALBP) or “Mechanical LBP.” [4] Mechanical low back is the general term used to any type of back pain caused by strain on muscle of the vertebral column and abnormal stress.[5] Because of related health costs, absenteeism and disability, low back pain is a substantial economic burden to society.[6,7]

Physical therapist use many exercise for back pain among these specific exercise, one is "Williams flexion exercise" also called lumbar flexion exercise. Williams flexion exercise program was developed in 1937 for patient with mechanical low back pain for men under 50 and female under 40 years who had exaggerated lumbosacral lordosis.[8] The solution, Williams explained, was to have the patient perform exercises and adhere to postural principles which serve to decrease the lumbar lordosis to a minimum, thereby reducing the pressure on the posterior elements of the lumbar spine.[9] Williams said: "The exercises outlined will accomplish a proper balance between the flexor and the extensor groups of postural muscles".[10] Williams suggested that a posterior pelvic-tilt position was necessary to obtain best results.[11]

Hamstrings muscle is a postural muscle and as it is biarticular, it has tendency to shorten even under normal circumstances.[12] This can give rise to number of postural problems and leave us open to muscle injury.[13] Prevalence and incidences of Hamstrings tightness in mechanical LBP individuals is high due to limited activity and lack of regular exercise.[14] Tight hamstring muscles limit anterior pelvic tilt of the pelvis in spinal flexion resulting in aggravated muscle and ligamentous tension in the lumbar region which leads to significantly higher compressive loads on the lumbar spine.[15] Anatomical causes of reduced muscle extensibility have been categorized as “muscle shortness” and “muscle stiffness”. Physiological cause of reduced muscle extensibility is related to the contractility of the muscle cell.[16] Mulligan BLR technique consist of gentle isometric stretching of hamstring in specific directions in progressively greater positions of the hip flexion, the expecting result are increased flexibility of hamstring muscle with increased ROM of active knee extension. Mulligan bent leg raise (BLR) technique has been described as a mean of improving range of straight leg raise (SLR) in subject with LBP and or referred thigh pain.[17]

There is lack of evidence revealing comparative effectiveness of William's Flexion Exercises in combination with Mulligan's two leg rotation and bent leg raise technique in patient with Mechanical LBP. Hence this study designed to find out the effect of William's Flexion Exercise as compared to Mulligan's two leg rotation and bent leg raise technique.

MATERIALAND METHODS

Thirty subjects fifteen in each group were taken from Parul Sevashram Hospital OPD and screened after finding their suitability as per inclusion and exclusion criteria. Subjects were randomly allocated in two groups with computer generated method. Group A was William's flexion exercise Group and Group B was Mulligan's technique Group. Treatment duration was 4 sessions per week for 4 weeks.

Individuals aged between 18 - 45 years and with complain of mechanical low back pain more than 3 months were included in the study. Individuals presenting symptoms of Sciatica, spinal tumors, low back pain due to road traffic accident, pregnancy, spinal stenosis, recent spinal fracture, lumbar spondylosis, abdominal surgery, back surgery, medication, muscle strain, spondylolisthesis were excluded from the study. All the study procedure was explained to the subjects prior to participation, and written in form concerned was obtained from all subjects. Initial evaluation of the patients having mechanical low back pain was done as per assessment format.

Pre - intervention outcome measures which were numerical pain rating scale and Modified Oswestry Disability Scale were assessed.

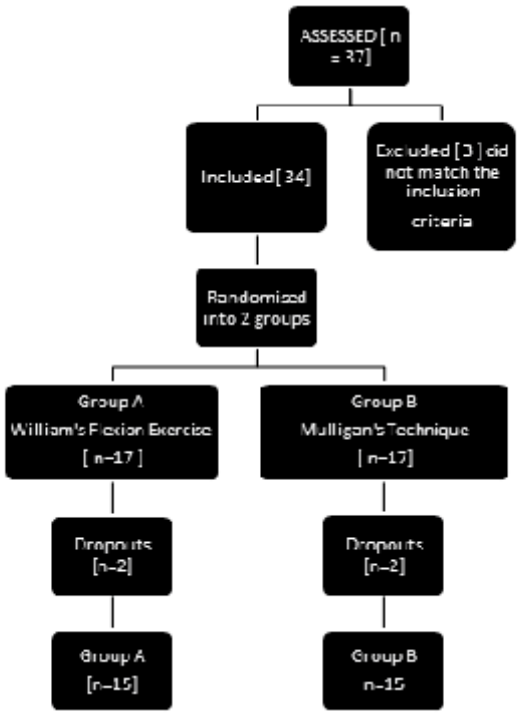

FIGURE 1: FLOWCHART OF SAMPLE RANDOMIZATION

Numeric pain rating scale (NPRS) is an 11-point scale ranging from 0-10. A 0 signifies "no pain" and a 10 indicates "the most intense pain imaginable". The scale continuum is as follows: 0 indicates "no pain", 5, "moderate pain" and 10, "the most intense pain imaginable". Participants verbally selected a value ranging from 0-10 that is most in line with the intensity of pain they currently experienced.[19]

The Modified Oswestry Disability Index (MODI)[18] is a self-administered questionnaire designed to evaluate level of function (disability) in activities of daily living for individuals rehabilitating for low back pain. The MODI consists of 10 sections with a scale ranging from 0 to 5, whereby the 5 represents the greatest disability. The total sum of the score is then multiplied with hundred and expressed as percentage. The MODI showed good construct validity at measuring disability cause by low back pain because it is consistent with other standard outcome measures which includes Low back outcome score, the Manniche Scale, the Aberdeen score, and The Curtin Scale. In addition, the test-retest reliability for the MODI is high with ranges r=0.83 to r=0.99 which vary based on the time interval between each measurements.The participants MODI scores were converted into percentage using the formula below:

Participants score / (50) x 100 = % The participants. (0 % to 20% - minimal disability, 21% to 40 % - moderate disability, 41% to 50% - severe disability, 61% to 80% - Crippled, 81% to 100% - bed-bound)

Table 1 - Treatment protocol performed by subjects in the Group A

PELVIC TILT	Lie on your back with knees bent, feet flat on floor. Flatten the small of your back against the floor, without pushing down with the legs. Hold for 5 to 10 seconds. 8-12 repetitions.
SINGLE KNEE TO CHEST	Lie on your back with knees bent and feet flat on the floor. Slowly pull your right knee toward your shoulder and hold 5 to 1seconds. Lower the knee and repeat with the other knee. 8-12 repetitions.
DOUBLE KNEE TO CHEST	Begin as in the previous exercise. After pulling right knee to chest, pull left knee to chest and hold both knees for 5 to 10 seconds. Slowly lower one leg at a time. 8-12 repetitions.
PARTIAL SIT UP	Do the pelvic tilt (exercise 1) and, while holding this position, slowly curl your head and shoulders off the floor. Hold briefly. Return slowly to the starting position. 8-12 repetitions.
HAMSTRING STRETCH	Start in long sitting with toes directed toward the ceiling and knees fully extended. Slowly lower the trunk forward over the legs, keeping knees extended, arms outstretched over the legs and eyes focus ahead.
HIP FLEXOR STRETCH	Place one foot in front of the other with the left (front) knee flexed and the right (back) knee held rigidly straight. Flex forward through the trunk until the left knee contacts the axillary fold (arm pit region). Repeat with right leg forward and left leg back.
SQUAT	Stand with both feet parallel, about shoulder's width apart. Attempting to maintain the trunk as perpendicular as possible to the floor, eyes focused ahead, and feet flat on the floor, the subject slowly lowers his body by flexing his knees. 8-12 repetitions.

Table 2 - Treatment protocol performed by subjects in the Group B	
Mulligan's Two Leg Rotation	Therapist stands at the limited hamstrings flexibility side of the supine subject on the plinth and grips the side of the plinth with the opposite side hand. Both legs will be flexed so that the feet are off the plinth. Keeping his (subject's) shoulders on the bed he takes hi s (subject's) legs slowly to the side of the limited hamstring muscle flexibility. When he (subject) reaches limit, the position is sustained for 30 seconds with over pressure applied by the therapist and then lower the legs to the plinth and repeat for 3 repetitions, and 1 minute rest between each stretch. And same procedure is done for the other side of limited hamstrings flexibility.
Mulligan's Bent Leg Raise	Therapist stands at the limited hamstrings flexibility side of the supine subject on the plinth. Therapist place the subject's flexed knee over his (therapist's) shoulder and now asks the subject to push the therapist with his leg and then relaxes. At this point therapist push his (subject's) bent knee up as far as possible in the direction of his (therapist's) shoulder on the same side. Sustain this stretch for 30 seconds and then lower the leg to the plinth and repeat for 3 repetitions, and 1 minute rest between each stretch. And same procedure is done for the other side of limited hamstrings flexibility.

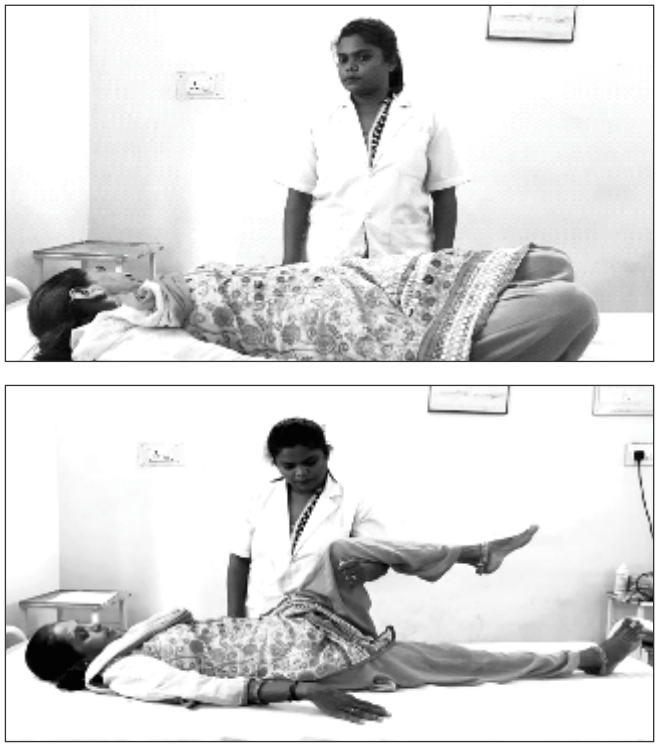

FIGURE – 3 Treatment protocol performed by subjects in the Group B

RESULT

Statistical Package for Social Sciences (SPSS) v20 was used for data analysis. Wilcoxon signed rank test were used to find the significance of parameters pre and post test. Mann-Whitney test were used to find the significance of difference between two groups. As the study included human subject ethical clearance was obtained from Parul University Institutional Ethics Committee for Human Research (PU – IECHR). Baseline characteristics and initial assessment of each outcome measure of the subjects were done. No meaningful differences existed between groups at baseline. In present study 34 subjects of age of 18 - 45 years were taken and divided into two groups. Group A (William's Flexion Exercise) and Group B (Mulligan's Technique). 30 individuals completed the study program without any complications. The data obtained in the groups are as follows.

A summary of change scores and mean differences for each of the outcome measure are presented in table 2. Negative change scores on NPRS and MODI are indicative of improvement; A main effect for change over time was demonstrated as both groups significantly improved in all outcome measures by the end of 4 weeks. there is statistically high significant difference($p<0.05$) showing improvement in means of NPRS and MODI for William's flexion exercise and Mulligan's technique before and after intervention in both the groups but group A showed more significant improvement in compared to group B. The group B showed comparatively lower changes in any of the outcome measures, The mean of NPRS for Group A was 3.800 with the SD of 0.744. when it was compared with the mean of NPRS for Group B which was 2.200 after 4 weeks of intervention with the SD of 0.676, the obtained z-value was 4.280 . This finding had showed that there was a highly significant difference in NPRS for Group A and Group B. ($p<0.005$) Mean difference of Group A shows high significant improvement compared to mean difference of Group B after 4 weeks of intervention. The mean of MODI for Group A was 24.53 with the SD of 7.229. when it was compared with the mean of MODI for Group B which was 12.86 after 4 weeks of intervention with the SD of 4.845, the obtained z-value was 4.025 . This finding had showed that there was a highly significant difference in NPRS for Group A and Group B. ($p<0.005$) Mean difference of Group A shows high significant improvement compared to mean difference of Group B after 4 weeks of intervention.

DISCUSSION

The results of this study showed that the individual who participated in treatment program that included William's flexion exercise and the Mulligan's technique experienced greater improvements for pain and disability which has decreased mechanical low back pain to the individuals who participated in treatment program. Physical therapist use many exercise for back pain among this specific exercise William's flexion exercise has showed significant improvements. Mulligan's bent leg raise technique has been described as a means of improving range of straight leg raise (SLR) in subject of LBP. Williams flexion exercise reduces the pressure on the posterior element of lumbar spine and preventing recurrence of low back pain. These exercises restore functional strength of lower back is helpful for relieving symptoms of low back pain. Strengthening of abdominal and back muscle which maintain all structure align and prevent stress of lumbar spine. William flexion exercises using valsalva maneuver were particularly beneficial for patient with lumbar lordosis. It is effective to correct the faulty lumbar lordosis and decrease low back pain. During the sit-ups exercise the pelvis was found to be tilted and put the spine in hypertension before forward trunk displacement. [16]. posterior pelvic tilt requires moderate activity of internal and external oblique muscles their helps to generate the intra abdominal pressure. Curl ups exercise produce lumbar flexion and provided maximum activity of external and rectus abdominal muscle.

Pratik .A. Phansopkar, Vijay Kage demonstrated that both the treatment techniques that is Mulligan's Two Leg Rotation and Bent Leg Raise techniques are effective in increasing the hamstrings flexibility in subjects with acute non specific low back pain in terms of pain, range of motion and functional disability. Thus Mulligan's Two Leg Rotation can also be used commonly as other mulligan techniques in clinical practice for improving the hamstrings flexibility. [17]

Tight hamstring muscles limit anterior pelvic tilt of the pelvis in spinal flexion resulting in aggravated muscle and ligamentous tension in the lumbar region which leads to significantly higher compressive loads on the lumbar spine.[15] Anatomical causes of reduced muscle extensibility have been categorized as “muscle shortness” and “muscle stiffness”. Physiological cause of reduced muscle extensibility

is related to the contractility of the muscle cell.[18] Mulligan BLR technique consist of gentle isometric stretching of hamstring in specific directions in progressively greater positions of the hip flexion, the expecting result are increased flexibility of hamstring muscle with increased ROM of active knee extension. Mulligan bent leg raise (BLR) technique has been described as a mean of improving range of straight leg raise (SLR) in subject with LBP and or referred thigh pain.

CONCLUSION

It has been concluded that William's flexion exercise and Mulligan's two leg rotation and bent leg raise technique both significantly improved the pain and disability in patients with mechanical low back pain but the group receiving William's flexion exercise improved more compared to Mulligan's technique.

LIMITATIONS

Smaller number of subjects, lack of follow ups and long term effects can be included in limitations of this study.

FUTURE RECOMMENDATION

Future studies should be done on larger sample size and its effectiveness in various sample sizes.

RANDOMISED CONTROL TRIAL TO EVALUATE EFFECT OF UTERUS MOBILIZATION WITH THERAPEUTIC TENS AS COMPARED WITH ONLY CONVENTIONAL TENS ON PRIMARY DYSMENORRHEA

Namita Chatwal* . Prof Maneesh R Arora , Dr Pooja Yadav*****

BACKGROUND: In India, prevalence of dysmenorrhea is 87.7%. Dysmenorrhea is a common problem among females. The purpose of this study was to examine the effect of Uterus Mobilization with TENS on primary dysmenorrhea and to compare it with only Transcutaneous Electrical Nerve Stimulation (TENS) in a randomized controlled trial study.

METHODOLOGY: Thirty female aged between 18-25 year randomly divided in two groups (Uterus Mobilization with TENS or only TENS). Participants' physical characteristics and menstrual history were recorded. Menstrual pain was measured by self-reported pain intensity using visual analog scale (VAS) before and just after treatment. Paired t-test and unpaired t-test was conducted to compare pain intensity between pre and post treatment within the group and between the two groups respectively.

RESULTS: The decrease in pain intensity after Uterus Mobilization with TENS and only TENS were both significant, (Experimental group: 8.67 ± 0.98 to 2.6 ± 2.06, $p<0.0001$; Control group: 7.27 ± 1.39 to 4.87 ± 2.2, $p<0.001$). However, pain intensity in experimental group was significantly decreased than the control group ($p=0.0001$).

Conclusions: This result supports that using Uterus Mobilization with TENS could be effective in pain reduction among females who suffered from primary dysmenorrhea.

Key Words: Transcutaneous Electrical Nerve Stimulation (TENS), Dysmenorrhea, Menstruation, Visceral Mobilization.

INTRODUCTION:

"Dysmenorrhea" is derived from Greek means difficult monthly flow but by usage refers to painful menstruation1. The pain of Dysmenorrhea includes cramping pain in lower abdominal area. The discomfort tends to remit as menstrual flow decreases. George and Bhaduri found Dysmenorrhea to be a common problem in India with prevalence of 87.7%4. Dysmenorrhea can feature different kinds of pain, including sharp, throbbing, dull, burning, or shooting pain. Dysmenorrhea may precede menstruation by several days or may accompany it, and it usually subsides as menstruation tapers off2, 3.

Dysmenorrhea can be classified into Primary and Secondary Dysmenorrhea. Primary Dysmenorrhea should be defined as painful period in which no macroscopically identifiable Pelvic Pathology is present. The prevalence of primary Dysmenorrhea decreases with increasing age and it is highest in between 20-24 years of age because of hyper contractility of uterus at menstruation in women with Primary Dysmenorrhea, blood now uterus is compromised and uterine ischemia occurs5. Thus, the pain is thought to be due three factors: increased abnormal uterine activity, uterine ischemia and sensitization of the nerve terminals to Prostaglandins6, 7.

"Visceral Mobilization" is organ specific fascial mobilization and is based on the premise that free movement within the body is vital, and thus any restriction will adversely affect health. Visceral mobilization treats functional and structural imbalances throughout the body. It evaluates and treats the dynamics of motion and suspension in

Scholar*Principal*** Scholar*** SBSPGI, Balawala Dehradun

relation to organs, membrane, fascia and ligaments and relieving symptoms of pain, dysfunction, and poor posture8.

Visceral mobilization returns physiologic motion to the tissues, thereby enhancing normal movement of the body, including the movement of visceral structures in relation to each other and the motion within each structure. It also increases communication within the body through improved functioning of nervous system, circulation, lymphatic, and respiratory systems by softening the fascia that surrounds each of these structures, thereby reducing pressure on them, as well as allowing better exchange of fluids. This improves breakdown and removal of waste products, reduces inflammation and pain, and improves the delivery of hormones and chemicals to the cells. Visceral Mobilization aims to find and resolves tensions in the tissue and thereby restore normal motion of the tissue. Visceral Mobilization is a hands-on manual therapy that only requires the skillful application of therapist's hand to evaluate and treat, along with an in-depth knowledge of anatomy. The treatment is through gentle compression, mobilization and elongation of the tissues.9

METHODOLOGY:

A total of 30 females aged between 18-25 years with dysmenorrhea pain participated in this study. All cases were diagnosed as primary dysmenorrhea on the basis of their menstrual history. Subjects were randomly assigned to experimental and control groups. All subjects were assessed and treated on 4 days before the day of their menstruation for experimental group and on the day of their menstruation for control group. The procedure was fully explained to the participants and they were required to sign the consent form. Subjects were not allowed to take any analgesics before this treatment. Intensity of menstrual pain was evaluated by a 0-10 visual analog scale (VAS), where "0" point indicated "no pain" and "10" indicated "unbearable pain." The VAS evaluations were performed before and just after treatment as the primary outcome.

In Control Group(group 1), a TENS device with a frequency of 0- 100/HZ and 90-100 pulse /seconds was applied for 20 minutes10, to increase circulation and to have pain relief at the first day of menstrual complaints without taking any analgesics. Patients lied in prone position with a thin pillow placed under their abdomen. Two electrodes were placed to the proximal margin of low back area, and two others were placed to the proximal of gluteal region laterally. The intensity of stimulation was increased up to the tolerated level without causing any contraction.

In Experimental Group(group 2), Uterus Mobilization was given 3 days before the first day of menses and TENS was given for 20 minutes on the first day of menses. The procedure for Uterus Mobilization is as follows:

Subject was asked to lie in supine position with both the knees flexed. Therapist placed his non dominant hand on the lumbosacral region and dominant hand over the bladder area for releasing the muscular tension and increasing the depth of the field which was palpated. It was begun by stretching the fundus from lateral to medial side and was holded for one minute and relaxed for one minute. The procedure was repeated 3 times per session for 3 days consecutively.

RESULTS:

Table 1 summarizes the mean average of VAS before and after the intervention. There was reduction in VAS by 2.4 which was found to be statistically very significant ($p < 0.001$).

	Mean ± SD	p value
Pre intervention	7.27 ± 1.39	<0.001 (Significant)
Post intervention	4.87 ±2.2	

Table showing Comparison of Mean & SD between pre and post value of Group 1

Table 2 summarizes the mean average of VAS before and after the intervention. There was reduction in VAS was 6.07 which was found statistically extremely significant.

	Mean ± SD	p value
Pre intervention	8.67 ± 0.98	<0.0001 (Extremely Significant)
Post intervention	2.6 ± 2.06

DISCUSSION:

This study includes an experimental design consisting of two groups, Group 1 (conventional TENS), Group B (Uterus Mobilization with TENS). This study aims to compare the Effect of Uterus Mobilization with TENS and only TENS on pain in Young Females with Primary Dysmenorrhea.

After studying 30 subjects (15 Visceral mobilization with TENS, 15 TENS) and on the basis of hypothesis when mean difference in data was compared between group 1 and 2, we got significant improvements within the groups i.e. for uterus mobilization with TENS and only TENS. Therefore in this study, experimental hypothesis is accepted and there is significant difference in the VAS scores between Uterus Mobilization with TENS and only TENS and thus concludes by rejecting null hypothesis that there is no significant reduction in VAS scores between group 1 (conventional TENS) and group 2 (Uterus Mobilization with TENS). However, pain scores on VAS within the groups showed significant reduction in primary dysmenorrhea.

The primary findings of this study were a significant improvement from pretest to posttest variability of VAS scores after intervention with Uterus Mobilization with TENS ($p<0.0001$). The mean average of VAS before the treatment was 8.67 ± 0.98 and after the intervention was 2.6 ± 2.06. There was reduction in VAS was 6.07 which was found statistically extremely significant.

In previous study used a pragmatic design to assess the effect of osteopathic manipulative therapy (OMTh; manipulative care provided by foreign trained osteopaths) on women with diagnosed primary dysmenorrhea and the results were showed significant for reduction of pain intensity in the OMTh group, with mean (SD) NRS scores of 4.6 (1.2) before intervention and 1.9 (1.4) after intervention (P<.0005). The mean (SD) reported days of general pain was also significantly reduced in this group (4.5 [1.8] days before intervention to 2.2 [1.8] after intervention; P<.0005), as was reported duration of intense pain (2.2 [1.4] days before intervention to 0.2 [0.6] days after intervention; P<.0005). No changes in these measures were observed for the control group this study design produced dramatic reduction in the symptoms of primary dysmenorrhea, although it has not been used in many osteopathic research projects.11

In our study, Control group also shows significant improvement in VAS scores with Therapeutic TENS ($p \leqslant 0.001$). The mean average of VAS before the treatment was 7.27 ± 1.39 and after the intervention the VAS was 4.87 ± 2.2. There was reduction in VAS by 2.4 which was found to be statistically significant.

In one study which is done by Proctor ML et al (1994) who had compared the effectiveness of high and low frequency transcutaneous electrical nerve stimulation and acupuncture to each other, placebo, and no treatment, or medical treatment for primary dysmenorrhea and showed that high frequency TENS was more effective for pain relief than placebo TENS. Low frequency TENS was found to be no more effective in reducing pain than placebo TENS. Acupuncture is thought to excite receptors or nerve fibers which, through a complicated interaction with mediators such as serotonin and endorphins, blocks pain impulses.12

The result of current study is also supported by Deborah et al13(1989) who showed the effectiveness of acupuncture-like transcutaneous electrical nerve stimulation in treating primary dysmenorrhea and showed significant pain relief for the subjects receiving acupuncture-like TENS. Acupuncture-like TENS is believed to work via release of endorphins in the brain.14 Endorphins are a natural opiate that blocks the input of pain, possibly via the dorsolateral funiculus. These endorphins bind to receptors in the periaqueductal gray matter and lead to an antidromic inhibitory process that blocks the nocioceptive impulses from reaching the substantia gelatinosa. Another hypothesis was that the auricle has rich sensory innervations that have led investigators to believe that stimulation to the auricle may affect different areas of the body, depending on the area stimulated. Investigators have suggested that there is a link between sensory nerves of the auricle and the central nervous system that may produce analgesic effect.

Although the end results did exhibit statistical significant between the two groups of intervention ($p<0.05$), on the basis of mean difference between pre and post measurement of VAS scores. We found that Uterus mobilization with TENS was found to be more effective in reduction of pain scores in females suffering from primary dysmenorrhea than that of only therapeutic TENS treatment.

Limitation to the present study include the duration of treatment for experimental group was only 4 days as was hypothesized in that manner as there were no previous evidences in regard to that. The physiology of the Primary Dysmenorrhea pain can be multifactor. The difficulty in deferentially altering the techniques was not possible so the intervention was limited to a single protocol. Further studies should focus on conducted on larger sample size, Long duration of the study could have brought in more clarity in observed trends, It can also be done on different age groups.

Clinical implication of the study include that Dysmenorrhea is the most common Gynecological problem faced by the young females. It is a disease that refrains the females from physical activities like absence from work and college. Apart from this restriction of the physical activity, it also causes psychological, social and behavioral problems like Stress, Anxiety, Confusion, Social Fear, lack of Confidence, poor academic performances, disputes in Relationships etc. This study will be helpful in improving quality of life, decreasing the use of NSAID'S as they have numerous side effects and there are also very less treatment options available for this disease. So this study aims at use of Non-Pharmacological treatment and Non invasive treatment options which were found to be effective in decreasing the Pain in young females with Primary Dysmenorrhea and thus giving them the necessary options in avail. It can also be used in our OPD's as an adjunct to other treatment options available an additional option for prevention and control of dysmenorrhea.

CONCLUSION:

The present study concluded that 30 Females suffering from primary dysmenorrhea with increased VAS score were investigated and divided into two group i.e. Uterus mobilization with TENS and only TENS regime. The results showed significant improvement in VAS within the groups, but interestingly Uterus mobilization with TENS showed better improvement.

The efficacy of two different frequencies NMES applications to gastrocnemius muscle on increase venous flow. A systematic review

Dr. Vinod Nair

Abstract

Introduction

Many individuals are at risk for developing deep vein thrombosis (DVT) or venous thrombo embolism (VTE), or both owing to immobilization, surgery, or trauma injury: venous stasis, endothelial damage or increased coagulation. There are 2 main types for preventing deep vein thrombosis: chemical and physical. Despite chemical prophylaxis being the preferred method, it has a high risk of bleeding and must be avoided in some patients. There is also increasing evidence supporting the use of mechanical devices as intermittent pneumatic compression (IPC) and compression stockings in surgical patients at high risk of developing deep vein thrombosis. These options can still have certain limitations such as patient discomfort, tissue injury, improper fitting or arterial insufficiencies in patients with peripheral arterial disease so alternative physical strategies like electrical stimulation (ES) are being investigated. Electrical stimulation has been shown to have an additive effect to compression stockings and to be at least as effective as intermittent pneumatic compression in terms of the venous hemodynamic response, and besides, to show some other advantages such as arterial and microcirculatory flux enhancement. In addition, electrical stimulation can also play a specific role by stimulating or replacing the neural supply to the veins, which has been proposed recently as the fourth factor in thrombus pathogenesis. Electrical stimulation may be even more necessary when early active motion is difficult or unavailable as in traumatology patients because of an immobilized extremity or muscle inhibition after surgery, and in critically ill patients. The primary objective of this study was to compare the effect of two frequency and electrode placement at the maximum tolerated intensity on hemodynamic popliteal venous flow and peak velocity (PV) using Doppler ultrasound in healthy volunteers. A further objective was to compare the participants' relative discomfort among the 2 applications using a visual analogue scale and verbal rating scoring index.

Methods :

Electrical stimulation devices neuromuscular electrical stimulation (NMES), have been used to enhance venous hemodynamics via skeletal muscles. NMES and TENS are different ES modalities, but there is confusion regarding the description of the Electrical stimulation forms among researchers and clinicians. As both Electrical stimulation modalities can be delivered by surface electrodes for stimulating muscles and nerves, the differences are related to their original purpose. TENS has been primarily developed for pain relief, whereas NMES has been primarily developed for the improvement of muscle strength eliciting smooth tetanic muscle contraction and relaxation, similar to an exercise therapy session. Therefore, an on-off time in seconds (duty-cycle) is necessary in NMES for minimizing muscular fatigue and discomfort.

Results :

Despite electrical stimulation having been experimentally proved to be effective in improving venous flow and velocity, the stimulation parameters vary greatly and it is necessary to clarify which parameters are optimal for venous return Frequencies from 1 to 10 Hz have been tested at muscle locations. To the best of the authors' knowledge, only one study has compared, but used different electrical stimulation frequencies and intensities for each placement.

Materials and methods

Design and sample

A large variation in hemodynamic response to electrical stimulation has been found in healthy population. Therefore, a within-subjects cross-over design was used to determine differences in hemodynamic effects and discomfort. A random assignment of the NMES was used to avoid possible systematic effects of order. The order of testing was introduced in opaque envelopes to be randomly selected by each participant, who was not aware of it. Study protocol was reviewed and approved by hospital. Informed consent was obtained from each subject before enrolment.

The optimal sample size was determined from a pilot sample of 12 subjects. The venous flow volume (FV), in ml per minute, was measured 3 times and the mean was considered, both basal and after the NMES protocol. The FV increment was computed relatively with respect to basal levels, and given as percentage. A 1-way analysis of variance with repeated-measures was used to compare the difference among the 3 electrical stimulation results. From the estimated correlation among repeated-measures of 0.7 and a standard deviation within each group of 90%, we obtained that, with a sample size of 24 subjects, the test would have a power of 0.8 to detect significant differences in the relative FV increments if they were 40%, 175%, and 150%, with a type I error of 0.05.

Participants

Students from the Faculty of Physical Therapy were initially invited to participate in a screening session. A university notice board was used to recruit the volunteers. The specific inclusion criteria were: healthy subjects aged between 18 and 39 years. Exclusion criteria included factors that might affect venous return or current flow: body mass index (BMI) <18 or >30 kg/m2, smokers, oral contraceptive use, recent surgery/trauma to lower limbs, any diagnosed disease that could affect hemodynamics, clinically significant varicose veins, or ulceration of the lower limbs. Among 30 volunteers assessed for eligibility, 4 women and 2 man were excluded for meeting some exclusion criteria. The pilot sample was included within the final sample of 24 subjects (12 men) selected for evaluation. All of them completed the experimental session.

Experimental procedure

All examinations were performed in the same room, in which the temperature was controlled

The subjects lay in the prone position 15 to 20 minutes before the experiment with their feet off the table and a soft cushion beneath the ankle. Stimulation electrodes sites were previously clipped of hairs. Three electrical stimulation protocols were applied using a 2-channel portable stimulator (NMES-BIOTECH) and matching self-adhesive electrodes. All the electrical stimulation protocols selected were delivered without a duty cycle (on-off time). Electrode placements on tibial nerve, and the motor points of the gastrocnemius muscle, where skin area was most responsive to electrical stimulation. A charge-balanced biphasic square wave with phase duration of 0.35 milliseconds was applied at 1 and 5 Hz over the muscle to obtain a twitch contraction. The frequency of 1 and 5 Hz was chosen instead of 10 Hz and 15 Hz, as 10 Hz and 15 Hz was felt uncomfortable and fatiguing because of the almost tetanic muscle response it originated without a resting time. Stimulation amplitude was increased gradually, 0.5 mA per second to find the pain threshold for each application in the random order assigned. The stimulation intensity was set 10% below the pain threshold, and the values (median, first–second quartiles) were 30.5 (22.1–43) mA, 20.0 (14.5–24.3) mA, when applying 1 Hz and 5 Hz on muscle site, respectively.

Primary outcome

A baseline duplex venous ultrasound scan was performed at least 5 minutes after the last pain threshold determination. The popliteal vein of the nondominant leg was examined with a 6 to 13 MHz linear transducer . It was placed at the back of the knee by a fixed-arm, once the optimal location was reached. Vein diameter was measured using B-mode. The venous FV (mm per minute) was calculated by the Doppler unit's software. The venous PV (centimeters per second) was recorded from the Doppler waveform. The electrical stimulation sequences were applied for 1 minute before recording echographic measures during stimulation. They were followed by a 5-minute recovery phase and a new baseline ultrasound was examined. Measurements were taken over a period of 16 seconds, to obtain several endogenous or ES-superimposed blood movement cycles. Three measurements were made for each condition and the mean of them was used for analysis. The same well-trained examiner with >6 years of experience performed all measurements and asked the subjects to remain stationary and maintain a stable breathing pattern during data collection.

Secondary outcome

Participants compared discomfort after the 2 TENS applications using a 100-mm visual analogue score (VAS). This scale was modified from traditional pain VAS with 0 mm denoting no sensation, and 100 mm indicating pain onset. Subjects' relative comfort perception was also assessed by a verbal rating score (VRS): 1, no sensation; 2, minimal discomfort; 3, mild discomfort; 4, moderate discomfort; and 5, severe discomfort.

Statistical analysis

Data are presented as mean ± standard deviation (SD); if the distribution is asymmetrical, median and first and third quartiles (Q1 and Q2) are also given. The Kolmogorov-Smirnov-Lilliefors test was used to test for normal distribution of the data. To compare the effects in hemodynamics and discomfort the 2 NMES applications, a 1-way ANOVA with repeated-measures, or Friedman test was carried out. To identify differences in the NMES results, post hoc pairwise comparisons were considered with Bonferroni correction. To ensure comparability, standardized effect sizes were calculated by the partial eta-squared η2p (partial variance explained in ANOVA). A P value <.05 was assumed to denote statistical significance. Statistical analyses were carried out using IBM SPSS for Windows, version 21.0 (IBM Corporation).

Results

Table1 presents the physical baseline characteristics of the participants. Typical Doppler waveforms of baseline and the 2 TENS protocols (1 and 5 Hz via muscle). The effect of the different NMES programs on both FV and PV was statistically significant. The increment of hemodynamics responses has been computed relatively from baseline and given as a percentage. The relative increments of the hemodynamic responses (in %) varied significantly with the NMES interventions for FV (P < .001) and PV (P < .001). FV was higher with NMES applications of 5 Hz than of 1 Hz (P<.001).

Table 1 : Subject physical characteristics.

	Male (n=12)	**Female (n=12)**
Age,Y	22.5±3.23	19.42±0.90
BMI, Kg/m2	24.17±2.41	22.17±1.90
Calf perimeter, cm	37.05±1.74	32.93±2.64

Table 2

	NMES	Baseline Median(Q1-Q2)	Stimulation Median(Q1-Q2)	Difference Mean	Effect Size	p
FV	1Hz	80.1 (65.3-100.6)	97.8 (73.9-153.1)	24.49 (9.08-39.91)	0.320	.003
	5Hz	75.1 (55.5-114.7)	174.0 (120.1-251.2)	115.26 (74.74-155.79)	0.601	<.001
PV	1Hz	13.4 (10.5-18.3)	55.1 (45.4-67.7)	39.93 (34.01-45.86)	0.894	<.001
	5Hz	13.1 (9.9-17.6)	48.9 (39.4-62.2)	34.61 (28.08-41.13)	0.839	<.001

Table 3: Comparison of the relative increment of FV and PV among the different protocols of electrical stimulation (n=24).

	1Hz	5Hz	Effect Size	p
FV(%)	32.6±46.1	146.8±115.9	0.482	<.001
PV(%)	291.9±136.2	258.6±126.8	0.585	<.001

Duplex Doppler ultrasound recordings used for blood flow analysis. Representative capture window measuring popliteal blood flow waveform in basal condition is displayed. The response to NMES stimulation at 1 Hz applied on gastrocnemius muscle is seen. The spikes reflect the altered flow pattern at the frequency delivered. Effect on waveform of NMES at 5 Hz on gastrocnemius muscle site. More spikes are seen as frequency is increased 5 times. The flow pattern obtained is different from previous electrical applications as the spikes are less pronounced and there is more regularity in the venous blood flow.

There were no adverse effects at the end of the intervention or reported afterwards by the subjects.

Discussion

This study compared the efficacy of 2 NMES applications. Increased FV and PV in the ipsilateral popliteal vein were seen in muscle stimulation, and using 1 and 5 Hz. This is concordant with the existing literature, despite NMES parameters' differences and missing data or discrepancies when reporting it. A review provided a range of 60% to 615% FV increasing from baseline and 25% to 650% for PV. The much higher values were from studies in operated on and healthy people at bed rest using NMES. This can be explained by 2 factors: bed rest causes a decline in venous blood flow, so a higher increase compared to resting values can be expected; in addition, in these researches only the NMES "on time" was compared to baseline, not considering off time where a subsequent cessation in blood flow might happen. Few studies have considered percentage of change, and lower range values have been reported stimulating common tibial nerve or different muscle locations, In healthy volunteers. In these studies a long-lasting hemodynamic recording of 15 seconds was used, as has been also recorded in the present study, to deal with cardiac and respiratory variations.

When looking for the differences among the 2 NMES protocols, NMES at 5 Hz (on muscle) obtained a higher FV than at 1 Hz on muscle site. The latter has not been shown in the previous study comparing nerve and muscle ES, but significantly lower VAS was achieved in nerve site. Likely, the discrepancies may be attributed to the distinctive current densities, muscle sites, and frequencies tested.

Current density is estimated as intensity per electrode area. Whereas in the mentioned study identical current densities were applied (same intensity and small sized electrodes for both locations), in the present study the highest tolerated intensity for each protocol was selected. Indeed, in consonance with ES-recommended parameters, greater electrode size was chosen on muscle. Tibial nerve was stimulated at a site where good accessibility is considered and small electrodes have been found more comfortable and selective for thin fat layers and superficial nerves.

Tibialis anterior was the chosen muscle site in Izumi et al's study, whereas gastrocnemius muscle was the stimulated muscle in the present research. When comparing tibialis anterior and soleus muscle, soleus muscle expelled higher volume and achieved lower peak velocities, which were on average 35% lower than tibialis anterior. In another study testing different muscles soleus was the only muscle where, besides an increased PV from baseline, a higher FV was detected. Explanations from the authors in both researches are in connection with the intimate relationship among the muscles and plexus of deep veins. The leg pump—located in the veins of the gastrocnemius which is the most important pump in the lower limb. The medial gastrocnemius veins play a major role pushing the blood column upwards and creating an aspiration effect in the popliteal roots below. These muscles are innervated from the tibial nerve. Stimulation of the tibial nerve produced nearly identical hemodynamics responses as voluntary contractions when controlling force, duty cycle, and active muscle mass.

Regarding the frequency, the previous study used

10 Hz on nerve and 50 Hz on muscle site, whereas in this study, 1Hz &5 Hz was used in muscle locations. Other studies have examined the effect of frequency on venous hemodynamics, with diverse results. Stimulating the tibial nerve (1–40 mA, 1–5 Hz), venous FV and PV have been enhanced, with both intensity and frequency showing moderate to strong positive correlations. In the present research, increased FV at higher frequency was also found, but the same relationship between frequency and PV was not. Different factors can be responsible for the differences. Likely, the most relevant is using the highest tolerated intensity, which was lower at 5 Hz than at 1 Hz, whereas the same intensities were selected by Izumi et al. Another study testing 0.13 to 2 Hz in a muscle location on the calf showed that different rates of stimulation had a different effect on PV and FV, as PV decreased and FV increased. Perhaps the effect of diminishing PV at increasing frequency is most patent when comparing to frequencies below 1 Hz, as seems to happen in the graphic data presented in this work.

ES at 5 Hz on gastrocnemius muscle rather than ES at 1 Hz on gastrocnemius muscle. First, 5 Hz on muscle site originated higher PV increment and it has been noted than an excessive increase in PV can be dangerous. NMES has obtained even higher PV than voluntary exercise when applied at high intensity and pulse duration. In IPC devices, a decline in blood flow velocity has been found in the first section of deflation phase. A negative pressure is generated in the inner vessel, and it pulls blood into the decompressed vessels. There is a possibility of a non desirable backward flow when a strong negative pressure—related to a high PV—is generated. This can be amplified when partial venous obstruction with stenosis or malfunctioning venous valves exists, as it creates the conditions for eddy blood flow. For this reason, other factors related to venous volume have been proposed to test the different applications. Second, when subjects compared the applications using VRS, 5 Hz on muscle was felt more comfortable (close to statistical significance). Discomfort assessment by VRS showed mild discomfort in 1 Hz muscle. This level of discomfort is in consonance with the application of 1 Hz TENS device at normal clinical use setting. Despite healthy subjects have been assessed in the present study, it would be useful for collecting normative data to help with better treatment choices in patient population.

Limitations

There are 2 main limitations to this study. First, although increasing venous flow is assumed to correlate with reduction of thrombosis risk, the data obtained from young healthy people might not be directly translated to patients with a vascular disease or at high risk of suffering it. Second, the medium- and long-term effects of NMES can differ from immediate-effects of a brief intervention investigated in this study.

Conclusions

In conclusion, when considering the highest venous FV increase, the lowest peak venous velocity change, and comparative tolerance, NMES at 5 Hz on gastrocnemius muscle is the most beneficial protocol. Future studies may investigate the electrical stimulation of tibial nerve and compare it to common peroneal nerve effects on hemodynamics. Furthermore, the influence of frequency and electrode location parameters on population at high risk from suffering DVT has to be established.

Footnotes

This research was supported by the Psychosocial and Functional Rehabilitation Research Group, based at the Faculty of Physiotherapy. There are not any financial benefits to the authors. The supporting and funding sources had no involvement in study design or any decision related with the study.

PHYSIOTHERAPY & STRESS

Physiotherapy is the treatment of disease, injury, or deformity by physical methods such as massage, treatment by various modalities, and exercise rather than by drugs or surgery. It not only eases the song of one's stressful burden, but also stimulates both the mind and body to rebalance and usher in harmony and emotional poise.

Dr. Shailendra Mehta

Stress is your body's response to certain situations. It's subjective, so something that is stressful for you may not be stressful for someone else. There are many different kinds of stress and not all of them are bad. Stress can help you act quickly in an emergency or help you meet a deadline.

Stress can affect your physical and mental health, and your behavior. Your body responds to stress by producing chemicals and hormones to help you rise to the challenge. Your heart rate increases, your brain works faster, and you have a sudden burst of energy. This response is basic and natural and is what kept our ancestors from falling victim to hungry predators. But too much stress can have harmful effects. It's impossible to completely eliminate bad stress from your life, but you can learn to avoid and manage it.

Stress is an inevitable part of life and existence. It makes us ready for what is referred to as short term response, or 'fight-or-flight' response. Most of the biological changes that comeswith the stress response are designed to rally the body's fuel reserve-to convert them for immediate use. This includes providing extra oxygen required for the organs most likely to need it-for example, the brain and the muscles. Prolonged stress impacts the secretion of certain hormones, including the sex hormones,

Stress also acts as a go-between for one part of the nervous apparatus-called the sympathetic nervous system which deals with the body's maintenance functions under normal conditions. It is, therefore, well placed for rapidly re-adjusting our priorities.

CAUSES OF STRESS

Everyone has different stress triggers. Work stress tops the list, according to surveys. Causes of work stress include:

·Being unhappy in your job

- Having a heavy workload or too much responsibility
- Working long hours
- Having poor management, unclear expectations of your work, or no say in the decision-making process
- Physical illness
- Neglect by society or family
- Life stresses can also have a big impact. Examples of life stresses are:
- The death of a loved one
- Divorce
- Loss of a job
- Increase in financial obligations
- Getting married
- ·Moving to a new home

Sometimes the stress comes from inside, rather than outside. You can stress yourself out just by worrying about things. All of these factors can lead to stress:

Fear and uncertainty. When you regularly hear about the threat of terrorist attacks, global warming, and toxic chemicals on the news, it can cause you to feel stressed, especially because you feel like you have no control over those events.

What Are the Symptoms of Stress?

Stress can affect all aspects of your life, including your emotions, behaviors, thinking ability, and

Principal, Deptartment of physiotherapy
Janaran Rai Nagar Rajasthan Vidyapeeth, (Deemed To-Be University) Dabok Udaipur

physical health. No part of the body is immune. But, because people handle stress differently, symptoms of stress can vary. Symptoms can be vague and may be the same as those caused by medical conditions. So it is important to discuss them with your doctor. You may experience any of the following symptoms of stress.

Emotional symptoms of stress include:

·Becoming easily agitated, frustrated, and moody

·Feeling overwhelmed, like you are losing control or need to take control

·Having difficulty relaxing and quieting your mind

·Feeling bad about yourself (low self-esteem), lonely, worthless, and depressed

- Avoiding others
- Physical symptoms of stress include:
- Low energy
- Headaches
- Upset stomach , including diarrhea, constipation, and nausea
- Aches, pains, and tense muscles
- Chest pain and rapid heartbeat
- Insomnia
- Frequent colds and infections
- Loss of sexual desire and/or ability
- Nervousness and shaking, ringing in the ear, cold or sweaty hands and feet
- Dry mouth and difficulty swallowing
- Clenched jaw and grinding teeth

Cognitive symptoms of stress include:

- Constant worrying
- Racing thoughts
- Forgetfulness and disorganization
- Inability to focus
- Poor judgment
- Being pessimistic or seeing only the negative side

Behavioral symptoms of stress include:

- Changes in appetite -- either not eating or eating too much
- Procrastinating and avoiding responsibilities
- Increased use of alcohol, drugs, or cigarettes
- Exhibiting more nervous behaviors, such as nail biting, fidgeting, and pacing

Types of stress

1. Acute stress

Acute stress is the most common type of stress. It's your body's immediate reaction to a new challenge, event, or demand, and it triggers your fight-or-flight response. As the pressures of a near-miss automobile accident, an argument with a family member, or a costly mistake at work sink in, your body turns on this biological response.

Acute stress isn't always negative. It's also the experience you have when riding a rollercoaster or having a person jump out at you in a haunted house. Isolated episodes of acute stress should not have any lingering health effects. In fact, they might actually be healthy for you, as these stressful situations give your body and brain practice in developing the best response to future stressful situations.

Severe acute stress such as stress suffered as the victim of a crime or life-threatening situation can lead to mental health problems, such as post-traumatic stress disorder or acute stress disorder.

2. Episodic acute stress

When acute stress happens frequently, it's called episodic acute stress. People who always seem to be having a crisis tend to have episodic acute stress. They are often short-tempered, irritable, and anxious. People who are “worry warts” or pessimistic or who tend to see the negative side of everything also tend to have episodic acute stress.

Negative health effects are persistent in people with episodic acute stress. It may be hard for people with this type of stress to change their lifestyle, as they accept stress as a part of life.

3. Chronic stress

If acute stress isn't resolved and begins to increase or lasts for long periods of time, it becomes chronic

stress. This stress is constant and doesn't go away. It can stem from such things as:

- poverty
- a dysfunctional family
- an unhappy marriage
- a bad job

Chronic stress can be detrimental to your health, as it can contribute to several serious diseases or health risks, such as:

- heart disease
- cancer
- lung disease
- accidents
- cirrhosis of the liver
- suicide

The Four Common Types of Stress

Dr Karl Albrecht, a management consultant and conference speaker based in California, is a pioneer in the development of stress-reduction training for businesspeople. He defined four common types of stress in his 1979 book, "Stress and the Manager."

Albrecht's four common types of stress are:

- Time stress.
- Anticipatory stress.
- Situational stress.
- Encounter stress.

1. Time Stress

You experience time stress when you worry about time, or the lack thereof. You worry about the number of things that you have to do, and you fear that you'll fail to achieve something important. You might feel trapped, unhappy, or even hopeless.

Common examples of time stress include worrying about deadlines or rushing to avoid being late for a meeting.

2. Anticipatory Stress

Anticipatory stress describes stress that you experience concerning the future. Sometimes this stress can be focused on a specific event, such as an upcoming presentation that you're going to give. However, anticipatory stress can also be vague and undefined, such as an overall sense of dread about the future, or a worry that "something will go wrong."

3. Situational Stress

You experience situational stress when you're in a scary situation that you have no control over. This could be an emergency. More commonly, however, it's a situation that involves conflict, or a loss of status or acceptance in the eyes of your group. For instance, getting laid off or making a major mistake in front of your team are examples of events that can cause situational stress.

4. Encounter Stress

Encounter stress revolves around people. You experience encounter stress when you worry about interacting with a certain person or group of people – you may not like them, or you might think that they're unpredictable.

Encounter stress can also occur if your role involves a lot of personal interactions with customers or clients, especially if those groups are in distress. For instance, physicians and social workers have high rates of encounter stress, because the people they work with routinely don't feel well, or are deeply upset.

This type of stress also occurs from "contact overload": when you feel overwhelmed or drained from interacting with too many people.

STRESS RESPONSE

In the wake of stress, your pulse, blood pressure, and breathing rate increase-to help boost the supply of available energy. The heart beats faster under stress and pumps a greater quantity of blood than usual with each beat.

The bronchial tubes dilate to assist the passage for more air with each breath. The blood vessels supplying the muscles expand just as well. The palms of the hands and the soles of the feet begin to

perspire, primarily because a damp surface provides a much better grip of things.

The pupils of your eyes dialate to let in more light and perk up your vision. Likewise, your mental alertness and reaction time are also speeded up.

During a stressful episode, long-term energy reserves such as stored fat are also broken down into fatty acids and glycerol to be metabolized right away. Likewise, carbohydrates stored in the liver are metabolised and converted into glucose, as blood is shunted from the extremities towards the heart, muscles and brain.

When stress goes far beyond one's control, the situation becomes terrifying for other part of the nervous system-the parasympathetic mechanism. This leads to involuntary urination [rushing to the washroom] and also stools.

What also happens is that your peripheral blood vessels constrict- you get cold hands and develop cold feet, a famed literary expresiion, in anticipation of an unpleasant event. This in effect, leads to the shutting down of energy consumption processes, including salivation. The result is a parched mouth, loss of appetite and troubled bowels. Put simply, these are nothing but physiological responses of our nervous system.

FACT-FILE

1.Stress has psychological causes as also psychological outcomes. It changes the way we perceive the world, our senses, memory, judgemet and also behavior.

2.During a stressful episode, your network of cells provides the boost to your general level of arousal and awareness-to make you more responsive to signals from your sensory organs and less receptive to information that is of no immediate significance. For example, in times of severe stress, an itchy or runny nose will not divert your attention.

3.It is not infrequent for people with severe stress to be subject to frequent colds and infections, or allergies, thanks to reduced immune system reaction time, or function. As a matter of fact, stress can set off skin condition such as itching and rashes, including atopic dermatitis [eczema] and psoriasis.

4.Panic [stress] attacks are characteristically distinct and intense. They have an abrupt onset with symptoms peaking in intensity within minutes of onset. Symptoms include feeling of terror and a fear of dying.

GOOD & BAD

The stress response is entirely normal. We have evolved to respond to stressors over the ages.it drives us to reach our goals faster. Yet, it is not surprising to find threats to our health and well-being unpleasant; so, we have the urge to avoid them. However, it is a totally different thing if stress is triggered several times a day, under unusual circumstances, or for long periods. This can lead to adjustment difficulties and also illness.

HORMONAL CHANGES IN STRESS

ADRENALINE

Commonly known as the fight or flight hormone, it is produced by the adrenal glands after receiving a message from the brain that a stressful situation has presented itself.

What It Does: Adrenaline, along with norepinephrine (more on that below), is largely responsible for the immediate reactions we feel when stressed. Imagine you're trying to change lanes in your car, says Amit Sood, M.D., director of research at the Complementary and Integrative Medicine and chair of Mayo Mind Body Initiative at Mayo Clinic. Suddenly, from your blind spot, comes a car racing at 100 miles per hour. You return to your original lane and your heart is pounding. Your muscles are tense, you're breathing faster, you may start sweating. That's adrenaline.

Along with the increase in heart rate, adrenaline also gives you a surge of energy -- which you might need to run away from a dangerous situation -- and also focuses your attention.

NOREPINEPHRINE

A hormone similar to adrenaline, released from the adrenal glands and also from the brain, says Sood.

What It Does: The primary role of norepinephrine, like adrenaline, is arousal, says Sood. "When you are stressed, you become more aware, awake, focused," he says. "You are just generally more responsive." It also helps to shift blood flow away from areas where it might not be so crucial, like the skin, and toward more essential areas at the time, like the muscles, so you can flee the stressful scene.

Although norepinephrine might seem redundant given adrenaline (which is also sometimes called epinephrine), Sood imagines we have both hormones as a type of backup system. "Say your adrenal glands are not working well," he says. "I still want something to save me from acute catastrophe."

Depending on the long-term impact of whatever's stressing you out -- and how you personally handle stress -- it could take anywhere from half an hour to a couple of days to return to your normal resting state, says Sood.

CORTISOL

A high cortisol- the stress chemical- level is a characteristic feature of stress. This is followed by a reduction in sensory acuity. When someone has high cortisol level, they will not be able to decode the presence of a weak resonance, but they will be able to tell 2-3 somewhat different sounds apart, because of the heightened state of sensitive-receptivity aroused by stress.

Whatever the nature of our evolutionalry origins, a readjustment in our sensory abilities makes good biological sense. It is established that a hormone released during the stress response- noradrenaline- also enhances the signal-processing capability of our sensory system. It must be remembered too that several parts of the brain plays a key role in processing information.

When your brain decides-consciously or unconsciously- that all is not well, the hypothalamus is activated. The hypothalamus is the seat of many electrical and chemical signals which trigger stress responses in our body. The hypothalamus also regulates functions such as eating, drinking and sensual pleasures.

During the preliminary phase of a stress response, the hypothalamus, as touched upon earlier, stimulus the nerve endingsin the sympathetic nervous system and the adrenal glands- this causes them to release the two hormones, adrenaline and noradrenaline. A slightly stressful activity, such as public speaking, may generally bring forth a 50 percent rise in noradrenaline. People having chronic stress or anxiety tend to have persistently raised levels of adrenaline and noradrenaline.

The Effects of Stress on Your Body

You're sitting in traffic, late for an important meeting, watching the minutes tick away. Your hypothalamus, a tiny control tower in your brain, decides to send out the order: Send in the stress hormones! These stress hormones are the same ones that trigger your body's “fight or flight” response. Your heart races, your breath quickens, and your muscles ready for action. This response was designed to protect your body in an emergency by preparing you to react quickly. But when the stress response keeps firing, day after day, it could put your health at serious risk.

Stress is a natural physical and mental reaction to life experiences. Everyone expresses stress from time to time. Anything from everyday responsibilities like work and family to serious life events such as a new diagnosis, war, or the death of a loved one can trigger stress. For immediate, short-term situations, stress can be beneficial to your health. It can help you cope with potentially serious situations. Your body responds to stress by releasing hormones that increase your heart and breathing rates and ready your muscles to respond.

Yet if your stress response doesn't stop firing, and these stress levels stay elevated far longer than is necessary for survival, it can take a toll on your

health. Chronic stress can cause a variety of symptoms and affect your overall well-being. Symptoms of chronic stress include:

- irritability
- anxiety
- depression
- headaches
- insomnia

Central nervous and endocrine systems

Your central nervous system (CNS) is in charge of your "fight or flight" response. In your brain, the hypothalamus gets the ball rolling, telling your adrenal glands to release the stress hormones adrenaline and cortisol. These hormones rev up your heartbeat and send blood rushing to the areas that need it most in an emergency, such as your muscles, heart, and other important organs.

When the perceived fear is gone, the hypothalamus should tell all systems to go back to normal. If the CNS fails to return to normal, or if the stressor doesn't go away, the response will continue.

Chronic stress is also a factor in behaviors such as overeating or not eating enough, alcohol or drug abuse, and social withdrawal.

Respiratory and cardiovascular systems

Stress hormones affect your respiratory and cardiovascular systems. During the stress response, you breathe faster in an effort to quickly distribute oxygen-rich blood to your body. If you already have a breathing problem like asthma or emphysema, stress can make it even harder to breathe.

Under stress, your heart also pumps faster. Stress hormones cause your blood vessels to constrict and divert more oxygen to your muscles so you'll have more strength to take action. But this also raises your blood pressure.

As a result, frequent or chronic stress will make your heart work too hard for too long. When your blood pressure rises, so do your risks for having a stroke or heart attack.

Digestive system

Under stress, your liver produces extra blood sugar (glucose) to give you a boost of energy. If you're under chronic stress, your body may not be able to keep up with this extra glucose surge. Chronic stress may increase your risk of developing type 2 diabetes.

The rush of hormones, rapid breathing, and increased heart rate can also upset your digestive system. You're more likely to have heartburn or acid reflux thanks to an increase in stomach acid. Stress doesn't cause ulcers (a bacterium called H. pylori often does), but it can increase your risk for them and cause existing ulcers to act up.

Stress can also affect the way food moves through your body, leading to diarrhea or constipation. You might also experience nausea, vomiting, or a stomachache.

Muscular system

Your muscles tense up to protect themselves from injury when you're stressed. They tend to release again once you relax, but if you're constantly under stress, your muscles may not get the chance to relax. Tight muscles cause headaches, back and shoulder pain, and body aches. Over time, this can set off an unhealthy cycle as you stop exercising and turn to pain medication for relief.

Sexuality and reproductive system

Stress is exhausting for both the body and mind. It's not unusual to lose your desire when you're under constant stress. While short-term stress may cause men to produce more of the male hormone testosterone, this effect doesn't last.

If stress continues for a long time, a man's testosterone levels can begin to drop. This can interfere with sperm production and cause erectile dysfunction or impotence. Chronic stress may also increase risk of infection for male reproductive organs like the prostate and testes.

For women, stress can affect the menstrual cycle. It

can lead to irregular, heavier, or more painful periods. Chronic stress can also magnify the physical symptoms of menopause.

Immune system

Stress stimulates the immune system, which can be a plus for immediate situations. This stimulation can help you avoid infections and heal wounds. But over time, stress hormones will weaken your immune system and reduce your body's response to foreign invaders. People under chronic stress are more susceptible to viral illnesses like the flu and the common cold, as well as other infections. Stress can also increase the time it takes you to recover from an illness or injury.

Stress-related illness

Prolonged stress puts your body in a continuous state readiness for physical action. When your body has no time to re-establish equilibrium, it becomes overworked and your immune system weakens, making you susceptible to sickness. Many essential bodily processes are disrupted and your risk of health problems increases.

Some common effects include:

- memory impairment
- depression
- skin conditions, such as eczema
- difficulty sleeping
- obesity
- heart disease
- digestive problems
- autoimmune diseases

10 Health Problems Related to Stress

- **Heart disease:** Researchers have long suspected that the stressed-out, type A personality has a higher risk of high blood pressure and heart problems. We don't know why, exactly. Stress can directly increase heart rate and blood flow, and causes the release of cholesterol and triglycerides into the blood stream. It's also possible that stress is related to other problems -- an increased likelihood of smoking or obesity -- that indirectly increase the heart risks.Doctors do know that sudden emotional stress can be a trigger for serious cardiac problems, including heart attacks. People who have chronic heart problems need to avoid acute stress -- and learn how to successfully manage life's unavoidable stresses -- as much as they can.
- **Asthma:** Many studies have shown that stress can worsen asthma. Some evidence suggests that a parent's chronic stress might even increase the risk of developing asthma in their children. One study looked at how parental stress affected the asthma rates of young children who were also exposed to air pollution or whose mothers smoked during pregnancy. The kids with stressed out parents had a substantially higher risk of developing asthma.
- **Obesity:** Excess fat in the belly seems to pose greater health risks than fat on the legs or hips -- and unfortunately, that's just where people with high stress seem to store it. "Stress causes higher levels of the hormone cortisol," says Winner, "and that seems to increase the amount of fat that's deposited in the abdomen."
- **Diabetes:** Stress can worsen diabetes in two ways. First, it increases the likelihood of bad behaviours, such as unhealthy eating and excessive drinking. Second, stress seems to raise the glucose levels of people with type 2 diabetes directly.
- **Headaches:** Stress is considered one of the most common triggers for headaches -- not just tension headaches, but migraines as well.
- **Depression and anxiety:** It's probably no surprise that chronic stress is connected with higher rates of depression and anxiety. One survey of recent studies found that people who had stress related to their jobs -- like demanding work with few rewards -- had an 80% higher risk of developing depression within a few years than people with lower stress.

- **Gastrointestinal problems:** Here's one thing that stress doesn't do -- it doesn't cause ulcers. However, it can make them worse. Stress is also a common factor in many other GI conditions, such as chronic heartburn (or gastroesophageal reflux disease, GERD) and irritable bowel syndrome (IBS), Winner says.
- **Alzheimer's disease:** One animal study found that stress might worsen Alzheimer's disease, causing its brain lesions to form more quickly. Some researchers speculate that reducing stress has the potential to slow down the progression of the disease.
- **Accelerated aging:** There's actually evidence that stress can affect how you age. One study compared the DNA of mothers who were under high stress -- they were caring for a chronically ill child -- with women who were not. Researchers found that a particular region of the chromosomes showed the effects of accelerated aging. Stress seemed to accelerate aging about 9 to 17 additional years.
- **Premature death:** A study looked at the health effects of stress by studying elderly caregivers looking after their spouses -- people who are naturally under a great deal of stress. It found that caregivers had a 63% higher rate of death than people their age who were not caregivers.

Effects of Stress on Your Health

When you are in a stressful situation, your body launches a physical response. Your nervous system springs into action, releasing hormones that prepare you to either fight or take off. It's called the "fight or flight" response, and it's why, when you're in a stressful situation, you may notice that your heartbeat speeds up, your breathing gets faster, your muscles tense, and you start to sweat. This kind of stress is short-term and temporary (acute stress), and your body usually recovers quickly from it.

But if your stress system stays activated over a long period of time (chronic stress), it can lead to or aggravate more serious health problems. The constant rush of stress hormones can put a lot of wear and tear on your body, causing it to age more quickly and making it more prone to illness.

If you've been stressed out for a short period of time, you may start to notice some of these physical signs:

- Headache
- Fatigue
- Difficulty sleeping
- Difficulty concentrating
- Upset stomach
- Irritability

When stress becomes long-term and is not properly addressed, it can lead to a number of more serious health conditions, including:

- Depression
- High blood pressure
- Abnormal heartbeat (arrhythmia)
- Hardening of the arteries (atherosclerosis)
- Heart disease
- Heart attack
- Heartburn, ulcers, irritable bowel syndrome

Stress Fantasies vs. Stress Realities

Stress Fantasy: Overwhelmed by the relentless p_a_c_e of it all, I decide to abandon the Internet and live a simpler life founded on principles of health and self-sufficiency. I move to an organic farm and learn to make my own yogurt.

Reality: I cannot boil water, let alone handle live cultures. I become incredibly sick after eating the yogurt and blog about it before I die.

Stress Fantasy: After a series of increasingly terrible interactions with garbage humans, I swear off all sexual relations forever. Untouched, my skin takes on the radiant glow of the Virgin Mary. My hair grows long because no man's hands ever get tangled up in it. Increasingly brilliant thoughts fire at a rapidfire rate in my pure, smooth brain.

Stress Reality: I buy a vibrator and halfheartedly text inappropriate people until I develop a new crush.

Stress Fantasy: I move to Montreal, where everyone is young and beautiful even when they're not, and all my friends live for their art and make their own brunch because they have the time for happiness.

Stress Reality: I find myself desperately trying to befriend 21-year-olds because everyone my age either lives with their partner and infant child in NDG or does not speak English. A 21-year-old feels bad for me and takes me to parties, where I stand around with a Maudite beer trying to talk to 21-year-olds; eventually I give up and try desperately to befriend a 48-year-old in a contemporary flute ensemble. I splurge on a beautiful Mile End one-bedroom that resembles a beautiful New York one-bedroom for four times the price, but run out of money because it's still a beautiful Mile End one-bedroom. I never once make my own brunch.

Stress Fantasy: I take a month off to read every book I've ever said I would read. I read every book I didn't read because I dropped out of university; I read every book every friend has ever recommend. I read every book referenced in the books written by my favorite authors. I never check my phone. Behind my eyes, a bottomless pool of hard-won knowledge becomes visible.

Stress Reality: I abandon this project ten minutes in because lol oh my god I can't believe he retweeted me.

Stress Fantasy: I give up on trying to make rent in the city and move to Dartmouth and buy a husky for companionship.

Stress Reality: I realize I've never even been to Dartmouth, I just like that the houses are painted pretty colors and the rent seems sustainable on a savings budget, but more people get the same idea and the rent rises and soon I'm priced out of my sweet Dartmouth apartment (are there sweet Dartmouth apartments?) and into a cabin somewhere. I also realize that a "mild dog allergy" is a major dog allergy in a cabin full of airborne dog fur and I'm a million miles from all my friends but I can't afford an Internet connection.

Stress Fantasy: I become an itinerant hippie. Living on the road, I never have to worry about domestic business. I make friends all over the world and their love follows me wherever I go.

Stress Reality: I plan the first leg of my journey very poorly and spend most of my time at the hostel. I hate everyone I meet and want to go home.

Stress Fantasy: I learn code and make a shit ton of money through very little effort. The money funds my "work."

Stress Reality: I am incapable of learning code, make no money, and spend my free time napping.

Stress Fantasy: I kill myself.

Stress Reality: I die.

Self-treatment

In some cases, a person can treat an anxiety disorder at home without clinical supervision. However, this may not be effective for severe or long-term anxiety disorders.

There are several exercises and actions to help a person cope with milder, more focused, or shorter-term anxiety disorders, including:

- **Stress management:** Learning to manage stress can help limit potential triggers. Organize any upcoming pressures and deadlines, compile lists to make daunting tasks more manageable, and commit to taking time off from study or work.
- **Relaxation techniques:** Simple activities can help soothe the mental and physical signs of anxiety. These techniques include meditation, deep breathing exercises, long baths, resting in the dark, and yoga.
- **Exercises to replace negative thoughts with positive ones:** Make a list of the negative thoughts that might be cycling as a result of anxiety, and write down another list next to it containing positive, believable thoughts to replace them. Creating a mental image of

successfully facing and conquering a specific fear can also provide benefits if anxiety symptoms relate to a specific cause, such as in a phobia.

- **Support network:** Talk with familiar people who are supportive, such as a family member or friend. Support group services may also be available in the local area and online.
- **Exercise:** Physical exertion can improve self-image and release chemicals in the brain that trigger positive feelings.

Stress Management

Stress and its management in the community is a growing issue for many health practitioners.

Physiotherapists offer a number of stress management techniques and treatments which can help to improve a patient's health and well-being, whether it be specially designed stress management programs, exercise programs, massage, muscle relaxation or general fitness advice.

Role of physiotherapy

Physiotherapists use an initial assessment to clarify the nature of the problem and develop strategies and treatment which are acceptable to the individual.

Treatment can take the form of individual consultation, group relaxation classes, relaxation audio tapes or information sessions for the general public. As part of the treatment program, physiotherapists offer close professional follow up with the patient to ensure a positive treatment outcome.

Physiotherapists with a special interest in stress management can offer many different types of relaxation therapy including guided imagery, progressive muscle relaxation, breathing techniques, thought stopping, stretching, massage and general fitness advice.

Benefits of physiotherapy

Research continues to indicate a positive correlation between a person's ability to cope with stressors and the likelihood of disease during their lifetime. **Physiotherapy can assist by:**

- reducing muscle tension;
- increasing vitality and decreasing reported tiredness;
- improving concentration span;
- improving feeling of general well-being;
- decreasing blood pressure;
- reducing risk of cardiovascular disease;
- improving attitude to work and leisure activity;
- reducing pain states such as headache, chronic pain syndromes and work related anxiety;
- Possibly decreasing dosage of psycho-active medication.

OBESITY STIGMA IN ONLINE NEWS: A VISUAL CONTENT ANALYSIS

Dr. Satya Bhushan Nagar,

ABSTRACT : This study conducted a content analysis to examine the types of images that accompany online news stories about obesity and to determine how obese people are portrayed in news photographs. Images were selected from news articles about obesity obtained from 5 major news Web sites, during 2011-2018. Images accompanying news stories about obesity 859 were systematically coded. Of 441 individuals identified in news photographs, 65% were overweight / obese and 27% were non overweight. Overall, 72% of images that depicted an overweight or obese person were portrayed in a negative, stigmatizing manner. Overweight/obese individuals were significantly more likely to have their heads cut out of the photos, to be portrayed showing only their abdomens or lower bodies, and to be shown eating or drinking than were non overweight individuals. Overweight/obese individuals were significantly less likely to be shown fully clothed, wearing professional clothing, or exercising than were non overweight individuals. Obese individuals are frequently stigmatized in online news photographs; this phenomenon has important implications for public perceptions of obese persons and may reinforce pervasive prejudice and discrimination. The study revealed that as a result of social weight stigma, overweight individuals are vulnerable to serious health complications, and they face disadvantages in health care, employment, education, and beyond. Just as the news media have the power to perpetuate these disparities, they may also play a vital role in correcting them.

Key words: obesity stigma, Overweight, portrayed

As obesity presents a major public health challenge, stigma against obese individuals threatens to undermine efforts to confront this challenge (Puhl & Heuer, 2010). Obese people are highly stigmatized in our society in important domains of living, including education, employment, and health care (Puhl & Brownell, 2001; Puhl & Heuer, 2009). The mass media is an especially compelling example of the social acceptability of weight stigma. Weight stigmatization is common in several forms of popular media (Puhl & Heuer, 2009). Overweight and obese persons are frequently ridiculed and stereotyped in popular television shows and movies (Fouts

Address correspondence to Rebecca M. Puhl, Rudd Center for Food Policy and Obesity, Yale University, 309 Edwards Street, New Haven, CT 06511, USA. E-mail: rebecca.puhl@ yale.edu & Burggraf, 1999, 2000; Fouts & Vaughan, 2002; Greenberg, Eastin, Hofshire, Lachlan, & Brownell, 2003; Herbozo, Tantleff-Dunn, Gokee-Larose, & Thompson, 2004; Himes & Thompson, 2007; Klein & Shiffman, 2005, 2006; Robinson, Callister, & Jankoski, 2008), and the news media often takes a victim-blaming approach in their coverage of obesity (Boero, 2007; Bonfiglioli, Smith, King, Chapman, & Holding, 2007; Kim & Willis, 2007; Lawrence, 2004; Rich & Evans, 2005). Research demonstrates that the news media disproportionately frames obesity in terms of personal responsibility, focusing on individual-level causes and solutions while ignoring important societal and environmental contributors (Bonfiglioli et al., 2007; Kim & Willis, 2007; Lawrence, 2004). As the news media tends to cast blame on obese persons, weight stigmatization can be perpetuated (Crandall & Reser, 2005; Weiner, Perry, & Magnusson, 1988). To date, research in this area has primarily analyzed written content of news reports about obesity.

These studies are guided by Goffman's (1974) frame

Assistant Professor, Deptartment of physiotherapy
Janaran Rai Nagar Rajasthan Vidyapeeth, (Deemed To-Be University) Dabok Udaipur

analysis theory, which provides the theoretical foundation for the stereotyping process. Framing theory explains the process by which a source (e.g., a news story) defines a particular social issue and outlines the fundamental problems and considerations relevant to that issue (Nelson, Oxley, & Clawson, 1997). Framing theory has often been used in media studies as a basis for studying how a communication source (e.g., a news organization) constructs social or political problems (Nelson et al., 1997).

Visual framing, or pictorial framing, of an issue is also of particular importance because viewers tend to accept visual images as reality while being unaware of the influence of visual framing (Messaris & Abraham, 2001). According to Messaris and Abraham, "Pictorial framing is worthy of investigation not only because images are capable of conveying unverbalized meanings, but also because awareness of those meanings may be particularly elusive." Furthermore, news photos may be noticed even when the accompanying story is not read, and photographs help readers interpret news stories (Messaris & Abraham).

Studies guided by framing theory have used visual content analysis techniques and demonstrated that news photographs can communicate stereotypes (Fahmy, 2004) and racial, gender, and age biases (Entman, 1992; Martindale, 1990; Rodgers & Thorson, 2000).
